ALL Detailed Program of Accepted Minisymposia

[00023] Recent advances on application driven nonlinear optimization

[01318] A Unified Single-loop Alternating Gradient Projection Algorithm for Nonconvex-Concave and Convex-Nonconcave Minimax Problems

[01287] Accelerated ADMM-type Methods for Convex and Noncovex Optimization Problems

[01284] On a special discrete phase constrained complex-field optimization problem

[01368] Stochastic regularized Newton methods for nonlinear equations

[01475] An Efficient Quadratic-Programming Relaxation Based Algorithm for Large-Scale MIMO Detection

[01487] Uniform Framework of Convergence Analysis for Nesterov's Accelerated Gradient Method

[01285] Exact continuous relaxations and algorithms for regularized optimization problems

[00024] Geometric methods in machine learning and data analysis

[03148] Geometric Data Analysis via Discrete Curvature

[02978] Large data limit of the MBO scheme for data clustering

[03210] Topologies of convergences for discrete-to-continuum limit on Poission point clouds

[03219] Spectral Methods for Data Sets of Mixed Dimensions

[03228] An information geometric and optimal transport framework for Gaussian processes

[03101] Data analysis and optimal transport: some statistical tools

[02871] Multispecies Optimal Transport and its Linearization

[03196] Semi-supervised learning with the p-Laplacian

[03217] The passive symmetries of machine learning

[03186] Graphons in Machine Learning

[03178] Graphon Analysis of Graph Neural Networks

[03202] Graph Neural Networks on Large Random Graphs: Convergence, Stability, Universality

[00027] Recent trends on crowd management

[05480] Crowd Management Platform as a Service

[05405] 3D Visualization of Crowd Motion

[05377] Numerical description of pedestrian crowds: are we really particles?

[05404] Crowd management and visitors' attitudes in natural recreational areas

[00029] New Trends in Structural and Engineering Optimization

[04641] Topology optimization reducing the dynamic instability of squeal noise

[03974] Structural simulation and optimization to improve the quality of metal additive manufacturing

[03594] Machine-learning assisted topology optimization with structural gene inheritance

[03346] Numerical and experimental investigation on process parameters optimization in rapid heat cycle molding

[01219] Acoustic metamaterials design with non-gradient material-field series-expansion topology optimization

[04675] Multiscale topology optimization to maximize dissipated energy

[03135] Multiscale topology optimization of fiber reinforced composite using homogenization design method.

[00033] Recent Advances on Quantitative Finance

[04926] Neural Stopping Boundaries

[05322] Learning Equilibrium Mean-Variance Strategy

[05301] On Consistency of Selecting Signatures Using Lasso: A Tale of Ito and Stratonovich

[02766] Portfolio choice with transaction costs and reinforcement learning

[05335] Dynamic programming for mean-variance portfolio selection

[05363] Non-Concave Utility Maximization with Transaction Costs

[05320] Optimal stopping without time consistency

[03404] Optimal dividend payout with non-decreasing constraint

[05500] Extended mean-field control problems with multi-dimensional singular controls

[05172] Lightning Network Economics: Channels and Topology

[05309] Non-monotone linear-quadratic mean field games with a major player

[05501] Large ranking games with diffusion control

[00036] Different perspectives in non-linear and non-local PDEs

[04031] Quantified overdamped limit for Vlasov-Fokker-Planck equations with singular interaction forces

[04055] A Degenerate Cross-Diffusion System as the Inviscid Limit of a Nonlocal Tissue Growth Model

[03802] Nonlocal particle approximations of the porous medium equation

[05056] A convergent discretization of the porous medium equation with fractional pressure

[05097] Uniform spectral gap in nonlocal-to-local approximations of diffusion

[03996] Concentration phenomena arising in Aggregation Fast-Diffusion equations

[05394] Sharp uniform-in-time propagation of chaos on the torus

[04109] Limiting gradient flow structure of deep linear neural networks

[04224] Deterministic Particle Approximation for aggregation-diffusion equations: entropy solutions, gradient flows, graph.

[03893] Non-local PDEs on graphs

[00037] Recent advances in modelling and simulation of interfacial flows

[02292] Interfacial flows and their modelling and control

[05417] New perspectives on continuous film flow over non-planar substrate: a family affair

[02788] Nonlinear dynamics of unstably stratified two-layer shear flow in a horizontal channel

[04110] Neural network methods for solving interface problems

[05355] On the transition to dripping of an inverted liquid film

[03447] Influence of an elastic sheet on impact on a liquid surface

[03420] Spin Coating on a Non-Axisymmetric Curved Substrate
[05432] Evaporation and the coffee-ring effect for non-circular droplets

[00038] Frontiers of gradient flows: well-posedness, asymptotics, singular limits

[05191] Existence for a class of fourth-order quasilinear parabolic systems
[03572] Evolutionary limit of gradient flows in heterogeneous Wasserstein space
[04719] The fourth-order total variation flow in R^n
[05426] Global existence for the p-Sobolev flow
[02587] Weak solutions to gradient flows in metric measure spaces
[04233] Duality methods for gradient flows of linear growth functionals
[04556] Convergence of Sobolev gradient trajectories to elastica
[05251] Recent advances in Sobolev gradient flows of plane curves

[00047] Combining Machine Learning and Stochastic Methods for Modeling and Forecasting Complex Systems

[03378] Generative modelling through diffusion maps
[04604] Tracer Prediction in Simplified Stochastic Geophysical Models through Kalman Filters and Related Methods
[05043] Machine Learning for Stochastic Parametrisation
[03280] Explainable AI to Detect, Predict and Discover Climate Variability and Change
[05245] semi-supervised active learning on graphs
[04307] Integrating the spectral analyses of neural networks and nonlinear physics for explainability, generalizability, and stability
[03737] Shock trace prediction by reduced models for a viscous stochastic Burgers equation
[01386] A Multi-Fidelity Ensemble Kalman Filter with Adaptive Reduced-Order Models
[05228] Embedding classical dynamics in a quantum computer
[05225] Machine learning correction operators for capturing extremes in coarse scale climate models
[04015] A Framework for Machine Learning of Model Error in Dynamical Systems
[05032] Combining physical and machine learning forecasts for Earth system prediction

[00048] Interfaces between kinetic equations and many-agent social systems. Part I

[03361] Multi Agent System for Inverse Problems
[03822] Parameter estimation for macroscopic pedestrian dynamics models using microscopic data
[03518] Navigation system based routing strategies in traffic flows on networks
[02357] Uncertainty quantification in vehicular traffic models
[04654] On a kinetic Elo rating model for players with dynamical strength
[04235] Nonlocal approximation of nonlinear diffusion equations and cross-diffusion systems
[04374] Kinetic models for multi-agent systems with multiple microscopic states
[03362] Modelling coevolutionary dynamics in heterogeneous SI epidemiological systems across scales
[05559] The Collisional Particle-In-Cell Method for the Vlasov-Maxwell-Landau System

[00049] Interfaces between kinetic equations and many-agent social systems. Part II

[04948] Weak couplings of Lohe type aggregation models
[03897] Quantified overdamped limit for Kinetic Vlasov-Fokker-Planck equations
[04724] Phase-coupled models for synchronization with nonlocal temporal interactions
[04208] Rigorous derivation of the Euler-Alignment model with singular communication weights from a kinetic Fokker-Planck-Alignment model
[04945] Sticky-particle Cucker-Smale dynamics and the entropic selection principle for the Euler-alignment system
[04190] Structure-preserving particle method for the Vlasov-Landau-Maxwell system
[03372] On solutions to the kinetic Cucker-Smale model with singular communication weights
[03940] Interaction energy minimizers on bounded domains
[03933] Analytical approaches to the problem of emergence arising in systems of collective behavior

[00052] Efficient numerical methods for high-dimensional PDEs

[04856] Sparse grid techniques for particle-in-cell simulation of kinetic plasmas
[03639] Nonlinear model reduction with adaptive bases and adaptive sampling
[04871] Quantum Algorithms for Accelerating the Solution of Partial Differential Equations
[03854] A Hybrid AMR Low-Rank Tensor Approach for Solving the Boltzmann Equation
[04128] Designing High-Dimensional Closed-Loop Optimal Control Using Deep Neural Networks
[04563] An Inverse Problem in Mean Field Games from Partial Boundary Measurement
[04470] Automatic partitioning for Boolean CME Low-Rank integrator

[00057] Many-agent systems and mean-field models for socio-economic and life sciences dynamics

[04044] Data-driven kinetic model for opinion dynamics and contacts
[02360] Asymptotic-preserving neural networks for kinetic equations in socio-epidemics
[04507] Many-agent systems and mean-field models for semi-supervised learning
[03820] Trends to equilibrium for nonlocal Fokker-Planck equations with discontinuous drift
[04768] Kinetic modelling of swarming dynamics with transient leadership
[02465] Kernel learning method for multiagent systems and its mean-field limit
[03937] Bounded-confidence models of opinion dynamics on networks
[03493] Mean-field models for many agent systems with co-evolving network structure

[00059] Numerical solutions for differential equations: Probabilistic approaches and statistical perspectives

[00066] Probabilistic Numerical Methods
[04930] Prior models for enforcing boundary constraints in state-space probabilistic PDE solvers

[04408] GParareal: Towards a time-parallel probabilistic ODE solver

Session Time & Room :

00023 (1/2) : 5B (Aug.25, 10:40-12:20) @F402

00023 (2/2) : 5C (Aug.25, 13:20-15:00) @F402

Type : Proposal of Minisymposium

Abstract : This minisymposium focuses on the new optimization techniques for application problems. Different application scenarios like machine learning and signal processing will be referred.

Organizer(s) : Cong Sun

Classification : 49M37, 65K05
Minisymposium Program :

00023 (1/2) : 5B @F402

[01318] A Unified Single-loop Alternating Gradient Projection Algorithm for Nonconvex-Concave and Convex-Nonconcave Minimax Problems

Format : Talk at Waseda University
Author(s) : Zi Xu (Shanghai University)Huiling Zhang (Shanghai University)Guanghui Lan (Georgia Institute of Technology)
Abstract : Much recent research effort has been directed to the development of efficient algorithms for solving minimax problems with theoretical convergence guarantees due to the relevance of these problems to a few emergent applications. In this paper, we propose a unified single-loop alternating gradient projection (AGP) algorithm for solving smooth nonconvex-(strongly) concave and (strongly) convex-nonconcave minimax problems. AGP employs simple gradient projection steps for updating the primal and dual variables alternatively at each iteration. We show that it can find an ε-stationary point of the objective function in $O(\varepsilon^{-2})$ (resp. $O(\varepsilon^{-4})$) iterations under nonconvex-strongly concave (resp. nonconvex-concave) setting. Moreover, its gradient complexity to obtain an ε-stationary point of the objective function is bounded by $\mathcal{O}(\varepsilon^{-2})$ (resp., $O(\varepsilon^{-4})$) under the strongly convex-nonconcave (resp., convex-nonconcave) setting. To the best of our knowledge, this is the first time that a simple and unified single-loop algorithm is developed for solving both nonconvex-(strongly) concave and (strongly) convex-nonconcave minimax problems. Moreover, the complexity results for solving the latter (strongly) convex-nonconcave minimax problems have never been obtained before in the literature. Numerical results show the efficiency of the proposed AGP algorithm.
Furthermore, we extend the AGP algorithm by presenting a block alternating proximal gradient (BAPG) algorithm for solving more general multi-block nonsmooth nonconvex-(strongly) concave and (strongly) convex-nonconcave minimax problems. We can similarly establish the gradient complexity of the proposed algorithm under these four different settings.

[01287] Accelerated ADMM-type Methods for Convex and Noncovex Optimization Problems

Format : Talk at Waseda University
Author(s) : Jianchao Bai (Northwestern Polytechnical University)
Abstract : In this talk, several accelerated stochastic and deterministic Alternating Direction Method of Multipliers, abbreviated as ADMM, are presented for solving separable convex optimization problems whose objective function is the sum of a possibly nonsmooth convex function and a smooth function which is an average of many component convex functions. We also show an advanced inexact accelerated ADMM for solving separable nonsmooth and nonconvex optimization problem. The convergence and complexity of these algorithms are discussed briefly, and a number of large-scale examples have verified the effectiveness of our algorithms compared with state-of-the-art first-order methods.

[01284] On a special discrete phase constrained complex-field optimization problem

Format : Talk at Waseda University
Author(s) : Cong Sun (Beijing University of Posts and Telecommunications)
Abstract : Reconfigurable intelligent surface (RIS) with discrete phase shifts aided wireless communication network is considered. The resource allocation problem of sum rate maximization with power constraints and discrete phase shifts is solved. The complicated objective function is approximated by its upper bound. The difficult orthogonal constraint is penalized to the objective function through Courant penalty function technique. Two algorithms are proposed for the approximated problem based on alternating direction of multipliers method and proximal gradient method, respectively. Simulations show that the two proposed algorithms achieve higher sum rate with significantly lower computational cost than the sate of the art.

[01368] Stochastic regularized Newton methods for nonlinear equations

Format : Talk at Waseda University
Author(s) : Jiani Wang (Chinese Academy of Sciences)Xiao Wang (Peng Cheng Laboratory)Liwei Zhang (Dalian University of Technology)
Abstract : In this talk, we study finding zeros of nonlinear equations, whose exact function information is normally expensive to calculate but approximations can be easily accessed via calls to stochastic oracles. Based on inexact line search we propose a stochastic regularised Newton method and investigate its global convergence and local convergence rate. We also propose a variant of algorithm incorporating variance reduction scheme and we establish its sample complexity. We also report some numerical results.

00023 (2/2) : 5C @F402

[01475] An Efficient Quadratic-Programming Relaxation Based Algorithm for Large-Scale MIMO Detection

Format : Talk at Waseda University
Author(s) : Ping-Fan ZHAO (Beijing Institute of Technology)Qing-Na LI (Beijing Insitute of Technology)Wei-Kun CHEN (Beijing Institute of Technology)Ya-Feng LIU (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Massive MIMO has been recognized as a key technology in 5G and beyond communication networks, which can significantly improve the communication performance, but also poses new challenges of solving the corresponding optimization problems due to the large problem size. In this talk, we propose an efficient sparse QP relaxation based algorithm for solving the large-scale MIMO detection problem. With exact recovery guaranteed, the algorithm achieves better detection performance compared with the state-of-art algorithms.

[01487] Uniform Framework of Convergence Analysis for Nesterov's Accelerated Gradient Method

Format : Talk at Waseda University
Author(s) : Shuo Chen (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Nesterov's accelerated gradient method (`NAG`) is one of the most influenced methods used in machine learning and other fields. In this talk, we give a new framework to analyze convergence property of `NAG` based on the high-resolution differential equation, phase-space representation and Lyapunov functions. New convergence rate for gradient norm is revealed in convex case, while the requirement for stepsize is loosed and the convergence rate is improved for strongly convex objective.

[01285] Exact continuous relaxations and algorithms for regularized optimization problems

Author(s) : Wei Bian (Harbin Institute of Technology)
Abstract : In this talk, we consider two classes of regularized optimization problems, in which the group sparsity is considered. Firstly, we give the continuous relaxation models of the considered problem and establish the equivalence of these two problems in the sense of global minimizers. Then, we define a class of stationary points of the relaxation problem, and prove that any defined stationary point is a local minimizer of the considered regularized problem and satisfies a desirable property of its global minimizers. Further, based on the difference-of-convex (DC) structure of the relaxation problem, we design some corresponding algorithms and prove their convergence properties.

[00024] Geometric methods in machine learning and data analysis

Session Time & Room :

00024 (1/3) : 1C (Aug.21, 13:20-15:00) @G709

00024 (2/3) : 1D (Aug.21, 15:30-17:10) @G709

00024 (3/3) : 1E (Aug.21, 17:40-19:20) @G709

Type : Proposal of Minisymposium
Abstract : Geometry plays a paramount role in many aspects of data analysis and machine learning: Graphs on high-dimensional datasets encode interactions between geometry and data; Geometries on the space of probability measures give rise to new optimization and sampling algorithms; Geometric deep learning translates deep learning to new domains; Adversarial regularization of neural networks corresponds to geometric regularization. In this minisymposium we gather junior and senior researchers who have been driving the research in the field, using geometric methods for both analysis and algorithms. We aim at sparking new collaborations in this vibrant field and offering a platform for scientific exchange.
Organizer(s) : Leon Bungert, Jeff Calder
Classification : 35R02, 68T05, 49Q22
Minisymposium Program :

00024 (1/3) : 1C @G709 [Chair: Leon Bungert]

[03148] Geometric Data Analysis via Discrete Curvature

Format : Talk at Waseda University
Author(s) : Melanie Weber (Harvard University)
Abstract : The problem of identifying geometric structure in heterogeneous, high-dimensional data is a cornerstone of Machine Learning. In this talk, we approach this problem from the perspective of Discrete Geometry. We begin by reviewing discrete notions of curvature, where we focus especially on discrete Ricci curvature. Then we consider a setting, where a given point cloud was sampled from an (unknown) manifold. We give pointwise consistency results for the discrete curvature of a geometric graph build from the point cloud and the curvature of the manifold. We further show that if the manifold has curvature bounded from below by a positive constant, the geometric graph will inherit this global structural property with high probability. Finally, we discuss applications of discrete curvature and our consistency results in Geometric Data Analysis, including graph-based clustering and regression. The talk is based on joint work with Nicolas Garcia Trillos, Zachary Lubberts and Yu Tian.

[02978] Large data limit of the MBO scheme for data clustering

Format : Online Talk on Zoom
Author(s) : Jona Lelmi (University of Bonn)Tim Laux (University of Bonn)
Abstract : The MBO scheme is a highly performant scheme used for data clustering. Given some data, one constructs the similarity graph associated with the data points. The goal is to split the data into meaningful clusters. The algorithm produces the clusters by alternating between diffusion on the graph and pointwise thresholding. In this talk, I will present the first theoretical studies of the scheme in the large data limit. We will see how the final state of the algorithm is asymptotically related to minimal surfaces in the data manifold and how the dynamic of the scheme is asymptotically related to the trajectory of steepest descent for surfaces, which is mean curvature flow. The tools employed are variational methods and viscosity solutions techniques. Based on joint work with Tim Laux (U Bonn).

[03210] Topologies of convergences for discrete-to-continuum limit on Poission point clouds

Format : Talk at Waseda University
Author(s) : Marco Caroccia (Politecnico di Milano)
Abstract : Energies on point clouds have attracted increasing attention in the last decades, especially due to their application to machine learning and data analysis. What seems to arise from the collection of the results at several scales is that a change in the topology of Gamma-convergence occur when the point clouds is connected at a very short-range interaction scale. Typically, in literature, the interaction range considered is big enough to neglect the defects arising from the stochastic geometry of the point clouds. In the small range interaction regime instead the geometry of the point clouds
cannot be neglected in the analysis of the discrete-to-continuum limit. We will present the various topologies of convergence and the different techniques that are required to obtain the discrete-to-continuum limit at different scales.

[03219] Spectral Methods for Data Sets of Mixed Dimensions

Format : Talk at Waseda University
Author(s) : Leon Bungert (Technical University of Berlin)Dejan Slepcev (Carnegie Mellon University)
Abstract : High dimensional data often consist of parts with different intrinsic dimension. We study how spectral methods on graphs adapt to data containing intersecting pieces of different dimensions. We show that unnormalized Laplacian strongly prefer the highest dimension, while appropriately normalized Laplacian converges to Laplace-Beltrami operator in all dimensions simultaneously. For intersecting manifolds we identify when and how is the information transferred between manifolds.

00024 (2/3) : 1D @G709 [Chair: Jeff Calder]

[03228] An information geometric and optimal transport framework for Gaussian processes

Format : Talk at Waseda University
Author(s) : Minh Ha Quang (RIKEN Center for Advanced Intelligence Project)
Abstract : Information geometry (IG) and Optimal transport (OT) have been attracting much research attention in various fields, in particular machine learning and statistics. In this talk, we present results on the generalization of IG and OT distances for finite-dimensional Gaussian measures to the setting of infinite-dimensional Gaussian measures and Gaussian processes. Our focus is on the Entropic Regularization of the 2-Wasserstein distance and the generalization of the Fisher-Rao distance and related quantities. In both settings, regularization leads to many desirable theoretical properties, including in particular dimension-independent convergence and sample complexity. The mathematical formulation involves the interplay of IG and OT with Gaussian processes and the methodology of reproducing kernel

Hilbert spaces (RKHS). All of the presented formulations admit closed form expressions that can be efficiently computed and applied practically. The theoretical formulations will be illustrated with numerical experiments on Gaussian processes.

[03101] Data analysis and optimal transport: some statistical tools

Format : Talk at Waseda University
Author(s) : Elsa Cazelles (CNRS, Université de Toulouse)
Abstract : We focus on the analysis of data that can be described by probability measures supported on a Euclidean space, through optimal transport. Our main objective is to present first and second order statistical analyses in the space of distributions, as a first approach to understand the general modes of variation of a set of observations. These studies correspond to the barycenter and the decomposition into geodesic principal components in the Wasserstein space.

[02871] Multispecies Optimal Transport and its Linearization

Format : Talk at Waseda University
Author(s) : Katy Craig (Department of Mathematics at the University of California Santa Barbara)Nicolás García Trillos (Department of Statistics at the University of Wisconsin Madison)Dorde Nikolic (Department of Mathematics at the University of California Santa Barbara)
Abstract : The discovery of linear optimal transport by Wang et al. in 2013 improved the computational efficiency of optimal transport algorithms for grayscale image classification. Our main goal is to classify multicolor images arising in collider events. We will introduce the basics of linear optimal transport theory, and the multispecies distance. I will discuss similarities of the multispecies case with the Hellinger-Kantorovich distance, which was linearized in 2021 by Cai et al., via its Riemannian structure.

[03196] Semi-supervised learning with the p-Laplacian

Format : Talk at Waseda University
Author(s) : Nadejda Drenska (Louisiana State University)Jeff Calder (University of Minnesota, Twin Cities)
Abstract : Semi-supervised learning involves learning from both labeled and unlabeled data. In this talk we apply p-Laplacian regularization to cases of very low labeling rate; in such applications this approach classifies properly when the standard Laplacian regularization does not. Using the two-player stochastic game interpretation of the p-Laplacian, we prove asymptotic consistency of p-Laplacian regularized semi-supervised learning, thus justifying the utility of the p-Laplacian.
This is joint work with Jeff Calder.

00024 (3/3) : 1E @G709 [Chair: Leon Bungert]

[03217] The passive symmetries of machine learning

Format : Talk at Waseda University
Author(s) : Soledad Villar (Johns Hopkins University)
Abstract : Any representation of data involves arbitrary investigator choices. Because those choices are external to the data-generating process, each choice leads to an exact symmetry, corresponding to the group of transformations that takes one possible representation to another. These are the passive symmetries; they include coordinate freedom, gauge symmetry and units covariance, all of which have led to important results in physics. Our goal is to understand the implications of passive symmetries for machine learning: Which passive symmetries play a role (e.g., permutation symmetry in graph neural networks)? What are dos and don'ts in machine learning practice? We assay conditions under which passive symmetries can be implemented as group equivariances. We also discuss links to causal modeling, and argue that the implementation of passive symmetries is particularly valuable when the goal of the learning problem is to generalize out of sample.

[03186] Graphons in Machine Learning

Format : Talk at Waseda University
Author(s) : Luana Ruiz (Johns Hopkins University)
Abstract : Graph neural networks are successful at learning representations from graph data but suffer from limitations in large graphs. Yet, large graphs can be identified as being similar to each other in the sense that they share structural properties. Indeed, graphs can be grouped in families converging to a common graph limit--- the graphon. In this talk, I discuss how graphons can be used to lay the theoretical foundations for machine learning on large-scale graphs.

[03178] Graphon Analysis of Graph Neural Networks

Format : Talk at Waseda University
Author(s) : Ron Levie (Technion - Israel Institute of Technology)
Abstract : In recent years, graph neural networks have led to ground-breaking achievements in the applied sciences and industry. These achievements pose exciting theoretical challenges: can the success of graph neural networks (GNNs) be grounded in solid mathematical frameworks?

In this talk, I will show how to define GNN input domains using graphon analysis, and how such domains lead to a universal analysis of GNNs, with generalization bounds and approximation theorems.

[03202] Graph Neural Networks on Large Random Graphs: Convergence, Stability, Universality

Format : Talk at Waseda University
Author(s) : Nicolas Keriven (CNRS, IRISA)
Abstract : In this talk, we will discuss some theoretical properties of GNNs on large graphs. We assume that the graphs are generated with classical models of random graphs. We characterize the convergence of GNNs as the number of nodes grows. We study their stability to small deformations of the underlying model, a crucial property in traditional CNNs. Finally, we study their approximation power, and show how some recent GNNs are more powerful than others.

[00027] Recent trends on crowd management

Session Time & Room : 3E (Aug.23, 17:40-19:20) @A208

Type : Proposal of Minisymposium
Abstract : Crowd management is an interdisciplinary field that has received much attention in recent year, and various scientific methods for reducing the risk of crowd avalanches and infections are being studied. In addition, encouraging decentralized behavior not only enhances safety, but also improves services from marketing viewpoints. Latest research results on sensing, simulation and guidance of crowds, which are all very important in crowd management, will be discussed by applied mathematicians from different backgrounds.
Organizer(s) : Katsuhito Nishinari, Claudio Feliciani, Kensuke Yasufuku ,Tetsuya Aiko
Classification : 91C05, 00A71, 62P25, 68U07, 62P15
Minisymposium Program :

00027 (1/1) : 3E @A208 [Chair: Katsuhiro Nishinari]

[05480] Crowd Management Platform as a Service

Format : Talk at Waseda University
Author(s) : Katsuhiro Nishinari (The University of Tokyo)
Abstract : Crowd management is important for safety and efficient movement of individuals. The process involves sensing crowd conditions in real time, predicting the near future from that data, and then guiding the crowd through a risk assessment to prevent accidents before they happen. The platform supporting this series of functions is named Crowd Management Platform as a Service (CMPaaS).In the presentation, actual case studies using CMPaaS will be presented.

[05405] 3D Visualization of Crowd Motion

Format : Online Talk on Zoom
Author(s) : Kensuke Yasufuku (Osaka University)
Abstract : This presentation proposes methods for effective 3D visualization of crowd motion in large sites under both normal and emergency conditions. We utilize agent-based crowd simulations to model and predict behavioral patterns under various scenarios. These simulations serve as critical tools for predicting congestion within these sites and for evaluating and optimizing appropriate evacuation plans. Furthermore, we will discuss visualization techniques for sharing information among stakeholders.

[05377] Numerical description of pedestrian crowds: are we really particles?

Format : Talk at Waseda University
Author(s) : Claudio Feliciani (The University of Tokyo)
Abstract : Quantification of properties related to pedestrian crowds is necessary for analyzing pedestrian flows and automating real-time control. Often, models inspired by physics and fluid dynamics are used to describe crowds by simplifying people as particles. While these models often yield good results, they are typically only valid for specific conditions. This highlights the need to better understand the cognitive and psychological aspects of human motion in crowds to improve the quantification of pedestrian collective dynamics.

[05404] Crowd management and visitors' attitudes in natural recreational areas

Format : Talk at Waseda University
Author(s) : Tetsuya Aikoh (Hokkaido University)Hyerin Kim (Hokkaido University)Yasushi Shoji (Hokkaido University)
Abstract : While outdoor recreation areas are expected to attract visitors, there are concerns about overtourism. Outdoor spaces without obvious entrances and exits present many sensing challenges. In addition, controlling crowding in public recreation areas requires consensus with visitors and local stakeholders. We will report on recent research findings and their contribution to management in World Heritage areas and urban greening events.

[00029] New Trends in Structural and Engineering Optimization

Session Time & Room :

00029 (1/2) : 4E (Aug.24, 17:40-19:20) @A508

00029 (2/2) : 5C (Aug.25, 13:20-15:00) @A508

Type : Proposal of Minisymposium
Abstract : Over a wide range of modern engineering design, numerical optimization plays crucial roles in diverse decision-making processes. This minisymposium aims to bring together recent advances in various aspects of structural and engineering optimization. The topics of interest include, but are not limited to

- new advances in structural optimization methods,
- surrogate modeling and digital twins for engineering optimization,
- multi-scale and microstructral topology optimization,
- machine learning and data-driven approaches to optimization.

Organizer(s) : Yoshihiro Kanno, Satoshi Kitayama, Akihiro Takezawa
Classification : 90C90, 65K10, 49M37, 74P05, 74P10
Minisymposium Program :

00029 (1/2) : 4E @A508 [Chair: Satoshi Kitayama]

[04641] Topology optimization reducing the dynamic instability of squeal noise

Format : Talk at Waseda University
Author(s) : SolJi Han (Hanyang University)GilHo Yoon (hanyang university)
Abstract : This study focuses on topology optimization considering the dynamic instability of squeal noise. In this study, the instability value caused by the frictional force is analysed through the eigenvalue analysis, and the sensitivity is calculated by left and right eigenvectors. With the present development, it is possible to optimize a structure that effectively reduces the instability value. To verify this study, several optimization examples are considered.

[03974] Structural simulation and optimization to improve the quality of metal additive manufacturing

Format : Talk at Waseda University
Author(s) : Akihiro Takezawa (Waseda University)
Abstract : Reduction of the residual warpage generated through fabrication is an emerging issue in metal laser powder bed fusion additive manufacturing (AM). Regarding the minimization of the residual warpage of the lattice infill structures, simultaneous optimization of the laser hatching orientation and lattice density distribution is conducted in this study to confirm their synergetic effect.

[03594] Machine-learning assisted topology optimization with structural gene inheritance

Format : Talk at Waseda University
Author(s) : Weisheng Zhang (Dalian University of Technology)Sung-Kie Youn (KAIST)Xu Guo (Dalian University of Technology)
Abstract : A machine-learning assisted topology optimization approach is proposed for structural design with structural gene inheritance. This work establishes a novel framework to systematically integrate structural topology optimization with subjective human design preferences. To embed the structural gene into the design, neural style transfer technique is adopted to measure and generate the prior knowledge from a reference image with the concerned structural gene (such as biological characteristic, artistic flavor and manufacturing requirement, etc.). By using different convolutional layers in the VGG-19 model-based CNN, both the style and content of the structural gene can be constructed from low to high levels of abstraction. The measured knowledge can then be integrated into pixel-based topology optimization as a formal similarity constraint. Both 2D and 3D problems are solved to illustrate the effectiveness of the proposed approach where the inheritance of the structural gene can be achieved in a systematic manner.

00029 (2/2) : 5C @A508 [Chair: Akihiro Takezawa]

[03346] Numerical and experimental investigation on process parameters optimization in rapid heat cycle molding

Format : Talk at Waseda University
Author(s) : Satoshi Kitayama (Kanazawa University)Yusuke Yamazaki (Sodick Co. Ltd.)Yoshikazu Kubo (Sodick Co. Ltd.)Shuji Aiba (Sodick Co. Ltd.)
Abstract : Weldline that is forms when two or more melt fronts meet is one of the major defects in plastic injection molding (PIM), and it is important to reduce the wedline as much as possible. Rapid heat cycle molding (RHCM) is one of the effective PIMs for weldline reduction, but the process parameters are determined by the trial and error method. This paper optimizes the process parameters in RHCM by CAE and design optimization technique. The experiment is also conducted to examine the validity of the proposed approach.

[01219] Acoustic metamaterials design with non-gradient material-field series-expansion topology optimization

Format : Talk at Waseda University
Author(s) : Xiaopeng Zhang (Dalian Dalian University of TechnologyUniversity of Technology)
Abstract : Designing bandgap acoustic metamaterial has important application potential but is also challenging. This study proposes a systematic topology optimization method of acoustic metamaterial to open single and multiple low-frequency bandgaps. To describe the complicated topologies of the multi-material acoustic metamaterial with a lower number of design variables, the material-field series expansion (MFSE) technique is adopted. With the interpolated scheme and the multi-material field description model, a clear three-material topology can be determined by two independent material-field functions with only 100 independent design variables. This greatly reduces the design variables for the topological description of the microstructure, enabling the problem to be solved using non-gradient optimization algorithms. The self-adaptive strategy based sequential Kriging optimization algorithm is then introduced to solve the optimization problems. Numerical examples prove the proposed topology optimization method can effectively provide the acoustic metamaterial designs with ultra-wide low-frequency bandgaps.

[04675] Multiscale topology optimization to maximize dissipated energy

Format : Talk at Waseda University
Author(s) : Takashi Yamamoto (Kogakuin University)
Abstract : In this study, a multiscale topology optimization method for micro structure is proposed utilizing the homogenization method based on the asymptotic expansion. Energy dissipated in macroscopic component is maximized at a prescribed frequency. Design sensitivities of the homogenized macroscopic properties are calculated by applying the

adjoint variable method in the frame work of the homogenization method. Adjoint variable method is hierarchically applied to obtain design sensitivities of the macroscopic dissipated energy.

[03135] Multiscale topology optimization of fiber reinforced composite using homogenization design method.

Format : Talk at Waseda University
Author(s) : Jaewook Lee (Gwangju Institute of Science and Technology (GIST))
Abstract : This presentation shows topology optimization of fiber reinforced composite with spatially-varying fiber structure. The numerical homogenization of the microscale unit-cell is performed at various fiber sizes. Then, the effective elasticity tensor is represented as the function of fiber size and orientations, together with the density. Topology optimization is carried out at macroscale, and the microscale composite structure is restored using the de-homogenization method. Both 2D and 3D design examples will be provided.

[00033] Recent Advances on Quantitative Finance

Session Time & Room :

00033 (1/3) : 5B (Aug.25, 10:40-12:20) @A510

00033 (2/3) : 5C (Aug.25, 13:20-15:00) @A510

00033 (3/3) : 5D (Aug.25, 15:30-17:10) @A510

Type : Proposal of Minisymposium
Abstract : The mini-symposium we propose aims to feature the latest developments and promote research in the field of quantitative finance. The mini-symposium will enhance interaction and cooperation among researchers worldwide working on some specific topics in the field. In particular, we will focus on, but are not limited to, the following three topics:
- stochastic control in quantitative finance,
- dynamic game and mean-field game in quantitative finance, and
- machine learning and reinforcement learning in quantitative finance.

Consequently, we plan to have three sessions on the above three topics, respectively

Organizer(s) : Min Dai, Zuoquan Xu, Chao ZhouSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.
Classification : 91G10, 93E20, 35Q91, 49N90
Minisymposium Program :

00033 (1/3) : 5B @A510 [Chair: Min Dai]

[04926] Neural Stopping Boundaries

Format : Talk at Waseda University
Author(s) : Halil Mete Soner (Princeton University)Anders Max Reppen (Boston University Questrom School of Business)Valentin Tissot-Daguette (Princeton University)
Abstract : A method based on deep artificial neural networks and empirical risk minimization is developed to calculate the boundary separating the stopping and continuation regions in optimal stopping. The algorithm parameterizes the stopping boundary as the graph of a function and introduces relaxed stopping rules based on fuzzy boundaries to facilitate efficient optimization. Several examples related to financial instruments, some in high dimensions, are analyzed through this method, demonstrating its effectiveness. The existence of the stopping boundary is also proved under natural structural assumptions. We also briefly show how this method applies tis the classical Stefan problem of solidification.

[05322] Learning Equilibrium Mean-Variance Strategy

Format : Talk at Waseda University
Author(s) : Min Dai (The Hong Kong Polytechnic University)Yuchao Dong (Tongji University)Yanwei Jia (Columbia University)
Abstract : We study a dynamic mean-variance portfolio optimization problem under the reinforcement learning framework,

where an entropy regularizer is introduced to induce exploration. Due to the time–inconsistency involved in a mean-variance criterion, we aim to learn an equilibrium policy. Under an incomplete market setting, we obtain a semi-analytical, exploratory, equilibrium mean-variance policy that turns out to follow a Gaussian distribution. We then focus on a Gaussian mean return model and propose a reinforcement learning algorithm to find the equilibrium policy. Thanks to a thoroughly designed policy iteration procedure in our algorithm, we prove the convergence of our algorithm under mild conditions, despite that dynamic programming principle and the usual policy improvement theorem failing to hold for an equilibrium policy. Numerical experiments are given to demonstrate our algorithm. The design and implementation of our reinforcement learning algorithm apply to a general market setup.

[05301] On Consistency of Selecting Signatures Using Lasso: A Tale of Ito and Stratonovich

Format : Talk at Waseda University
Author(s) : Xin Guo (UC Berkeley)Ruixun Zhang (Peking University)Chaoyi Zhao (Peking University)
Abstract : We investigate the statistical consistency of using Lasso to select signatures in machine learning predictions. Signatures are defined as iterated path integrals of stochastic processes, and their universal nonlinearity warrants Lasso as a common tool to select sparse linear approximations. We study the consistency of Lasso for selecting signatures for the Brownian motion, the Ornstein--Uhlenbeck process, and the fractional Brownian motion, both theoretically and numerically. Our findings show that, for signatures defined by Ito integrals, Lasso is more consistent for processes that are closer to Brownian motion and have weaker inter-dimensional correlations. For signatures defined by Stratonovich integrals, we observe better Lasso consistency for mean-reverting processes than for mean-averting processes. Our results emphasize the importance of choosing appropriate definitions of signatures in statistical inference and machine learning, particularly for non-Brownian processes.

[02766] Portfolio choice with transaction costs and reinforcement learning

Format : Talk at Waseda University
Author(s) : Min Dai (Hong Kong Polytechnic University)
Abstract : We provide a reinforcement learning approach for portfolio choice with transaction costs. Numerical results are provided to demonstrate the efficiency of our approach.

00033 (2/3) : 5C @A510 [Chair: Zuoquan Xu]

[05335] Dynamic programming for mean-variance portfolio selection

Format : Talk at Waseda University
Author(s) : Martin Schweizer (ETH Zurich)
Abstract : We present a dynamic programming approach to solving the mean-variance portfolio selection problem in finite discrete time. This bypasses issues of time-inconsistency and hence does not need the introduction of an equilibrium or game-theoretic approach. The talk is based on joint work with Zhouyi Tan.

[05363] Non-Concave Utility Maximization with Transaction Costs

Format : Talk at Waseda University
Author(s) : shuaijie qian (Hong Kong University of Science and Technology)Chen Yang (The Chinese University of Hong Kong)
Abstract : We consider the non-concave utility maximization problem, which appears in plenty of areas in finance, with transaction costs. Technically, we propose a proper terminal condition and lay the corresponding theoretical foundation of viscosity solutions. This terminal condition implies that any transaction close to maturity provides a marginal contribution to the target. We find that the introduction of transaction costs into non-concave utility problems can prevent the portfolio from unbounded leverage and also result in richer action regions than classical transaction costs problems with concave utilities.

[05320] Optimal stopping without time consistency

Format : Talk at Waseda University
Author(s) : Hanqing Jin (University of Oxford)Yanzhao Yang (University of Oxford)
Abstract : We study a continuous time dynamic optimal stopping problem with a flow of preferences, which can be in non-expectation form and can depend on both the current time and state of the system in general. We will define a solution to the problem by the rationality of the agent, and compare it with other solutions appeared in literature.

[03404] Optimal dividend payout with non-decreasing constraint

Format : Talk at Waseda University
Author(s) : Zuo Quan Xu (The Hong Kong Polytechnic University)Chonghu Guan (Jiaying University)
Abstract : We study a dividend payout problem under the classical Cram ́er-Lundberg model. The dividend payout must be non-decreasing over time and is subject to an upper bound constraint. Finding the optimal dividend payout strategy in this model is a long-standing open problem in risk theory. To overcome the difficulty, we first introduce a regime-switching problem --- a sequence of single-obstacle problems in ODE --- to approximate the original two-dimensional HJB equation and then take limit. We find a smooth switching boundary and the optimal strategy is given by the boundary.

00033 (3/3) : 5D @A510 [Chair: Chao Zhou]

[05500] Extended mean-field control problems with multi-dimensional singular controls

Format : Talk at Waseda University
Author(s) : Ulrich Horst (Humboldt University Berlin)Robert Denkert (Humboldt University Berlin)
Abstract : We consider extended mean-field control problems with multi-dimensional singular controls. A key challenge when analysing singular controls are jump costs. When controls are one-dimensional, jump costs are most naturally computed by linear interpolation. When the controls are multi-dimensional the situation is more complex, especially when the model parameters depend on an additional mean-field interaction term, in which case one needs to `jointly'' and`consistently'' interpolate jumps both on a distributional and a pathwise level. This is achieved by introducing the novel concept of two-layer parametrisations of stochastic processes. Two-layer parametrisations allow us to equivalently rewrite rewards in terms of continuous functions of parametrisations of control process and to derive an explicit representation of rewards in terms of minimal jump costs. From this we derive a DPP for extended mean-field control problems with multi-dimensional singular controls. Under the additional assumption that the value function is continuous we characterise the value function as the minimal super-solution to a certain quasi-variational inequality in the Wasserstein space.

[05172] Lightning Network Economics: Channels and Topology

Format : Talk at Waseda University
Author(s) : Paolo Guasoni (Dublin City University)Gur Huberman (Columbia Business School)Clara Shikhelman (Chaincode Labs)
Abstract : Designed to address Bitcoin's scalability challenge, the Lightning Network (LN) is a protocol allowing two parties to secure bitcoin payments and escrow holdings between them. In a lightning channel, each party commits collateral towards future payments to the counterparty and payments are cryptographically secured updates of collaterals. First, we identify conditions for two parties to optimally establish a channel, find explicit formulas for channel costs and optimal collaterals, and derive the implied reduction in congestion of the blockchain. Then we obtain necessary conditions for cost-minimizing topologies and bounds on the cost of the optimal topology, showing the unusual circumstances in which it is a hub that connects all other nodes.

[05309] Non-monotone linear-quadratic mean field games with a major player

Format : Talk at Waseda University
Author(s) : Chenchen Mou (City University of Hong Kong)Min Li (Shandong University)Zhen Wu (Shandong University)Chao Zhou (National University of Singapore)
Abstract : In this talk, we consider a class of linear-quadratic mean field games with a major player. The game has the feature that the major player can have an impact on all the minor players while the miner players as a whole influence the major player. The value functions corresponding to the major and minor players satisfy the corresponding master equations, which generate the so-called master system. To the best of our knowledge, the global wellposedness of the master system remains open. The main focus of the paper is to tackle the open problem in the linear-quadratic setting without any monotonicity conditions. The key idea is to use the non-degeneracy of the common noise to show the global wellposedness of the Nash certainty equivalence system for the minor players. Meanwhile, we also study the corresponding N-minor player and a major player game. More precisely, we show the quantitative convergence from the N-minor player and a major player game to the mean field game and the propagation of chaos property for the related optimal trajectories for both the minor players and the major player. This is based on a joint work with M. Li, Z. Wu and C. Zhou.

[05501] Large ranking games with diffusion control

Format : Talk at Waseda University
Author(s) : Stefan Ankirchner (University of Jena)Nabil Kazi-Tani (Université de Lorraine)Julian Wendt (University of Jena)Chao Zhou (National University of Singapore)
Abstract : We consider a symmetric stochastic differential game where each player can control the diffusion intensity of an individual dynamic state process, and the players whose states at a deterministic finite time horizon are among the best $\alpha \in (0, 1)$ of all states receive a fixed prize. Within the mean field limit version of the game we compute an explicit equilibrium, a threshold strategy that consists in choosing the maximal fluctuation intensity when the state is below a given threshold, and the minimal intensity else. We show that for large n the symmetric n-tuple of the threshold strategy provides an approximate Nash equilibrium of the n-player game. We also derive the rate at which the approximate equilibrium reward and the best response reward converge to each other, as the number of players n tends to infinity. Finally, we compare the approximate equilibrium for large games with the equilibrium of the two player case.

[00036] Different perspectives in non-linear and non-local PDEs

Session Time & Room :

00036 (1/3) : 1C (Aug.21, 13:20-15:00) @G602

00036 (2/3) : 1D (Aug.21, 15:30-17:10) @G602

00036 (3/3) : 1E (Aug.21, 17:40-19:20) @G602

Type : Proposal of Minisymposium
Abstract : The aim of this minisymposium is to gather researchers involved in the mathematical analysis of non-linear and non-local partial differential equations (PDEs), with emphasis on those modelling aggregation and/or diffusion phenomena. These PDEs are relevant in applications to physics, biology, population dynamics, data science, etc. The spectrum of possible mathematical approaches involves techniques from functional analysis, optimal transport theory, variational methods, etc. It is at the core of our minisymposium to touch upon recent advances in the study of aggregation-diffusion PDEs obtained, e.g., using generalised gradient flows, incompressible limits, particle approximations, numerical methods, symmetrisation and rearrangements, and Fourier analysis.

[04031] Quantified overdamped limit for Vlasov-Fokker-Planck equations with singular interaction forces

Format : Talk at Waseda University
Author(s) : Young-Pil Choi (Yonsei University)
Abstract : In this talk, I will discuss a quantified overdamped limit for kinetic Vlasov-Fokker-Planck equations with nonlocal interaction forces. We provide explicit bounds on the error between solutions of that kinetic equation and the limiting equation, which is known under the names of aggregation-diffusion equation or McKean-Vlasov equation. Our strategy only requires weak
integrability of the interaction potentials, thus in particular it includes the quantified overdamped limit of the kinetic Vlasov-Poisson-Fokker-Planck system to the aggregation-diffusion equation with either repulsive electrostatic or attractive gravitational interactions.

[04055] A Degenerate Cross-Diffusion System as the Inviscid Limit of a Nonlocal Tissue Growth Model

Format : Talk at Waseda University
Author(s) : Noemi David (University of Lyon)Tomasz Dębiec (University of Warsaw)Mainak Mandal (Technische Universität Dresden)Markus Schmidtchen (Technische Universität Dresden)
Abstract : In recent years, there has been a spike in interest in multi-phase tissue growth models. Depending on the type of tissue, the velocity is linked to the pressure through Stoke's law, Brinkman's law or Darcy's law. While each of these velocity-pressure relations has been studied in the literature, little emphasis has been placed on the fine relationship

between them. In this paper, we want to address this dearth in the literature, providing a rigorous argument that bridges the gap between a viscoelastic tumour model (of Brinkman type) and an inviscid tumour model (of Darcy type).

[03802] Nonlocal particle approximations of the porous medium equation

Format : Online Talk on Zoom
Author(s) : Katy Craig (University of California, Santa Barbara)Olga Turanova (Michigan State University)Karthik Elamvazhuthi (University of California, Riverside)Matt Haberland (Cal Poly, San Luis Obispo)
Abstract : Given a desired target distribution and an initial guess of its samples, what is the best way to evolve the locations of the samples so that they accurately represent the desired distribution? A classical solution to this problem is to evolve the samples according to Langevin dynamics, a stochastic particle method for the Fokker-Planck equation. In today's talk, I will contrast this with a nonlocal, deterministic particle method inspired by the porous medium equation. Using the Wasserstein gradient flow structure of the equations and Serfaty's scheme of Gamma-convergence of gradient flows, I will show that, as the number of samples increases and the interaction scale goes to zero, the interacting particle system indeed converges to a solution of the porous medium equation. I will close by discussing practical implications of this result to both sampling and the training dynamics two-layer neural networks. This is based on joint work with Karthik Elamvazhuthi, Matt Haberland, and Olga Turanova.

[05056] A convergent discretization of the porous medium equation with fractional pressure

Format : Talk at Waseda University
Author(s) : Félix del Teso (Universidad Autónoma de MadridU)
Abstract : We carefully construct and prove convergence of what is to our knowledge the first numerical discretization of the porous medium equation with fractional pressure,
\begin{equation}\tag{FPE}
\frac{\partial u}{\partial t}-\nabla\cdot\left(u^{m-1}\nabla(-\Delta)^{-\sigma}u\right)=0,
\end{equation}
for $\sigma \in (0,1)$. The model was introduced by Caffarelli and Vázques in 2011, and is currently one of two main nonlocal extensions of the local porous medium equation. It has finite speed of propagation and comes from a nonlocal Fick's law, but as opposed to the other extension, it does not satisfy the comparison principle. Without comparison, the analysis is difficult. Uniqueness is only known in 1d, where one can exploit that the ``cumulative density'' $v(x,t)=\int_{-\infty}^{y} u(y,t)dy$ satisfies
\begin{equation}
\frac{\partial v}{\partial t}+|\partial_xv|^{m-1}(-\Delta)^s v=0,\quad s=1-\sigma,
\end{equation}
which is a nonlocal quasilinear parabolic equation in nondivergence form that can be analyzed through viscosity solution methods.

Our numerical method then loosely speaking consists in discretizing this ``integrated'' equation with a difference quadrature scheme and then compute the solution u of (FPE) via numerical differentiation. Using upwinding in non-traditional way, we obtain a new type of monotone schemes that allows for convergence analysis via the Barles-Perthame-Souganidis half-relaxed limit method. Combining this result with tightness arguments, we then prove convergence of the approximations of the original problem in the Rubinstein-Kantorovich/Wasserstein-1 distance uniformly in time.

Our results cover both absolutely continuous and Dirac or point mass initial data, and in the latter case, machinery for discontinuous viscosity solutions are needed in the analysis.

00036 (2/3) : 1D @G602 [Chair: David Gómez-Castro]

[05097] Uniform spectral gap in nonlocal-to-local approximations of diffusion

Format : Talk at Waseda University
Author(s) : José Cañizo (Universidad de Granada)
Abstract : We consider the nonlocal diffusion equation $\partial_t u = \frac{1}{\epsilon^2}(J_\epsilon * u - u) + \nabla \cdot (xu)$, where $J_\epsilon(x) = \epsilon^{-d} J(x/\epsilon)$, posed for $t \geq 0$ and $x \in \mathbb{R}^d$. This equation approximates the standard Fokker-Planck equation as $\epsilon \to 0$, and serves as a good test ground for several techniques used to study the long-time behaviour of nonlocal PDE. In particular, entropy techniques are not easy to apply here, and lead to functional inequalities which are not well understood. Using probabilistic techniques we show that the above equation has a uniformly positive spectral gap as $\epsilon \to 0$, and we link this to quantitative versions of the central limit theorem. This problem has links to numerical analysis and to some models in mathematical biology, which will also be discussed.

[03996] Concentration phenomena arising in Aggregation Fast-Diffusion equations

Format : Talk at Waseda University
Author(s) : Alejandro Fernández-Jiménez (University of Oxford)
Abstract : We will discuss about the asymptotic behaviour of the family of Aggregation-Diffusion Equations

$$\partial_t \rho = \Delta \rho^m + div(\rho \nabla (V + W * \rho)), \tag{1}$$

for $0

[05394] Sharp uniform-in-time propagation of chaos on the torus

Format : Online Talk on Zoom
Author(s) : Rishabh Sunil Gvalani (Max Planck Institute for Mathematics in the Sciences)Matías Delgadino (The University of Texas at Austin)
Abstract : We prove uniform-in-time propagation of chaos for weakly interacting diffusions with gradient drift on the torus. Our results are sharp both in terms of the rate (i.e. $N^{-\frac{1}{2}}$) and validity (they hold in the full subcritical range of temperatures). The proof relies on directly controlling the path-space relative entropy between the N particle system and N i.i.d copies of the synchronously-coupled limiting McKean SDE. This is joint work with Matías Delgadino.

[04109] Limiting gradient flow structure of deep linear neural networks

Format : Online Talk on Zoom
Author(s) : Xavier Fernandez-Real (EPFL)
Abstract : We present recent results with L. Chizat, M. Colombo, A. Figalli, on the infinite-width limit of deep linear neural networks initialized with random parameters. We show that, when the number of neurons diverges, the training dynamics converge (in a precise sense) to the dynamics obtained from a gradient descent on an infinitely wide deterministic linear neural network.

00036 (3/3) : 1E @G602 [Chair: José Antonio Carrillo]

[04224] Deterministic Particle Approximation for aggregation-diffusion equations: entropy solutions, gradient flows, graph.

Format : Talk at Waseda University
Author(s) : Simone Fagioli (University of L'Aquila)
Abstract : We investigate the existence of weak type solutions for a class of aggregation–diffusion PDEs with nonlinear mobility obtained as deterministic large particle limit of a suitable nonlocal versions of the follow-the-leader scheme, which is interpreted as the discrete Lagrangian approximation of the target continuity equation. We prove the well-posedness of entropy solutions for a wide class of nonlocal transport equations with nonlinear mobility in one spatial dimension. At the same time, we expose a rigorous gradient flow structure for this class of equations in terms of an Energy-Dissipation balance, which we obtain via the asymptotic convergence of functionals. The well-posedness is also investigated for aggregation/diffusion equation modeling the evolution of opinion formation on an evolving graph.

[03893] Non-local PDEs on graphs

Format : Online Talk on Zoom
Author(s) : André Schlichting (University of Münster)
Abstract : This talk reviews some recent results on nonlocal PDEs describing the evolution of a density on discrete graph structures. These structures can arise from applications in the data science field, or they can also be obtained by a numerical discretization of a continuum problem. We also show how those equations are linked to their continuous counterpart in suitable local limits.

[00037] Recent advances in modelling and simulation of interfacial flows

Session Time & Room :

00037 (1/2) : 3D (Aug.23, 15:30-17:10) @D402

00037 (2/2) : 3E (Aug.23, 17:40-19:20) @D402

Type : Proposal of Minisymposium
Abstract : Interfacial flows arise in numerous natural and technological applications spanning a wide range of length scales from lab-on-a-chip systems to planetary-scale flows. From a purely scientific perspective, these flows pose fundamental theoretical, computational, and experimental challenges to explain complex phenomena including the formation of coherent structures and wave-breaking, as well as phase and topological transitions. Advances in understanding have opened the way for new schemes that allow for precision optimisation and control. This minisymposium will bring together an array of cross-disciplinary specialists, working at the cutting edge of the field, to share their expertise and to exchange ideas.

[02292] Interfacial flows and their modelling and control

Format : Online Talk on Zoom
Author(s) : Alexander Wray (University of Strathclyde)Radu Cimpeanu (University of Warwick)Susana Gomes (University of Warwick)
Abstract : Interfacial flows are ubiquitous in nature and industry, and modelling, understanding and controlling them has applications everywhere from carbon sequestration to medical diagnostics. As an introduction to this session, we provide an overview of the topic area, particularly with regards to the state of the art and relevant applications. We also discuss our recent work on controlling the full Navier-Stokes equations using reduced-order models as an example of tying together many of these research strands.

[05417] New perspectives on continuous film flow over non-planar substrate: a family affair

Format : Talk at Waseda University
Author(s) : Markus Scholle (Heilbronn University)Philip H. Gaskell (Durham University)
Abstract : Film flow on curved substrate is investigated theoretically for: (i) continuously-fed, full coverage; (ii) partial coverage following deposition of a fixed liquid volume; (iii) rivulet formation. Using a novel variational formulation uncovers the presence of an interrelated family of flows for 3D axisymmetric geometries and related 2D counterparts. Analytic solutions for local film thickness and the internal flow are obtained, together with rigorous identification of associated timescales, via asymptotic analysis combined with the long-wave approximation.

[02788] Nonlinear dynamics of unstably stratified two-layer shear flow in a horizontal channel

Format : Talk at Waseda University
Author(s) : Anna Kalogirou (University of Nottingham)Mark Blyth (University of East Anglia)
Abstract : The Rayleigh-Taylor instability at the interface of two sheared fluid layers in a horizontal channel is investigated. The dynamics of the flow is described by a nonlinear lubrication equation which is solved numerically for adverse density stratifications, revealing a number of interfacial phenomena including finger-like protrusions, coalescence, saturated travelling waves, and near-segregation of the two fluids. The finer structure of the interface is exposed through asymptotic analysis and is compared to numerical results of the lubrication model as well as direct numerical simulations, displaying an excellent agreement between the three in terms of interfacial structure, wave speed and film thicknesses.

[04110] Neural network methods for solving interface problems

Format : Talk at Waseda University
Author(s) : Te-Sheng Lin (National Yang Ming Chiao Tung University)Ming-Chih Lai (National Yang Ming Chiao Tung University, Taiwan)Wei-Fan Hu (National Central University)Yu-Hau Tseng (National University of Kaohsiung)
Abstract : Neural networks have emerged as powerful tools for numerically solving partial differential equations. In this talk, we will discuss our recent work using neural network approaches to elliptic interface problems, and possible extensions to deal with models arising from interfacial phenomena. Specifically, we will introduce a structure enforcement layer in the network to enforce the inherent properties of the solutions to given problems, such as discontinuity or periodicity. The structure enforcement layer offers a new approach to solving such problems compared to traditional neural networks, which may struggle to represent discontinuous functions and may not have built-in periodicity.

00037 (2/2) : 3E @D402 [Chair: Anna Kalogirou]

[05355] On the transition to dripping of an inverted liquid film

Format : Talk at Waseda University
Author(s) : Mark Blyth (University of East Anglia)Dmitri Tseluiko (Loughborough)Te-Sheng Lin (National Yang Ming Chiao Tung University)
Abstract : We discuss the transition to dripping in the gravity-driven motion of a liquid film under an inclined plate. Attention is focused on calculating travelling-wave solutions, for fixed fluid volume and fixed flow rate, using model lubrication equations and the full Stokes equations, and tracking the travelling-wave solution branch as the inclination angle of the plate is increased. Where the branch reaches a turning point we posit that the onset to dripping occurs.

[03447] Influence of an elastic sheet on impact on a liquid surface

Format : Talk at Waseda University
Author(s) : Doireann O'Kiely (MACSI, University of Limerick)Finn Box (University of Manchester)Ousmane Kodio (MIT)Dominic Vella (University of Oxford)
Abstract : Impact at a liquid-air interface changes when an elastic sheet floats on the liquid surface. A ripple propagates out from the point of impact, but has a wavefront $r_m \sim t^{1/2}$ rather than the $r_m \sim t^{2/3}$ typical of capillary waves. We discuss the behaviour of the ``elastocapillary ripple'', and reduce this new impact problem to a one-parameter similarity problem which interpolates between the limits of a point impactor and Wagner theory.

[03420] Spin Coating on a Non-Axisymmetric Curved Substrate

Format : Talk at Waseda University
Author(s) : Ross Geoffrey Shepherd (University of Cambridge)Edouard Boujo (Ecole Polytechnique Federale de Lausanne)Mathieu Sellier (University of Canterbury)
Abstract : Spin coating is used to apply functional coatings to flat substrates in the manufacturing of a range of electronic and optical components. Here, we develop a generalised model for the flow of a spin-coated film over an arbitrary substrate geometry, incorporating gravitational, surface tension, centrifugal, and Coriolis forces. In particular, we demonstrate the effects of the Coriolis force on the formation of fingering instabilities and the flow during the early stages of spin coating.

[05432] Evaporation and the coffee-ring effect for non-circular droplets

Format : Online Talk on Zoom
Author(s) : Madeleine Moore (University of Hull)Alexander Wray (University of Strathclyde)
Abstract : Diffusion-limited evaporation of liquid droplets is commonplace in industrial applications such as microscale patterning and Q/OLED production. However, beyond simple geometries, there are few analytical solutions. Here, we derive asymptotic results for the evaporative flux of a weakly non-circular droplet and demonstrate how these may be used to find the 'coffee ring' for large droplets, with excellent agreement to numerical simulations. Then, we show how the mathematical framework may be extended to polygonal drops.

[00038] Frontiers of gradient flows: well-posedness, asymptotics, singular limits

Session Time & Room :

00038 (1/2) : 1C (Aug.21, 13:20-15:00) @G710

00038 (2/2) : 1D (Aug.21, 15:30-17:10) @G710

Type : Proposal of Minisymposium
Abstract : Gradient flows, a type of dynamics where systems follow steepest descent paths of various functionals, are ubiquitous in many areas of science and technology. Their mathematical understanding is still developing. Ideas like evolutionary variational inequalities, notions of slope, or very weak definitions originating from dynamical systems allow for far-reaching generalizations. Nonetheless, obstacles such as lack of convexity, non-trivial weights, or complicated geometric settings still cause difficulties. We would like to gather experts within the broad limits we stated, dealing with well-posedness and properties of gradient flows in non-classical cases, as well as singular limits or asymptotics.

[05191] Existence for a class of fourth-order quasilinear parabolic systems

Format : Talk at Waseda University
Author(s) : Michal Lasica (Polish Academy of Sciences)Yoshikazu Giga (the University of Tokyo)
Abstract : We consider a class of nonlinear fourth-order parabolic systems of PDEs formally arising as gradient flows of p-Dirichlet type energies with respect to H^{-1} metrics weighted by spatial derivatives of the solution up to second order. PDEs with such structure appear for example in modeling of thermal fluctuations in crystal surfaces. We prove global existence of weak solutions. Our tools include a variant of Galerkin scheme, monotonicity methods, and interpolation.

[03572] Evolutionary limit of gradient flows in heterogeneous Wasserstein space

Format : Online Talk on Zoom
Author(s) : Yuan Gao (Purdue University)
Abstract : The Fokker-Planck equation with fast oscillated coefficients can be regarded as a gradient flow in Wasserstein space with heterogeneous medium. We will use an evolutionary variational approach to obtain the homogenized dynamics, which preserves the gradient flow structure in a limiting homogenized Wasserstein space. Equivalent formulations for heterogeneous Wasserstein distance and their limits will also be discussed.

[04719] The fourth-order total variation flow in R^n

Format : Talk at Waseda University
Author(s) : Hirotoshi Kuroda (Hokkaido University)Yoshikazu Giga (the University of Tokyo)Michał Łasica (Polish Academy of Sciences)
Abstract : We characterize the solution in terms of what is called the Cahn-Hoffman vector field, and introduce a notion of calibrability of a set in our fourth-order setting.
This notion is related to whether a characteristic function preserves its form throughout the evolution.
If $n \neq 2$, all annuli are calibrable.
In the case $n = 2$, if an annulus is too thick, it is not calibrable.

[05426] Global existence for the p-Sobolev flow

Format : Online Talk on Zoom
Author(s) : Masashi Misawa (Kumamoto University)
Abstract : We shall talk about the global existence of the p-Sobolev flow.
The p-Sobolev flow is regarded as the heat flow associated with
the Sobolev inequality and the nonlinear eigenvalue problem
corresponding to it. We shall study the asymptotic behavior
of the p-Sobolev flow and present the so-called volume concentration
phenomenon at time-infinity.

00038 (2/2) : 1D @G710 [Chair: Piotr Rybka]

[02587] Weak solutions to gradient flows in metric measure spaces

Format : Talk at Waseda University
Author(s) : Jose M Mazon (Universitat de Valencia)
Abstract : We show how to introduce the notion of weak solutions in metric measure spaces in the model case of the p-Laplacian evolution equation, including the borderline case $p = 1$, i.e., the total variation flow. For $p > 1$, it has been previously studied as the gradient flow in $L^2$of the p-Cheeger energy. Using the first-order differential structure on a metric measure space introduced by Gigli, we characterise the subdifferential in L^2 of the p-Cheeger energy. This leads to a new definition of solutions to the p-Laplacian evolution equation in metric measure spaces, in which the gradient is replaced by a vector field, defined via Gigli's differential structure, satisfying some compatibility conditions.

[04233] Duality methods for gradient flows of linear growth functionals

Format : Online Talk on Zoom
Author(s) : Wojciech Górny (University of Vienna; University of Warsaw)Jose M Mazón (University of València)
Abstract : We study gradient flows in L^2 of general convex and lower semicontinuous functionals with linear growth. Typical examples of such evolution equations are the time-dependent minimal surface equation and the total variation flow. Classical results concerning characterisation of solutions require a special form or differentiability of the

Lagrangian; we apply a duality-based method to formulate a general definition of solutions, prove their existence and uniqueness, and reduce the regularity and structure assumptions on the Lagrangian.

[04556] Convergence of Sobolev gradient trajectories to elastica

Format : Talk at Waseda University
Author(s) : Shinya Okabe (Tohoku University)
Abstract : In this talk we consider the $H^2(ds)$-gradient flow for the modified elastic energy defined on closed immersed curves in $\mathbb{R}^n$. We prove (i) the existence of a unique global-in-time solution to the flow; (ii) the full limit convergence of solutions to elastica without any additional reparametrization and translation. The main ingredients of the proof of (ii) are a Lojasiewicz--Simon's gradient inequality and the completeness of a $H^2(ds)$-Riemannian metric space.

[05251] Recent advances in Sobolev gradient flows of plane curves

Format : Talk at Waseda University
Author(s) : Glen Wheeler (University of Wollongong)
Abstract : In this talk, we discuss recent progress made alongside Shinya Okabe, Philip Schrader, and Valentina-Mira Wheeler in studying the relationship between the classical curve shortening flow and the triviality of the L^2(ds) metric.
Our method is to study gradient flows with different metrics (that give rise to non-trivial metric spaces).
Our investigation with global analysis reveals intriguing behavior.

[00047] Combining Machine Learning and Stochastic Methods for Modeling and Forecasting Complex Systems

Session Time & Room :

00047 (1/3) : 3E (Aug.23, 17:40-19:20) @E804

00047 (2/3) : 4C (Aug.24, 13:20-15:00) @E804

00047 (3/3) : 4D (Aug.24, 15:30-17:10) @E804

Type : Proposal of Minisymposium
Abstract : Complex Systems are ubiquitous in different areas. Recent development of advanced machine learning tools and new stochastic modeling strategies introduce new insights and approaches of advancing the study of complex systems. This minisymposium aims at combining data-driven and physics-based methods to improve the current understanding, modeling and forecasting methods of various complex systems containing different features. Topics of this minisymposium include, but are not limited to, physics-driven machine learning techniques, efficient stochastic multiscale modeling approaches, data assimilation, uncertainty quantification, inverse problems, statistical control, surrogate and reduced order models as well as efficient forecast algorithms.

[03378] Generative modelling through diffusion maps

Format : Talk at Waseda University
Author(s) : Georg A. Gottwald (University of Sydney)Sebastian Reich (Universität Potsdam)Fengyi Li (MIT)
Abstract : We propose a Langevin sampler as a generative modelling method. The Langevin sampler is constructed using diffusion maps. We show how this method can be used to perform inverse modelling tasks as well as providing a stochastic subgrid-scale parametrisation.

[04604] Tracer Prediction in Simplified Stochastic Geophysical Models through Kalman Filters and Related Methods

Format : Talk at Waseda University
Author(s) : Mustafa A Mohamad (University of Calgary)
Abstract : Transport-dominated phenomena represents a major challenge for reduction techniques due to the presence of nonlinear coherent wave structures. Here we discuss the assimilation and prediction of a turbulent complex flow field given a stream of measurements provided by passively advected Lagrangian drifters. We quantify recovery of the Eulerian energy spectra from observations of Lagrangian drifters by special data assimilation algorithms. We primarily focus on algorithms based on Kalman filters, but also discuss related methods for comparison. The focus is on statistical properties of the tracer.

[05043] Machine Learning for Stochastic Parametrisation

Format : Online Talk on Zoom
Author(s) : Hannah Christensen (University of Oxford)
Abstract : The use of stochastic techniques in atmospheric models to characterise uncertainty in small-scale processes has proved beneficial for forecasts on weather, seasonal and climate timescales. We have also recently seen significant progress in replacing the parametrisation schemes which represent these small-scale processes using machine learning (ML). This has the potential to speed up and improve numerical models. In this presentation I bring together these two developments, and discuss approaches to use ML for stochastic parametrisation.

[03280] Explainable AI to Detect, Predict and Discover Climate Variability and Change

Format : Online Talk on Zoom
Author(s) : Elizabeth Barnes (Colorado State University)
Abstract : Earth's climate is chaotic and noisy. Finding usable signals amidst all of the noise can be challenging: be it predicting if it will rain, knowing which direction a hurricane will go, understanding the implications of melting Arctic ice, or detecting the impacts of human-induced climate warming. Here, I will demonstrate how explainable artificial intelligence (XAI) techniques can sift through vast amounts of climate data and push the bounds of scientific discovery: allowing scientists to ask "why?" but now with the power of machine learning.

00047 (2/3) : 4C @E804 [Chair: Nan Chen]

[05245] semi-supervised active learning on graphs

Format : Online Talk on Zoom
Author(s) : Andrea Bertozzi (UCLA)
Abstract : Similarity graphs are a popular technique for semi-supervised machine learning. They have an advantage over more modern neural network methods in that they can perform well with a modest amount of training data. I will present an active learning framework in which additional training data is introduced through a human in the loop. This approach can outperform prior state of the art on several remote sensing problems such as object recognition in sythetic aperture radar and multispectral and hyperspectral imagery.

[04307] Integrating the spectral analyses of neural networks and nonlinear physics for explainability, generalizability, and stability

Format : Talk at Waseda University
Author(s) : Pedram Hassanzadeh (Rice U)Ashesh Chattopadhyay (PARC)Yifei Guan (Rice U)Adam Subel (NYU)
Abstract : I will introduce a new framework that combines the spectral (Fourier) analyses of NNs and nonlinear physics, and leverages recent advances in theory and applications of deep learning, to move toward rigorous analysis of deep NNs for applications involving dynamical systems. I will use examples from subgrid-scale modeling of 2D turbulence and Rayleigh-Bernard turbulence and forecasting extreme weather to show how this framework can be used to systematically address challenges about explainability, generalizability, and stability.

[03737] Shock trace prediction by reduced models for a viscous stochastic Burgers equation

Format : Talk at Waseda University
Author(s) : Fei Lu (Johns Hopkins University)
Abstract : Can data-driven reduced models predict extreme events in nonlinear multiscale systems? Using stochastic Burgers equation's random shocks as a prototype of extreme events, we demonstrate that although large-scale dominating dynamics-focused reduced models cannot represent shocks, they can accurately predict shock trace—the timing and locations of shocks —with relatively low false prediction rates. The data-driven closure terms are critical in capturing unresolved small-scale dynamics' effects on resolved ones.

[01386] A Multi-Fidelity Ensemble Kalman Filter with Adaptive Reduced-Order Models

Author(s) : Francesco Attilio Bruno Silva (Eindhoven University of Technology)Cecilia Pagliantini (Eindhoven University of Technology)Karen Veroy (Eindhoven University of Technology)
Abstract : Recently there has been an increased interest in combining model order reduction techniques and ensemble-based methods for state estimation of complex systems. Data assimilation algorithms have been proposed to jointly use low and high-fidelity ensembles, e.g., the MFEnKF. The construction of low-fidelity models in the offline stage, however, leads these methods into a trade-off between accuracy and computational costs. In our research, we developed adaptive reduced-basis techniques with online modified approximation spaces to mitigate this issue.

00047 (3/3) : 4D @E804 [Chair: Mustafa Mohamad]

[05228] Embedding classical dynamics in a quantum computer

Format : Online Talk on Zoom
Author(s) : Dimitrios Giannakis (Dartmouth College)
Abstract : We present a framework for simulating classical dynamical systems by quantum systems running on a quantum computer. The framework employs a quantum feature map for representing classical states by density operators on a reproducing kernel Hilbert space, $\mathcal{H}$. Simultaneously, a mapping is employed from classical observables into self-adjoint operators on $\mathcal{H}$ such that quantum expectation values are consistent with pointwise function evaluation. We illustrate our approach with quantum circuit simulations and experiments on quantum computers.

[05225] Machine learning correction operators for capturing extremes in coarse scale climate models

Format : Online Talk on Zoom
Author(s) : Themistoklis Sapsis (MIT)
Abstract : This work presents a systematic framework for improving the predictions of statistical quantities for turbulent systems, with a focus on correcting coarse climate simulations. We also provide quantification measures for the value of data towards this goal. Machine learning correction operators for chaotic systems is challenging as learning errors due to chaotic divergence is not meaningful. The presented approach combines dynamical systems and probabilistic data-driven ideas. We apply the framework to E3SM climate simulations.

[04015] A Framework for Machine Learning of Model Error in Dynamical Systems

Format : Talk at Waseda University
Author(s) : Matthew Levine (Caltech)Andrew Stuart (Caltech)
Abstract : The development of data-informed predictive models for dynamical systems is of widespread interest in many disciplines. Here, we present a unifying framework for blending mechanistic and machine-learning approaches for identifying dynamical systems from data. This framework is agnostic to the chosen machine learning model parameterization, and casts the problem in both continuous- and discrete-time. We will also show recent developments that allow these methods to learn from noisy, partial observations. We first study model error from the learning theory perspective, defining the excess risk and generalization error. For a linear model of the error used to learn about ergodic dynamical systems, both excess risk and generalization error are bounded by terms that diminish with the square-root of T (the length of the training trajectory data). In our numerical examples, we first study an idealized, fully-observed Lorenz system with model error, and demonstrate that hybrid methods substantially outperform solely data-driven and solely mechanistic-approaches. Then, we present recent results for modeling partially observed Lorenz dynamics that leverages both data assimilation and neural differential equations. Joint work with Andrew Stuart.

[05032] Combining physical and machine learning forecasts for Earth system prediction

Format : Talk at Waseda University
Author(s) : Eviatar Bach (California Institute of Technoloy)
Abstract : Machine learning (ML) holds the potential to improve Earth system prediction by learning directly from data, bypassing deficiencies in existing dynamical models. Hybrid methods, which combine ML with dynamical models, leverage the strengths of both approaches. I will present two hybrid methods that use tools from data assimilation: Ensemble Oscillation Correction, a forecasting method for combining ML forecasts of specific modes with a full-field dynamical model, and the Multi-Model Ensemble Kalman Filter, a more general method for integrating multiple forecast models with observations.

[00048] Interfaces between kinetic equations and many-agent social systems. Part I

Session Time & Room :

00048 (1/3) : 2C (Aug.22, 13:20-15:00) @G702

00048 (2/3) : 2D (Aug.22, 15:30-17:10) @G702

00048 (3/3) : 2E (Aug.22, 17:40-19:20) @G702

Type : Proposal of Minisymposium
Abstract : In recent years, kinetic-type models emerged to be a powerful mathematical framework for the description of emerging patterns in systems composed by a large number of agents. Furthermore, the natural multiscale nature of these equations, linking microscopic unobservable social forces to macroscopic measurable patterns, permits an efficient investigation of collective phenomena in a heterogeneity of disciplines, like biology, social sciences and robotics. In this minisymposium we collect novel perspectives from experts actively working on these research problems.
Organizer(s) : Giacomo Dimarco, Young-Pil Choi

Minisymposium Program :

00048 (1/3) : 2C @G702 [Chair: Mattia Zanella]

[03361] Multi Agent System for Inverse Problems

Format : Talk at Waseda University
Author(s) : Michael Herty (RWTH Aachen University)
Abstract : We are interested in the construction of numerical methods for constrained high-dimensional constrained nonlinear optimization problems by gradient free techniques. Gradients are replaced by particle approximations and recently different methods have been proposed, e.g. consensus-based, swarm-based or ensemble Kalman based methods. We discuss recent extensions to the constrained and the parametric case as well as their corresponding mean field descriptions in the many particle limit. Those allow to show convergence as well as the analysis of properties of the new algorithm. Several numerical examples, also in high dimensions, illustrate the theoretical findings as well as the performance of those methods.

[03822] Parameter estimation for macroscopic pedestrian dynamics models using microscopic data

Format : Talk at Waseda University
Author(s) : Susana Gomes (University of Warwick)
Abstract : I will present a framework for estimating relevant parameters for pedestrian dynamics by fitting a macroscopic model for crowd dynamics using data from pedestrian trajectories. The model couples a density dependent stochastic differential equation, to a nonlinear partial differential equation for the density via the fundamental diagram. I will discuss identifiability of the parameters, introduce optimisation and Bayesian methods to perform the identification, and analyse the performance of the proposed methodology in various realistic situations.

[03518] Navigation system based routing strategies in traffic flows on networks

Format : Talk at Waseda University
Author(s) : Adriano Festa (Politecnico di Torino)
Abstract : Navigation choices play an important role in modeling and forecasting traffic flows on road networks. We introduce a macroscopic differential model coupling a conservation law with a Hamilton-Jacobi equation to respectively model the nonlinear transportation process and the strategic choices of users. Furthermore, the model is adapted to the multi-population case, where every population differs in the level of traffic information about the system.

[02357] Uncertainty quantification in vehicular traffic models

Format : Talk at Waseda University
Author(s) : Elisa Iacomini (University of Ferrara, Department of Mathematics and Computer Science)
Abstract : Traffic models have been widely studied, however limitations for obtaining reliable forecasts are still present. Recently it has been pointed out how traffic is exposed to the presence of uncertainties. In this talk, starting from the hierarchy between microscopic, kinetic and macroscopic scales, we will investigate the propagation of uncertainties through the models. Connections between the scales will be presented in the stochastic scenario and numerical simulations will be performed.

00048 (2/3) : 2D @G702 [Chair: Giacomo Dimarco]

[04654] On a kinetic Elo rating model for players with dynamical strength

Format : Talk at Waseda University
Author(s) : Bertram Düring (University of Warwick)
Abstract : We discuss a new kinetic rating model for a large number of players, which is motivated by the well-known Elo
rating system. Each player is characterised by an intrinsic strength and a rating, which are both updated
after each game. We state and analyse the respective Boltzmann-type equation and derive the corresponding
nonlinear, nonlocal Fokker-Planck equation. We investigate the existence of solutions to the Fokker-Planck
equation and discuss their behaviour in the long time limit. Furthermore, we illustrate the dynamics of the
Boltzmann and Fokker-Planck equation with various numerical experiments.

[04235] Nonlocal approximation of nonlinear diffusion equations and cross-diffusion systems

Format : Talk at Waseda University
Author(s) : Antonio Esposito (University of Oxford)Martin Burger (University of Hamburg)José Antonio Carrillo (University of Oxford)Jeremy S.-H. Wu (UCLA)
Abstract : In this talk I will discuss the connection between a class of nonlocal PDEs and nonlinear diffusion equations, including porous medium PDEs and cross-diffusion systems. As byproduct of this link, one can obtain a rigorous deterministic particle approximation for the PDEs considered. The analysis is based on a suitable regularisation of the associated free energy using gradient flow techniques. However, the strategy proposed relies on a discretisation scheme, so-called JKO, which can be slightly modified in order to extend the results to PDEs without gradient flow structure. In particular, it does not require convexity of the associated energies. The talk is based on two joint works with M. Burger (FAU Erlangen-Nuremberg), and J. A. Carrillo (Oxford) and J. Wu (UCLA).

[04374] Kinetic models for multi-agent systems with multiple microscopic states

Format : Talk at Waseda University
Author(s) : Nadia Loy (Politecnico di Torino)
Abstract : In this talk we present a class of kinetic models describing interactions among individuals having multiple microscopic states. We shall consider microscopic states evolving according to both stochastic dependent and independent processes. In particular, we shall consider interacting agents who are divided into multiple sub-populations. As such, the agents are not indistinguishable, as classically assumed in kinetic theory, within the whole population.
A general framework allowing to describe binary interactions and transfers among different sub-groups by deriving the model from microscopic stochastic processes will be presented. We shall discuss formal results concerning existence, uniqueness and equilibria. Moreover, we shall illustrate applications to wealth exchange models with migration.

[03362] Modelling coevolutionary dynamics in heterogeneous SI epidemiological systems across scales

Format : Talk at Waseda University
Author(s) : Elisa Paparelli (Politecnico di Torino)Tommaso Lorenzi (Politecnico di Torino)Andrea Tosin (Politecnico di Torino)
Abstract : We present a new structured compartmental epidemiological model for the coevolutionary dynamics between susceptible and infectious individuals. Specifically, continuous structuring variables capture interindividual variability in resistance to infection and viral load. The model comprises a system of integro-differential equations providing a Boltzmann-type kinetic description of corresponding stochastic particle dynamics. We discuss a formal derivation of this model from the underlying particle dynamics and present analytical and numerical results on the long-time behaviour of its solutions.

00048 (3/3) : 2E @G702 [Chair: Giacomo Dimarco]

[05559] The Collisional Particle-In-Cell Method for the Vlasov-Maxwell-Landau System

Format : Talk at Waseda University
Author(s) : Rafael Bailo (University of Oxford, Mathematical Institute)José Antonio Carrillo (University of Oxford, Mathematical Institute)Jingwei Hu (University of Washington)
Abstract : In this talk we will present an extension of the classical Particle-In-Cell (PIC) method
for plasmas which can account for the collisional effects modelled by the Landau operator.
The method is derived form the gradient-flow formulation of the Landau equation, thereby
preserving the collision invariants and the entropy structure. We will discuss the derivation
and implementation of the method, as well as several numerical examples to showcase the
effects of collisions in plasma simulations.

[00049] Interfaces between kinetic equations and many-agent social systems. Part II

[04948] Weak couplings of Lohe type aggregation models

Format : Online Talk on Zoom
Author(s) : Seung Yeal Ha (Seoul National University)Dohyun Kim (Sungkyunkwan University)Hansol Park (Simon Fraser University)
Abstract : In this talk, we present a systematic algebraic approach for the weak coupling of Cauchy problems to multiple Lohe tensor models. For this, we identify an admissible Cauchy problem to the Lohe tensor (LT) model with a characteristic symbol consisting of four tuples in terms of a size vector, a natural frequency tensor, a coupling strength tensor and admissible initial configuration. In this way, the collection of all admissible Cauchy problems to the LT models is equivalent to the space of characteristic symbols. On the other hand, we introduce a binary operation, namely

fusion operation" as a binary operation between characteristic symbols. It turns out that the fusion operation satisfies an associativity and admits the identity element in the space of characteristic symbols which naturally forms a monoid. By virtue of the fusion operation, the weakly coupled system of multi tensor models can be obtained by applying the fusion operation of multiple characteristic symbols corresponding to the Lohe tensor models. As a concrete example, we consider a weak coupling of the swarm sphere model and the Lohe matrix model, and provide sufficient framework leading to emergent dynamics to the proposed weakly coupled model. This is a joint work with Dohyun Kim (Sungshin Women's Univ.) and Hansol Park (Simon Fraser Univ.)

[03897] Quantified overdamped limit for Kinetic Vlasov-Fokker-Planck equations

Format : Talk at Waseda University
Author(s) : Oliver Tse (Eindhoven University of Technology)Young-Pil Choi (Yonsei University)
Abstract : The study of the overdamped limit for the kinetic Fokker-Planck equation has been of interest since the seminal work of Kramers in 1940, where he formally discussed the convergence by introducing a coarse-graining map. This talk is based on work with Young-Pil Choi, where we provide a framework to establish quantitative estimates for the overdamped limit of the kinetic Vlasov-Fokker-Planck with singular interaction in terms of the 2-Wasserstein distance.

[04724] Phase-coupled models for synchronization with nonlocal temporal interactions

Format : Talk at Waseda University
Author(s) : Myeongju Kang (Korea Institute for Advanced Study)
Abstract : We study the emergent dynamics and global well-posedness of the Kuramoto model with memory effect, which is a system of Volterra-type integro-differential equations on unit circle. We adopt nonlocal temporal interactions to design synchronized behavior of oscillators affected by memories of the past. We first establish the global well-posedness of the Kuramoto model with memory effect, and provide sufficient frameworks for uniform boundedness of the phase diameter. Then, we define an energy functional whose boundedness is guaranteed by the boundedness of the phase diameter. We show that energy functional is monotonically decreasing, which implies complete frequency synchronization. Moreover, when natural frequencies are all identical we show the emergence of complete phase synchronization.

[04208] Rigorous derivation of the Euler-Alignment model with singular communication weights from a kinetic Fokker-Planck-Alignment model

Format : Online Talk on Zoom
Author(s) : Young-Pil Choi (Yonsei University)Jeongho Kim (Kyung Hee University)
Abstract : We present a rigorous derivation of the isothermal Euler-alignment model with singular communication weights. We consider a hydrodynamic limit of a kinetic Fokker-Planck-alignment model, which is the nonlinear Fokker-Planck equation with the Cucker-Smale alignment force. Our analysis is based on the estimate of relative entropy between macroscopic quantities, together with careful analysis on the singular communication weights.

00049 (2/3) : 3D @G702 [Chair: Giacomo Dimarco]

[04945] Sticky-particle Cucker-Smale dynamics and the entropic selection principle for the Euler-alignment system

Format : Talk at Waseda University
Author(s) : Trevor Leslie (University of Southern California)Changhui Tan (University of South Carolina)
Abstract : In this talk, I will discuss weak solutions to the Euler-alignment system for collective behaviors. I will introduce an entropic selection principle that serves to isolate a unique weak solution. Notably, the solution can be constructed and approximated using Cucker-Smale dynamics, with sticky particle collision rules. I will present an analytical convergence result, as well as the formation of finite and infinite time clusters.

[04190] Structure-preserving particle method for the Vlasov-Landau-Maxwell system

Format : Online Talk on Zoom
Author(s) : Rafa Bailo (University of Oxford)Jose Carrillo (University of Oxford)Jingwei Hu (University of Washington)
Abstract : Vlasov-Landau-Maxwell equation is often considered as the first-principle physics model for plasmas. We introduce a novel particle method for this equation which preserves the basic physical properties such as conservation of mass, momentum, and energy, and even decay of entropy. The method is based on a proper regularization of the Landau collision operator so that it can be naturally coupled with the classical particle-in-cell (PIC) method to preserve the

structure. Various plasma benchmark tests such as collisional Landau damping and two-stream instability will be presented.

[03372] On solutions to the kinetic Cucker-Smale model with singular communication weights

Format : Talk at Waseda University
Author(s) : Jinwook Jung (Jeonbuk National University)Young-Pil Choi (Yonsei University)
Abstract : In this talk, we investigate the existence of solutions to the kinetic Cucker-Smale model with singular communication weights $\phi(r) = r^{-\gamma}$. First, we establish the local-in-time well-posedness of strong solutions to the equation in a weighted Sobolev space for $\gamma \in [d-1, d+1/4) \setminus \{d\}$. Secondly, we present the existence of weak solutions for $\gamma \in [d-1, d)$ and also the uniqueness result when $\gamma = d-1$. This talk is based on the collaboration with Y.-P. Choi.

[03940] Interaction energy minimizers on bounded domains

Format : Online Talk on Zoom
Author(s) : Ruiwen Shu (University of Georgia)José Carrillo (University of Oxford)
Abstract : I will discuss the behavior of interaction energy minimizers on bounded domains. When the interaction potential is more singular than Newtonian, then mass does not tend to concentrate on the boundary; when it is Newtonian or less singular, then mass necessarily concentrate on the boundary for purely repulsive potentials. We also draw a connection between bounded-domain minimizers and whole-space minimizers.

00049 (3/3) : 3E @G702 [Chair: Mattia Zanella]

[03933] Analytical approaches to the problem of emergence arising in systems of collective behavior

Format : Online Talk on Zoom
Author(s) : Roman Shvydkoy (University of Illinois at Chicago)
Abstract : Emergence is a phenomenon of formation of collective outcomes in systems where communications between agents has local range. For a wide range of applications, such as swarming behavior of animals or exchange of opinions between individuals, such outcomes result in a globally aligned state or congregation of aligned clusters. The classical result of Cucker and Smale states that alignment is unconditional in flocks that have global communication with non-integrable radial tails. Proving a similar statement for purely local interactions is a challenging mathematical problem. In this talk we will overview three programs of research directed on understanding the emergent phenomena: statistical approach to generic alignment for agent-based systems, kinetic approach based on relaxation and hypocoercivity, and hydrodynamic models incorporating a novel way of interaction based on topological communication.

[00052] Efficient numerical methods for high-dimensional PDEs

Session Time & Room :

00052 (1/2) : 1C (Aug.21, 13:20-15:00) @E705

00052 (2/2) : 1D (Aug.21, 15:30-17:10) @E705

Type : Proposal of Minisymposium
Abstract : Many problems in science and engineering are described by high-dimensional PDEs. Over the years, different numerical techniques have been developed for these problems, including low rank method, sparse grid, tensor method, reduced order modeling, machine learning, optimization, and quantum algorithms, to name a few. In this minisymposium, we bring researchers from a wide spectrum of application areas, such as plasma physics, quantum dynamics, biology, etc. to address the common theme of solving high-dimensional PDEs and exchange ideas.

00052 (1/2) : 1C @E705 [Chair: Jingwei Hu]

[04856] Sparse grid techniques for particle-in-cell simulation of kinetic plasmas

Format : Online Talk on Zoom
Author(s) : Lee Forrest Ricketson (Lawrence Livermore National Laboratory)
Abstract : The Vlasov equation, which models collisionless plasma dynamics, is six-dimensional in general. To combat this high dimensionality, the most prevalent numerical method has long been particle-in-cell (PIC), in which the plasma is represented by particles which interact with electromagnetic fields specified on a spatial mesh. However, the inclusion of particles subjects the scheme to slow-converging sampling errors, while use of a spatial mesh admits only partial mitigation of the curse of dimensionality. We show that using sparse grids with PIC makes the algorithm's complexity only logarithmically dependent on dimension and dramatically reduces the impact of sampling noise. We report recent progress combining sparse PIC advanced symplectic and implicit methods. Finally, we report on ongoing work toward adaptively choosing suitable coordinates for these sparse grid computations.

[03639] Nonlinear model reduction with adaptive bases and adaptive sampling

Format : Online Talk on Zoom
Author(s) : Benjamin Peherstorfer (Courant Institute of Mathematical Sciences, New York University)
Abstract : We introduce an online-adaptive model reduction approach that can efficiently reduce convection-dominated problems. It exploits that manifolds are low dimensional in a local sense in time and iteratively learns and adapts reduced spaces from randomly sampled data of the full models to locally approximate the solution manifolds. Numerical experiments to predict pressure waves in combustion dynamics demonstrate that our approach achieves significant speedups in contrast to classical, static reduced models.

[04871] Quantum Algorithms for Accelerating the Solution of Partial Differential Equations

Format : Online Talk on Zoom
Author(s) : Ilon Joseph (Lawrence Livermore National Laboratory)
Abstract : Quantum algorithms have been proposed to accelerate the solution of linear partial differential equations (PDEs) with polynomial to exponential speedup. Recent progress has significantly improved these algorithms with respect to numerical methods and error convergence. Due to the "no-cloning" theorem, solving nonlinear PDEs is more challenging. Newly proposed Koopman and Carleman approaches solve for the linear evolution of the probability distribution function of the solution and are closely related to simulating stochastic PDEs and quantum fields.

[03854] A Hybrid AMR Low-Rank Tensor Approach for Solving the Boltzmann Equation

Format : Talk at Waseda University
Author(s) : William Tsubasa Taitano (Los Alamos National Laboratory)Samuel Jun Araki (Air Force Research Laboratory)
Abstract : The Boltzmann equation describes the time evolution of a particle distribution function in a six-dimensional position-velocity phase space. The exponential growth in computational complexity often challenges a grid-based approach to modeling the Boltzmann equation as the dimensionality grows. Scalable low-rank tensor decomposition techniques have recently been developed with applications to high-dimension PDEs to address this issue. Despite the remarkable progress made in the community, low-rank structures in the phase-space are not evident in realistic engineering systems with complex geometries (e.g., electric propulsion systems and fusion reactors), where discontinuities, shocks, complex boundary conditions, and material-dependent physics (e.g., collisions, fusion reactions, ionization/excitation, charge-exchange processes) pose formidable challenges. In this talk, we propose a novel hybrid algorithm where quad-tree adaptive mesh refinement (AMR) is applied in real space while a low-rank approximation is applied in the velocity space. The AMR algorithm efficiently handles challenges pertaining to complex structures in real space, while the low-rank formulation targets dimensionality challenges in the velocity space. We present preliminary results on the new algorithm applied to challenging multi-dimensional gas kinetics problems.

00052 (2/2) : 1D @E705 [Chair: Lukas Einkemmer]

[04128] Designing High-Dimensional Closed-Loop Optimal Control Using Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Jiequn Han (Flatiron Institute, Simons Foundation)
Abstract : Designing closed-loop optimal control for high-dimensional nonlinear systems remains a long-standing challenge. Traditional methods, such as solving the Hamilton-Jacobi-Bellman equation, suffer from the curse of dimensionality. Recent studies introduced a promising supervised learning approach, utilizing deep neural networks to learn from open-loop optimal control solutions. From a PDE standpoint, this method learns solutions along characteristic lines.

This talk will first overview this method and identify a limitation in its basic form, the distribution mismatch phenomenon, caused by controlled dynamics. We then propose the initial value problem enhanced sampling method to address this issue. The proposed method presents theoretical guarantees of improvement over the basic version in the classical linear-quadratic regulator and demonstrates significant improvement numerically on several high-dimensional nonlinear problems.

[04563] An Inverse Problem in Mean Field Games from Partial Boundary Measurement

Format : Talk at Waseda University
Author(s) : Yat Tin Chow (University of California, Riverside)Samy Wu Fung (Colorado School of Mines)Siting Liu (University of California, Los Angeles)Levon Nurbekyan (University of California, Los Angeles)Stanley Osher (University of California, Los Angeles)
Abstract : In this talk, we consider a novel inverse problem in mean-field games (MFG). We aim to recover the MFG model parameters that govern the underlying interactions among the population based on a limited set of noisy partial observations of the population dynamics under the limited aperture. Due to its severe ill-posedness, obtaining a good quality reconstruction is very difficult. Nonetheless, it is vital to recovering the model parameters stably and efficiently to uncover the underlying causes of population dynamics for practical needs.

Our work focuses on the simultaneous recovery of running cost and interaction energy in the MFG equations from a finite number of boundary measurements of population profile and boundary movement. To achieve this goal, we formalize the inverse problem as a constrained optimization problem of a least squares residual functional under suitable norms. We then develop a fast and robust operator splitting algorithm to solve the optimization using techniques including harmonic extensions, three-operator splitting scheme, and primal-dual hybrid gradient method. Numerical experiments illustrate the effectiveness and robustness of the algorithm.

[04470] Automatic partitioning for Boolean CME Low-Rank integrator

Format : Talk at Waseda University
Author(s) : Martina Prugger (University of Innsbruck)Lukas Einkemmer (University of Innsbruck)
Abstract : Cell signaling processes are usually modeled by chemical reactions encoded in a system of ordinary differential equations. The resulting model is deterministic and omits the inherent stochasticity of cell reactions. This is mostly due do the fact, that solving the Chemical Master Equation (CME), which resolves the inherent probabilistic states of the chemical system suffers from the curse of dimensionality. This results in high computational and memory requirements, that prohibit the simulation of the CME for system sizes that are usually required for practical applications.

We developed a low-rank integrator for the CME for Boolean networks that enables us to simulate systems to a size of up to 41 different chemical species on a workstation. An integral part of this method is to partition the network into multiple sub-partition, on which the CME is solved exactly. Key to an efficient solver is the distribution of species, while keeping the approximation error between the networks to a minimum. While for small networks, this can still be done easily by a person, for a network of the size of e.g., 41 species, this is no longer feasible. We therefore introduce an automatic partitioner by using the Kernighan-Lin algorithm to select multiple networks that minimize the amount of connections between the sub-networks. We then use information enthropy that evaluates each of the chosen networks. This results in an automatic partitioning tool that reduces the rank that is required to faithfully resolve the biological dynamics.

[00057] Many-agent systems and mean-field models for socio-economic and life sciences dynamics

Session Time & Room :

00057 (1/2) : 4C (Aug.24, 13:20-15:00) @G702

00057 (2/2) : 4D (Aug.24, 15:30-17:10) @G702

Type : Proposal of Minisymposium
Abstract : Complex, real-life systems in sociology, economics, and life sciences often consist of a large number of individuals. Through interactions among these individuals a collective behaviour may emerge over time and certain patterns may develop. Examples include pedestrian, evacuation and traffic models, opinion formation, wealth distribution, chemotaxis and flocking/swarming. The aim of the mini-symposium is to highlight recent advances in modelling, analysis, numerics and optimal control of kinetic and PDE models in this area.

[04044] Data-driven kinetic model for opinion dynamics and contacts

Format : Talk at Waseda University
Author(s) : Giacomo Dimarco (University of Ferrara, Department of Mathematics and Computer Science)
Abstract : Opinion dynamics is an important area of research that studies how individuals form and change their opinions in a social context. Understanding the mechanisms that drive opinion formation and change is essential for predicting social phenomena, such as political polarization and the spread of misinformation. In this talk, we present a new model for opinion dynamics in presence of social media contacts, using real-life data from Twitter in order to retrieve the parameters appearing in our model so to make it as close as possible to what happens in reality.

[02360] Asymptotic-preserving neural networks for kinetic equations in socio-epidemics

Format : Talk at Waseda University
Author(s) : Giulia Bertaglia (University of Ferrara)
Abstract : Data-driven approaches have proven to be powerful tools with a direct impact on society. However, the use of standard neural networks to investigate multiscale dynamics can lead to erroneous inferences and predictions, because the presence of small scales leads to reduced-order models that must be considered in the learning phase. In this talk, I will address these issues by presenting asymptotic-preserving neural networks, focusing on their use to study the spatial spread of epidemics.

[04507] Many-agent systems and mean-field models for semi-supervised learning

Format : Talk at Waseda University
Author(s) : Lisa Maria Kreusser (University of Bath)Marie-Therese Wolfram (University of Warwick)
Abstract : In many problems in data classification, it is desirable to assign labels to points in a point cloud where a certain number of them is already correctly labeled. In this talk, we propose a microscopic ODE approach, in which information about correct labels propagates to neighbouring points. Its dynamics are based on alignment mechanisms, often used in collective and consensus models. We derive the respective continuum description, which corresponds to an anisotropic diffusion equation with a reaction term. Solutions of the continuum model inherit interesting properties of the underlying point cloud. We discuss the qualitative behaviour of solutions and exemplify the results with micro- and macroscopic simulations.

[03820] Trends to equilibrium for nonlocal Fokker-Planck equations with discontinuous drift

Format : Talk at Waseda University
Author(s) : Mattia Zanella (University of Pavia)
Abstract : We study equilibration rates for nonlocal Fokker-Planck equations with time-dependent diffusion coefficient and drift, modeling the relaxation of a large swarms of agents, feeling each other in terms of their distance, towards the steady profile characterized by a uniform spreading over a finite domain. The result follows by combining entropy methods for quantifying the decay of the solution towards its quasi-stationary distribution, with the properties of the quasi-stationary profile.

[04768] Kinetic modelling of swarming dynamics with transient leadership

Format : Talk at Waseda University
Author(s) : Giacomo Albi (University of Verona)
Abstract : In this talk, we will focus on swarming dynamics with topological interactions and where leaders' emergence initializes spontaneous changes of direction. In this context, we will provide a kinetic model for leader-follower dynamics with mass transfer among the two populations modeled as a transition process on a space of labels. This model allows the transition from followers to leaders and vice-versa, with scalar-valued transition rates depending on the state of the system. Furthermore, we will propose an efficient stochastic algorithm for the identification of the k-nearest neighbors at mesoscopic level, and the simulation of the swarming dynamics. Several numerical experiments are presented for different scenarios both to validate the algorithm and to study the collective dynamics.

[02465] Kernel learning method for multiagent systems and its mean-field limit

Format : Talk at Waseda University
Author(s) : Chiara Segala (RWTH Aachen University)Michael Herty (RWTH Aachen University)Christian Fiedler (RWTH Aachen University)
Abstract : Kernel methods are among the most popular and successful machine learning techniques. From a mathematical point of view, these methods rest on the concept of kernels and function spaces generated by kernels. Motivated by recent developments of learning approaches in the context of interacting particle systems, we investigate kernel methods acting on data with many measurement variables. We present efficient learning algorithms both on microscopic and mean-field level.

[03937] Bounded-confidence models of opinion dynamics on networks

Format : Talk at Waseda University
Author(s) : Heather Zinn Brooks (Harvey Mudd College)
Abstract : In this talk, I will introduce you to a class of models of opinion dynamics on networks called bounded-confidence models. These relatively simple models can produce delightfully complicated dynamics and provide a rich source of study for the interplay between dynamics and structure. I will discuss some novel twists on bounded-confidence models that my collaborators and I have been developing, including information cascades, bifurcations in “smoothed” bounded-confidence models, and extensions to hypergraphs.

[03493] Mean-field models for many agent systems with co-evolving network structure

Format : Online Talk on Zoom
Author(s) : Martin Burger (DESY and University of Hamburg)
Abstract : In this talk we discuss the derivation of kinetic and sub mean-field equations for processes related to processes on networks, such as opinion formation on social networks. We consider in particular the case when networks are co-evolving during other processes and discuss suitable descriptions as well as issues to derive simple closure relations. Moreover, we discuss aspects of pattern
formation such as consensus or the formation of echo chambers.

[00059] Numerical solutions for differential equations: Probabilistic approaches and statistical perspectives

Session Time & Room :

00059 (1/2) : 1C (Aug.21, 13:20-15:00) @E503

00059 (2/2) : 1D (Aug.21, 15:30-17:10) @E503

Type : Proposal of Minisymposium

Abstract : Many applications involve predicting the dynamics of a system by solving differential equations. Due to the increased demand for predictive power of these models, numerically solving a differential equation is now often combined with parameter estimation or uncertainty quantification. This paradigm shift drives the need for probabilistic approaches that are compatible with statistical inference, or that improve the robustness of inference to possibly inaccurate mathematical models. The talks in this minisymposium will present recent work that addresses these challenges for deterministic ODEs and PDEs, by using ideas from numerical analysis, probability theory, and Bayesian statistical inference.

[00066] Probabilistic Numerical Methods

Format : Online Talk on Zoom

Author(s) : Chris Oates (Newcastle University)

Abstract : The scale and complexity of modern scientific computer codes typically precludes a detailed analysis of how the code is numerically implemented. For example, multi-scale and multi-physics models of the human heart call on diverse numerical sub-routines to integrate differential equations, perform interpolation and optimise over some parameters of the model. As such, the computer output is acknowledged to be inexact and some alternative form of uncertainty quantification is needed for the output to be properly interpreted. This talk will provide an introduction to probabilistic numerical methods, which aim to provide probabilistic uncertainty quantification for computer code output. These methods are composed of "modules", such that a probabilistic description of numerical error can be automatically propagated, and some of the most useful modules will be discussed.

[04930] Prior models for enforcing boundary constraints in state-space probabilistic PDE solvers

Format : Online Talk on Zoom

Author(s) : Oksana Chkrebtii (The Ohio State University)Yue Ma (The Ohio State Univeristy)

Abstract : Probabilistic numerics is an active field of research that seeks to construct stochastic analogues of numerical methods, including the solution of ordinary and partial differential equations. Probabilistic solvers for partial differential equations require the specification of flexible prior models that respect physical constraints while allowing for computational efficiencies of the sequential updates. We focus on state-space based probabilistic PDE solvers and describe advances in nonparametric modeling of system states with boundary constraints.

[04408] GParareal: Towards a time-parallel probabilistic ODE solver

Format : Talk at Waseda University

Author(s) : T J Sullivan (University of Warwick)Kamran Pentland (University of Warwick)Massimiliano Tamborrino (University of Warwick)Lynton Appel (Culham Centre for Fusion Energy)James Buchanan (Culham Centre for Fusion Energy)

Abstract : Numerical solution of complex ODEs can be accelerated with time-parallel integration, predicting the solution serially using a cheap solver and correcting these values in parallel using an expensive solver. We propose a time-parallel ODE solver (GParareal) that models the prediction-correction term using a Gaussian process emulator. GParareal compares favourably with the classic parareal algorithm, locates solutions to certain ODEs where parareal fails, and can also use archives of legacy solutions to further accelerate convergence.

[00148] Theoretical Guarantees for the Statistical Finite Element Method

Format : Online Talk on Zoom

Author(s) : Yanni Papandreou (Imperial College London)Jon Cockayne (University of Southampton)Mark Girolami (University of Cambridge)Andrew B. Duncan (Imperial College London)

Abstract : The statistical finite element method (StatFEM) is an emerging probabilistic method that allows observations of a physical system to be synthesized with the numerical solution of a PDE intended to describe it in a coherent statistical framework, to compensate for model error. This work presents a new theoretical analysis of the statistical finite element method demonstrating that it has similar convergence properties to the finite element method on which it is based. Our results constitute a bound on the Wasserstein-2 distance between the ideal prior and posterior and the StatFEM approximation thereof, and show that this distance converges at the same mesh-dependent rate as finite element solutions converge to the true solution. Several numerical examples are presented to demonstrate our theory, including an example which test the robustness of StatFEM when extended to nonlinear quantities of interest.

00059 (2/2) : 1D @E503 [Chair: Yuto Miyatake]

[00714] Approximating the solutions of delay differential equations via the randomized Euler method

Format : Talk at Waseda University

Author(s) : Yue Wu (University of Strathclyde)Fabio Difonzo (University of Bari Aldo Moro)Pawel Przybyl (AGH University of Science and Technology)

Abstract : In this talk, we consider Caratheodory delay ODEs with time-irregular coefficients, where a randomized Euler scheme is proposed to approximate the exact solution. This is the case when there is a lack of convergence for deterministic algorithms.

[00186] Posterior error estimates for statistical finite element methods with Sobolev priors

Format : Talk at Waseda University

Author(s) : Toni Karvonen (University of Helsinki)Fehmi Cirak (University of Cambridge)Mark Girolami (University of Cambridge)

Abstract : The statistical finite element, statFEM, approach synthesises measurement data with finite element models and allows for making predictions about the system response. Suppose that noisy measurement data are generated by a deterministic true system response function satisfying a second-order elliptic partial differential equation for an unknown true source term. In this setting, we provide probabilistic error analysis for a prototypical statFEM setup based on a Gaussian process prior whose covariance kernel induces a Sobolev space.

[04863] The Bayesian approach to inverse Robin problems

Format : Talk at Waseda University

Author(s) : Ieva Kazlauskaite (University of Cambridge)

Abstract : In this talk, I will present the Bayesian approach to inverse Robin problems. The problem of interest is a certain elliptic boundary value problem of determining a Robin coefficient on a hidden part of the boundary from Cauchy data on the observable part. Such an inverse problem arises naturally in the initialisation of large-scale ice sheet models that are crucial in climate and sea-level predictions. We motivate the Bayesian approach for a prototypical Robin inverse problem by showing that the posterior mean converges in probability to the data-generating ground truth as the number of observations increases. Related to the stability theory for inverse Robin problems, we establish a logarithmic convergence rate for regular Robin coefficients, whereas for analytic coefficients we can attain an algebraic rate. Further, our numerical results demonstrate the effectiveness of the approach in recovering the Robin coefficient for an ice sheet model.

[02954] Statistical finite elements for misspecified models

Format : Talk at Waseda University

Author(s) : Connor Duffin (University of Cambridge)Edward Cripps (University of Western Australia)Thomas Stemler (University of Western Australia)Mark Girolami (University of Cambridge)

Abstract : I will present a statistical finite element method for nonlinear, time-dependent problems. This is a statistical augmentation of the finite element method which admits model misspecification inside of the governing equations, via Gaussian processes. The method is Bayesian, sequentially updates model mismatch upon receipt of observed data, and ensures scalability through low-rank approximations to the posterior. In this talk I will present statFEM and discuss various case studies with experimental and synthetic data.

[00060] Mathematical approaches to collective phenomena

Session Time & Room : 3C (Aug.23, 13:20-15:00) @E803

Type : Proposal of Industrial Minisymposium

Abstract : The contributions of the mathematics to understanding of collective phenomena such as the fluid dynamics are certainly conspicuous. In particular, developments of the numerical method to solve PDE, PDE analysis of the hydrodynamic equation or Boltzmann equation by applied mathematicians are quite significant in the industry. This minisymposium invites four eminent researchers, who study various types of collective phenomena such as the gas dynamics, biological swarming, electrically charged fluids and so on. Their presentations will indicate new insights and inspirations in the future applied mathematics.

[04763] Multi-fidelity method for a class of kinetic equations with uncertainties

Format : Talk at Waseda University

Author(s) : Liu Liu (The Chinese University of Hong Kong)Lorenzo Pareschi (University of Ferrara)xueyu zhu (University of Iowa)

Abstract : In this talk, we will discuss some recent development on the topic of multi-fidelity methods for solving a class of kinetic equations with uncertainties and multiple scales. The Boltzmann equation, linear transport equation and epidemic transport system will be particularly studied, together with formal error estimates. We will also briefly discuss application of deep learning approaches to study kinetic problems.

[04788] Brownian HydroDynamics for Confined Electrolyte Solutions

Format : Talk at Waseda University

Author(s) : Aleksandar Donev (Courant Institute, New York University)

Abstract : Electrolyte solutions appear in many engineering systems and processes, such as desalination, microfluidic pumps, and batteries. For confined electrolytes, (quasistatic) long-ranged electrostatic interactions among the particles play a crucial role in the static structure. Similarly, hydrodynamic interactions (HIs) mediated by the solvent are also long-ranged and affect the dynamics in crucial ways. Confinement in slit channel geometries is of particular importance, especially for electrohydrodynamics and electrochemistry near electrodes in devices and batteries. In particular, very thin electric (Debye) double layers with complex structure form near dielectric or metallic boundaries and many important electro-hydrodynamic phenomena occur in this layer. I will discuss the limitations of the classical Poisson-Nernst-Planck-Stokes equations for non-dilute electrolytes, in which the Debye scale is molecular, and present an alternative Brownian HydroDynamics (BD-HI) approach that uses fluctuating hydrodynamics for the solvent but represents the ions as explicit Brownian particles. By using BD-HI we are able to reach much longer (diffusive) time scales than molecular dynamics because of the implicit overdamped solvent, at the expense of loosing some microscopic details.

[04809] Delay Models of Collective Behavior with Biological and Industrial Applications

Format : Talk at Waseda University

Author(s) : Jan Haskovec (King Abdullah University of Science and Technology)

Abstract : The talk will give an overview of recent results for models of collective behavior governed by delay differential equations. It will focus on models of interacting agents with applications in biology (flocking, swarming), social sciences (opinion formation) and engineering (swarm robotics), where latency (delay) plays a significant role. We will explain that there are two main sources of delay - inter-agent communications and information processing - and show that they have qualitatively different impacts on the group dynamics. We will give an ovierview of analytical methods for studying the asymptotic behavior of the models and their mean-field limits. Finally, motivated by situations where finite speed of information propagation is significant, we will introduce an interesting class of problems where the delay depens nontrivially and nonlinearly on the state of the system, and discuss the available analytical results and open problems here.

[04973] Model Cascades for Dilute Gases Based on Moment Equations

Format : Talk at Waseda University
Author(s) : Manuel Torrilhon (RWTH Aachen)
Abstract : Dilute gas flows show thermal non-equilibrium due to lack of particle collisions. This requires modeling using the statistical description of kinetic gas theory. Moment equations extend the classical fluid dynamic equations for processes with moderate Knudsen numbers. We will present non-equilibrium models based on moment approximations, which provide a hierarchy of models in a cascading nature. This can be used to estimate model errors and perform model-adaptive simulations.

[00061] Reaction-Diffusion models in Ecology and Evolution

Session Time & Room :

00061 (1/2) : 3C (Aug.23, 13:20-15:00) @G602

00061 (2/2) : 3D (Aug.23, 15:30-17:10) @G602

Type : Proposal of Minisymposium
Abstract : Reaction-diffusion equations have been a powerful tool in studying population dynamics since the seminal works of Fisher, Kolmogorov-Petrovsky-Piskunov, Turing, and many others. In recent years many important questions from ecology, such as habitat fragmentation and shifting environment change, and life sciences, such as tumor growth, required new mathematical models and gave rise to challenging problems in analysis. This mini-symposium aims to showcase some recent development in the theory of reaction-diffusion equations and its applications to some emerging ecological and evolutionary questions.

[00123] Propagation direction of the traveling wave in the Lotka-Volterra competition-diffusion system

Format : Talk at Waseda University
Author(s) : Chiun-Chuan Chen (National Taiwan University)
Abstract : We consider the two species Lotka-Volterra competition-diffusion system and assume that the species are in strong competition. It is well-known that up to a translation, there exists a unique monotone traveling wave solution. The sign of the wave speed provides significant information about which species can wipe out the other. However, it is a difficult problem to determine the sign of the speed. In this talk, we will present some estimates for the relation between the wave speed and the growth rates of the species. With these estimates, we are able to determine the speed sign under some suitable conditions.

[00124] Principal eigenvalue problem with large advection in 2 dimensional case

Format : Talk at Waseda University
Author(s) : Maolin Zhou (Nankai University)
Abstract : In this talk, we will discuss the recent progress on the limit of the principal eigenvalue of some second order operators with large advection: 1. degenerate case; 2. parabolic case (1-d); 3. elliptic case (2-d).

[00099] Some game theoretical models in population dynamics

Format : Talk at Waseda University
Author(s) : Idriss Mazari-Fouquer (CEREMADE, Paris Dauphine Université, PSL)
Abstract : We review several recent contributions aimed at providing a better understanding of optimal fishing strategies in spatial ecology: how should one fish in order to maximise the fishing output? If several players are fishing, can they reach an equilibrium situation? Formulated in terms of optimal control problems and Nash equilibria properties, these problems are amenable to mathematical analysis, and we present a variety of related results. Joint work with D. Ruiz-Balet.

[00125] Free boundary problem for the curve shortening flow with driving force in undulating cylindrical domains

Format : Talk at Waseda University
Author(s) : Ryunosuke Mori (Meiji University)
Abstract : We study a free boundary problem for the curve shortening flow with driving force in a two-dimensional cylindrical domain with periodically undulating boundary. We consider the large time behavior of the graph-like solution. The classical solution generally does not exist in global time, since the solution may touch the boundary of the domain in finite time. To overcome this difficulty, we prove that the set of singularities of the solution is discrete under some assumptions.

00061 (2/2) : 3D @G602 [Chair: Maolin Zhou]

[00120] Front Propagation in the Shadow Wave-Pinning Model

Format : Talk at Waseda University
Author(s) : Daniel Gomez (University of Pennsylvania)King-Yeung Lam (The Ohio State University)Yoichiro Mori (University of Pennsylvania)
Abstract : In this paper we consider a non-local bistable reaction-diffusion equation arising from cell polarization. A typical solution of this model exhibits an interface with velocity regulated by the total mass. The feedback between mass-conservation and bistablity causes the interface to approach a fixed limit. In the limit of a small diffusivity $\varepsilon^2 \ll 1$, we prove that for any $0 < \gamma < 1/2$ the interface can be estimated within $O(\varepsilon^\gamma)$ of the location as predicted using formal asymptotics.

[00109] Propagation speeds in a shifting environment

Format : Talk at Waseda University
Author(s) : Thomas Giletti (University of Lorraine)
Abstract : I will discuss the asymptotic behavior of solutions of reaction-diffusion equations with shifting heterogeneity. Such a situation arises in the modeling of population dynamics under an environmental change, due to global warming or the invasion by competing species. Two situations will be considered, depending on whether the reaction or the diffusion is heterogeneous. We will see that the heterogeneity may modify the nature of the propagation by inducing some unexpected threshold or acceleration phenomena.

[00067] Lotka-Volterra competition-diffusion system: the critical competition case

Format : Talk at Waseda University
Author(s) : Dongyuan XIAO (Meiji University)Matthieu Alfaro (Universite de Rouen Normandie)
Abstract : We consider the competition system in the so-called critical competition case. The associated ODE system then admits infinitely many equilibria. We first show the non-existence of ultimately monotone traveling waves. Next, we study the large-time behavior of the solution of the Cauchy problem with a compactly supported initial datum and provide a sharp description of the profile of the solution.

[00080] Coexistence of strains in some reaction-diffusion systems for infectious disease

Format : Talk at Waseda University
Author(s) : Lou Yuan (Shanghai Jiao Tong University)Rachidi Salako (University of Nevada at Las vegas)
Abstract : We study the global dynamics of some reaction-diffusion systems for multiple strains and investigate how the coexistence of strains is impacted by the movement of populations and spatial heterogeneity of the environment. For the case of two strains, general conditions for the existence, uniqueness and stability of coexistence steady states are found. Surprisingly, when there is no coexistence of strains, it is possible for the weak strain to be dominant for intermediate diffusion rates, in strong contrast to small and large diffusion cases where the weak strain goes extinct.

[00062] Analysis and computation of vortical flows

Session Time & Room :

00062 (1/3) : 1C (Aug.21, 13:20-15:00) @D102

00062 (2/3) : 1D (Aug.21, 15:30-17:10) @D102

Type : Proposal of Minisymposium
Abstract : Vortex dynamics is a classical but ever active topic in the study of fluid flows. Despite huge efforts to understand vortex phenomena, many aspects are still not properly understood. In this minisymposium, Elling and Jeong are presenting mathematical and rigorous results of self-similar vortices. Xu will describe computations of elliptical vortices. Kim and Krishnamurthy will discuss point vortex dynamics and generalized geostrophic models. Nitsche and Sohn speak on computational issues for interfacial flows and application to swimming. Krasny will present computations of plasma vortices in the Vlasov-Poisson equation.

Minisymposium Program :

00062 (1/3) : 1C @D102 [Chair: Sun-Chul Kim]

[00106] Logarithmic vortex spirals

Format : Talk at Waseda University
Author(s) : In-Jee Jeong (Seoul National University)
Abstract : We investigate the dynamics of logarithmic vortex for the two-dimensional incompressible Euler equations. More precisely, we consider vorticity which is invariant under the transformation $(r,\theta)\mapsto(\lambda r,\theta+c\ln(\lambda))$ for any $\lambda>0$ and some $c>0$. Within this class of vorticities, one can consider various types, including patches and sheets. We derive the equations of motion for logarithmic vortex and consider the limit problem where patches become sheets.

[00069] Dynamics of elliptical vortices

Format : Online Talk on Zoom
Author(s) : Ling Xu (North Carolina Agricultural and Mechanical State University)Robert Krasny (University of Michigan, Ann Arbor)
Abstract : We examine the dynamics of elliptical vortices in 2D ideal fluid using an adaptively refined and remeshed vortex method. Four cases are considered: the compact MMZ and POLY vortices, and noncompact Gaussian and smooth Kirchhoff vortices (SK). The vortices have the same maximum vorticity and 2:1 initial aspect ratio, but unlike the top-hat Kirchhoff vortex, they have continuous profiles with different regularity. In all cases the co-rotating phase portrait has two hyperbolic points. At early time two filaments emerge and form a halo around the core as vorticity is advected along the unstable manifold of each hyperbolic point. The Gaussian vortex rapidly axisymmetrizes, but later on the core begins to oscillate and two small lobes emerge adjacent to the core; this is attributed to a resonance. For the MMZ, POLY, and SK vortices, the core maintains its ellipticity for longer time and the filaments entrain fluid into two large lobes forming a non-axisymmetric tripole state; afterwards the lobes repeatedly detrain fluid into the halo; this is attributed to a heteroclinic tangle. While prior work suggested that elliptical vortices evolve to either an axisymmetric state or a non-axisymmetric tripole state, our results suggest that such vortices may oscillate between these states.

[00121] The N-vortex problem in doubly-periodic domains with background vorticity

Format : Talk at Waseda University
Author(s) : Vikas Krishnamurthy (IIT Hyderabad)Takashi Sakajo (Kyoto University)
Abstract : We study the N-vortex problem in a doubly periodic rectangular domain in the presence of a constant background vorticity field. Using a conformal mapping approach, we derive an explicit formula for the hydrodynamic Green's function. We show that the point vortices form a Hamiltonian system and that the two-vortex problem is integrable. Several fixed lattice configurations are obtained for general N, some of which consist of vortices with inhomogeneous strengths and lattice defects.

[00127] Swimming of a Fish-like Body by using a Vortex Shedding Model

Format : Talk at Waseda University

Author(s) : SUNG-IK SOHN (Gangneung-Wonju National University)

Abstract : We consider the undulatory motion of a body translating through a quiescent fluid, which is motivated by the anguilliform swimming of aquatic animals, e.g., eels. We use an inviscid vortex shedding model to investigate the swimming dynamics. The model demonstrates the self-propulsion of the swimming body and yields pairs of anti-rotating vortices shed from the body. We examine the wake pattern and swimming efficiency which depends on the recoil motions of a body.

00062 (2/3) : 1D @D102 [Chair: Sung-Ik Sohn]

[00075] Motion of three geostrophic vortices

Format : Talk at Waseda University

Author(s) : Sun-Chul Kim (Chung-Ang University, Seoul, Korea (Republic of))Habin Yim (Chung-Ang University, Seoul, Korea (Republic of))Sung-Ik Sohn (Gangneung-Wonju National University)

Abstract : We investigate the dynamics of geostrophic Bessel vortices focusing on the three-vortex case, where the possibility of self-similar motion and general dynamics for arbitrary strengths is studied. It is found that self-similar motions are limited to rigid rotations and self-similar triple collapse is impossible. For a general description, trilinear coordinates are adopted. The physical regions in the phase plane cannot be directly identified, but the boundary approaches the vertices of the triangle in trilinear coordinates in geostrophic vortices.

[00126] Self-similar vortical flows

Format : Talk at Waseda University

Author(s) : Volker Wilhelm Elling (Academia Sinica, Taipei)

Abstract : Vortex spirals and vortex cusps are important features of self-similar vortical flows near stagnation points. Vortex sheets produced at triple points of Mach reflection have distinguished signs that determine whether interaction with walls or symmetry axes can be attached cusps or detached jets. Progress on analysis, modelling and numerics for such phenomena is discussed, along with applications to shock reflection or non-uniqueness of vortical flows.

[00150] Near-singular integrals in 3D interfacial Stokes and potential flows

Format : Talk at Waseda University

Author(s) : Monika Nitsche (University of New Mexico)

Abstract : Boundary integral formulations yield efficient numerical methods to solve elliptic boundary value problems. They are the method of choice for interfacial fluid flow in either the inviscid vortex sheet limit, or the viscous Stokes limit. The fluid velocity at a target point is given by an integral over all interfaces. However, for target points near, but not on the interface, the integrals are near-singular and standard quadratures lose accuracy. While several accurate methods for near-singular integrals exist in planar geometries, they do not generally apply to the non-analytic case that arises in axisymmetric or 3D geometries. We present a method based on Taylor series expansions of the integrand about basepoints on the interface that accurately resolve a large class of integrals, and apply it to solve the near-interface problem in planar vortex sheet flow, axisymmetric Stokes flow, and Stokes flow in 3D. The application to multi-nested Stokes flow uses a novel representation of the fluid velocity.

[00147] The FARSIGHT Vlasov-Poisson code

Format : Talk at Waseda University

Author(s) : Robert Krasny (University of Michigan)Ryan Sandberg (Lawrence Berkeley National Laboratory)Alexander Thomas (University of Michigan)

Abstract : We present electrostatic plasma simulations using a new semi-Lagrangian particle method for the Vlasov-Poisson equations called FARSIGHT. The electron density is represented on adaptively refined and remeshed panels in phase space, and the macroparticles are advected using a regularized electric field kernel and a GPU-accelerated barycentric Lagrange treecode. Results are presented for Landau damping, two-stream instability, and ion beam propagation. Work supported by AFOSR grant FA9550-19-1-0072.

00062 (3/3) : 1E @D102

[00063] Recent Advances on Nonlocal Interaction Models

Session Time & Room :

Type : Proposal of Minisymposium
Abstract : From biological swarming and n-body dynamics to self-assembly of nanoparticles, crystallization and granular media, many physical and biological systems are described by mathematical models involving nonlocal interactions. Mostly due to their purely nonlocal character, these models present mathematical challenges that require a combination of different techniques of applied mathematics. With this scientific session we aim to bring together young researchers and leading scholars who study nonlocal interaction models and their applications. In particular, we hope that by inviting applied and pure analysts we will create a platform that will lead to a more complete and reliable understanding of these models.

[04295] Patterns in block copolymers

Format : Talk at Waseda University
Author(s) : Stan Alama (McMaster University)Lia Bronsard (McMaster University)Xin Yang Lu (Lakehead University)Chong Wang (Washington and Lee University)
Abstract : We study a nonlocal isoperimetric problem for several interacting phase domains which consists of a local interface energy and of a longer-range Coulomb interaction energy. We consider global minimizers on the two-dimensional torus, in a limit in which some of the species have vanishingly small mass. Depending on the relative strengths of the coefficients we may see different structures for the global minimizers. This represents work with S. Alama, X. Lu, and C. Wang.

00063 (2/4) : 2C @F311 [Chair: Ihsan Topaloglu]

[00152] Patterns in tri-block copolymers: droplets, double-bubbles and core-shells.

Format : Talk at Waseda University
Author(s) : Stan Alama (McMaster Univ)Lia Bronsard (McMaster University)Xin Yang Lu (Lakehead Univ)Chong Wang (Washington and Lee Univ)
Abstract : We study the Nakazawa-Ohta ternary inhibitory system, which describes domain morphologies in a triblock copolymer as a nonlocal isoperimetric problem for three interacting phase domains. The free energy consists of two parts: the local interface energy measures the total perimeter of the phase boundaries, while a longer-range Coulomb interaction energy reflects the connectivity of the polymer chains and promotes splitting into micro-domains. We consider global minimizers on the two-dimensional torus, in a limit in which two of the species have vanishingly small mass but the interaction strength is correspondingly large. In this limit there is splitting of the masses, and each vanishing component rescales to a minimizer of an isoperimetric problem for clusters in 2D. Depending on the relative strengths of the coefficients of the interaction terms we may see different structures for the global minimizers, ranging from a lattice of isolated simple droplets of each minority species to double-bubbles or core-shells. This represents work with S. Alama, X. Lu, and C. Wang.

[00113] Ground states for aggregation-diffusion models on Cartan-Hadamard manifolds

Format : Talk at Waseda University
Author(s) : Hansol Park (Simon Fraser University)
Abstract : We investigate the existence of ground states of a free energy functional defined on Cartan-Hadamard manifolds. There are two competing effects in the free energy: repulsion modelled by linear diffusion and attraction modelled by a nonlocal interaction term. Nonexistence of energy minimizers can occur if either the diffusion is too strong (spreading) or attraction is dominant (blow-up). Variational approaches have been used to provide sufficient conditions of the attractive interaction to prevent the two scenarios from happening, and thus establishing the existence of global minimizers of the free energy.

[00101] Well-posedness and asymptotic behaviour of an interaction model on Riemannian manifolds

Format : Talk at Waseda University
Author(s) : Razvan C Fetecau (Simon Fraser University)
Abstract : We consider a model for collective behaviour with intrinsic interactions on Riemannian manifolds. We establish the well-posedness of measure solutions and study the long-time behaviour of solutions. For the latter, the primary goal is to establish sufficient conditions for a consensus state to form asymptotically. The analytical results are illustrated with numerical experiments that exhibit various asymptotic patterns.

[00131] Mean field games with aggregating interaction potentials of nonlocal type

Format : Talk at Waseda University
Author(s) : Annalisa Cesaroni (University of Padova)
Abstract : We discuss existence/non existence of solutions to ergodic mean field game systems in the whole space with interactions of aggregative Riesz type, in dependance on the strength of the interaction term.
Moreover, we present qualitative properties of the solutions and concentration phenomena, as the diffusion term vanishes. Finally we discuss some open problems related to stability of equilibria.

00063 (3/4) : 2D @F311 [Chair: Hansol Park]

[00105] Deterministic particle approximation for a nonlocal interaction equation with repulsive singular potential

Format : Talk at Waseda University
Author(s) : Marco Di Francesco (University of L'Aquila)Markus Schmidtchen (TU Dresden)
Abstract : We consider a variant of a deterministic particle approximation for a nonlocal interaction equation with repulsive Morse potential in 1d, which is not covered by previous similar results in the literature. We prove convergence in a weak sense towards solutions to the corresponding continuum PDE. We prove our scheme is able to capture L^p contractivity and a smoothing effect which allows to extend the result to initial data in the set of probability measures.

[00155] Nonlocal deterministic and stochastic models for collective movement in biology

Format : Talk at Waseda University
Author(s) : Raluca EFTIMIE (University of Franche-Comté)
Abstract : The collective movement of animals occurs as a result of communication between the members of the community. However, inter-individual communication can be affected by the stochasticity of the environment, leading to changes in the perception of neighbours and subsequent changes in individual behaviour, which then influence the overall behaviour of the animal aggregations. To investigate the effect of noise on the overall behaviour of animal aggregations, we consider a class of nonlocal hyperbolic models for the collective movement of animals. We show numerically that for some sets of model parameters associated with individual communication, strong noise does not influence the spatio-temporal pattern (i.e., travelling aggregations) observed when all neighbours are perceived with the same intensity (i.e., the environment is homogeneous). However, when neighbours ahead/behind are perceived differently by a reference individual, noise can lead to the destruction of the spatio-temporal pattern.

[00117] Zero-Inertia Limit: from Particle Swarm Optimization to Consensus-Based Optimization

Format : Talk at Waseda University
Author(s) : Hui Huang (University of Graz)
Abstract : Large systems of interacting particles are widely used to investigate self-organization and collective behavior. They have also been used in metaheuristic methods, which can provide empirically robust solutions to tackle hard optimization problems with fast algorithms. In this talk, we will focus on two examples of metaheuristics, i.e. Particle Swarm Optimization (PSO) and Consensus-Based Optimization (CBO). In particular, we shall provide a rigorous derivation of CBO from PSO through the limit of zero inertia. This is also related to the problems of overdamped limit and large-friction limit.

[00093] Many-spike limits of reaction-diffusion systems of PDEs

Format : Talk at Waseda University
Author(s) : Theodore Kolokolnikov (Dalhousie University)
Abstract : Many reaction-diffusion have solutions consisting of spots or spikes. We consider the problem of describing the density distribution of these spikes when the number of spikes is large. This naturally leads to integral equation for spike density.

00063 (4/4) : 2E @F311 [Chair: Razvan C Fetecau]

[00157] Pattern formation in particle systems: spherical shells to regular simplices

Format : Talk at Waseda University
Author(s) : Robert John McCann (University of Toronto, Department of Mathematics)
Abstract : Flocking and swarming models address mathematical biological pattern formation. When organisms interact through a difference of power laws attractive over large distances yet repulsive at short distances, we detail a phase transition which separates a region where the minimum energy configuration is uniquely attained by a uniform distribution of organisms over a spherical shell, from a region in which it is uniquely attained by equidistributing the organisms over the vertices of a regular top-dimensional simplex.

[05071] Some remarks on minimization of nonlocal attracting repulsing energies

Format : Online Talk on Zoom
Author(s) : Aldo Pratelli (University of Pisa)Ihsan Topaloglu (Virginia Commonwealth University)Davide Carazzato (SNS, Pisa)Nicola Fusco (University of Naples)
Abstract : We will discuss some results on the minimization of nonlocal energies of attraction-repulsion type. In particular, we will be interested in existence and regularity of minimizing sets, and of generalised solutions, i.e., functions or measures. Some of the presented results are well-known, some others are recent or very recent developments. Some of the results have been obtained in various collaborations with D. Carazzato, N. Fusco, I. Topaloglu.

[00145] On a Becker-Döring model for prions and an associated nonlocal problem.

Format : Online Talk on Zoom
Author(s) : Klemens Fellner (University of Graz)
Abstract : Prions are able to self-propagate biological information through the transfer of structural information from a misfolded/infectious protein in a prion state to a protein in a non-prion state. Prions cause diseases like Creuzfeldt-Jakob. Prion-like mechanisms are associated to Alzheimer, Parkinson ans Huntington diseases. We present a fundamental bi-monomeric, nonlinear Becker-Döring type model, which aims to explain experiments in the lab of Human Rezaei showing sustained oscillatory behaviour over multiple hours. We exemplify a mechanism of oscillatory behaviour and show numerical simulations. An interesting non-local problem describes an associated self-similar structure.

[04453] Shape Optimization for nonlocal anisotropic energies

Author(s) : Lucia Scardia (Heriot-Watt University)
Abstract : We address the problem of shape optimisation for sets with fixed mass, in the case of attractive-repulsive nonlocal energies. More precisely, we focus on energies whose repulsive part is an anisotropic Newtonian potential, and whose attractive part is radially symmetric, and quadratic.

For the fully radially symmetric case, it is known that the existence of minimisers depends on the value of the mass: there is a critical value such that minimisers
are balls above it, and do not exist below it. We show that a similar dichotomy occurs also in the anisotropic case.
The anisotropy, however, introduces an additional critical value that makes the analysis subtle.

This is work in collaboration with Riccardo Cristoferi and Maria Giovanna Mora.

[00065] Recent Advances on Stochastic Hamiltonian Dynamical Systems

Session Time & Room :

00065 (1/3) : 2C (Aug.22, 13:20-15:00) @E819

00065 (2/3) : 2D (Aug.22, 15:30-17:10) @E819

00065 (3/3) : 2E (Aug.22, 17:40-19:20) @E819

Type : Proposal of Minisymposium
Abstract : The generalization of classical geometric mechanics (including the study of symmetries, Hamiltonian and Lagrangian mechanics, and the Hamilton-Jacobi theory, etc.) to the context of stochastic dynamics has drawn more and more attention in recent decades. One of the important motivations behind some pieces of work related to this field is establishing a framework adapted to the handling of mechanical systems subjected to random perturbations or whose parameters are not precisely determined and are hence modeled as realizations of a random variable. This minisymposium will bring together speakers with diverse but related background, discussing recent developments on general topics of stochastic dynamical systems with Hamiltonian or other geometric structure.
Organizer(s) : Pingyuan Wei, Qiao Huang
Classification : 70L10, 37H05, 37J65, 70H05, 70H09
Minisymposium Program :

00065 (1/3) : 2C @E819

[04102] The Hamilton-Jacobi Theory for Stochastic Hamiltonian Systems on Jacobi Manifold

Format : Talk at Waseda University
Author(s) : Pingyuan Wei (Beijing International Center for Mathematical Research, Peking University, Beijing 100871, China)Qiao Huang (Nanyang Technological University)
Abstract : In this talk, we generalize the systems of Hamiltonian diffusions, which were introduced and studied by Bismut, to accommodate arbitrary Jacobi manifolds as phase spaces and general continuous semimartingales as forcing noises. As is well-known, Jacobi structures are the natural generalization of Poisson structure and in particular of symplectic, cosymplectic and Lie-Poisson structures. However, very interesting manifolds like contact and locally conformal symplectic manifolds are also Jacobi but not Poisson. We are interested in the systems such that the phase flows preserve characteristic structures, and develop a Hamilton-Jacobi theory which is regarded as an alternative method for formulating the dynamics. A particular example is the case of thermodynamic dynamics in which we apply our methods on a manifold with its canonical contact form.

[02876] Homogenization of Dissipative Hamiltonian Systems under L'evy Fluctuations

Format : Talk at Waseda University
Author(s) : Zibo Wang (Huazhong University of Science and Technology)
Abstract : We study the small mass limit for a class of Hamiltonian systems with multiplicative non-Gaussian L'evy noise. The limiting equation has a discontinuous noise-induced drift term. First, we show that the momentum in the stochastic Hamiltonian system converges to zero when the kinetic energy has polynomial growth. Then we prove that

the stochastic Hamiltonian system with classical kinetic energy converges to the limiting equation in probability with respect to Skorohod topology.

[02877] The stochastic flocking model with far-field degenerate communication

Format : Talk at Waseda University
Author(s) : Li Lv (Huazhong University of Science and Technology)
Abstract : We reconsider the stochastic kinetic Cucker-Smale model with multiplicative Brownian noise, in which we remove the positive lower bound assumption on the communication. First we prove the emergence of conditional flocking in strong sense. Then, we show that unconditional strong flocking occurs when communication weight decays slowly at the far field. These results imply uniform stability and mean-field limit. In particular, strong stability and mean-field limit in the expectation sense are established in one-dimensional case.

[04106] The Most Likely Transition Path for a Class of Distribution-Dependent Stochastic Systems

Format : Talk at Waseda University
Author(s) : Wei Wei (Shanghai Jiao Tong University)Jianyu Hu (Nanyang Technological University)
Abstract : Distribution-dependent stochastic dynamical systems arise widely in engineering and science. We consider a class of such systems which model the limit behaviors of interacting particles moving in a vector field with random fluctuations. We aim to examine the most likely transition path between equilibrium stable states of the vector field. In the small noise regime, we find that the action functional (or rate function) does not involve with the solution of the skeleton equation, which describes unperturbed deterministic flow of the vector field shifted by the interaction at zero distance. As a result, we are led to study the most likely transition path for a stochastic differential equation without distribution-dependency. This enables the computation of the most likely transition path for these distribution-dependent stochastic dynamical systems by the adaptive minimum action method and we illustrate our approach in two examples.

00065 (2/3) : 2D @E819

[00862] A parameterization method for quasi-periodic systems with noise

Format : Talk at Waseda University
Author(s) : Lei Zhang (Dalian University of Technology)Pingyuan Wei (Beijing International Center for Mathematical Research, Peking University)
Abstract : This work is devoted to studying the existence of invariant tori for a class of quasi-periodically forced systems with stochastic noise, and implementing an efficient method to compute the tori as well as Lyapunov exponents. These systems are skew-product systems driven by small perturbations. Two very common cases of noise included in our treatment are continuous stationary stochastic process and white noise. The existence of invariant tori is established by developing a parameterization method in random setting and applying an elementary fixed point theorem in Banach spaces. Based on this, we describe a numerical algorithm for the computation of them. Moreover, by considering the reducibility for random manifold, we also propose a numerical algorithm for the computation of the corresponding Lyapunov exponents.

[04265] Parametric Resonance for Enhancing the Rate of Metastable Transition

Format : Talk at Waseda University
Author(s) : Ying Chao (Xi'an Jiaotong University)Molei Tao (Georgia Inistitute of Technology)
Abstract : In this talk, we will introduce a way to quantify how periodic perturbation can change the rate of metastable transition in stochastic mechanical systems with weak noises. A closed-form explicit expression for approximating the rate change is provided, and the corresponding transition mechanism can also be approximated. Unlike the majority of existing relevant works, these results apply to kinetic Langevin equations with high-dimensional potentials and nonlinear perturbations. They are obtained based on a higher-order Hamiltonian formalism and perturbation analysis for the Freidlin-Wentzell action functional. This tool allowed us to show that parametric excitation at a resonant frequency can significantly enhance the rate of metastable transitions. Numerical experiments for both low-dimensional toy models and a molecular cluster are also provided. For the latter, we show that vibrating a material appropriately can help heal its defect, and our theory provides the appropriate vibration.

[04127] An end-to-end deep learning approach for extracting stochastic dynamical systems with α-stable Lévy noise

Format : Talk at Waseda University
Author(s) : Cheng Fang (Huazhong University of Science and Technology)Yubin Lu (Illinois Institute of Technology)Ting Gao (Huazhong University of Science and Technology)Jinqiao Duan (Great Bay University)
Abstract : Recently, extracting data-driven governing laws of dynamical systems through deep learning frameworks has gained a lot of attention in various fields. Moreover, a growing amount of research work tends to transfer deterministic dynamical systems to stochastic dynamical systems, especially those driven by non-Gaussian multiplicative noise. However, lots of log-likelihood based algorithms that work well for Gaussian cases cannot be directly extended to non-Gaussian scenarios which could have high error and low convergence issues. In this work, we overcome some of these challenges and identify stochastic dynamical systems driven by α-stable Lévy noise from only random pairwise data. Our innovations include: (1) designing a deep learning approach to learn both drift and diffusion coefficients for Lévy induced noise with α across all values, (2) learning complex multiplicative noise without restrictions on small noise intensity, (3) proposing an end-to-end complete framework for stochastic systems identification under a general input data assumption, that is, α-stable random variable. Finally, numerical experiments and comparisons with the non-local Kramers-Moyal formulas with moment generating function confirm the effectiveness of our method.

00065 (3/3) : 2E @E819

[04130] Schrodinger Meets Onsager

Format : Online Talk on Zoom
Author(s) : Qiao Huang (Nanyang Technological University)
Abstract : In this talk, we will use the framework of stochastic geometric mechanics to describe relations between Schrodinger's variational problem and Onsager's approach to nonequilibrium statistical mechanics. Especially, we will rebuild Onsager's reciprocal relations by introducing Riemannian structures on thermodynamic spaces, and propose a definition of entropy for nonequilibrium systems. This is joint work with Jean-Claude Zambrini.

[00806] Recent progress in spatial isosceles three body problem

Format : Online Talk on Zoom
Author(s) : Lei Liu (Peking University)
Abstract : Recently, we discovered some new and strong connections between the spatial isosceles three body problem and Symplectic Dynamics. From this perspective, more information can be obtained. Therefore, under the light of Symplectic Dynamics, we obtain plenty of new results. In this talk, we will introduce the isosceles three body problem in symplectic and dynamical point of view, including the dimensional reduction, dynamical analysis, index estimates, open book decomposition and convexity. Finally, I will prove the existence of infinite many oscillate periodic motions in certain parametrical setting.

[00068] Models for collective behavior and emergent phenomena

Session Time & Room :

00068 (1/3) : 2D (Aug.22, 15:30-17:10) @G501

00068 (2/3) : 2E (Aug.22, 17:40-19:20) @G501

00068 (3/3) : 3C (Aug.23, 13:20-15:00) @G501

Type : Proposal of Minisymposium
Abstract : Emergent structures are patterns arising via collective actions of many individual entities. In the context of life sciences, they range from the subatomic level to the entire anthropo- and biosphere. The main objective of this minisymposium is to bring together experts working in diverse areas of modeling of collective behavior and emergent phenomena, employing ordinary, stochastic, partial and functional differential equations. Applications include self-organizing systems of interacting agents, flocking and swarming, pedestrian dynamics, and network dynamics. The minisymposium will cover mathematical modeling, analytical and numerical results, focusing on applications and gaining new insights into the principles of emergence and self-organization.
Organizer(s) : Lisa Kreusser, Jan Haskovec

[03562] Emergence of Biological Transportation Networks as a Self-Regulated Process

Format : Talk at Waseda University
Author(s) : Simone Portaro (KAUST)
Abstract : Our purpose is to investigate self-regulating processes modeling biological transportation networks by writing formal L^2-gradient flow for a tensor valued diffusivity D. We will explore a broad class of entropy dissipations associated with a purely diffusive model and investigate the formal L^2-gradient flow of the Fokker-Planck equation. It derives an integral formula for the second variation of the dissipation functional, proving convexity, and couples the Poisson equation for electric potential obtaining the Poisson-Nernst-Planck system. Numerical results are also presented.

[03929] Bifurcations in collective dynamics: ordered and disordered behaviour

Format : Talk at Waseda University
Author(s) : Sara Merino-Aceituno (University of Vienna)Raphael Winter (University of Vienna)Christian Schmeiser (University of Vienna)Pierre Degond (University of Toulouse)
Abstract : In this talk, I will review some questions that arise around the classical Vicsek model - which is a model for collective dynamics where agents move at a constant speed while trying to adopt the averaged orientation of their neighbours, up
to some noise. I will discuss the emergence of bifurcations leading to disordered and ordered motion, depending on the local density of the agents.
This is a very interesting phenomenon: it showcases how two completely different observed behaviours can appear simultaneously from agents that interact following the same rules.

[04259] A new approach to upscaling of KTEs modelling cell migration

Format : Talk at Waseda University
Author(s) : Anna Zhigun (Queen's University Belfast)Christina Surulescu (University of Kaiserslautern-Landau)
Abstract : A new approach to upscaling of a class of kinetic transport equations that can, e.g. model cell migration in a fibrous environment under the influence of attractants will be presented. It doesn't rely on a Hilbert space setting and provides a unified and transparent way of obtaining both parabolic and hyperbolic scalings. Formal computations are mimicked by rigorous operations with Radon measures. A key tool is a PDE that connects zero and second order moments.

[04922] Asymptotic limits of transient patterns in a continuous-space interacting particle system.

Format : Talk at Waseda University
Author(s) : Dietmar B Oelz (University of Queensland)Cecilia Gonzalez Tokman (University of Queensland)
Abstract : We study a discrete-time interacting particle system with continuous state space. The process has applications in the modeling of actin filament turnover in biological cells through branching and subsequent rapid debranching. In continuous phase space, it can be interpreted as a voter model and as a step-wise mutation model. Its solutions are characterized by transient clusters reminiscent of either actin filament assemblies in the cell cortex or of the formation of opinion clusters.

We reformulate the process in terms of the inter-particle distances and focus on their marginal and joint distributions. We construct a recurrence relation for the associated characteristic functions and pass to the large population limit reminiscent of the Fleming-Viot super-processes. The precise characterization of all marginal distributions established in this work opens the way to a detailed analysis of cluster dynamics. We also obtain a recurrence relation which enables us to compute the moments of the asymptotic single particle distribution characterizing the transient aggregates. Our results indicate that aggregates have a fat-tailed distribution.

00068 (2/3) : 2E @G501 [Chair: Jan Haskovec]

[04504] Model Reduction and Coarse-Graining of Complex Systems

Format : Online Talk on Zoom
Author(s) : Hong Duong (University of Birmingham)
Abstract : Complex systems in nature and in applications (such as molecular systems, crowd dynamics, swarming, opinion formation, just to name a few) are often described by systems of stochastic differential equations (SDEs) and partial differential equations (PDEs). It is often analytically impossible or computationally prohibitively expensive to deal

with the full models due to their high dimensionality (degrees of freedom, number of involved parameters, etc.). It is thus of great importance to approximate such large and complex systems by simpler and lower dimensional ones, while still preserving the essential information from the original model. This procedure is referred to as model reduction or coarse-graining in the literature. In this talk, I will present methods for qualitative and quantitative coarse-graining of several SDEs and PDEs, in the presence or absence of a scale-separation.

[05047] Splitting methods for optimal control

Format : Online Talk on Zoom
Author(s) : David Goodwin (Aarhaus University)Mohammadali Foroozandeh (Zurich Instruments)Pranav Singh (University of Bath)
Abstract : The optimal control of a physical system requires efficient numerical solvers for computing dynamics, accurate gradients, and efficient optimization routines.

Of particular interest in this talk are quantum systems such as spins and electrons under the influence of external time-dependent controls such as lasers and magnetic fields. In this talk I will present a highly efficient optimal control procedure called QOALA which adaptively switches splitting based solvers and utilizes exact gradients.

[05107] Nonlocal Cross-interaction Systems on Graphs: Energy Landscape and Dynamics

Format : Online Talk on Zoom
Author(s) : Jan-Frederik Pietschmann (University of Augsburg)Markus Schmidtchen (Technische Universität Dresden)Georg Heinze (University of Augsburg)
Abstract : We explore the dynamical behavior and energetic properties of a model of two species that interact nonlocally on finite graphs. We introduce the setting of nonquadratic Finslerian gradient flows on generalized graphs featuring nonlinear mobilities. In a continuous and local setting, this class of systems exhibits a wide variety of patterns, including mixing of the two species, partial engulfment, or phase separation. We showcase how this rich behavior carries over to the graph structure. We present analytical and numerical evidence thereof.

00068 (3/3) : 3C @G501

[00072] Evolution equations in materials science: Multiscale modeling, analysis, and simulation

Session Time & Room :

00072 (1/3) : 3C (Aug.23, 13:20-15:00) @G502

00072 (2/3) : 3D (Aug.23, 15:30-17:10) @G502

00072 (3/3) : 3E (Aug.23, 17:40-19:20) @G502

Type : Proposal of Minisymposium
Abstract : Materials science has become increasingly efficient and contributes with new products. The increased material functionality relies on good experimental grip on microstructure evolution. Mathematics plays a crucial role in using experimental understanding to shed light where experiments are inaccessible. Mathematical challenges are though unsolved. Elastic porous materials have many practical applications, however the mathematical treatment of elasticity equations for realistic media is underdeveloped as the small-strains-hypothesis needs to be adopted while the porosity of real materials (e. g. when biology is involved) disagrees. Our symposium focuses on the development of advanced mathematical methodologies applicable to materials having complex microstructures.

00072 (1/3) : 3C @G502 [Chair: Toyohiko Aiki]

[04859] Diffusion in the presence of microstructures: Does vesicle micro-dynamics enhance the signalling among plants macro-transport?

Format : Talk at Waseda University
Author(s) : Adrian Muntean (Karlstad University)Sander Hille (Leiden University)Omar Richardson (Simula Consulting)
Abstract : We study a diffusion-drift problem for signalling among plants in the context of measure-valued equations. We show preliminary results concerning the modelling and mathematical analysis of scenarios involving the macroscopic diffusion of signalling molecules enhanced by a finite number of microvesicles, with own dynamics able to capture and release signals as a relay system. The macro-micro coupling relies on a two-scale transmission condition. Mild solutions will turn to exist and will be positive weak solutions.

[04217] Morphology formation in ternary mixtures: A continuum model

Format : Talk at Waseda University
Author(s) : Rainey Lyons (Karlstad University)
Abstract : We study the ability of a coupled nonlocal system of two quasilinear parabolic partial differential equations to produce phase separation patterns. This system is derived in the literature as the rigorous hydrodynamic limit of a suitably scaled interacting particle system of Blume–Capel–type driven by Kawasaki dynamics. In this talk, we will discuss the potential of the model to produce morphologies, the growth of these patterns, well-posedness, and regularity of solutions.

[05044] Homogenisation of an advection–reaction–diffusion process in a porous medium with coupled evolving microstructure

Format : Talk at Waseda University
Author(s) : Markus Gahn (Heidelberg University)Malte A. Peter (University of Augsburg)Iuliu Sorin Pop (Hasselt University)David Wiedemann (University of Ausgburg)
Abstract : We consider the homogenization of an advection–reaction–diffusion equation in an evolving porous medium. The microstructure's evolution is coupled with the unknown concentration of a substance, resulting in a free boundary value problem. To rigorously pass to the homogenization limit, we transform the problem into a periodic fixed domain, which results in a highly non-linear problem. We then pass to the homogenization limit.

[04239] Partial differential equations for moisture transport in porous materials

Format : Talk at Waseda University
Author(s) : Akiko Morimura (Japan Women's University)Toyohiko Aiki (Japan Women's Univeristy)
Abstract : We consider the initial-boundary value problems for nonlinear parabolic equations describing moisture transport in a porous material. As a first step in this research, we suppose that the mass distribution in air is given and propose the problem for equation called ellipitic-parabolic type. The purpose of this talk is to establish existence and uniqueness of solutions to the approximate problem by applying the evolution equation theory and the standard fixed-point argument.

00072 (2/3) : 3D @G502 [Chair: Adrian Muntean]

[04230] A two-scale model describing swelling phenomenon in porous materials

Format : Talk at Waseda University
Author(s) : Kota Kumazaki (Kyoto University of Education)Adrian Muntean (Karlstad University)
Abstract : In this talk, we propose a two-scale model describing the swelling phenomenon in porous materials. This model consists of a diffusion equation for the relative humidity distributed in materials and a free boundary problem describing the swelling process in microscopic pores. We consider each microscopic pore as a one-dimensional interval and correspond the interval to each point of materials. In this talk, we discuss the global solvability of this model.

[04483] Improved corrector regularity in homogenization with non-smooth coefficients

Format : Talk at Waseda University
Author(s) : Grigor Nika (Karlstad University)
Abstract : We propose an advanced model of microscopic heat conduction, capable of addressing size effects in heterogeneous media. By leveraging sound scaling arguments, we enhance the differentiability of the corrector in the classical problem of periodic homogenization of linear elliptic equations in three dimensions. This enables us to elucidate the crucial role that correctors play in quantifying the differences between the microscopic and macroscopic solutions in heterogeneous media. Furthermore, if the data are of the form $f = \mathrm{div}\,\mathbf{F}$ with $\mathbf{F} \in \mathrm{L}^3(\Omega, \mathbb{R}^3)$, then we recover a stronger version of the classical corrector convergence theorem.

[03965] Solvability of a dynamical model for the elastic curves

Format : Talk at Waseda University
Author(s) : Chiharu Kosugi (Yamaguchi University)Toyohiko Aiki (Japan Women's Univeristy)
Abstract : To establish a mathematical model for stretching and shrinking motions of the compressible elastic curves like rubber bands, we discuss problems whose feature is that the strain function is nonlinear and non-smooth, and the stress function has singularity. For the problem, thanks to a priori estimates for the strain from below and center of mass globally in time we can show results on existence, uniqueness, and large time behavior of solutions.

[04592] Numerical simulations and analysis for mathematical modeling of adsorption phenomena

Format : Talk at Waseda University
Author(s) : Yusuke Murase (Meijo University)
Abstract : In this talk, we discuss numerical simulations ans mathematical properties of mathematical modeling for adsorption phenomena and modeling for moisture transport in concrete material. The adsorption model is a free boundary problem composed by heat equation and free boundary equation, and the moisture transport model is combined with adsorption model and diffusion equations. Which is proposed by T. Aiki, K. Kumazaki, N. Sato, and Y. Murase.

00072 (3/3) : 3E @G502 [Chair: Kota Kumazaki]

[04388] Decay estimates for a unit cell model of composite materials

Format : Talk at Waseda University
Author(s) : Shuji Yoshikawa (Oita University)
Abstract : We shall introduce decay estimates for a unit cell model of composite materials. The model we study here is the one of toy models, but the result corresponds to the first step of a mixture of transmission and waveguide problems from the viewpoint of PDEs.

[04211] Effective hydromechanic models for fibre-reinforced hydrogels

Format : Talk at Waseda University
Author(s) : Michael Eden (Karlstad University)Hari Shankar Mahato (IIT Kharagpur)
Abstract : We consider highly heterogeneous two-component media composed of a connected fibre-scaffold with periodically distributed inclusions of hydrogel. While the fibres are assumed to be elastic, the hydromechanical response of hydrogel is modeled via Biot’s poroelasticity. We show that the resulting mathematical problem admits a unique weak solution and investigate the limit behavior of the solutions with respect to a scale parameter characterizing the heterogeneity of the medium.

[04680] An elastoplastic model with a time-dependent threshold function

Format : Talk at Waseda University
Author(s) : Yoshiho Akagawa Takeshi Fukao (Ryukoku University)Risei Kano (Kochi University)
Abstract : We investigate the well-posedness of an elastoplastic model described by quasi-variational inequalities, applying the abstract theory of evolution equation. The prototype model is introduced by Duvau-Lions. It is characterized by the constraint for the deviatoric part of the stress tensor. In the case when the constraints depend on time and some unknown strain history, then the model represents more realistic phenomena. This is joint work with Risei Kano (Kochi University), and Takeshi Fukao (Ryukoku University).

[00082] Development in fractional diffusion equations: models and methods

Session Time & Room :

00082 (1/3) : 1E (Aug.21, 17:40-19:20) @A618

00082 (2/3) : 4D (Aug.24, 15:30-17:10) @A618

00082 (3/3) : 4E (Aug.24, 17:40-19:20) @A618

Type : Proposal of Minisymposium
Abstract : The mathematical study of diffusion and its applications has played an important role in modern mathematics. The study of fractional diffusion has become a new trend as a mathematical framework to describe anomalous diffusion. Indeed, in the real world anomalous diffusion is common. We wish to present the
last and novel techniques regarding modeling with FDE and its mathematical analysis. In particular we are interested in modeling with the help of FDE, the
resulting IBV problems, including free boundary problems. We also pursue the study of the qualitative properties of solutions including self-similar and
fundamental solutions.

[00162] Solution of a fractional Stefan problem using a Landau transformation

Format : Talk at Waseda University
Author(s) : Vaughan Richard Voller (University of Minnesota)
Abstract : The Stefan problem, tracking the motion of a heat conduction driven melt interface, is the classical moving boundary problem. A means of obtaining a solution for such problems is through the use of a variable transformation --- the Landau transformation --- immobilizing the melt interface. Here we apply this technique for the approximate solution of a fractional Stefan problem where the integer time derivative, in the governing diffusion equation, is replaced with a fractional derivative.

[00166] Fractional diffusion as an intermediate asymptotic regime

Format : Talk at Waseda University
Author(s) : Gianni Pagnini (BCAM - Basque Center for Applied Mathematics)Paolo Paradisi (ISTI-CNR, Pisa)Silvia Vitali (Eurecat Centre Tecnològic de Catalunya Barcellona)
Abstract : A continuous-time random walk driven by two different Markovian hopping-trap mechanisms is investigated and it is shown that paradigmatic features of anomalous diffusion are met. More precisely, anomalous diffusion results from a process that goes through the action of two co-existing Markovian mechanisms acting with different statistical frequency, and the probability of occurrence of this switch between the two Markovian settings originates and fully characterizes the anomalous diffusion. In fact, ensemble and single-particle observables of this model have been studied and they match the main characteristics of anomalous diffusion as they are typically measured in living systems. In particular, the celebrated transition of the walker's distribution from exponential to stretched-exponential and finally to Gaussian distribution is displayed by including also the Brownian yet non-Gaussian interval. Moreover, the model dynamically provides the power-law exponent of the mean-square displacement as a function of the probability of switching between the two Markovian states, namely the fractional order. Hence, fractional diffusion emerges as an intermediate asymptotic regime. Finally, within the present approach, fractional diffusion can be interpreted as a mathematical method for bridging two co-existing equilibrium states in a disordered medium.

[02596] Dissipativity of the energy functional in time-fractional gradient flows

Format : Talk at Waseda University
Author(s) : Marvin Fritz (Johann Radon Institute for Computational and Applied Mathematics (RICAM))
Abstract : In this talk, the monotonicity of the energy functional of time-fractional gradient flows is investigated. It is still unknown whether the energy is dissipating in a timely manner. This characteristic is critical for integer-order gradient flows, and many numerical systems utilize it. We suggest an energy functional that incorporates the solution's

history, which is reasonable given that time-fractional partial differential equations are nonlocal in time and feature a natural memory effect. On the basis of this new energy, we demonstrate that a time-fractional gradient flow is equivalent to an integer-order flow. In addition, this connection guarantees the dissipative nature of the augmented energy and permits the development of numerical schemes.

[00119] Weak and entropy solutions of time-fractional porous medium type equations

Format : Online Talk on Zoom
Author(s) : Petra Wittbold (University of Duisburg-Essen)
Abstract : We present results on existence and uniqueness of bounded weak and also unbounded entropy solutions to a degenerate quasilinear subdiffusion problem of porous medium type with bounded measurable diffusion coefficients that may explicitly depend on time. The integro-differential operator in the equation includes, in particular, the time-fractional derivative case.
A key ingredient in the proof of existence is a new compactness criterion of Aubin-Lions type which involves the non-local in time operator.

[00167] On different formulations for time-fractional Stefan problems

Format : Online Talk on Zoom
Author(s) : Sabrina Roscani (CONICET - Universidad Austral)
Abstract : We present a one-dimensional fractional Stefan problem for a memory flux derived from thermodynamic balance statements and provide a memory enthalpy formulation related to the previous model. The Stefan condition for each problem at the free interface is analyzed and numerical simulations obtained from the enthalpy model are given.

[00163] Numerical methods for nonlocal and nonlinear parabolic equations with applications in hydrology and climatology

Format : Online Talk on Zoom
Author(s) : Lukasz Plociniczak (Wroclaw University of Science and Technology)
Abstract : We present some of our results concerning numerical discretizations of nonlinear and fractional in time parabolic equations. Along with a collection of various methods and statements about their convergence and stability, we stress their motivation and real-world applications.

[00160] Regularity of weak solutions to parabolic-type problems with distributed order time-fractional derivative

Format : Online Talk on Zoom
Author(s) : Katarzyna Ryszewska (Warsaw University of Technology)
Abstract : In this talk we will discuss Holder continuity of weak solutions to evolution equations with distributed order time-fractional derivative. It is a generalization of the result for a single order fractional derivative obtained by Prof. Zacher in 2010. The main difficulty to overcome in this case, is the lack of a natural scaling property of the equation.
This is a joint work with Adam Kubica and Prof. Rico Zacher.

[04911] Uniqueness for inverse source problems for time-fractional diffusion-wave equations

Format : Talk at Waseda University
Author(s) : Masahiro Yamamoto (The Univ. Tokyo)
Abstract : For time-fractional diffusion-wave equations, $\partial_t^\alpha u(x,t) = -Au + \mu(t)f(x)$ for $x\in \Omega,
0

[02617] Fractional diffusion equation with psi-Hilfer derivative

Format : Talk at Waseda University
Author(s) : M. Manuela Rodrigues (University of Aveiro, Portugal)
Abstract : We consider the multidimensional time-fractional diffusion equation with ψ-Hilfer derivative. An integral representation of the solution to the associated Cauchy problem involving Fox H-functions is obtained. Fractional

moments of arbitrary order are computed. Series representations of the first fundamental solution are presented. Some plots of the fundamental solution are presented for particular choices of the function ψ and the fractional parameters.

Joint work with N. Vieira (UA - CIDMA), M. Ferreira (IPLeiria~ & ~ CIDMA)

[02623] On the ψ-Hilfer time-fractional telegraph equation in higher dimensions

Format : Talk at Waseda University
Author(s) : Nelson Vieira (CIDMA - University of Aveiro)
Abstract : We consider the time-fractional telegraph equation in $\mathbb{R}^n \times \mathbb{R}^+$ with ψ-Hilfer fractional derivatives. For the solution, we present an integral representation involving Fox H-functions of two variables, and in terms of double series. For $n = 1$, we prove the conditions under which we can interpret the first fundamental solution as a probability density function. Some plots of the fundamental solutions are presented. Joint work with M. Ferreira (IPLeiria & CIDMA) and M.M. Rodrigues (CIDMA).

[02767] The fundamental solution to the space fractional diffusion equation

Format : Talk at Waseda University
Author(s) : Piotr Rybka (University of Warsaw)Tokinaga Namba (Nippon Steel Corporation)Shoichi Sato (University of Tokyo)
Abstract : We consider a one dimensional diffusion equation equation involving the divergence of the Caputo space derivative of order less than one. We construct a self-similar solution, $\mathcal{E}$, which permits us to derive the representation formulas for boundary value problem on the half line. We also present properties of $\mathcal{E}$, and we show the infinite speed of signal propagation.

This is a joint research with T.Namaba and S.Sato.

[00084] Asymptotic approaches to multi-scale PDEs in mathematical physics

Session Time & Room :

00084 (1/2) : 5B (Aug.25, 10:40-12:20) @G405

00084 (2/2) : 5C (Aug.25, 13:20-15:00) @G405

Type : Proposal of Minisymposium
Abstract : Nonlinear PDEs play an important role in modelling many important phenomena observed in physics. One of the main challenges is that the physical problem at hand usually manifests its properties on a hierarchy of scales: the behaviour of the system at the large scale can only be understood by accessing a number of finer scales. Discovering the numerous scales in the governing equations and describing the singularities which appear in asymptotic processes give rise to exciting and difficult research problems (e.g. singular limits in fluid mechanics, macroscopic closures of kinetic models, or incompressible limits for tissue growth models).

Organizer(s) : Tomasz Dębiec, Agnieszka Świerczewska-Gwiazda

[04992] Relative entropy and application to asymptotic limits for bipolar Euler-Poisson systems.

Format : Talk at Waseda University
Author(s) : Athanasios Tzavaras (King Abdullah University of Science and Technology (KAUST))Nuno Alves (King Abdullah University of Science and Technology (KAUST))
Abstract : The relative entropy method has been a very effective tool for describing asymptotic limit problems in mechanics and mathematical physics. A formalism for Hamiltonian systems can be easily extended to the system of bipolar Euler-Maxwell equations. We will describe here various results on asymptotic limits from bipolar Euler Poisson to

models that are used for the description of plasmas, or (when combined with high-friction limits) to semi-conductors (joint work with Nuno Alves).

[04461] From compressible euler equation to porous media

Format : Talk at Waseda University
Author(s) : Piotr Gwiazda (Institute of Mathematics of Polish Academy of Sciences)
Abstract : We consider a combined system of Euler, Euler–Korteweg and Euler–Poisson equations. We show the existence of dissipative measure-valued solutions in the cases of repulsive and attractive potential in Euler–Poisson system. Furthermore we show that the strong solutions to the Cahn–Hillard–Keller–Segel system are a high-friction limit of the dissipative measure-valued solutions to Euler–Korteweg–Poisson equations.

[03337] On the asymptotic dynamics of point vortices for the lake equations

Format : Talk at Waseda University
Author(s) : Lars Eric Hientzsch (Bielefeld University)Christophe Lacave (University Grenoble Alpes)Evelyne Miot (University Grenoble Alpes)
Abstract : The lake equations describe the evolution of the vertically averaged velocity field of an incompressible inviscid 3D fluid in a domain with spatially varying topography (depth).
We derive the asymptotic dynamics of point vortices for the lake equations with positive depth, when the vorticity is initially sharply concentrated around N points. More precisely, we show that the vorticity remains concentrated in suitable sense around N points for all times, and that the trajectories follow the level lines of the depth function.
This is joint work with Christophe Lacave and Evelyne Miot (Université Grenoble Alpes).

[03190] Strong Convergence of Vorticity in the Viscosity Limit

Format : Talk at Waseda University
Author(s) : Emil Wiedemann (Universität Erlangen-Nürnberg)
Abstract : Consider the 2D incompressible Navier-Stokes equations with initial vorticity in L^p ($1

00084 (2/2) : 5C @G405 [Chair: Agnieszka Świerczewska-Gwiazda]

[05460] Local smooth solvability for the Relativistic Vlasov-Maxwell system.

Format : Online Talk on Zoom
Author(s) : Slim IBRAHIM (UNIVERSITY OF VICTORIA)Christophe Cheverry (University of Rennes)
Abstract : This talk is devoted to the Relativistic Vlasov-Maxwell system in space
dimension three. We prove the local smooth solvability for weak topologies (and its long time version for small data).
This result is derived from a representation formula decoding how the momentum spreads, and showing that the
domain of influence in momentum is controlled by mild information. We do so by developing a Radon
Fourier analysis on the RVM system, leading to the study of a class of singular weighted integrals. In the end,
we implement our method to construct smooth solutions to the RVM system in the regime of dense, hot and
strongly magnetized plasmas. This is done by investigating the stability properties near a class of approximate
solutions. This is a joint work with C. Cheverry.

[04487] Incompressible limit for tumor growth models with convective effects

Format : Talk at Waseda University
Author(s) : Noemi David (Université de Lyon)Tomasz Dębiec (University of Warsaw)Benoit Perthame (Sorbonne Université)Markus Schmidtchen (Technische Universität Dresden)
Abstract : Both compressible and incompressible models have been used in the literature to describe the mechanical aspects of living tissues. Using a stiff pressure law, it is possible to build a bridge between density-based models and free boundary problems where saturation holds. I will present the study of the incompressible limit for advection-porous medium equations and discuss the convergence rate of solutions of the compressible model to solutions of the limit Hele-Shaw problem.

[03628] Construction of weak solutions to Compressible Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Piotr B. Mucha (University of Warsaw)
Abstract : We calibrate neural stochastic differential equations jointly to S&P 500 smiles, VIX futures, and VIX smiles. Drifts and volatilities are modeled as neural networks. Minimizing a suitable loss allows us to fit market data for multiple S&P 500 and VIX maturities. A one-factor Markovian stochastic local volatility model is shown to fit both smiles and VIX

futures within bid-ask spreads. The joint calibration actually makes it a pure path-dependent volatility model, confirming the findings in (Guyon, 2022, The VIX Future in Bergomi Models: Fast Approximation Formulas and Joint Calibration with S&P 500 Skew).

[00085] Singular Problems in Mechanics

Session Time & Room :

00085 (1/3) : 1C (Aug.21, 13:20-15:00) @G406

00085 (2/3) : 1D (Aug.21, 15:30-17:10) @G406

00085 (3/3) : 1E (Aug.21, 17:40-19:20) @G406

Type : Proposal of Minisymposium
Abstract : The problem area addresses non-smooth problems stemming from mechanics and described by partial differential equations, inverse and ill-posed problems, non-smooth and nonconvex optimization, optimal control problems, multiscale analysis and homogenization, shape and topology optimization. We focus but are not limited to singularities like cracks, inclusions, aerofoils, defects and inhomogeneities arising in composite structures and multi-phase continua, which are governed by systems of variational equations and inequalities. The minisymposium objectives are directed toward sharing advances attained in the mathematical theory, numerical methods, and application of non-smooth problems.

[00222] Recent progress on the irreversible fracture phase field model

Format : Talk at Waseda University
Author(s) : Masato Kimura (Kanazawa University)
Abstract : We would like to present our recent progress in the study of the fracture phase field model of the irreversible type. It not only enables us to simulate various kinds of crack propagation phenomena but also realizes a non-healing property and a natural energy gradient structure simultaneously.

[00267] Fractional Korn inequalities in bounded domains

Format : Talk at Waseda University
Author(s) : Davit Harutyunyan (University of California Santa Barbara)Hayk Mikayelyan (University of Nottingham Ningbo China)
Abstract :
The validity of Korn's first inequality in the fractional setting in bounded domains has been open. We resolve this problem by proving that in fact Korn's first inequality holds in the case $ps>1$ for fractional $W_0^{s,p}(\Omega)$ Sobolev fields in open and bounded C^1-regular domains $\Omega\subset\mathbb{R}^n$. Also, in the case $ps<1$, for any open bounded C^1 domain $\Omega\subset\mathbb{R}^n$ we construct counterexamples to the inequality, i.e., Korn's first inequality fails to hold in bounded domains. The proof of the inequality in the case $ps>1$ follows a standard compactness approach adopted in the classical case, combined with a Hardy inequality, and a recently proven Korn second inequality by Mengesha and Scott [\textit{Commun. Math. Sci.,} Vol. 20, N0. 2, 405--423, 2022]. The counterexamples constructed in the case $ps<1$ are interpolations of a constant affine rigid motion inside the domain away from the boundary, and of the zero field close to the boundary.

[00266] On Phase Field Approach for Crack Propagation due to Water Pressure in Porous Medium

Format : Talk at Waseda University
Author(s) : Sayahdin Alfat (Kanazawa University)Masato Kimura (Kanazawa University)
Abstract : The crack propagation in the material due to water pressure was studied. This study involved the poroelasticity theory proposed by M. A. Biot. This study is divided into two parts. In the first part, we derived the poroelasticity theory, and its energy equality and presented several numerical examples. In the second part, we introduce our phase field model with unilateral contact conditions for desiccation cracking by coupling with the Biot model and show energy equality.

[00171] Asymptotic series solution of variational Stokes problems in planar domain with crack-like singularity

Format : Talk at Waseda University
Author(s) : Victor Kovtunenko (University of Graz)
Abstract : Variational problems for incompressible fluids and solids descried by stationary Stokes equations in a planar domain with crack are considered. Based on the Fourier asymptotic analysis, general solutions are derived analytically as power series with respect to the distance to the crack tip. The logarithm terms and angular functions are accounted in the asymptotic expansion using recurrence relations. Boundary conditions of Dirichlet, Neumann, impermeability, non-penetration, and shear at the crack faces determine admissible exponents and parameters in the power series. The principal asymptotic terms are derived in the sector of angle 2π, which determine a square-root singularity at the crack tip and presence of log-oscillations of variational solutions for the Stokes problems.

00085 (2/3) : 1D @G406 [Chair: Victor Kovtunenko]

[00288] Evolution equations with complete irreversibility

Format : Talk at Waseda University
Author(s) : Goro Akagi (Tohoku University)
Abstract : In this talk, recent developments of studies on evolution equations with complete irreversibility, i.e., solutions are constrained to be monotone in time, will be reviewed. In particular, such evolution equations often arise from fracture and damage mechanics. From mathematical points of view, they are classified as fully nonlinear PDEs, and therefore, it is in general more difficult to prove their well-posedness and reveal dynamics of their solutions. However, by change of variables, they can be rewritten as doubly-nonlinear evolution equations, whose energy and variational structures are available for the analysis. Moreover, they are sometimes equivalently reformulated as semilinear obstacle problems whose obstacle functions coincide with initial data. It will also give us a clue for the analysis. In this talk, we shall overview recent results on diffusion equations and Allen-Cahn equations with complete irreversibility and also some phase-field systems arising from fracture models.

[00285] H^2-regularity up to boundary for a Bingham fluid model

Format : Talk at Waseda University
Author(s) : Takahito Kashiwabara (The University of Tokyo)
Abstract : Bingham fluid is a model describing the motion of viscoplastic materials. The problem is formulated by a variational inequality, to which weak solvability in the Sobolev space H^1 is well known. However, regularity in H^2 up to the boundary, unlike its interior counterpart, seems to remain open. In this talk, we present such a result for the homogeneous slip boundary value problem, avoiding the difficulty of being unable to get good pressure estimates.

[00279] On a generalization Kelvin–Voigt model with pressure-dependent moduli

Format : Talk at Waseda University
Author(s) : Hiromichi Itou (Tokyo University of Science)Victor Kovtunenko (University of Graz)Kumbakonam Rajagopal (Texas A&M University)
Abstract : In this talk, we discuss a generalization Kelvin–Voigt model of viscoelasticity whose material moduli depend on the pressure in which both the Cauchy stress and the linearized strain appear linearly. This model is derived from an implicit constitutive relation, and is well-suited to describe porous materials like concrete, ceramics. We show well-posedness for the corresponding variational problem by thresholding the moduli.

[00287] A reconstruction problem in nanoscale processing by transverse dynamic force microscopy

Format : Online Talk on Zoom
Author(s) : Alemdar Hasanov Hasanoglu (Kocaeli University)
Abstract : In this study, the dynamic model of reconstruction of the shear force in the transverse dynamic force microscopy (TDFM)-cantilever tip-sample interaction is proposed. For this inverse problem, an input-output operator is introduced and then the compactness of this operator, thus, the ill-posedness of the inverse problems is proved. The least square solution of the inverse problem is introduced through the Tikhonov functional. The Lipschitz continuity of the input-output operator is proved. As a consequence of this, the existence of the least square solution is proved. An explicit formula for the Fr'{e}chet gradient is derived by making use of the unique solution of the corresponding adjoint problem. This allows us to construct an effective and fast reconstruction algorithm, as the presented computational experiments show.

00085 (3/3) : 1E @G406 [Chair: Hayk Mikayelyan]

[00203] On Kirchhoff-Love plates with thin elastic junction

Format : Online Talk on Zoom
Author(s) : Alexander Khludnev (Lavrentyev Institute of Hydrodynamics of RAS)
Abstract : The talk concerns an equilibrium problem for two elastic plates connected by a thin junction (bridge) in a case of Neumann boundary conditions, which provide a non-coercivity for the problem. An existence of solutions is proved. Passages to limits are justified with respect to the rigidity parameter of the junction. In particular, the rigidity parameter tends to infinity and to zero. Limit models are investigated.

[00235] Optimal Location Problem for Heterogeneous Bodies with Separate and Joined Rigid Inclusions

Format : Online Talk on Zoom
Author(s) : Niurgun Lazarev (North Eastern Federal University)
Abstract : Nonlinear mathematical models describing an equilibrium state of heterogeneous bodies which may come into contact with a fixed non-deformable obstacle are investigated. A possible mechanical interaction of the body and the obstacle is described with the help of the Signorini-type non-penetration condition. We suppose that the heterogeneous bodies consist of an elastic matrix and one or two built-in volume (bulk) rigid inclusions. One of the inclusions can vary its location along a given curve. Considering a location parameter as a control parameter, we formulate an optimal control problem with a cost functional specified by an arbitrary continuous functional on the solution space. Assuming that the location parameter varies in a given closed interval, the solvability of the optimal control problem is established. Furthermore, it is shown that the equilibrium problem for the heterogeneous body with joined two inclusions can be considered as a limiting problem for the family of equilibrium problems for heterogeneous bodies with two separate inclusions.

[00210] Multiscale analysis of stationary thermoelastic vibrations of a composite material

Format : Online Talk on Zoom
Author(s) : Evgeny Rudoy (Lavrentyev Institute of Hydrodynamics of the Siberian Branch of the Russian Academy of Sciences)
Abstract : The stationary vibrations problem is studied for a planar thermoelastic body incorporating thin inclusions. This problem contains two small positive, which describe the thickness of an individual inclusion and the distance between two neighboring inclusions. Relying on the variational formulation, by means of methods of asymptotic analysis, we investigate the behavior of solutions as parameters tend to zero. We construct models corresponding to limit cases. The work is supported by Russian Scientific Foundation (№ 22-21-00627).

[00207] An impulsive pseudoparabolic equation with an infinitesimal transition layer

Format : Online Talk on Zoom
Author(s) : Sergey Alexandrovich Sazhenkov (Altay State University, Barnaul)
Abstract : We study the two-dimensional Cauchy problem for the non-instantaneous impulsive pseudoparabolic equation. Such equations arise in filtration theory, thermodynamics, etc. We rigorously justify the passage to the instantaneous impulsive equation and show that, as the duration of the impulse tends to zero, the infinitesimal transition layer is formed, which inherits the profile of the original non-instantaneous impulsive impact. This is a joint work with Dr. Ivan Kuznetsov of the Lavrentyev Institute of Hydrodynamics, Russia.

[00086] Recent advances in the theory of rogue waves: stability and universality of wave pattern formation

Session Time & Room :

00086 (1/3) : 5B (Aug.25, 10:40-12:20) @G701

00086 (2/3) : 5C (Aug.25, 13:20-15:00) @G701

00086 (3/3) : 5D (Aug.25, 15:30-17:10) @G701

Type : Proposal of Minisymposium
Abstract : In the last decade, there have been some new developments in the study of rogue-waves of nonlinear integrable evolutionary equations, such as their long-time asymptotics, their stability, their universal patterns, and their onset mechanisms. This minisymposium aims to bring together a group of world-leading researchers to discuss the theoretical, computational, and experimental aspects of this type of extreme wave phenomena.
Organizer(s) : Bao-Feng Feng; Peter Miller
Classification : 35Q51, 39A36, 35C08
Minisymposium Program :

00086 (1/3) : 5B @G701 [Chair: Peter Miller]

[05527] Universal rogue wave patterns and their connections with special polynomials

Format : Online Talk on Zoom
Author(s) : Jianke Yang (University of Vermont)
Abstract : Rogue wave patterns in integrable systems are investigated. We show that universal rogue patterns of various types appear in integrable systems when one of the internal parameters in bilinear expressions of rogue waves gets large, and these universal rogue patterns can be predicted asymptotically by root structures of certain special polynomials, such as the Yablonskii–Vorob'ev polynomial hierarchy and the Okamoto polynomial hierarchies. This is joint work with Dr. Bo Yang of Ningbo University.

[05532] Determinant formula for Rogue waves and the binomial theorem

Format : Talk at Waseda University
Author(s) : Yasuhiro Ohta (Kobe University)
Abstract : The rogue wave solutions for integrable systems are often given by the determinant formula for tau functions explicitly. The determinant expression is related with the binomial theorem of rational type. We report an observation about the bilinear structure for the tau functions derived through the binomial theorem.

[05549] Two-dimensional rogue waves generated by resonance collision

Format : Online Talk on Zoom
Author(s) : Jingsong He (Shenzhen University)
Abstract : It is one of important topics to construct rogue waves in two-dimensional integrable systems. In recent years, we have obtained two kinds of rogue wave in few two-dimensional integrable systems by Hirota method. The generating mechanism of them is the resonant collision between different nonlinear waves. In this talk, two kinds of rogue wave of the Davey–Stewartson I equation are discussed with details by analytical and graphic ways. The main
results have been published in two papers: Journal of Nonlinear Science 31(2021) 67 and Letters in Mathematical Physics112(2022)75, co-authored with Jiguang Rao, Athanassios S. Fokas, Yi Cheng.

00086 (2/3) : 5C @G701 [Chair: Baofeng Feng]

[04902] Rogue waves of infinite order and their properties, Part 1

Author(s) : Deniz Bilman (University of Cincinnati)
Abstract : In a study of high-order fundamental rogue wave solutions of the focusing nonlinear Schrödinger equation, a new limiting object termed the rogue wave of infinite order was found in a high-order near-field limit. Subsequently it has been shown that this same limiting object, itself a solution of the focusing nonlinear Schrödinger equation in rescaled variables that also solves differential equations in the Painlevé-III hierarchy, also arises in numerous other settings such as high-order solitons, semiclassical asymptotics, iterated Bäcklund transformations of arbitrary backgrounds, and even other related nonlinear systems. This talk will describe this story and introduce the rogue wave of infinite order and some generalizations of it. This is joint work with Peter D. Miller.

[04895] Rogue waves of infinite order and their properties, Part 2

Author(s) : Peter David Miller (University of Michigan)
Abstract : The general rogue wave of infinite order is a family of exact solutions of the focusing nonlinear Schr"odinger equation that also solve ordinary differential equations related to Painlev'e-III and while being highly-transcendental, nonetheless arise in several natural limits. From their Riemann-Hilbert representation we deduce some elementary properties, detailed asymptotics for large values of the independent variables, and a double-scaling limit. This is joint work with Deniz Bilman.

[05529] Universality and rogue waves in semi-classical sine-Gordon equation

Author(s) : Bingying Lu (SISSA)Peter David Miller (University of Michigan)
Abstract : We study the semiclassical sine-Gordon equation with below threshold pure impulse initial data of Klaus-Shaw type. The system exhibits both phase transition and a gradient catastrophe in finite time. Near the gradient catastrophe point, the asymptotics are universally described by the Painlevé I tritronquée solution away from the poles and the rogue wave solutions of sG near the poles; away from the gradient catastrophe, the phase transition exhibits another type of universality.

[05518] Large order breathers of the nonlinear Schodinger equation

Format : Talk at Waseda University
Author(s) : Xiaoen Zhang (Shandong University of Science and Technology)
Abstract : Multi-soliton and high-order soliton solutions are famous in the integrable focusing nonlinear Schrodinger equation. The dynamics of multi-solitons have been well known to us since the 70s of the last century by the determinant analysis. However, there is little progress in the study of high-order solitons. In this work, we would like to analyze the large-order asymptotics for the high-order breathers, which are special cases of double high-order solitons with the same velocity. To analyze the large order dynamics, we first convert the representation of Darboux transformation into a framework of the Riemann-Hilbert problem. Then we show that there exist five distinct asymptotic regions by the Deift-Zhou nonlinear steepest descent method. More importantly, we first find a novel genus-three asymptotic region, which uncovers that the maximal genus is connected with the number of spectral parameters. All results of the asymptotic analysis are verified by the numerical method.

00086 (3/3) : 5D @G701 [Chair: Y. Ohta]

[04536] On stability of KdV solitons

Format : Talk at Waseda University
Author(s) : Derchyi Wu (Institute of Mathematics, Academia Sinica,)
Abstract : Applying the inverse scattering theory, we present an orbital stability theorem of KdV n-solitons with explicit phase shifts.

[05530] Rogue waves in the massive Thirring model

Format : Online Talk on Zoom
Author(s) : Junchao Chen (Lishui University)
Abstract : In this talk, I will talk about general rogue wave solutions in the massive Thirring (MT) model. These rational solutions are derived by using the KP hierarchy reduction method and presented explicitly in terms of determinants whose matrix elements are elementary Schur polynomials. In the reduction process, three reduction conditions including one index- and two dimension-ones are proved to be consistent by only one constraint relation on parameters of tau-functions of the KP-Toda hierarchy. It is found that the rogue wave solutions in the MT model depend on two background parameters, which influence their orientation and duration. Differing from many other coupled integrable systems, the MT model only admits the rogue waves of bright-type, and the higher-order rogue waves represent the superposition of fundamental ones in which the non-reducible parameters determine the arrangement patterns of

fundamental rogue waves. Particularly, the super rogue wave at each order can be achieved simply by setting all internal parameters to be zero, resulting in the amplitude of the sole huge peak of order N being 2N + 1 times the background. Finally, rogue wave patterns are discussed when one of the internal parameters is large. Similar to other integrable equations, the patterns are shown to be associated with the root structures of the Yablonskii-Vorob'ev polynomial hierarchy through a linear transformation. This work is joint with Bo Yang and Bao-Feng Feng.

[03606] Resonant breather and rogue wave solutions to a coupled Sasa-Satsuma equation

Format : Talk at Waseda University
Author(s) : Baofeng Feng (University of Texas Rio Grande Valley)Chengfa Wu (Shenzhen University)
Abstract : We firstly derive a set of 7 bilinear equations for a coupled Sasa-Sastsuma (CSSI) equation under nonzero boundary conditions and show that they can be reduced from the discrete and continuous KP-Toda hierarchy through a series of reductions such as the CKP-, dimension- and complex conjugate reductions. Then, we derive breather and rogue wave solutions in determinant form. In the last, we show the dynamical behavior of these solutions especially resonant breather solutions.

[03607] Resonant breather and rogue wave solutions to a coupled Sasa-Satsuma equation

Author(s) : Baofeng Feng (University of Texas Rio Grande Valley)Chengfa Wu (Shenzhen University)

Then, we derive breather and rogue wave solutions in determinant form. In the last, we show the dynamical behavior of these solutions especially resonant breather solutions.

[00087] Intersection of Machine Learning, Dynamical Systems and Control

Session Time & Room :

00087 (1/2) : 2C (Aug.22, 13:20-15:00) @A615

00087 (2/2) : 2D (Aug.22, 15:30-17:10) @A615

Type : Proposal of Minisymposium
Abstract : In recent years, the intersection of machine learning, dynamical systems and control has created some new excitement in different disciplines. On the one hand, machine learning-based algorithms have opened up new opportunities in studying dynamical systems and control problems, particularly in high dimensions. On the other hand, the controlled dynamical system perspective of deep learning has also brought new insight in machine learning. This minisymposium will bring together experts in different areas to explore these new exciting opportunities. The goal is to stimulate researchers from different communities to think rigorously across disciplines and move toward new questions.
Organizer(s) : Jiequn Han, Qianxiao Li, Xiang Zhou
Classification : 65Lxx, 65Mxx, 49Mxx, 68T07, Machine Learning, Dynamical Systems, Control Theory
Minisymposium Program :

00087 (1/2) : 2C @A615 [Chair: Jiequn Han]

[02826] Solving Parametric PDEs by Deep Learning

Format : Talk at Waseda University
Author(s) : Bin Dong (Peking University)
Abstract : Deep learning continues to dominate machine learning and has been successful in computer vision, natural language processing, etc. Its impact has now expanded to many research areas in science and engineering. In this talk, I will present a series of our recent works on combining wisdom from traditional numerical PDE methods and machine learning to design data-driven solvers for parametric PDEs and their applications in fluid simulations. This is joint work with Professor Jinchao Xu, my previous Ph.D. student Yuyan Chen, and my colleagues from Huawei MindSpore AI + Scientific Computing team and the Shanghai Aircraft Design and Research Institute of The Commercial Aircraft Corporation of China.

[02805] Training Deep ResNet with Batch Normalization as a First-order Mean Field Type Problem

Format : Talk at Waseda University
Author(s) : Phillip Sheung Chi Yam (Department of Statistics, Chinese University of Hong Kong)
Abstract : In this talk, we shall discuss a numerical scheme for training Deep Residual Networks that incorporates the popular Batch Normalization technique into the recently proposed extended Method of Successive Approximation in the work of Li, Chen, Tai and E, The Journal of Machine Learning Research (2017), 18: 5998–6026, and its effectiveness has been demonstrated by numerical studies. The convergence of this proposed scheme depends on the first-order mean field theory, namely the resolution of the corresponding generic first-order mean field type problems inherited from the augmented Hamiltonian, and we shall introduce this brand-new fundamental theory behind.

[02933] Dynamics-Quantified Implicit Biases of Large Learning Rates

Format : Talk at Waseda University
Author(s) : Molei Tao (Georgia Inisitute of Technology)
Abstract : This talk will describe some nontrivial (and pleasant) effects of large learning rates, which are often used in machine learning practice but defy traditional optimization theory. I will first show how large learning rates can lead to quantitative escapes from local minima, via chaos, which is an alternative mechanism to commonly known noisy escapes due to stochastic gradients. I will then report how large learning rates provably bias toward flatter minimizers, which arguably generalize better.

[04799] An optimal control perspective on diffusion-based generative modeling leading to robust numerical methods

Format : Talk at Waseda University
Author(s) : Lorenz Richter (Zuse Institute Berlin, dida)
Abstract : This talk establishes a connection between generative modeling based on SDEs and three classical fields of mathematics, namely stochastic optimal control, PDEs and path space measures. Those perspectives will be both of theoretical and practical value, for instance allowing to transfer methods from one to the respective other field or leading to novel algorithms for sampling from unnormalized densities. Further, the connection to HJB equations leads to novel loss functions which exhibit favorable statistical properties and result in improved convergence of respective algorithms.

00087 (2/2) : 2D @A615 [Chair: Qianxiao Li]

[04826] Learning high-dimensional feedback laws for collective dynamics control

Format : Talk at Waseda University
Author(s) : Dante Kalise (Imperial College London)Giacomo Albi (University of Verona)Sara Bicego (Imperial College London)
Abstract : We discuss the control of collective dynamics for an ensemble of high-dimensional particles. The collective behaviour of the system is modelled using a kinetic approach, reducing the problem to efficiently sampling binary interactions between controlled agents. However, as individual agents are high-dimensional themselves, the controlled binary interactions correspond to large-scale dynamic programming problems, for which we propose a supervised learning approach based on discrete-time State-dependent Riccati Equations and recurrent neural networks.

[05378] Sparse Kernel Flows for Learning 132 Chaotic Dynamical Systems from Data

Format : Talk at Waseda University
Author(s) : Boumediene Hamzi (Caltech)Lu Yang (Nanjing University of Aeronautics and Astronautics)Xiuwen Sun (Nanjing University of Aeronautics and Astronautics)Houman Owhadi (California Institute of Technology)Naiming Xie (NUAA)
Abstract : Regressing the vector field of a dynamical system from a finite number of observed
states is a natural way to learn surrogate models for such systems. As shown in previous work, a simple and interpretable way to learn a dynamical system from data is to
interpolate its vector-field with a data-adapted kernel which can be learned by using Kernel
Flows.
The method of Kernel Flows is a trainable machine learning method that learns the optimal
parameters of a kernel based on the premise that a kernel is good if there is no significant loss
in accuracy if half of the data is used. The objective function could be a short-term prediction
or some other objective. However, this

method is limited by the choice of the base kernel.
In this paper, we introduce the method of Sparse Kernel Flows in order to learn the "best" kernel by starting from a large dictionary of kernels. It is based on sparsifying a kernel that is a linear combination of elemental kernels. We apply this approach to a library of 132 chaotic systems. Presentation based on https://arxiv.org/pdf/2301.10321.pdf

[05395] Distributed Control of Partial Differential Equations Using Convolutional Reinforcement Learning

Format : Talk at Waseda University
Author(s) : Sebastian Peitz (Universität Paderborn)Jan Stenner (Universität Paderborn)Vikas Chidananda (Universität Paderborn)Steven Brunton (UW)Kunihiko Taira (UCLA)
Abstract : We present a convolutional framework which significantly reduces the complexity and thus, the computational effort for distributed reinforcement learning control of partial differential equations (PDEs). Exploiting translational invariances, the high-dimensional distributed control problem can be transformed into a multi-agent control problem with many identical agents. Furthermore, using the fact that information is transported with finite velocity in many cases, the dimension of the agents' environment can be drastically reduced using a convolution operation over the state space of the PDE. In this setting, the complexity can be flexibly adjusted via the kernel width or using a stride greater than one. A central question in this framework is the definition of the reward function, which may consist of both local and global contributions. We demonstrate the performance of the proposed framework using several standard PDE examples with increasing complexity, where stabilization is achieved by training a low-dimensional DDPG agent with small training effort.

[00088] Machine learning in infinite dimensions

Session Time & Room :

00088 (1/3) : 4C (Aug.24, 13:20-15:00) @F311

00088 (2/3) : 4D (Aug.24, 15:30-17:10) @F311

00088 (3/3) : 4E (Aug.24, 17:40-19:20) @F311

Type : Proposal of Minisymposium
Abstract : Lifting high-dimensional problems to an infinite-dimensional space and designing algorithms in that setting has been a fruitful idea in many areas of applied mathematics, including inverse problems, optimisation, and partial differential equations. This approach is sometimes referred to as "optimise-then-discretise" and allows one to develop algorithms that are inherently dimension- and discretisation-independent and typically perform better in high-dimensional problems. In the context of machine learning, this approach has gained significant attention in the context of operator learning. This workshop explores approaches that involve the approximation of functions with values in an infinite-dimensional space and their connections to partial differential equations.

[02760] Approximation by structured deep neural networks

Format : Talk at Waseda University
Author(s) : Dingxuan Zhou (University of Sydney)
Abstract : Deep learning based on deep neural networks possessing network architectures has been powerful in practical applications but is less understood theoretically. Structured neural networks are particularly difficult to analyze. An important family of structured neural networks is deep convolutional neural networks possessing convolutional structures. The convolutional architecture is key for the computational efficiency but raises scientific challenges. We describe a mathematical theory of approximating and learning functions or operators by structured deep neural networks.

[03794] Learning High-Dimensional Banach-Valued Functions from Limited Data with Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Nick Dexter (Florida State University)Ben Adcock (Simon Fraser University)Sebastian Moraga (Simon Fraser University)Simone Brugiapaglia (Concordia University)
Abstract : Reconstructing high-dimensional functions from few samples is important for uncertainty quantification in computational science. Deep learning has achieved impressive results in parameterized PDE problems with solutions in Hilbert or Banach spaces. This work proposes a novel algorithmic approach using DL, compressed sensing, orthogonal polynomials, and finite elements to approximate smooth functions in infinite-dimensional Banach spaces. Theoretical analysis provides explicit guarantees on error and sample complexity, and numerical experiments demonstrate accurate approximations on challenging benchmark problems.

[04519] Kernel methods for learning operators between infinite dimensional Banach spaces

Format : Talk at Waseda University
Author(s) : Pau Batlle (California Institute of Technology)Matthieu Darcy (California Institute of Technology)Houman Owhadi (California Institute of Technology)Bamdad Hosseini (University of Washington)
Abstract : We introduce a kernel-based framework for learning operators between Banach spaces. We show that even with simple kernels, our approach is competitive in terms of cost-accuracy trade-off and either matches or beats the performance of NN methods on a majority of PDE-based benchmarks. Additionally, our framework offers several advantages inherited from kernel methods: simplicity, interpretability, convergence guarantees, a priori error estimates, and Bayesian UQ. It is therefore a natural benchmark for operator learning problems.

[03223] A duality framework for generalization analysis of random feature models and two-layer neural networks

Format : Talk at Waseda University
Author(s) : Hongrui Chen (Peking University)Jihao Long (Princeton University)Lei Wu (Peking University)
Abstract : We consider the problem of learning functions in the $\mathcal{F}_{p,\pi}$ and Barron spaces, which are natural function spaces that arise in the high-dimensional analysis of random feature models (RFMs) and two-layer neural networks. Through a duality analysis, we reveal that the approximation and estimation of these spaces can be considered equivalent in a certain sense. This enables us to focus on the easier problem of approximation and estimation when studying the generalization of both models. The dual equivalence is established by defining an information-based complexity that can effectively control estimation errors. Additionally, we demonstrate the flexibility of our duality framework through comprehensive analyses of two concrete applications.

The first application is to study learning functions in $\mathcal{F}_{p,\pi}$ with RFMs. We prove that the learning does not suffer from the curse of dimensionality as long as $p > 1$, implying RFMs can work beyond the kernel regime. Our analysis extends existing results (Celentano et al., 2021) to the noisy case and removes the requirement of overparameterization.

The second application is to investigate the learnability of reproducing kernel Hilbert space (RKHS) under the {\em uniform metric}. We derive both lower and upper bounds of the minimax estimation error by using the spectrum of the associated kernel. We then apply these bounds to dot-product kernels and analyze how they scale with the input dimension. Our results suggest that learning with ReLU (random) features is generally intractable in terms of reaching high uniform accuracy.

00088 (2/3) : 4D @F311 [Chair: Bamdad Hosseini]

[03216] Reliable extrapolation of deep neural operators informed by physics or sparse observations

Author(s) : Lu Lu (University of Pennsylvania)Min Zhu (University of Pennsylvania)
Abstract : Deep neural operators can learn nonlinear mappings between infinite-dimensional function spaces via deep neural networks. As promising surrogate solvers of partial differential equations (PDEs) for real-time prediction, deep neural operators such as deep operator networks (DeepONets) provide a new simulation paradigm in science and engineering. Pure data-driven neural operators and deep learning models, in general, are usually limited to interpolation scenarios, where new predictions utilize inputs within the support of the training set. However, in the inference stage of real-world applications, the input may lie outside the support, i.e., extrapolation is required, which may result to large errors and unavoidable failure of deep learning models. Here, we address this challenge of extrapolation for deep neural operators. First, we systematically investigate the extrapolation behavior of DeepONets by quantifying the extrapolation complexity via the 2-Wasserstein distance between two function spaces and propose a new behavior of bias-variance trade-off for extrapolation with respect to model capacity. Subsequently, we develop a complete workflow, including

extrapolation determination, and we propose five reliable learning methods that guarantee a safe prediction under extrapolation by requiring additional information -- the governing PDEs of the system or sparse new observations. The proposed methods are based on either fine-tuning a pre-trained DeepONet or multifidelity learning. We demonstrate the effectiveness of the proposed framework for various types of parametric PDEs. Our systematic comparisons provide practical guidelines for selecting a proper extrapolation method depending on the available information, desired accuracy, and required inference speed.

[04824] Analysis of Neural Networks : Blessings of Width, Curses of Depth

Format : Online Talk on Zoom
Author(s) : Lénaïc Chizat (EPFL)
Abstract : I will present several results around the large-width limit of gradient-based algorithms for artificial neural networks (NNs). After a review of two-layer NNs, I will discuss the case of deep NNs where the non-linear dynamics that arises turns out much less tractable, because of how the random matrices of the initialization interact. I will finally elaborate on the case of deep linear NNs where we have obtained a complete description of the dynamics.

[02466] Mirror Descent with Relative Smoothness in Measure Spaces, with application to Sinkhorn and EM

Format : Talk at Waseda University
Author(s) : Anna Korba (ENSAE/CREST)Pierre-Cyril Aubin-Frankowski (INRIA/Ecole Normale Supérieure)Flavien Léger (INRIA)
Abstract : Many problems in machine learning can be formulated as optimizing a convex
functional over a vector space of measures. This paper studies the convergence of
the mirror descent algorithm in this infinite-dimensional setting. Defining Bregman divergences through directional derivatives, we derive the convergence of the
scheme for relatively smooth and convex pairs of functionals. Such assumptions
allow to handle non-smooth functionals such as the Kullback–Leibler (KL) divergence. Applying our result to joint distributions and KL, we show that Sinkhorn's
primal iterations for entropic optimal transport in the continuous setting correspond to a mirror descent, and we obtain a new proof of its (sub)linear convergence. We also show that Expectation Maximization (EM) can always formally
be written as a mirror descent. When optimizing only on the latent distribution
while fixing the mixtures parameters – which corresponds to the Richardson–Lucy
deconvolution scheme in signal processing – we derive sublinear rates of convergence.

[05291] Covariance-Modulated Optimal Transport Geometry

Format : Talk at Waseda University
Author(s) : Franca Hoffmann (California Institute of Technology)André Schlichting (University of Münster)Martin Burger (DESY and University of Hamburg)Daniel Matthes (Technische Universitaet Muenchen)Matthias Erbar (Universitaet Bielefeld)
Abstract : We present a variant of the dynamical optimal transport problem in which the energy to be minimised is modulated by the covariance matrix of the current distribution. Such transport metrics arise naturally in mean-field limits of certain ensemble Kalman methods for solving inverse problems. We show that the transport problem splits into two coupled minimization problems up to degrees of freedom given by rotations: one for the evolution of mean and covariance of the interpolating curve, and one for its shape. Similarly, on the level of the gradient flows a similar splitting into the evolution of moments and shapes of the distribution can be observed. Those show better convergence properties in comparison to the classical Wasserstein metric in terms of exponential convergence rates independent of the Gaussian target.

00088 (3/3) : 4E @F311 [Chair: Bamdad Hosseini]

[04018] Learning PDE operators with neural networks

Format : Talk at Waseda University
Author(s) : Elizabeth Qian (Georgia Institute of Technology)
Abstract : The term 'surrogate modeling' in computational science and engineering refers to the development of computationally efficient approximations for expensive simulations such as those arising from numerical solution of partial differential equations (PDEs). Surrogate modeling is an enabling methodology for many-query computations in science and engineering which include iterative methods in optimization and sampling methods in uncertainty quantification. Over the last few years several approaches to surrogate modeling for PDEs using neural networks have emerged motivated by successes in using neural networks to approximate nonlinear maps in other areas. In principle the relative merits of these different approaches can be evaluated by understanding for each one the cost required to achieve a given level of accuracy. However the absence of a complete theory of approximation error for these approaches makes

it difficult to assess this cost-accuracy trade-off. In this talk we provide a careful numerical study of this issue comparing a variety of different neural network architectures for operator approximation across a range of problems arising from PDE models in continuum mechanics.

[04864] Learning solution operators for PDEs with uncertainty

Format : Talk at Waseda University
Author(s) : Emilia Magnani (University of Tübingen)Nicholas Krämer (University of Tübingen)Runa Eschenhagen (University of Cambridge)Philipp Hennig (University of Tübingen)Lorenzo Rosasco (University of Genova & MIT)
Abstract : We provide a Bayesian formulation of the problem of learning solution operators of PDEs in the formalism of Gaussian processes. We extend this treatment to recent deep architectures (neural operators) that have shown promising results to tackle this task. We provide them with uncertainty estimates through methods from Bayesian deep learning. Finally, we consider particular types of operators (convolutions) and investigate the process of learning these in the context of functional regression in inverse problems.

[04774] Unsupervised Learning of the Total Variation Flow

Format : Talk at Waseda University
Author(s) : Tamara G Grossmann (University of Cambridge)Sören Dittmer (University of Cambridge)Yury Korolev (University of Bath)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : The total variation (TV) flow generates a scale-space representation of an image based on the TV functional. This gradientflow observes desirable features for images and enables texture analysis. The standard numerical approach requires solving multiple non-smooth optimisation problems, this is often prohibitively expensive. We propose the TVflowNET, a neural network approach to compute the solution. We significantly speed up the computation time and show that the TVflowNET approximates the TV flow solution with high fidelity.

[03051] On solving/learning nonlinear PDEs with GPs

Format : Talk at Waseda University
Author(s) : Houman Owhadi (California Institute of Technology)
Abstract : We present a simple, rigorous, and unified framework for solving and learning arbitrary nonlinear PDEs with GPs. The proposed approach inherits the error bounds of kernel interpolation methods and the near-linear complexity of linear solvers for dense kernel matrices. Its generalization to high-dimensional PDEs comes with error bounds exhibiting a tradeoff between dimensionality and regularity. Parts of this talk are joint work with Pau Batlle Franch, Yifan Chen, Bamdad Hosseini, Florian Schäfer, and Andrew Stuart.

[00090] Recent advances in the theory of rogue waves: one- and multi-component models in 1+1 and 2+1 dimensions

Session Time & Room :

00090 (1/3) : 1C (Aug.21, 13:20-15:00) @G801

00090 (2/3) : 1D (Aug.21, 15:30-17:10) @G801

00090 (3/3) : 1E (Aug.21, 17:40-19:20) @G801

Type : Proposal of Minisymposium
Abstract : Recent advances in the theory of nonlinear waves have allowed a better understanding of the underlying mechanisms leading to the formation of space-time localised extreme waves, often referred in the literature as rogue waves, in systems modelled by nonlinear PDEs of integrable and non-integrable type. Many theoretical questions remain open as for a qualitative and quantitative description of the evolution of a localised or periodic perturbation on a given background. The aim of this minisymposium is to gather world-leading experts in the field to discuss the most recent results about the onset and recurrence of rogue waves in nonlinear media.
Organizer(s) : Prof Sara Lombardo (Heriot-Watt University, UK), Dr Matteo Sommacal (Northumbria University, UK)
Classification : 35Qxx, 35C08, 37K10, 76B15, 76E30, Nonlinear waves, Rational solutions, Rogue waves, Integrability, Stability
Minisymposium Program :

00090 (1/3) : 1C @G801 [Chair: Matteo Sommacal]

[03779] Maximal Amplitudes of N-Phase Solutions of a Modified NLS Equation

Format : Online Talk on Zoom
Author(s) : Otis Wright (Cedarville University)
Abstract : An effective method for finding the maximal amplitudes of N-phase solutions of a modified nonlinear Schrödinger equation is discussed.

[05214] The effects of damping on rogue wave formation and permanent downshifting

Format : Online Talk on Zoom
Author(s) : Cosntance Schober (University of Central Florida)Annalisa Maria Calini (College of Charleston)
Abstract : The effects of damping on the B-F instability, rogue wave formation, and permanent downshifting are discussed
in the framework of the viscous damped
higher order nonlinear Schrodinger (v-HONLS) equation. The linear stability analysis of the damped Stokes wave solution is presented.
Numerical simulations of the v-HONLS with unstable Stokes wave initial data indicate the
inclusion of viscosity enables permanent downshifting and rogue waves typically
do not develop after the time of permanent downshift.

[04450] Rogue-wave formation scenarios for focusing NLS with parabolic initial data

Format : Talk at Waseda University
Author(s) : Francesco Demontis (University of Cagliari)Giovanni Ortenzi (University of Torino)Giacomo Roberti (Northumbria University)Matteo Sommacal (Northumbria University)
Abstract : We study focussing NLS for compactly-supported parabolic initial data with constant chirp. In the absence of dispersion, we provide a criterion for blow-up, generalising a result by Talanov et al. In the presence of dispersion, the same criterion determines, even beyond the semi-classical regime, the formation of rogue-waves, whose onset time is predicted by the corresponding dispersionless catastrophe time. Numerics suggest that the chirp controls the prevailing scenario among two competing mechanisms for rogue-wave formation.

[04494] Stability of plane waves for the Yajima-Oikawa-Newell equation

Format : Talk at Waseda University
Author(s) : Marcos Caso-Huerta (Northumbria University)
Abstract : A new, integrable long wave-short wave model is proposed, encompassing Yajima-Oikawa and Newell systems as particular choices of the coefficients. The stability of its plane waves is studied in an algebraic-geometric approach making use of its Lax pair. The stability spectra are explicitly computed, leading to identifying a relation between the topology of the spectra and the gain of the system. This allows one to predict regions of existence for rogue wave type solutions.

00090 (2/3) : 1D @G801 [Chair: Sara Lombardo]

[04830] Rogue waves in 1+1 and in 2+1 dimensions

Format : Online Talk on Zoom
Author(s) : Paolo Maria Santini (Dept. of Physics, University "La Sapienza")Petr Grinevich (Steklov Math. Institute, Moscow)Francesco Coppini (Dept. of Physics, University "La Sapienza")
Abstract : We summarize recent results on the theory of rogue waves. 1) Relevant exact rogue wave (RW) solutions of integrable continuous, discrete, and relativistic NLS type field theories in 1+1 and/or 2+1 dimensions. 2) Analytic description of the recurrence of RWs. 3) Stability properties of exact RW solutions. 4) The effect of perturbations of the model on the RW dynamics.

[04499] Finite-gap approach to the Davey-Stewardson-2 rogue waves

Format : Online Talk on Zoom
Author(s) : Petr G. Grinevich (Steklov Mathematical Institute, RAS)Paolo Maria Santini (University Roma-1 "La Sapienza", INFT)
Abstract : In a recent series of paper we showed that for the 1+1 dimensional soliton systems the finite-gap formulas for solutions describing the generation of rogue waves can be essentially simplified in the leading order. The origin of this

simplification is that the Cauchy problem for rogue waves naturally contains a small parameter therefore the spectral curve is a small perturbation of a rational one.
We show that this approach can be naturally extended to the focusing Davey-Stewardson 2 equation, which is 2+1 integrable model admitting rogue waves type solutions. Again, in the leading order we obtain elementary formulas for the rogue waves Cauchy problem.

[04876] Non-commutative soliton equations: some solutions of matrix mKdV equation

Format : Online Talk on Zoom
Author(s) : Sandra Carillo (Dip SBAI, SAPIENZA UNIV. & INFN, Sez. IV, MMNLP)Cornelia Schiebold (Sundswall University)
Abstract : Solutions of matrix mKdV equation are presented. They can be termed soliton solutions since they exhibit the typical behaviour of solitons. The asymptotics of 2-soliton solutions of the d x d-matrix modified Korteweg de-Vries equation is given under the assumption that the involved spectral matrices are invertible. This work is motivated by explicit solutions by the authors, and bases on an explicit solution formula for the N-soliton solutions previously obtained.

[05198] Spectral approaches to wave instability

Format : Talk at Waseda University
Author(s) : Sara Lombardo (Heriot-Watt University)
Abstract : Recent spectral techniques to study the stability of nonlinear waves will be reviewed in connection with more established results, with a particular focus on the case of nonlinear evolution equations of integrable type.

00090 (3/3) : 1E @G801

[00107] Randomized numerical linear algebra

Session Time & Room :

00107 (1/3) : 4C (Aug.24, 13:20-15:00) @E603

00107 (2/3) : 4D (Aug.24, 15:30-17:10) @E603

00107 (3/3) : 4E (Aug.24, 17:40-19:20) @E603

Type : Proposal of Minisymposium
Abstract : Randomized numerical linear algebra (RNLA) is an emerging field of computational mathematics that has enabled matrix computations of unprecedented scale. Given the increasing size of data sets, RNLA is often the only way to reasonably perform computations. In addition to speed, RNLA provides solutions with exceptional accuracy and robustness. Success stories in RNLA include low-rank approximation, least-squares problems, and trace estimation. In addition, the field has witnessed recent progress in linear systems, eigenvalue problems, and tensor approximation. This minisymposium aims to bring together researchers working in RNLA to present recent progress, discuss challenges, and share ideas.
Organizer(s) : Ethan Epperly, Per-Gunnar Martinsson, Yuji Nakatsukasa, Robert WebberSponsor : This session is sponsored by the SIAM Activity Group on Computational Science and Engineering.

[03344] Randomized low-rank approximation: Where we've been and where we're going

Format : Talk at Waseda University
Author(s) : Robert Webber (California Institute of Technology)
Abstract : I will survey randomized algorithms for low-rank matrix approximation. These algorithms are helpful for speeding up computations involving high-dimensional matrices. When the singular values of the target matrix decay quickly, the most efficient low-rank approximation algorithms are "randomized SVD" and, if the matrix is positive semidefinite, "randomized Nyström". When the singular values of the target matrix decay slowly, low-rank approximation becomes more difficult and the best-performing algorithms are instead randomized block Krylov methods.

[04049] Efficient Bounds for Canonical Angles in Randomized Subspace Approximations

Format : Online Talk on Zoom
Author(s) : Yijun Dong (UT Austin)Per-Gunnar Martinsson (UT Austin)Yuji Nakatsukasa (University of Oxford)
Abstract : Randomized subspace approximation is an effective approach for approximating partial SVDs of large matrices, whose accuracy has been extensively analyzed in terms of residual errors. However, our understanding of the computed singular subspaces remains limited. We present bounds and estimates for canonical angles of randomized subspace approximation that can be computed efficiently either a priori or a posteriori. Numerical experiments demonstrate the empirical effectiveness of these canonical angle approximations under various algorithmic choices.

[03767] Randomized Nyström approximation for symmetric indefinite matrices

Format : Talk at Waseda University
Author(s) : Taejun Park (University of Oxford)Yuji Nakatsukasa (University of Oxford)
Abstract : In this talk, we present a variant of the Nyström method for symmetric indefinite matrices. The Nyström method is a popular choice for symmetric positive semi-definite matrices. However, the method can fail when the matrix is indefinite, for which the error can be large. We first identify the main challenges in finding a robust Nyström approximation to symmetric indefinite matrices and describe an algorithm, whose robustness for symmetric indefinite matrices is illustrated with experiments.

[04567] The Cluster and the Gap in Randomized Subspace Iteration

Format : Talk at Waseda University
Author(s) : Eric Hallman (Google)
Abstract : This talk concerns the convergence rates of the singular values and vectors when running randomized subspace iteration. Its aim is to present a single clean approach (based on the techniques of (Yuan/Gu/Li, 2018)) that can be used to derive a variety of existing bounds in the literature, both gap-dependent and gap-independent. Limitations of the proof strategy are discussed, as well as its extensions to randomized block Lanczos.

00107 (2/3) : 4D @E603 [Chair: Per-Gunnar Martinsson]

[04958] RandNLA for Faster Convex Optimization

Format : Talk at Waseda University
Author(s) : Zachary Frangella (Stanford University)
Abstract : In this talk, we show how to accelerate linear system solves and convex optimization, by exploiting low rank structure. Employing randomized low rank approximation, we design a new randomized preconditioner for the conjugate gradient method, and a method called NysADMM, for composite convex optimization. These methods come with strong theoretical and numerical support. Indeed, a simple implementation of NysADMM solves important problems like lasso, logistic regression, and support vector machines 2--42x faster than standard solvers.

[03373] Sketched Gaussian Model Linear Discriminant Analysis via the Randomized Kaczmarz Method

Format : Talk at Waseda University
Author(s) : Jocelyn T. Chi (Rice University)Deanna Needell (University of California at Los Angeles)
Abstract : We present an iterative randomized approach to Gaussian model linear discriminant analysis (LDA) for large data. Harnessing a least squares formulation, we mobilize the stochastic gradient descent framework and obtain a sketched classifier that is very comparable to full data LDA. Our convergence guarantees for the sketched predictions on new data account for both modeling and algorithmic randomness. Our experiments demonstrate that sketched LDA can offer a very viable alternative for very large data.

[03665] Moment Estimation of Nonparametric Mixtures Through Implicit Tensor Decomposition

Format : Talk at Waseda University
Author(s) : Joe Kileel (UT Austin)Yifan Zhang (UT Austin)
Abstract : I will present methods to estimate conditionally-independent multivariate mixture models, without assuming parameterizations of the distributions. Following the method of moments, I will tackle an incomplete tensor decomposition problem to compute the mixing weights and componentwise means. Then I will explain how to compute

the cumulative distribution functions and other statistics through linear solves. Crucially for computations in high dimensions, methods in this talk evade steep costs associated with high-order tensors, via efficient tensor-free operations.

[04802] Are sketch-and-precondition least squares solvers numerically stable?

Format : Talk at Waseda University
Author(s) : Maike Meier (University of Oxford)Yuji Nakatsukasa (University of Oxford)Alex Townsend (Cornell University)Marcus Webb (University of Manchester)
Abstract : Sketch-and-precondition solvers, such as Blendenpik and LSRN, are popular for solving large least squares (LS) problems of the form $Ax = b$ with $A \in \mathbb{R}^{m\times n}$ and $m \gg n$. In this talk, we show that the sketch-and-precondition technique is not numerically stable for highly ill-conditioned LS problems. We propose an alternative method, which we call *sketch-and-apply*, based on directly applying the randomized preconditioner and show it is numerically stable under moderate conditions.

00107 (3/3) : 4E @E603 [Chair: Yuji Nakatsukasa]

[04913] RandBLAS and RandLAPACK - Toward Standard Libraries for RandNLA

Format : Talk at Waseda University
Author(s) : Riley John Murray (ICSI, LBNL, and UC Berkeley)James Demmel (UC Berkeley)Michael Mahoney (ICSI, LBNL, and UC Berkeley)N. Benjamin Erichson (ICSI and LBNL)Maksim Melnichenko (UT Knoxville)Osman Asif Malik (LBNL)Laura Grigori (INRIA Paris and Sorbonne University)Piotr Luszczek (UT Knoxville)Michal Derezinski (University of Michigan)Miles Lopes (UC Davis)Tianyu Liang (UC Berkeley)Hengrui Luo (LBNL)Jack Dongarra (UT Knoxville)Burlen Loring (LBNL)Parth Nobel (Stanford University)
Abstract : This talk concerns an ongoing effort to bring RandNLA further into mainstream computing. It includes highlights from our recently released monograph (arXiv:2302.11474) as well as discussion of software. The software component focuses on our C++ library for sketching called RandBLAS. We showcase RandBLAS' capabilities by using it to implement a recently developed algorithm for pivoted QR decompositions of tall matrices. Experiments show the proposed algorithm is often faster than Intel MKL's unpivoted QR.

[04810] Error Estimation in Randomized Algorithms for Rank-Revealing Factorizations

Format : Online Talk on Zoom
Author(s) : Katherine Joyce Pearce (The Oden Institute at the University of Texas at Austin)Chao Chen (The Oden Institute at the University of Texas at Austin)Yijun Dong (The Oden Institute at the University of Texas at Austin)Per-Gunnar Martinsson (The Oden Institute at the University of Texas at Austin)
Abstract : Interpolative decompositions involve “natural bases” of row and column subsets of a given matrix that approximately span its row and column spaces.
For large-scale problems, randomized sketching can serve as an initial step in skeleton selection.
In this talk, we describe an adaptive, parallelizable algorithm applying LU with partial pivoting to randomized sketches to determine a target rank for the approximation.
Our algorithm exhibits improved efficiency over adaptive randomized column-pivoted QR while maintaining comparable accuracy.

[04484] Krylov-aware stochastic trace estimation

Format : Talk at Waseda University
Author(s) : Tyler Chen (New York University)Eric Hallman (Google)
Abstract : We discuss an algorithm for estimating the trace of a matrix function $f(\mathbf{A})$ using implicit products with a symmetric matrix $\mathbf{A}$. Existing methods for implicit trace estimation of a matrix function tend to treat matrix-vector products with $f(\mathbf{A})$ as a black-box to be computed by a Krylov subspace method. Like other algorithms for implicit trace estimation, our approach is based on a combination of deflation and stochastic trace estimation. However, we take a closer look at how products with $f(\mathbf{A})$ are integrated into these approaches which enables several efficiencies not present in previously studied methods. In particular, we describe a Krylov subspace method for computing a low-rank approximation of a matrix function by a computationally efficient projection onto Krylov subspace.

[04463] How and why to "uncompute" the randomized SVD

Format : Talk at Waseda University
Author(s) : Ethan Nicholas Epperly (California Institute of Technology)
Abstract : The randomized SVD is a low-rank approximation procedure and is a foundational tool in randomized matrix computations. This talk introduces a novel "uncomputing" operation in which the randomized SVD approximation is

downdated by deleting different columns from the random test matrix. Two examples of the use of this "uncomputing" primitive are presented: estimating the trace of a matrix accessed only through matrix–vector products and estimating the error of the randomized SVD low-rank approximation.

[00108] Recent Advances on Kinetic and Related Equations

Session Time & Room :

00108 (1/3) : 1C (Aug.21, 13:20-15:00) @G702

00108 (2/3) : 1D (Aug.21, 15:30-17:10) @G702

00108 (3/3) : 1E (Aug.21, 17:40-19:20) @G702

Type : Proposal of Minisymposium
Abstract : Kinetic theory has been expanding its frontier and emerged as promising in various fields of engineering and science. At the same time, it has been a source of unsolved mathematical problems at fundamental levels, which are still actively studied. This mini-symposium aims at bringing in international experts on mathematical analysis, modeling, and computation of kinetic theory and related topics, in order to present the field's state-of-the-art results and foster future academic exchanges and collaborations among researchers from different sub-fields. We propose three sessions which include 12 speakers from different generations of the field and 2 leading experts Tai-Ping Liu and Shih-Hsien Yu as chairpersons who can enhance the communication of the groups.
Organizer(s) : Jin-Cheng Jiang, Satoshi Taguchi, Hai-Tao Wang, Seok-Bae Yun
Classification : 35Q20, 76P05, 82C40, 82D05
Minisymposium Program :

00108 (1/3) : 1C @G702 [Chair: Satoshi Taguchi]

[01451] Boundary singularity of a mono-speed Lorentz model for molecules with the infinite-range potential

Format : Talk at Waseda University
Author(s) : Shigeru Takata (Kyoto University)Masanari Hattori (Kyoto University)Hayato Iida (Kyoto University)
Abstract : Possibility of the diverging gradient of the macroscopic quantity near the boundary is investigated by a mono-speed Lorentz-gas model, with a special attention to the regularizing effect
of the grazing collision for the infinite-range potential on the velocity distribution function
(VDF) and its influence on the macroscopic quantity. By careful numerical analyses of the
steady one-dimensional boundary-value problem, it is confirmed that the grazing collision
suppresses the occurrence of a jump discontinuity of the VDF on the boundary. However,
as the price for that regularization, the collision integral becomes no longer finite in the
direction of the molecular velocity parallel to the boundary. Consequently, the gradient of
the macroscopic quantity diverges, even stronger than the case of the finite-range potential.
A conjecture about the diverging rate in approaching the boundary is made as well for a wide
range of the infinite-range potentials, accompanied by numerical evidences.

[01849] On the Existence and Regularity for the Stationary Linearized Boltzmann Equation in a Small Domain

Format : Talk at Waseda University
Author(s) : I-Kun Chen (National Taiwan University)Ping-Han Chuang (National Taiwan University)Jhe-Kuan Su (National Taiwan University)Chun-Hsiung Hsia (National Taiwan University)Daisuke Kawagoe (Kyoto University)
Abstract : We consider the incoming boundary value problem for the
stationary linearized Boltzmann equation in a bounded domain with C^2
boundary of positive Gaussian curvature. We prove the existence of
H^1 of solutions under assumptions that the boundary data is good
enough and the domain is small enough. A counter example is provided
to demonstrate the role of the geometry.

[05464] Regularity estimates for the non-cutoff soft potential Boltzmann equation with typical rough and slowly decaying data

Format : Talk at Waseda University
Author(s) : Lingbing He (Tsinghua University)Jie Ji (Peking University)
Abstract : or the non-cutoff soft potential Boltzmann equation, if the Boltzmann collision operator is strictly elliptic in the v variable, it is conjectured that the solution to the equation will become infinitely smooth instantly for both spatial and velocity variables for any positive time, even if the initial data has only polynomial decay in high velocity regimes. This conjecture is significant because it is closely connected to the regularity problem of weak solutions, especially for the smoothing property of so-called `regular point''. In this work, we show that the conjecture may not hold for the general weak solution due to the degenerate and non-local properties of the collision operator. We demonstrate this in three steps: (i) constructing so-called`typical rough and slowly decaying data''; (ii) proving that such data induces only finite smoothing effect for weak solutions in Sobolev spaces; and (iii) proving that this finite smoothing property induces local properties for any positive time, including that the Leibniz rule does not hold for high derivatives of the collision operator (even in the weak sense) and that there is a discontinuity in the x variable for the average of weak solutions on certain domains.

[00646] Vanishing angular singularity limit to the hard-sphere Boltzmann equation

Format : Talk at Waseda University
Author(s) : Jin Woo Jang (Pohang University of Science and Technology)Bernhard Kepka (University of Bonn)Alessia Nota (Università degli Studi dell'Aquila)Juan J. L. Velázquez (University of Bonn)
Abstract : In this talk we consider Boltzmann's collision kernel for inverse power law interactions $U_s(r) = 1/r^{s-1}$ for $s > 2$ in dimension $d = 3$. We introduce the proof of the limit of the non-cutoff kernel to the hard-sphere kernel and give precise asymptotic formulas of the singular layer near $\theta \simeq 0$ in the limit $s \to \infty$. Consequently, we show that solutions to the homogeneous Boltzmann equation converge to the respective solutions.

00108 (2/3) : 1D @G702 [Chair: Jin-Cheng Jiang]

[04112] On BGK-type models with velocity-dependent collision frequency

Format : Talk at Waseda University
Author(s) : Doheon Kim (Hanyang University)Seok-Bae Yun (Sungkyunkwan University)
Abstract : In the original Bhatnagar-Gross-Krook (BGK) model, the collision term in the Boltzmann equation is replaced by a simpler expression, so that the model is easier-to-handle and satisfies the conservation laws and the H-Theorem. This model contains the collision frequency as a parameter independent of the particle velocity. In this talk, I will introduce variants of the BGK model which contain velocity-dependent collision frequency, thereby mimicing the behavior of the Boltzmann equation more closely.

[02844] Green's function for solving IBVP of evolutionary PDEs

Format : Talk at Waseda University
Author(s) : Hung-Wen Kuo (National Cheng Kung University)
Abstract : We propose a new method to solve the initial-boundary value problem for hyperbolic-dissipative PDEs based on the spirit of LY algorithm. Utilizing the idea of Laplace wave train and the notions of Rayleigh surface wave operators, we are able to obtain the complete representations of the Green's functions for the convection-diffusion equation and the drifted wave equation in a half space with various boundary conditions.

[00644] H"OLDER REGULARITY OF THE BOLTZMANN EQUATION PAST AN OBSTACLE

Format : Talk at Waseda University
Author(s) : donghyun lee (POSTECH)chanwoo Kim (University of Wisconsin, madison)
Abstract : Regularity and singularity of the Boltzmann equation with various shape of domains is a challenging research theme in the Boltzmann theory. In this talk, we discuss about H"oler regularity of the Boltzmann equation outiside of convex object under specular reflection boundary condition.

[03811] Solution to the Boltzmann equation without cutoff in $(L^1 \cap L^p)_k$

Format : Talk at Waseda University
Author(s) : Shota Sakamoto (Kyushu University)Renjun Duan (Chinese University of Hong Kong)Yoshihiro Ueda (Kobe University)
Abstract : We consider a Cauchy problem of the Boltzmann equation without angular cutoff near the global Maxwellian on the whole space. In this case, the control of the L^1 norm on the Fourier side is not sufficient for global existence due to low-frequency terms. Therefore, we employ the L^p norm estimates with respect to the frequency to control such parts. This $L^1 \cap L^p$ strategy will close a priori estimates when combined with a time-weighted energy method.

00108 (3/3) : 1E @G702 [Chair: Seok-Bae Yun]

[01835] Mixture estimate in fractional sense

Format : Talk at Waseda University
Author(s) : Kung-Chien Wu (National Cheng Kung University)
Abstract : In this talk, we consider the Boltzmann equation with angular-cutoff for very soft potential case. We prove a regularization mechanism that transfers the microscopic velocity regularity to macroscopic space regularity in the fractional sense. A precise pointwise estimate of the fractional derivative of collision kernel, and a connection between velocity derivative and space derivative in the fractional sense are exploited to overcome the high singularity for very soft potential case.

[03301] Dynamical behaviors in stochastic kinetic flocking models

Format : Talk at Waseda University
Author(s) : Xiongtao Zhang (Wuhan University)
Abstract : We will introduce some recent works on the stochastic flocking models. We are interested in the case when the noise is multiplicative and the flocking interaction vanishes at the far field. We will show rigorous proof of mean-field limit (weak or strong) and the emergence of flocking (conditional or unconditional) under various assumptions.

[04712] Kinetic study of a gas undergoing resonant collisions

Format : Online Talk on Zoom
Author(s) : Francesco Salvarani (DVRC &University of Pavia)Laurent Boudin (Sorbonne Université)Thomas Borsoni (Sorbonne Université)Julien Mathiaud (CEA & Université de Bordeaux)Alex Rossi (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : We study a kinetic model for a gas undergoing résonant collision. After proving the main properties of the model, we study the compactness of the corresponding linearized Boltzmann operator.

[00110] Computation on Supersingular and Superspecial Curves and its Applications

Session Time & Room : 5D (Aug.25, 15:30-17:10) @G302

Type : Proposal of Minisymposium
Abstract : Supersingular and superspecial algebraic curves have been studied in coding theory and cryptography for the last few decades. The applications are based on explicit constructions and computational aspects of such algebraic curves, which give novel and fascinating mathematical challenges. Interestingly, we have different kinds of problems depending on the genus of curves. The supersingular genus 1 curves, i.e., elliptic curves, are a central ingredient in quantum-resistant isogeny-based cryptography. A series of recent research shows that the security of the cryptosystems is closely related to arithmetic on superspecial curves of higher genera, whose study is the main topic in this minisymposium.
Organizer(s) : Katsuyuki Takashima
Classification : 14G50, 14H40, 14H45, 14K02, 14Q05
Minisymposium Program :

00110 (1/1) : 5D @G302 [Chair: Masaya Yasuda]

[04024] Decomposed Richelot isogenies of Jacobian varieties of hyperelliptic curves and generalized Howe curves

Format : Talk at Waseda University
Author(s) : Toshiyuki Katsura (University of Tokyo)Katsuyuki Takashima (Waseda University)
Abstract : We advance previous studies on decomposed Richelot isogenies (Katsura–Takashima (ANTS 2020) and Katsura (J. Algebra)) which are useful for analysing superspecial Richelot isogeny graphs in cryptography. We first give a characterization of decomposed Richelot isogenies between Jacobian varieties of hyperelliptic curves of any genus. We then define generalized Howe curves, and present two theorems on their relationships with decomposed Richelot isogenies. We also give new examples including a non-hyperelliptic (resp. hyperelliptic) generalized Howe curve of genus 5 (resp. of genus 4).

[04668] Some explicit arithmetics on curves of genus three and their applications

Format : Online Talk on Zoom
Author(s) : Tomoki Moriya (University of Birmingham)Momonari Kudo (Fukuoka Institute of Technology)
Abstract : A Richelot isogeny between Jacobian varieties is an isogeny whose kernel is included in the 2-torsion subgroup of the domain. In particular, a Richelot isogeny whose codomain is the product of two or more principally polarized abelian varieties is called a decomposed Richelot isogeny. In this talk, I provide some explicit arithmetics on curves of genus 3, including algorithms to compute the codomain of a decomposed Richelot isogeny. I also provide explicit formulae of defining equations for Howe curves of genus 3 as solutions to computing the domain of a decomposed Richelot isogeny. Finally, I give a construction of an algorithm with complexity O~(p^3) (resp. O~(p^4)) to enumerate all hyperelliptic (resp. non-hyperelliptic) superspecial Howe curves of genus 3.

[05345] Construction of superspecial curves of higher genera with extra automorphoisms

Format : Talk at Waseda University
Author(s) : Momonari Kudo (Fukuoka Institute of Technology)
Abstract : Superspecial curves are one of the most important objects in algebraic geometry over fields of positive characteristic, with applications to coding theory and cryptography, but explicit constructions and enumerations of such curves of higher genera are known to be quite difficult in general. In this talk, we develop several algorithms to construct superspecial curves of higher genera, restricting ourselves to the case of curves with non-trivial automorphisms, e.g., genus-4 hyperelliptic curves with order-6 automorphisms.

[04048] Several examples of curves whose superspeciality imply maximality or minimality

Format : Talk at Waseda University
Author(s) : Ryo Ohashi (University of Tokyo)Shushi Harashita (Yokohama National University)
Abstract : A curve over the finite field $\mathbb{F}_q$ of characteristic $p > 0$ is called maximal (resp. minimal) if the number of its $\mathbb{F}_q$-rational points attains the Hasse-Weil upper (resp. lower) bound. Maximal curves have been investigated for their applications to cryptography and coding theory. It is known that maximal or minimal curves over $\mathbb{F}_{p^2}$ are all superspecial, while superspecial curves over $\mathbb{F}_{p^2}$ are not necessary maximal nor minimal. However in this lecture, we will present several examples of curves C which have the following property: If C is superspecial, then C is maximal or minimal over $\mathbb{F}_{p^2}$.

[00114] Computational Biology

Session Time & Room :

00114 (1/3) : 3E (Aug.23, 17:40-19:20) @A508

00114 (2/3) : 4C (Aug.24, 13:20-15:00) @A508

00114 (3/3) : 4D (Aug.24, 15:30-17:10) @A508

Type : Proposal of Minisymposium

Abstract : Besides the traditional (experimental) and theoretical biology, computational biology is the third biology. Its mission is to visualize the activities of living things on the screen to understand their backgrounds theoretically and to predict future status for applications. For this purpose, experimental, data, and simulation sciences are applied, but mathematical formulae are obviously necessary. Computational biology is now widely spreading as a new challenge of industrial and applied mathematics. This minisymposium focuses on recent developments in computational biology.

Organizer(s) : Takashi Suzuki

00114 (1/3) : 3E @A508 [Chair: Takashi Suzuki]

[05357] Different mathematical models for membrane electroporation: from equivalent circuit to phase-field models

Format : Talk at Waseda University

Author(s) : Clair Poignard (INRIA Center of Bordeaux Univ.)

Abstract : Electroporation is a complex phenomenon consisting of defects creation in membranes subjected to high short electric pulses. The aim of the talk is to present the mathematical challenges in terms of PDEs and numerical analysis of the phenomenon. A comparison from the 90's biophysical models based on Deryagin theory to very recent phase-field model are performed. For each approach, advantages and disadvantages are discussed, in terms of physical meaning and validation with the experimental data.

[02031] Modeling and characterizing vaccine-elicited antibody responses

Format : Talk at Waseda University

Author(s) : Shingo Iwami (Nagoya University)

Abstract : Recent studies have provided insights into the effect of vaccine boosters on recall immunity. Given a limited global supply of the vaccinations, identifying vulnerable populations with lower sustained vaccine-elicited antibody titers is important to decide target individuals for the booster. Here we investigated longitudinal data among the cohort of the same individuals of 2,526 people in Fukushima, Japan. Antibody titers following a two-dose SARS-CoV-2 vaccination were repeatedly monitored along with the information on lifestyle habits, comorbidities, adverse reactions, and medication. By employing mathematical modeling and machine learning, we characterized the elicited immune response following a two-dose SARS-CoV-2 vaccination.

[03370] Mathematical analysis of bone metabolism markers in immobilization mice

Format : Talk at Waseda University

Author(s) : Marwa Akao (Nagoya University)

Abstract : Osteoporosis is a disease that affects more than 200 million people around the world. Although the mechanisms are gradually being revealed, osteoporosis cannot really be cured completely. This study aims to develop the most effective prevention for osteoporosis. We developed mathematical models describing interactions with cells related to bone metabolism and changes in bone mass. And we analyzed the data of bone metabolism markers and compared the difference between immobilization mice and normally fed mice.

[02284] Predicting clinical outcomes of acute liver failure

Format : Online Talk on Zoom

Author(s) : Raiki Yoshimura (Division of Natural Science, Graduate School of Science, Nagoya University)

Abstract : We used clinical data on acute liver failure to develop an approach for predicting its clinical outcomes. Specifically, we employed a supervised machine learning approach to analyze clinical datasets, including blood test data and medication history, at the admission to the hospital, and predicted final state, i.e., survived or died. In addition, we developed a scoring system to predict individual clinical outcomes. The findings of this study are expected to be utilized in actual clinical practice as a basis for initial response decisions and may also be applied to the detection of other signs of acute diseases.

00114 (2/3) : 4C @A508 [Chair: Isamu Doku]

[03648] Mathematical investigation into the mechanism of hair follicle morphogenesis

Format : Talk at Waseda University
Author(s) : Masaharu Nagayama (Hokkaido University)Makoto Okumura (Konan University)Yasuaki Kobayashi (Hokkaidio Universiy)Hironobu Fujiwara (Institute of Physical and Chemical Research)
Abstract : Long-term 3D live imaging of hair follicle morphogenesis during development was shown by Fujiwara et al. During hair follicle morphogenesis, basal cells, basement membrane, and mesenchyme were found to undergo dynamic changes. Fujiwara et al. proposed a telescopic model of hair follicle formation based on these results. In this study, to realize this telescope model, we will construct a mathematical model that reproduces 3D cylindrical compartments and investigate by what mechanism the cylindrical compartments are actively formed.

[03506] Parameter estimation of the compartmental model of systemic circulation describing the Glucose, Insulin and C peptide dynamics

Format : Talk at Waseda University
Author(s) : Yueyuan Gao (Hokkaido University)Hiroshi Suito (Tohoku University)Hayato Chiba (Tohoku University)Masaharu Nagayama (Hokkaido University)Hideki Katagiri (Tohoku University)
Abstract : In this talk, we explain the construction of the mathematical compartmental model of systemic circulation describing the Glucose, Insulin and C peptide dynamics and we present the application of Markov chain Monte Carlo method to estimate the parameters of the model from clinical data.

[02898] Effective nonlocal kernels on Reaction-diffusion networks

Format : Talk at Waseda University
Author(s) : Shin-Ichiro Ei (Hokkaido University)
Abstract : A new method to derive an essential integral kernel from any given reaction-diffusion network is proposed. Any network describing metabolites or signals with arbitrary many factors can be reduced to a single or a simpler system of integro-differential equations called “effective equation” in the convolution type.

00114 (3/3) : 4D @A508 [Chair: Takashi Suzuki]

[04349] Mathematical model of mTORC1 pathway sensing intracellular amino-acids and glucose

Format : Talk at Waseda University
Author(s) : Takanori Nakamura (Ehime University)Shigeyuki Nada (Osaka University)Takashi Suzuki (Osaka University)Masato Okada (Osaka University)
Abstract : mTORC1, a master regulator of metabolism, is activated upon Insulin and Amino-acids (AA) addition, but its regulatory mechanism is not fully understood. We therefore constructed an integrated mathematical model of mTORC1 regulation through the two distinct AA- and Insulin-sensing axes. Using the mathematical simulation with experimental data, we found the selective dephosphorylation during AA deprivation, which ensures full mTORC1 activation only upon the concurrently sensing of nutrient Insulin and AA.

[05379] Mathematical modeling of cancer immune escape

Format : Talk at Waseda University
Author(s) : Hiroshi Haeno (Tokyo University of Science)Koichi Saeki (Tokyo University of Science)
Abstract : A tumor evolves under the pressure of immune responses. Immune checkpoint inhibitors (ICIs) are expected to reactivate antitumor immunity and inhibit tumor progression. Here, we developed a mathematical model of the tumor evolution under immune responses. As a result, we confirmed that patients who had high mutational load were likely to have a durable benefit. Moreover, we found that the growth rate of tumor cells would be informative to identify responders to ICIs.

[02179] Computational modelling of cancer invasion using organotypic invasion assay data

Format : Talk at Waseda University
Author(s) : Mark Chaplain (University of St Andrews)Nikoloas Sfakianakis (University of St Andrews)Linnea Franssen (Roche, Basel)
Abstract : We present computational simulation results from a three-dimensional hybrid atomistic-continuum model that describes the invasive growth dynamics of individual cancer cells in tissue. The framework explicitly accounts for phenotypic variation by distinguishing between cancer cells of an epithelial-like and a mesenchymal-like phenotype. It

also describes mutations between these cell phenotypes. The full model consists of a hybrid system of partial and stochastic differential equations describing the evolution of cancer cells, extracellular matrix and matrix-degrading enzymes.

[05467] The prognostic value of immune infiltration patterns on the outcome of chemotherapy in breast cancer

Format : Online Talk on Zoom
Author(s) : Nikolaos Ioannis Kavallaris (Karlstad University)
Abstract : In this work, based on a breast cancer biopsy dataset, taken from the ADAPT clinical trial, we shed light on the changes of tumor microenvironment after cytostatic chemotherapy. We combine machine learning workflow to identify cell density patterns identifying responders and non-responders. We also develop a dynamic model that allows us to elucidate the reasons of therapy failure. Finally, using our model we can reason on therapy combinations that could improve the therapeutic outcomes.

[00118] On mathematical modeling and simulation of droplets

Session Time & Room :

00118 (1/3) : 1C (Aug.21, 13:20-15:00) @D402

00118 (2/3) : 1D (Aug.21, 15:30-17:10) @D402

00118 (3/3) : 1E (Aug.21, 17:40-19:20) @D402

Type : Proposal of Minisymposium
Abstract : The mathematical modeling and simulation of droplets is a basic and fundamental problem in the history of fluid mechanics. Droplets can undergo a variety of interesting nonlinear dynamics such as droplet coalescence/break up, electro-wetting, and traveling waves, etc, due to surface tension effects, substrate geometry and material, as well as external physical forces. This minisymposium will present recent advances in the modeling and simulation of droplets and focus on the mathematical challenges arising from different real-world applications.
Organizer(s) : Hangjie Ji, Pejman SanaeiSponsor : This session is sponsored by the SIAM Activity Group on Computational Science and Engineering.
Classification : 76D45, 35Q35, 76D08, 35G31, 65Mxx
Minisymposium Program :

00118 (1/3) : 1C @D402 [Chair: Pejman Sanaei]

[03374] Plug formation in models of falling viscous films inside tubes

Format : Online Talk on Zoom
Author(s) : H. Reed Ogrosky (Virginia Commonwealth University)
Abstract : Falling viscous liquid films coating the interior of a tube occur in a variety of applications. If the film is thick enough, it may pinch off and form a plug, occluding the tube. In this talk I will discuss recent work examining the impact of surfactant, slip, viscoelasticity, and viscosity stratification on plug formation in a model for film flow. Implications for understanding occlusion in human airways will be discussed.

[03547] Dipole-type solutions to the thin-film equation

Format : Talk at Waseda University
Author(s) : Mark Bowen (Waseda University)Thomas Witelski (Duke University)
Abstract : We investigate the dynamics of a thin liquid film spreading in a semi-infinite domain $x \geq 0$, so that $x = 0$ corresponds to an edge over which fluid can drain. In particular, we investigate self-similar solutions of the one-dimensional "thin-film" equation (a fourth order degenerate parabolic equation) on $x \geq 0$. We find classes of first- and second-kind similarity solutions and describe how these classes are connected. We also discuss the extension of our results to self-similar solutions featuring sign-changes.

[02422] Thermally-driven coalescence in thin liquid film flowing down a fiber

Format : Talk at Waseda University

Author(s) : Hangjie Ji (North Carolina State University)Claudia Falcon (Wake Forest University)Erfan Sedighi (University of California, Los Angeles)Abolfazl Sadeghpour (University of California, Los Angeles)Y. Sungtaek Ju (University of California, Los Angeles)Andrea L. Bertozzi (University of California, Los Angeles)

Abstract : This paper presents a study on the dynamics of a thin liquid film flowing down a vertical cylindrical fibre under a streamwise thermal gradient. Previous works on isothermal flows have shown that the inlet flow and fibre geometry are the main factors that determine a transition from the absolute to the convective instability flow regimes. Our experiments demonstrate that an irregular wavy pattern and bead coalescence, which are commonly seen in the convective regime, can also be triggered by applying a thermal gradient along the fibre. We develop a lubrication model that accounts for gravity, temperature-dependent viscosity and surface tension to describe the thermal effects on downstream bead dynamics. Numerical simulations of the model show good agreement between the predicted droplet coalescence dynamics and the experimental data.

00118 (2/3) : 1D @D402 [Chair: Hangjie Ji, Pejman Sanaei]

[01886] Hybrid Asymptotic-Numerical Methods for Two-Phase Flow With Soluble Surfactant

Format : Talk at Waseda University

Author(s) : Michael Booty (New Jersey Institute of Technology)

Abstract : Surfactant molecules diffuse slowly in bulk flows because of their size, so that the Peclet number of surfactant diffusion is large, and transfer between a stretched drop interface and bulk flow occurs in a thin layer adjacent to the interface that is about one thousandth of the drop radius. Analytical and numerical results of asymptotic, boundary integral, and conformal mapping techniques are presented. This is joint work with Michael Siegel, Ryan Atwater and Samantha Evans.

[01260] A phase field model for a drop suspended in viscous liquids under the influence of electric fields

Format : Talk at Waseda University

Author(s) : Shixin Xu (Duke Kunshan Univeristy)Yuzhe Qin (Shanxi University)Huangxiong Huang (Beijing Normal University)

Abstract : In this talk, we consider modeling the deformation of a droplet under an electric field. Firstly, we derive the Poisson-Nernst-Planck-Navier-Stokes phase field model based on the energy variational method, and then we obtain a general phase-field leaky dielectric model taking into account the capacitance according to the electroneutrality. Then a detailed asymptotic analysis confirms that the sharp interface limit of our proposed diffusive-interface model is consistent with the sharp interface model. We take a series of numerical experiments to validate the correctness and effectiveness of our model. The numerical result shows the validity of the asymptotic analysis by comparing the diffuse interface method and existing immersed boundary method results. Finally, we compare the deformations for the interface with and without the capacitance. It shows that the capacitance will weak the formation of droplets.

[05478] Phase-field modeling of colloid-polymer mixtures in microgravity

Format : Talk at Waseda University

Author(s) : Anand Oza (New Jersey Institute of Technology)

Abstract : We present a theoretical model for colloid-polymer mixtures in a microgravity environment. The addition of polymer to a colloidal suspension induces weakly attractive forces between the colloids and leads to a three-phase coexistence region, wherein liquid phase "droplets" coexist with a low-density gas phase and a high-density crystal phase. Colloid-polymer mixtures are thus an archetype for modeling phase transition processes, but the details of the observed colloidal structures remain poorly understood. We construct, analyze and numerically simulate a phase-field model for structure evolution in colloid-polymer mixtures. The model consists of the Cahn-Hilliard equation, which describes phase separation processes in multicomponent mixtures, coupled with the Stokes equation for viscous fluid flow. The results of the model are compared against experiments performed on the International Space Station, using data available on the NASA Physical Sciences Informatics system.

[02884] Capillary rebound of droplets impacting onto a liquid bath

Format : Talk at Waseda University
Author(s) : Radu Cimpeanu (University of Warwick)Luke F.L. Alventosa (Brown University)Daniel M. Harris (Brown University)
Abstract : We study millimetric drops impacting onto the free surface of a quiescent bath, a canonical scenario which provides excellent opportunities to co-develop experimental, analytical and computational techniques in a rich multi-scale context. We find that increases in gravitational forces or viscosity lead to a decrease in the coefficient of restitution and an increase in the contact time. The inertio-capillary limit defines an upper bound on the coefficient of restitution, depending only on the Weber number.

[01510] Motion of Liquid Droplets in Gas Channels

Format : Talk at Waseda University
Author(s) : Marina Chugunova (Claremont Graduate University)
Abstract : Understanding of liquid droplets dynamics in gas channels is critical for improvement of performance and durability of the catalysts made of a dense porous material. We derive a mathematical model to study how different surface properties and operating conditions affect the dynamics of liquid droplets. We present multiple numerical simulations of a single droplet dynamics for different sizes of droplets and different choices of contact angles. We show the influence of an air flow to a thin liquid film and analyze traveling wave type solutions.

Joint work with A. Nadim, Y Ruan, and R Taranets

[02886] On the immersed boundary method in simulating liquid-gas interfaces

Format : Talk at Waseda University
Author(s) : Pejman Sanaei (Georgia State University)Michael Y. Li (New York University)Daniel Chin (New York Universty)Charles Puelz (Baylor College of Medicine)
Abstract : In this work, we use the immersed boundary method with four extensions to simulate a moving liquid-gas interface on a solid surface. We first define a moving contact line model and implements a static-dynamic friction condition at the
immersed solid boundary. The dynamic contact angle is endogenous instead of prescribed, and the solid boundary
can be non-stationary with respect to time. Second, we simulate both a surface tension force and a Young's force with one
general equation that does not involve estimating local curvature. In the third extension, we splice liquid-gas
interfaces to handle topological changes, such as the coalescence and separation of liquid droplets or gas bubbles.
Finally, we re-sample liquid-gas interface markers to ensure a near-uniform distribution without exerting artificial
forces. We demonstrate empirical convergence of our methods on non-trivial examples and apply them to several
benchmark cases, including a slipping droplet on a wall and a rising bubble.

[00134] Evolution Equations for Interacting Species: Applications and Analysis

Session Time & Room :

00134 (1/3) : 2C (Aug.22, 13:20-15:00) @D407

00134 (2/3) : 2D (Aug.22, 15:30-17:10) @D407

00134 (3/3) : 2E (Aug.22, 17:40-19:20) @D407

Type : Proposal of Minisymposium
Abstract : This mini-symposium brings together leading experts in the field of systems of PDEs arising in the context of interacting particles. Steric effects and interactions between members of opposite or the same species typically lead to systems of nonlocal and cross-diffusion type. The interplay of degenerate parabolicity and nonlocalities leads to a myriad of interesting emergent behaviours including pattern formation and phase separation. At the same time, these systems pose a variety of challenging analytical mathematical problems including the dramatic loss of regularity at the onset of phase separation. Thus, new analytical techniques and reliable numerical methods are needed.
Organizer(s) : Jan-Frederik Pietschmann, Markus Schmidtchen, Havva Yoldaş

Minisymposium Program :

00134 (1/3) : 2C @D407 [Chair: Markus Schmidtchen]

[05128] Evolution Equations for Interacting Species: Applications and Analysis

Format : Online Talk on Zoom
Author(s) : Jan-Frederik Pietschmann (University of Augsburg)Markus Schmidtchen (Technische Universität Dresden)Havva Yoldaş (Delft University of Technology)
Abstract : This talks provides an overview of the mini-symposium's topic of systems of PDEs arising in the context of interacting particles. Steric effects and interactions between members of opposite or the same species typically lead to systems of nonlocal and cross-diffusion type. The interplay of degenerate parabolicity and nonlocalities leads to a myriad of interesting emergent behaviours including pattern formation and phase separation. At the same time, these systems pose a variety of challenging analytical mathematical problems including the dramatic loss of regularity at the onset of phase separation. Thus, new analytical techniques and reliable numerical methods are needed.

[05084] A Keller-Segel type approximation to a cell population dynamics model

Format : Talk at Waseda University
Author(s) : Hideki Murakawa (Ryukoku University)
Abstract : We deal with a cell population dynamics model with nonlocal advection term. Approximating non-local advection as a local problem can be useful for analysis and numerical analysis of the problem. In this talk, we present a Keller-Segel type approximation to the cell population dynamics model. The approximation consists only of local terms. We discuss convergence of the approximation and introduce some applications. This is a joint work with Yoshitaro Tanaka.

[04550] Convergence of position-based dynamics for first-order particle systems with volume exclusion

Format : Talk at Waseda University
Author(s) : Steffen Plunder (Kyoto University, ASHBi)Sara Merino-Aceituno (University of Vienna)
Abstract : To simulate first-order particle systems with volume exclusion, we adapted the position based dynamics (PBD) method from computer graphics. PBD is a simple, fast and explicit time-stepping method which is unconditionally stable.

Our contribution is the first convergence proof for PBD for first-order systems. Our proof uses the theory of differential inclusions on uniformly prox-regular sets and a new error estimate for alternating projections.

We successfully applied the method in various applications in developmental biology.

[04803] Graph-to-local limit for the nonlocal interaction equation

Format : Talk at Waseda University
Author(s) : Georg Heinze (University of Augsburg)
Abstract : In this talk I will discuss a proof of existence of solutions for the nonlocal interaction equation in Euclidean space using a graph-based nonlocal approximation. The graph equations are induced by an upwind interpolation, which leads to non-symmetric graph gradient structures that nevertheless converge to a symmetric Wasserstein-type local gradient structure. Furthermore, the flexibility of our graph model allows us to introduce a tensor to modify the geometry underlying the limiting model.

00134 (2/3) : 2D @D407 [Chair: Jan-Frederik Pietschmann]

[05193] A model for territorial dynamics: from particle to continuum

Format : Online Talk on Zoom
Author(s) : Alethea Barbaro (TU Delft)Abdulaziz Alsenafi (Kuwait University)
Abstract : Many species, including our own, demonstrate territoriality, with individuals or groups marking their territories either chemically or visually. Here, we present an agent-based lattice model for territorial development. In this model, there are several groups; agents from each group put down that group's territorial markings as they move on the lattice. Agents move away from areas with territorial markings which do not belong to their own group. The model was motivated by gangs expressing territoriality through graffiti markings, though the model itself could be applicable in any chemo-repellent situation. We show that this model undergoes a phase transition between well-mixed dynamics and the formation of distinct territories as parameters are varied. We formally derive a system of coupled convection-

diffusion equations from this model. The system is cross-diffusive due to the avoidance of other groups' markings. Using the PDE system, we pinpoint the critical value for the phase transition.

[04662] A variational approach for an existence result for a cross-diffusion model

Format : Talk at Waseda University
Author(s) : Havva Yoldaş (Delft University of Technology)Filippo Santambrogio (Université Claude Bernard - Lyon 1)Romain Ducasse (Université Paris Cité)
Abstract : In this talk, we look at a cross-diffusion system consisting of two Fokker-Planck equations where the gradient of the density for each species acts as a potential for the other one. The system is the gradient flow for the Wasserstein distance of a functional which is not lower semi-continuous, and the system is not well-posed. We compute the convexification of the integral and provide an existence proof in a suitable sense for the gradient flow of the corresponding relaxed functional.

[04745] A degenerate cross-diffusion system as the inviscid limit of a nonlocal tissue growth model

Format : Talk at Waseda University
Author(s) : Tomasz Dębiec (University of Warsaw)
Abstract : In recent years, there has been a spike in interest in multi-phase tissue growth models. Depending on the type of tissue, the velocity is linked to the pressure through Stoke's law, Brinkman's law or Darcy's law. While each of these velocity-pressure relations has been studied in the literature, little emphasis has been placed on the fine relationship between them. In this talk, we want to address this dearth of results in the literature, providing a rigorous argument that bridges the gap between a viscoelastic tumour model (of Brinkman type) and an inviscid tumour model (of Darcy type).

[04637] Proposing a Finite Volume Method for a Kinetic Model for Interacting Species

Format : Talk at Waseda University
Author(s) : Julia Ines Mareike Hauser (TU Dresden)
Abstract : We consider a system of two kinetic equations coupled by non-local interaction terms which are used to describe systems of indistinguishable agents such as flocks of birds.
In this talk we propose an upwind finite volume method for this model. The method is constructed in such that mass is preserved and positivity is maintained. We show the convergence of the method and we provide explicit error estimates. Finally, we underline our theoretical results with simulations.

00134 (3/3) : 2E @D407 [Chair: Havva Yoldaş]

[05038] Mean-field convergence in L^2-norm for a diffusion model with aggregation

Format : Online Talk on Zoom
Author(s) : Alexandra Holzinger (TU Wien)
Abstract : Aggregation effects appear in many applications arising from biology and physics which makes it interesting to study this phenomena also in mean-field settings. It is well-known that a class of local diffusion-aggregation equations can bederived by using classical mean-field limits. In this talk I will explain the benefits we get by showing a result in L^2-norm and how this is connected to fluctuations around the mean-field limit.

[04613] Macroscopic limits of kinetic equations for the switch in cell migration via binary interactions

Format : Talk at Waseda University
Author(s) : Gissell Estrada-Rodriguez (University of OxfordU)
Abstract : Motivated by experimental results on the immune response to cancer, we considered a system of particles, I, in an
inactive state, where they follow a nonlocal (Levy) movement. After a collision with particles in population D, they change to an active state, A, resulting in a more localised (Brownian) movement. Activation is described via binary interactions between I and D. Moreover, cell motion is represented as a velocity-jump process, with the running time of I following a long-tailed distribution, which is consistent with a Levy walk, and the running time of A following a Poisson distribution, which corresponds to Brownian motion. We formally show that the macroscopic limit of the model comprises a coupled system of balance equations for the one-particle distribution functions of populations I, D and A. The modelling approach presented here and its possible generalisations are expected to find applications in the study of

the immune response to cancer and in other biological contexts in which switch from non-local to localised migration patterns occurs.

[04647] Towards a new mathematical model of the visual cycle

Format : Talk at Waseda University
Author(s) : Luca Cesare Biagio Alasio (Sorbonne UniversitéSorbonne Université)
Abstract : The visual cycle is a fundamental bio-chemical process allowing photoreceptors to convert light into electrical signals and return to the dark state. I will present a new mathematical model involving coupled ODEs and PDEs for the kinetics of retinal photo-sensitive molecules after light exposure. This reaction-diffusion-type model provides a first step in the study of the accumulation of toxic by-products in the eye in connection with retinal diseases such as age-related macular degeneration.

[04418] Structured Model for the Size-spectrum Evolution in Aquatic Ecosystems

Format : Talk at Waseda University
Author(s) : Laura Kanzler (CEREMADE - Université Paris-Dauphine)
Abstract : Trophic interactions between animals in the ocean were matter of interest since the 60', where it was quickly discovered that the individuals' body size acts as 'master trait' in food webs of animals, giving rise to emergent distributions of biomass, abundance and production of organisms.

We propose and investigate a deterministic jump-growth model of Boltzmann type, aiming to capture this emergence phenomenon in aquatic ecosystems. The equation of interest is derived from individual based dynamics governed by a stochastic process. Following the observation of the body mass being the crucial trait in these dynamics it is based on the assumption that binary interactions between individuals in the ecosystem take place: A predator feeding on a prey, which then results in growth of the predator with assimilating a certain (usually very small) amount of its prey's mass as well as plankton production. Analytical results in various parameter regimes are discussed and numerical simulations underlying these observations are given.

[00135] Nonlinear PDEs and related diffusion phenomena

Session Time & Room :

00135 (1/3) : 4E (Aug.24, 17:40-19:20) @G602

00135 (2/3) : 5B (Aug.25, 10:40-12:20) @G602

00135 (3/3) : 5C (Aug.25, 13:20-15:00) @G602

Type : Proposal of Minisymposium
Abstract : Diffusion equations have a primary role in the description and modeling of several physical phenomena. A classical prototype is the heat equation, deriving from Fourier's law, which is by now a widely studied topic within the mathematical community, both in Euclidean and non-Euclidean frameworks such as manifolds or metric-measure spaces. In the last decades, many nonlinear and nonlocal versions of this equation and related ones have been proposed and analyzed, which gave rise to challenging mathematical problems. We aim at gathering international experts and talented young researchers that will discuss the most recent advances on the subject.
Organizer(s) : Kazuhiro Ishige, Tatsuki Kawakami, Matteo Muratori

Minisymposium Program :

00135 (1/3) : 4E @G602 [Chair: Kazuhiro Ishige]

[03392] Boundary Regularity of Local and Nonlocal Equations

Format : Talk at Waseda University
Author(s) : Ki-Ahm Lee (Seoul National University)
Abstract : In this talk, we are going to discuss boundary regularities of various
degenerate local equations and nonlocal equations.
Diffusion rates deform undefined geometry related to diffusion and the corresponding distance function

makes an important role in the theory of regularity.
And then we will also discuss the possible applications.

[04308] Well-posedness with large data for a weighted porous medium equation

Format : Talk at Waseda University
Author(s) : Troy Petitt (Politecnico di Milano)Matteo Muratori (Politecnico di Milano (Italy))
Abstract : The large data problem for the porous medium equation is to determine the largest class of initial data for which local well-posedness is guaranteed for the Cauchy problem. We review the classical results by Widder for the heat equation $u_t = \Delta u$. The corresponding problem for the porous medium equation $u_t = \Delta u^m$ for $m > 1$ was solved in the 1980s. We extend these results for weighted equations $\rho(x) u_t = \Delta u^m$ for $\rho(x) \cong |x|^{-\gamma}$ for $\gamma \in (0, 2)$.

[04047] Results on the Stokes eigenvalue problem under Navier boundary conditions

Format : Talk at Waseda University
Author(s) : Alessio Falocchi (Politecnico di Milano)Filippo Gazzola (Politecnico di Milano)
Abstract : We study the Stokes eigenvalue problem under Navier boundary conditions in 2D or 3D bounded domains with connected boundary of class C^1. Differently from the Dirichlet boundary conditions, zero may be the least eigenvalue. We fully characterize the domains where this happens. We then consider the general version of the problem in any space dimension with $n \geq 2$, characterizing the kernel of the strain tensor for solenoidal vector fields with homogeneous normal trace.

[03585] Weighted Trudinger-Moser inequalities in the subcritical Sobolev spaces

Format : Talk at Waseda University
Author(s) : Megumi Sano (Hiroshima University)
Abstract : Inspired by Ni's result about the H'enon equation with nonlinear term which has the strong polynomial growth beyond the Sobolev critical growth, we consider the exponential growth beyond the polynomial growth in a maximization problem. Also we discuss the optimality and the attainability of our maximization problem. Our inequalities are regarded as subcritical versions of the Trudinger-Moser inequalities in the critical Sobolev spaces.
This is a joint work with Masahiro Ikeda(RIKEN/Keio Univ.) and Koichi Taniguchi(Tohoku Univ.).

00135 (2/3) : 5B @G602 [Chair: Matteo Muratori]

[03273] First order fully nonlinear nonlocal evolution equations

Format : Talk at Waseda University
Author(s) : Takashi Kagaya (Muroran Institute of Technology)Qing Liu (Okinawa Institute of Science and Technology)Hiroyoshi Mitake (University of Tokyo)
Abstract : This talk is concerned with geometric motion of a closed surface whose normal velocity depends on a nonlocal quantity of the enclosed region. Using the level set formulation, we study a class of first order nonlocal evolution equations in the framework of viscosity solution theory. We prove the uniqueness of solutions by establishing a comparison principle. Our existence result is based on careful analysis on parallel surfaces and an optimal control interpretation. We also mention several properties of the solution such as quasiconvexity preserving, fattening phenomenon and large time behavior.

[02461] The generalized porous medium equation on graphs: Existence and uniqueness of solutions with l^1 data

Format : Talk at Waseda University
Author(s) : Davide Bianchi (Harbin Institute of Technology (Shenzhen))
Abstract : We study solutions of the generalized porous medium equation on infinite graphs. For nonnegative or nonpositive integrable data, we prove the existence and uniqueness of mild solutions on any graph. For changing sign integrable data, we show existence and uniqueness under extra assumptions such as local finiteness or a uniform lower bound on the node measure.

[03236] Global regularity estimates for the Poisson equation on complete manifolds

Format : Talk at Waseda University
Author(s) : Ludovico Marini (University of Milano-Bicocca (soon at Fukuoka University))Stefano Meda (University of Milano-Bicocca)Stefano Pigola (University of Milano-Bicocca)Giona Veronelli (University of Milano-Bicocca)
Abstract : In this talk, we investigate the validity of first and second-order, global L^p estimates for the solutions of the Poisson equation.
While these estimates always hold on $\mathbb{R}^n$, on complete non-compact manifolds their validity is strongly influenced by the large-scale geometry.
I will present some positive results and discuss the sharpness of certain assumptions through counterexamples.
This is a joint work with Stefano Meda, Stefano Pigola and Giona Veronelli of the University of Milano-Bicocca.

[03203] Radial solutions to a semilinear equation on Riemannian models

Format : Talk at Waseda University
Author(s) : Elvise Berchio (Politecnico di Torino)Alberto Ferrero (Università del Piemonte Orientale)Debdip Ganguly (Indian Institute of Technology Delhi)Prasun Roychowdhury (National Center for Theoretical Sciences)
Abstract : We provide a classification with respect to asymptotic behaviour, stability and intersections properties of radial smooth solutions to the equation $\Delta_g u = e^u$ on Riemannian models. Our assumptions include Riemannian manifolds with sectional curvatures bounded or unbounded from below. As it is well-known in the Euclidean case, intersection and stability properties are influenced by the dimension; here the analysis highlights properties of solutions that cannot be observed in the flat case.

00135 (3/3) : 5C @G602 [Chair: Tatsuki Kawakami]

[03548] Quasi self-similarity and its application to the global in time solvability of a superlinear heat equation

Format : Talk at Waseda University
Author(s) : Yohei Fujishima (Shizuoka University)
Abstract : We discuss the global in time existence of solutions for a superlinear heat equation. In particular, we determine the critical decay rate of initial functions for the global existence of solutions by introducing a quasi self-similar solution for the problem.

[03604] Stochastically perturbed log diffusion equations

Format : Talk at Waseda University
Author(s) : Reika Fukuizumi (Waseda University)
Abstract : We will present a result on the existence and uniqueness of the solution for the stochastic fast logarithmic equation with a Stratonovich multiplicative noise in R^d for d \ge 3. We overcome several technical difficulties due to the degeneracy properties of the logarithm and to the fact that the problem is treated in an unbounded domain. This is a joint work with Ioana Ciotir (INSA Rouen, France) and Dan Goreac (Univ Paris Est, France and Shandong University, China).

[03225] Spreading and extinction of solutions to the logarithmic diffusion with a logistic reaction

Format : Talk at Waseda University
Author(s) : Masahiko Shimojo (Tokyo Metropolitan University)Eiji Yanagida (University of Tokyo)Harunori Monobe (Osaka Metropolitan University)
Abstract : Logarithmic diffusion is observed in several fields of science, such as the central limit approximation of Carleman's model based on the Boltzmann equation, a model for long Van-der-Waals interactions in thin fluid films, and the evolution of conformal metric under the Ricci flow on the plane. We focus on the spreading and extinction phenomena of the solution to the logarithmic diffusion equation on a line, in the presence of a logistic reaction term. A Liouville-type theorem will be introduced to understand the extinction and interfacial phenomena from the point of entire solutions.

[03474] Characterization of F-concavity preserved by the Dirichlet heat flow

Format : Talk at Waseda University
Author(s) : Asuka Takatsu (Tokyo Metropolitan University)Paolo Salani (University of Florence)Kazuhiro Ishige (The University of Tokyo)
Abstract : F-concavity is a generalization of power concavity and, actually, the largest available generalization of the notion of
concavity. We characterize the F-concavities preserved by the Dirichlet heat flow in convex domains on Euclidean space, and complete the study of preservation of concavity properties by the Dirichlet heat flow, started by Brascamp and Lieb in 1976 and developed in some recent papers.

[00137] Mathematical Aspects of Multiscale Phenomena in Materials and Complex Fluids

Session Time & Room :

00137 (1/3) : 3C (Aug.23, 13:20-15:00) @E802

00137 (2/3) : 3D (Aug.23, 15:30-17:10) @E802

00137 (3/3) : 3E (Aug.23, 17:40-19:20) @E802

Type : Proposal of Minisymposium
Abstract : The mini-symposium will focus on mathematical aspects of multiscale phenomena in materials and complex fluids. New scientific problems along with novel mathematical techniques and computational tools have emerged from the study of multiscale phenomena, for example, in polycrystalline materials, biomaterials, flow through porous media, as well as liquid crystals, to name a few. The mini-symposium will bring together experts in the area of mathematical aspects of materials and complex fluids and will feature talks on the latest advances in the field that range from mathematical modeling and analysis of partial differential equations to algorithm design, simulation and data analysis.
Organizer(s) : Yekaterina Epshteyn, Chun Liu, Masashi Mizuno
Classification : 74Hxx, 76Txx, 35Qxx, 65Mxx, Materials, Complex Fluids, Modeling, Analysis of PDEs, Simulation
Minisymposium Program :

00137 (1/3) : 3C @E802 [Chair: Chun Liu]

[00142] New perspectives on modeling and analysis of grain growth in polycrystals

Format : Talk at Waseda University
Author(s) : Yekaterina Epshteyn (University of Utah)Katayun Barmak (Columbia University)Chun Liu (IIT)Masashi Mizuno (Nihon University)
Abstract : Grain growth in polycrystals is a very complex multiscale process. It can be regarded as the anisotropic evolution of a large cellular network, and can be described by a set of deterministic local evolution laws for the growth of an individual grain combined with stochastic models for the interaction between them. In this talk, we will present new perspectives on modeling, simulation and analysis of the evolution of the grain boundary network in polycrystalline materials.

[00183] Entropy dissipation methods for Nonlinear inhomogeneous Fokker-Planck models

Format : Talk at Waseda University
Author(s) : Masashi Mizuno (Nihon University)Yekaterina Epshteyn (University of Utah)Chun Liu (Illinois Institute of Technology)Chang Liu (University of Utah)
Abstract : This talk presents long-time asymptotic behavior for the nonlinear Fokker-Planck model: First, for the linear Fokker-Planck equation, we reformulate the entropy dissipation methods with the help of the velocity vector in the continuity equation. Next, we derive the evolution equation for the velocity vector for the nonlinear Fokker-Planck model. Finally, we give a sufficient condition to extend the entropy dissipation method to the nonlinear Fokker-Planck model.

[00198] Structure-preserving variational discretizations to generalized gradient flows

Format : Online Talk on Zoom
Author(s) : Chun Liu (Illinois Institute of Technology)Yiwei Wang (University of California, Riverside)
Abstract : We'll present a numerical framework for developing structure-preserving variational schemes for various complex fluids models built by the energetic variational approach. The numerical approach starts with the energy-dissipation law of the underlying system and can combine different spatial discretizations, including Eulerian, Lagrangian, particle, and neural-network-based methods. The numerical procedure guarantees the developed schemes are energy stable and can preserve the intrinsic physical constraints. Several applications of this numerical approach will be discussed.

[00248] Towards upscaling and simulation of coupled [THM] systems with applications to permafrost modeling

Format : Online Talk on Zoom
Author(s) : Malgorzata Peszynska (Oregon State UniversityOregon State University)Naren Vohra (Oregon State University)
Abstract : In the talk we discuss our progress towards multiscale computational modeling of coupled processes in permafrost, frozen ground which is ubiquitous in the Arctic. We focus on its active layer close to the surface whose depth is changing due to changing climate conditions, and we model its thermal state (temperature, and phase status: frozen or thawed), hydrological conditions, and mechanical response to hydrological and thermal controls. We present convergence studies and upscaling from porescale.

00137 (2/3) : 3D @E802 [Chair: Yekaterina Epshteyn]

[00202] Diffuse-interface approach to competition between viscous flow and diffusion in pinch-off dynamics

Format : Talk at Waseda University
Author(s) : Weizhu Bao (National University of Singapore)Fukeng Huang (National University of Singapore)Tiezheng Qian (Hong Kong University of Science and Technology)
Abstract : In this talk, we present numerical simulations for the pinch-off dynamics in the Stokes regime and the diffusion-dominated regime by adopting the Cahn-Hilliard-Navier-Stokes model derived by applying Onsager's variational principle. The Cahn-Hilliard-Navier-Stokes model is solved by using an accurate and efficient spectral method in a cylindrical domain with axisymmetry. Ample numerical examples are presented to show the pinch-off processes in the Stokes regime and the diffusion-dominated regime, respectively. In particular, the crossover between these two regimes is investigated numerically and analytically to reveal how the scaling behaviors of similarity solutions are to be qualitatively changed as the characteristic length scale is inevitably accessed by the pinching neck of the interface. Discussions are also provided for numerical examples that are performed for the breakup of long liquid filaments and show qualitatively different phenomena in different scaling regimes. This is a joint work with Fukeng Huang and Tiezheng Qian.

[00195] Multiscale analysis of nonlinear material models with carrier kinetics

Format : Talk at Waseda University
Author(s) : Qing Xia (KTH Royal Institute of Technology)Ludmila Prokopeva (Purdue University)William Henshaw (RPI)Alexander Kildishev (Purdue University)Gregor Kovacic (RPI)Jeffrey Banks (RPI)Donald Schwendeman (RPI)
Abstract : In this talk, we introduce Maxwell-Bloch equations for modeling interactions between light and nonlinear optics. The model is based on real-valued rate equations, which describe kinetics of electrons between the ground state and excited states in the multi-level atomic system. We will show the rate equation approach is connected to the complex-valued density matrix approach via the Schrödinger's equation. Different multi-level atomic systems will be shown and multi-scale analysis is performed.

[00209] Energetic-variational particle-based method for Fokker-Planck Models.

Format : Talk at Waseda University
Author(s) : Kaitlin O'Dell (University of Utah)Yekaterina Epshteyn (University of Utah)Chun Liu (Illinois Institute of Technology)
Abstract : Fokker-Planck models with energy-dissipation structures arise in many scientific and engineering applications. We present a novel energetic-variational particle-based approach for simulation of such nonlinear high-

dimensional Fokker-Planck systems which cannot be solved using traditional numerical methods. First, we compare the performance of the proposed particle-based scheme with the finite-volume structure-preserving method on low-dimensional Fokker-Planck systems. Then, we apply new method for the analysis of the high-dimensional Fokker-Planck equations that describe grain boundaries dynamics in polycrystalline materials.

[00214] Phase transitions in near-liquid solids

Format : Talk at Waseda University
Author(s) : Yury Grabovsky (Temple University)Lev Truskinovsky (ESPCI)
Abstract : We consider a class of two-dimensional compressible Hadamard materials with very small shear modulus and a double-well potential for the energy as a function of specific volume. Such energy is not rank one convex and is in need of relaxation. While computing energy relaxation seems hopeless, identifying its binodal - the boundary separating stable and unstable homogeneously deformed configurations seems more tractable. I will describe several necessary and sufficient conditions for stability and show how they allow us to bound hydrostatic strains on the binodal. Then, in a surprising twist, I will show how the optimality of our bound would generate an excellent approximation to the entire binodal. This is a joint work with Lev Truskinovsky.

00137 (3/3) : 3E @E802 [Chair: Masashi Mizuno]

[00243] A finer singular limit of the Kobayashi-Warren-Carter type functional and its gradient flow

Format : Talk at Waseda University
Author(s) : Masaaki Uesaka (Arithmer, Inc.)Yoshikazu Giga (the University of Tokyo)Koya Sakakibara (Okayama University of Science)Jun Okamoto (Kyoto University)
Abstract : We consider the singular limit of the Kobayashi-Warren-Carter type energy, which is derived from the physical model of grain boundary motion in polycrystals. The KWC-type energy contains the weighted total variation, and hence we must employ a topology finer than $L1$ to capture the singular limit's behavior in detail. We shall explain the key result of the singular limit of KWC-type energy and the behavior of its gradient flow.

[00249] Variational modeling of fluid in poroelastic medium

Format : Talk at Waseda University
Author(s) : Arkadz Kirshtein (Tufts University)James Haley Adler (Tufts University)Xiaozhe Hu (Tufts University)
Abstract : In this talk I will discuss modeling fluid flow through a deformable porous medium. I will start from introducing a variational approach for fluids and elasticity in Lagrangian coordinates. Next I will discuss an existing approach based on Biot's consolidation model. Ultimately I will introduce a system derived using energetic variational approach and discuss numerical methods and simulations based on it.

[00226] Phase field model for volume-preserving mean curvature flow

Format : Talk at Waseda University
Author(s) : Keisuke Takasao (Kyoto University)
Abstract : In this talk, we show a global existence of the weak solution for the volume-preserving mean curvature flow.
To construct the weak solution, we use the Allen-Cahn equation with non-local term given by the penalty method.
We prove the L^2-estimate of the non-local term and the monotonicity formula for the equation, which are the keys of the proof of the existence theorem.

[00257] A unified continuum model for grain boundary dynamics incorporating microscopic structure

Format : Talk at Waseda University
Author(s) : Yang Xiang (Hong Kong University of Science and Technology)
Abstract : We develop a unified continuum framework to account for the underlying line defect mechanisms. Conditions on the continuum level are imposed to account for the underlying microscopic mechanisms, which makes the continuum model more efficient to describe the collective behaviors of grain boundary networks at larger length scales.

[00140] Interacting particle systems: modeling, learning and applications

Session Time & Room :

00140 (1/2) : 3C (Aug.23, 13:20-15:00) @D407

00140 (2/2) : 3D (Aug.23, 15:30-17:10) @D407

Type : Proposal of Minisymposium
Abstract : Systems of interacting particles or agents are ubiquitous in science and technology, with new theory and applications developing at a rapid pace. This mini-symposium aims at a cross-fertilization of areas in the study of topics in interacting particle systems, including, but not limited to: their analysis, computational techniques, parametric and nonparametric inference problems, control, interacting particles on graphs, use of interacting particle-based methods in optimization and neural networks, modeling and applications.

Organizer(s) : Fei Lu, Mauro Maggioni
Classification : 82C22, 49Q99, 35R30, 68T09, 35Q83
Minisymposium Program :

00140 (1/2) : 3C @D407 [Chair: Mauro Maggioni]

[03778] The mean-field limit of non-exchangeable integrate and fire systems

Format : Online Talk on Zoom
Author(s) : Pierre-Emmanuel Jabin (Pennsylvania State University)Datong Zhou (Pennsylvania State University)
Abstract : We investigate the mean-field limit of large networks of interacting biological neurons. The neurons are represented by the so-called integrate and fire models that follow the membrane potential of each neurons and captures individual spikes. However we do not assume any structure on the graph of interactions but consider instead any connection weights between neurons that obey a generic mean-field scaling. We are able to extend the concept of extended graphons, introduced in Jabin-Poyato-Soler, by introducing a novel notion of discrete observables in the system.

[03624] Weak Form Equation Learning for Interacting Particle System Models of Collective Motion

Format : Online Talk on Zoom
Author(s) : David Bortz (University of Colorado - Boulder)Daniel Messenger (University of Colorado - Boulder)
Abstract : The Weak form Sparse Identification of Nonlinear Dynamics (WSINDy) methodology efficiently identifies governing equations from noisy data. We develop WSINDy for inference of 1st and 2nd-order IPS models as well as a joint model selection and classification method to both learn governing IPS equations and sort individuals into distinct interaction rule classes. We demonstrate the efficiency and proficiency of these methods on several test scenarios, motivated by common cell migration experiments.

[03774] Mean-field nonparametric estimation of interacting particle systems

Format : Online Talk on Zoom
Author(s) : Xiaohui Chen (University of Southern California)Rentian Yao (University of Illinois at Urbana-Champaign)Yun Yang (University of Illinois at Urbana-Champaign)
Abstract : This talk concerns the nonparametric estimation problem of the distribution-state dependent drift vector field in an interacting N-particle system. Observing single-trajectory data for each particle, we derive the mean-field rate of convergence for the maximum likelihood estimator (MLE), which depends on both Gaussian complexity and Rademacher complexity of the function class. In particular, when the function class contains α-smooth Hölder functions, our rate of convergence is minimax optimal on the order of $N^{-\frac{\alpha}{d+2\alpha}}$. Combining with a Fourier analytical deconvolution estimator, we derive the consistency of MLE for the external force and interaction kernel in the McKean-Vlasov equation.

[04754] Game-based learning of interaction rules for rational agents

Format : Online Talk on Zoom
Author(s) : Mauro Bonafini (University of Verona)Massimo Fornasier (Technical University of Munich)Bernhard Schmitzer (University of Göttingen)
Abstract : We introduce novel multi-agent interaction models obtained as fast-reaction limits of evolutionary games. We

discuss the well-posedness of these models and the learnability of individual payoff functions from observation data. We formulate the payoff learning as a variational problem, minimizing the discrepancy between the observations and the predictions by the payoff function. The abstract framework is fully constructive and numerically implementable. We illustrate this on computational examples.

00140 (2/2) : 3D @D407 [Chair: Fei Lu]

[04464] Data-driven discovery of interacting particle systems with Gaussian Processes

Format : Talk at Waseda University
Author(s) : Sui Tang (University of California Santa Barbara)Charles Kulick (University of California Santa Barabra)Jinchao Feng (Johns Hopkins University)
Abstract : We present a data-driven approach for discovering interacting particle models with latent interactions. Our approach uses Gaussian processes to model latent interactions, providing an uncertainty-aware approach to modeling interacting particle systems. We demonstrate the effectiveness of our approach through numerical experiments on prototype systems and real data. Moreover, we develop an operator-theoretic framework to provide theoretical guarantees for the proposed approach. We analyze recoverability conditions and establish the statistical optimality of our approach.

[03149] The mean field limit of random batch interacting particle systems

Format : Talk at Waseda University
Author(s) : Lei Li (Shanghai Jiao Tong University)
Abstract : The Random Batch Method proposed in our previous work (J Comput Phys, 2020) is not only a numerical method for interacting particle systems and its mean-field limit, but also can be viewed as a new model in which particles interact, at discrete time, with randomly selected mini-batch of particles. We investigate the mean-field limit of this model as the number of particles tends to infinity. The mean field limit now exhibits some new features. We will not only justify this mean-field limit (discrete in time) but will also show that the limit approaches to the solution of a nonlinear Fokker-Planck equation as the discrete time step goes to zero.

[04827] Neural parameter calibration for large-scale multi-agent systems

Format : Talk at Waseda University
Author(s) : Thomas Gaskin (University of Cambridge)
Abstract : I present a method to calibrate multi-agent systems to datasets using neural networks, allowing for uncertainty quantification in a manner that reflects both the noise on the data as well as the non-convexity of the parameter estimation problem. I will discuss applications to various different examples, including learning entire network adjacency matrices, and give a comparative analysis of the method’s performance in terms of speed, prediction accuracy, and uncertainty quantification to classical techniques.

[05244] Non-local regularization of Semilinear PDE for Probability Density Stabilization

Format : Talk at Waseda University
Author(s) : Karthik Elamvazhuthi (University of California, Riverside)
Abstract : In this talk, I will present some recent work on a particle method for numerically simulating a class of semilinear PDEs that provide strategies for probability density stabilization. These have important applications in problems such as sampling and multi-agent control. We will consider a semilinear diffusion model in which the reaction parameters are to be designed so that the solution of PDE converges to a target probability density. Since the parameters of these PDEs depend on the local density, they are not suitable for implementation on a finite number of particles. We construct a particle method by regularizing the local dependence to construct a non-local PDE. While the nonlocal approximations make numerical implementation easier, their local limits have good analytical properties from the point of view of understanding long-term behavior. Motivated by applications in robotics, the method also easily generalizes to situations where the particle diffusions are degenerate and hence, not elliptic, but only hypoelliptic.

[00143] Recent advances in stochastic optimal control and contract theory

Session Time & Room : 5D (Aug.25, 15:30-17:10) @D501

Type : Proposal of Minisymposium
Abstract : The aim of this session is to bring together some of the most active junior researchers in the areas of stochastic optimal control, with an emphasis on applications to contract theory and principal-agent problems. It will be a perfect and timely opportunity to take stock of the recent progresses in these very trendy topics, as well as to highlight the deep links that they share. In particular, a specific attention will be put on relationships with mean-field and Stackelberg games, McKean-Vlasov optimal control, and time-inconsistent optimal control problems.
Organizer(s) : Dylan PossamaïSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.
Classification : 91B41, 60H99, 93E20
Minisymposium Program :

00143 (1/1) : 5D @D501

[00182] Mean field optimal stopping and applications in contract theory

Author(s) : Mehdi Christian Talbi (ETH Zurich)Thibaut Mastrolia (UC Berkeley)
Abstract : Mean field optimal stopping problems correspond to optimization problems where a central planner controls a distribution of interacting agents by assigning each of them a stopping time. After explaining how these problems can be studied through dynamic programming, we propose an application to contract theory: one Principal proposes contracts to interacting Agents, and each contract includes a continuous payment and a retirement time, which leads the Principal to solve a mixed control-and-stopping mean field problem.

[00242] A stochastic target approach to Stackelberg games and moral hazard with constraints

Author(s) : Emma Hubert (Princeton University)
Abstract : In this talk, we provide a unifying framework for Stackelberg games and principal-agent problems with moral hazard and constraints on the terminal payment. The main idea is that this type of problems can be reformulated as more standard control problems with stochastic target. Indeed, the agent's problem can be rewritten as a BSDE, controlled by the principal, and then the constraint on the terminal payment is equivalent to a terminal constraint on this controlled process.

[05385] Asset Bubble Riding with Price-Dependent Entry: a Mean Field Game of Controls with Common Noise

Author(s) : Dylan Possamaï (ETH Zürich)Shichun Wang (Princeton University)
Abstract : In this talk, we present an existence result for mean field games of controls with common noise and random entry time. We obtain an equilibrium by first solving discretized versions of the game in the weak formulation and examining the measurability property in the limit. As a motivating example, we extend the existing game-theoretic model on optimal execution in the presence of an asset bubble by allowing for price-dependent entry times. Agents are characterized by their individual entry thresholds that represent their beliefs in the strength of the bubble. Conversely, the growth dynamics of the bubble is fueled by the influx of players. On top of the asset price, a second source of common noise is the exogenous bubble burst time, which we incorporate into the model via progressive enlargement of filtration. In the end, we show the equilibrium strategy can be decomposed into before-and-after-burst segments, each part containing only the market information.

[05410] Bubble Riding with Price-Dependent Entry: Mean Field Games of Controls with Common Noise

Author(s) : Ludovic Tangpi (Princeton University)Shichun Wang (Princeton University)
Abstract : In this talk, we present an existence result for mean field games of controls with common noise and random entry time. We obtain an equilibrium by first solving discretized versions of the game in the weak formulation and examining the measurability property in the limit. As a motivating example, we extend the existing game-theoretic model on optimal execution in the presence of an asset bubble by allowing for price-dependent entry times. Agents are characterized by their individual entry thresholds that represent their beliefs in the strength of the bubble. Conversely, the growth dynamics of the bubble is fueled by the influx of players. On top of the asset price, a second source of

common noise is the exogenous bubble burst time, which we incorporate into the model via progressive enlargement of filtration. In the end, we show the equilibrium strategy can be decomposed into before-and-after-burst segments, each part containing only the market information.

[00151] Recent trends in SHM: damage modeling and optimal experimental design from a mechanical and mathematical point of view

Session Time & Room :

00151 (1/2) : 4C (Aug.24, 13:20-15:00) @F403

00151 (2/2) : 4D (Aug.24, 15:30-17:10) @F403

Type : Proposal of Minisymposium
Abstract : Structural and mechanical systems like bridges, buildings and defense systems play an essential role in modern societies. The maintenance of these structures must provide their safety and prevent the loss of life but at the same time be cost-efficient. Usually, the monitoring issue has been tackled from an engineering point of view. Consequently, the number of possible problem-solving algorithms is drastically reduced. In this minisymposium, the approaches from a mathematical and mechanical point of view are presented. These lead from methods for optimal sensor placements and applications of shape optimization to numerical simulations of damage detection, evolution, and prognosis.

[00271] Optimization aspects of experimental design approaches for sensor placement

Format : Talk at Waseda University
Author(s) : Volker Schulz (Trier University)
Abstract : The information from sensors has to be treated in order to obtain properties of technical systems. The accuracy expressed in statistical concepts like covariance matrix and confidence regions depends on constituents of the measurement process. This talk discusses the effect of sensor placement and actuator design on these statistical properties and presents mathematical optimization approaches to optimize them.

[00272] Fracture propagation by using shape optimization techniques on Riemannian spaces

Format : Talk at Waseda University
Author(s) : Tim Suchan (Helmut Schmidt University/University of the Federal Armed Forces Hamburg)Kathrin Welker (TU Bergakademie Freiberg)Winnifried Wollner (University of Hamburg)
Abstract : The concept of smooth phase fields has been used successfully to predict fracture propagation. However, it usually requires minimum two regularization parameters to be tuned. We present a novel approach for numerical fracture simulation which avoids the usage of phase fields. Instead, an objective functional that drives the evolution of the fracture is minimized with shape optimization techniques. We present the mathematical approach and numerical results for various commonly-used benchmarks.

[00246] Numerical modeling of crack propagation in concrete by means of cohesive zone modeling and a novel phase-field fracture approach

Format : Talk at Waseda University
Author(s) : Rasoul Najafi Koopas (Helmut-Schmidt University)
Abstract : Two methodologies are developed for analyzing failure initiation and crack propagation in the highly inhomogeneous concrete mesostructure. By implementing efficient algorithms in Python, geometric features are

generated and packed into a continuous phase. In the case of concrete, the continuous phase represents the mortar matrix, while the geometric features are the aggregates and voids of different sizes distributed randomly within the mortar matrix to represent the complex two-dimensional mesostructures of the concrete. The failure initiation and crack propagation of mesoscale concrete specimens are investigated using two different approaches, namely the Cohesive Zone Model and a novel Phase-Field fracture model. In the first approach, crack propagation is realized by generating zero-thickness Cohesive Interface Elements at the interfaces of solid elements. For this purpose, two-dimensional cohesive interface elements are generated (i) within the constituent elements of the mortar matrix, (ii) within the elements constituting the aggregates, and (iii) at the Interfacial Transition Zone. Hence, all potential crack paths are simulated by assigning different Traction Separation laws to the cohesive interface elements generated in different regions of the mesoscale concrete specimen. In the second approach, a novel cohesive phase-field is developed by incorporating the idea proposed by Wu and Nguyen (2018) and Geelen et al. (2019) in which by a group of optimal characteristic functions, a phase-field regularized cohesive zone model with linear softening law is realized and applied to brittle fracture. Moreover, the implemented cohesive phase-field fracture is insensitive to the length scale parameter, which allows the use of a relatively coarser mesh, thereby significantly reducing the computational cost $[3]$. A series of mesoscale concrete specimens with identical properties $(volume density, size distribution, and aggregate shape)$ are simulated using the above approaches and the predicted crack paths are compared with each other.

[00231] Sequential subspace optimization for recovering stored-energy functions in hyperelastic materials

Format : Talk at Waseda University
Author(s) : Lukas Vierus (Saarland University)Rebecca Rothermel (Saarland University)Thomas Schuster (Saarland University)Anne Wald (University of Göttingen)
Abstract : Structural Health Monitoring demands for an efficient computation of parameters which characterize the mechanical behavior of elastic materials. Hyperelasticity describes a nonlinear elastic behavior where the second Piola-Kirchhoff stress tensor is given as a derivative of a scalar function representing the stored strain energy that encodes all mechanical properties of the underlying material. The mathematical model is represented by a high-dimensional parameter identification problem for a nonlinear, hyperbolic system with given initial and boundary values. We present an iterative method based on sequential subspace optimization leading to a significant acceleration compared to the Landweber method.

00151 (2/2) : 4D @F403 [Chair: Natalie Rauter]

[00230] A low power autonomous SHM node for aerospace applications

Format : Talk at Waseda University
Author(s) : Carol Featherston (School of Engineering, Cardiff University)Rhys Pullin (School of Engineering, Cardiff University)Stepehn Griggs (School of Engineering, Cardiff University)Matthew Pearson (School of Engineering, Cardiff University)
Abstract : Acoustic emission(AE) monitors the release of energy resulting from the growth of damage to determine structural integrity. It is difficult to apply in low-power systems as sensors must either be wired together or time synchronised, which is power intensive. A method based on three piezoelectric sensors in a small triangular array is proposed. Hardware is developed and the feasibility of powering the unit through energy harvesting explored. Results are obtained for a complex composite structure.

[00270] Damage parameter estimation in composite materials using data assimilation with reduced order models

Format : Online Talk on Zoom
Author(s) : Nanda Kishore Bellam Muralidhar (TU Braunschweig)Carmen Gräßle (TU Braunschweig)Natalie Rauter (HSU Hamburg)Rolf Lammering (HSU Hamburg)Andrey Mikhaylenko (HSU Hamburg)Dirk Lorenz (TU Braunschweig)
Abstract : In this work, we are concerned with estimating parameters that describe damage in composite materials. In particular, we consider fiber metal laminates which consist of metals and fiber reinforced plastics. Such materials are of great interest in e.g. aviation and automotive industries. We study structural health monitoring using guided ultrasonic waves utilizing an integrated sensor. In order to determine the damage parameters, we use techniques from Bayesian

inference and data assimilation together with model order reduction which enables to alleviate the computational efforts. Numerical simulations illustrate the approaches.

[00256] Coefficient Control for Variational Inequalities

Format : Talk at Waseda University
Author(s) : Nicolai Simon (Universität Hamburg)Winnifried Wollner (Universität Hamburg)
Abstract : We consider the effects of introducing a control variable into the coefficients of a variational inequality in an optimal control problem with complementarity constraints.
The novelty of this talk is the utilization of H-convergence methods to formulate limit arguments as the basis for a bootstrapping approach, used to prove strong L^p convergence of the coefficient control variable. Using the example of an obstacle problem, we compute a set of limiting optimality conditions using these arguments.

[00269] Optimal sparse sensor location for structural health monitoring

Format : Online Talk on Zoom
Author(s) : Olga Weiß (Helmut Schmidt University/ University of the Federal Armed Forces Hamburg)Kathrin Welker (TU Bergakademie Freiberg)Volker Schulz (Trier University)
Abstract : Bridge structures are indispensable components of the infrastructure of modern industrial societies, and maintaining their functionality and reliability is essential.
Hence, monitoring processes of the structure and health of bridges are indispensable. For this purpose, the efficient and optimal placement of appropriate sensors for the non-destructive permanent monitoring of the structures is an important component.
Determining the number and placement of sensors to provide valuable information about damage and impact to the structure is essential for cost-efficient monitoring and for minimizing the volume of data, however, to this date represents a challenge.

We consider this issue from a mathematical point of view and derive a suitable optimization problem in infinite-dimensional function spaces. This modeled optimization problem is to be solved numerically by adapted optimization methods. As a special feature, the desired resulting sparsity of the solution for the positioning of the sensors is to be incorporated and considered in the solving method.

[00153] Recent Advances on Inverse Analysis

Session Time & Room : 1E (Aug.21, 17:40-19:20) @E811

Type : Proposal of Minisymposium
Abstract : In inverse analysis, unknown design variables and parameters are calculated so as to satisfy observed values and design standard values, and this kind of analysis is widely performed in design problems, i.e., shape optimization and topology optimization problems, and parameter identification problems. The adjoint variable method, the direct differentiation method, the Kalman filter, etc. are generally employed to solve these problems. However, the solution may not be appropriately calculated unless special methods are used. In this mini symposium, the purpose is to discuss new numerical methods and considerations to solve problems in inverse analysis.
Organizer(s) : Takahiko Kurahashi, Jin-Xing Shi, Masayuki Kishida, Eiji Katamine
Classification : 74P05, 65K10, 37N10, 74F10, Inverse Analysis
Minisymposium Program :

00153 (1/1) : 1E @E811 [Chair: Takahiko Kurahashi]

[01421] Tidal current estimation based on the extended Kalman filter FEM

Format : Talk at Waseda University
Author(s) : Takahiko Kurahashi (Nagaoka University of Technology)
Abstract : In this presentation, some numerical results of tidal current estimation analysis for Tokyo bay model will be shown. The shallow water equation is introduced as the governing equation, and the discretized equation is employed as the system equation in the extended Kalman filter FEM. Numerical results will be compared with the result based on the normal Kalman filter FEM, and the superiority of extended Kalman filter FEM will be shown.

[01427] Optimal shape design of auxetic structures with periodicity

Format : Talk at Waseda University
Author(s) : Jin-Xing Shi (Komatsu University)
Abstract : Auxetic structures indicate structures with negative Poisson's ratio. To achieve their best auxetic performance, in this work, optimal shape design of periodic auxetic structures is performed for identification of the negative Poisson's ratio based on a gradient-based shape optimization method and the homogenization method. Numerical design examples are given to confirm the validity and efficiency of the proposed optimization approach. The present work aims to help design auxetic structures in industrial applications.

[01428] Density-based topology optimization using a modified optimality criteria method

Format : Online Talk on Zoom
Author(s) : Masayuki Kishida (National Institute of Technology (KOSEN), Gifu College)Takahiko Kurahashi (Nagaoka University of Technology)
Abstract : In this study, we present the density-based topology optimization for minimizing equivalent stress using our developed modified optimality criteria method. The method is an update method for density that incorporates the concepts of Newton's method for the conventional optimality criteria method. The number of arbitrary constants required for topology optimization can be reduced by using our proposed method. In this presentation, p-norm is employed for the performance function and several numerical results will be presented.

[03034] Shape Design Problems Considering Fluid-Structure-Interactive Fields

Format : Talk at Waseda University
Author(s) : Eiji Katamine (National Institute of Technology, Gifu College)Yashushi Yoshida (Gifu University)
Abstract : This paper presents numerical solution to a shape design of stationary fluid-structure-interactive fields. The minimization problem for total dissipation energy in the viscous flow field and the mean compliance minimization problem in order to achieve stiffness maximization in the structural field are considered for the shape optimization. Numerical analysis program for the shape design is developed by using FreeFEM, and the validity of proposed method is confirmed by results of 2D numerical analyses.

[00154] Homogenization of PDEs in domains with oscillating boundaries or interfaces

Session Time & Room :

00154 (1/2) : 2D (Aug.22, 15:30-17:10) @F312

00154 (2/2) : 2E (Aug.22, 17:40-19:20) @F312

Type : Proposal of Minisymposium
Abstract : Homogenization is a mathematical way of understanding microscopic structure via macroscopic medium and hence has enormous applications in science and engineering fields, including material science, as heat diffusion, fluid flows, deformations, and biological applications as electrical conduction in tissues like nerve or hearth fibers. In this symposium, we consider two types of closely related homogenization problems: complex domains consisting of a fixed part and a rapidly oscillating part, and domains with oscillating interfaces with jump-conditions.
The aim of this minisymposium is to present recent results in these two important subjects by known specialists worldwide, and allow discussions opening new directions.

[00392] Asymptotic analysis of a parabolic problem with a rough fast oscillating interface

Format : Talk at Waseda University

Author(s) : Patrizia Donato (Univ Rouen Normandie, France)Editha Carreon Jose (University of the Philippines Los Banos)Daniel Onofrei (University of Houston)

Abstract : In this talk, we will discuss the well posedness and prove several homogenization results for a parabolic problem with an imperfect contact on the rough fast oscillating interface separating a domain occupied by heterogeneous materials. The complexity of the domain geometry and the imperfect contact on the interface create interesting multiscale phenomena with different macroscale behaviors depending on model parameters.

[00417] A decomposition result for thin domains with rough boundary

Format : Talk at Waseda University

Author(s) : Juan Casado-Díaz (University of Seville)Manuel Luna-Laynez (University of Seville)Francisco Javier Suárez-Grau (University of Seville)

Abstract : We prove a decomposition result for the pressure of a fluid in a thin domain. This result extends to the linear elasticity framework, providing better estimates for the Korn constant and fine decompositions for the elastic deformations. We show how these results, which give additional compactness properties, apply to study the asymptotic behaviour of some problems in fluid mechanics and elasticity, posed in thin domains with rough boundaries.

[00412] Derivation of coupled Stokes-Plate-Equations for fluid flow through thin porous elastic layers

Format : Online Talk on Zoom

Author(s) : Maria Neuss-Radu (Friedrich-Alexander-Universität Erlangen-Nürnberg)Markus Gahn (University Heidelberg)Willi J"ager (University Heidelberg)

Abstract : We consider two fluid-filled bulk domains separated by a thin porous elastic layer with thickness and periodicity ϵ. The fluid flow is described by an instationary Stokes-system, and the solid via linear elasticity. By rigorous homogenization and dimension reduction methods, we derive for $\epsilon \to 0$ an effective model consisting of the Stokes-equations in the bulk domains coupled to a time dependent plate equation with homogenized coefficients on the effective interface separating the bulk regions.

[00416] Homogenization of a two-component domain with an oscillating thick interface

Format : Online Talk on Zoom

Author(s) : Klas Pettersson (Freelance)Patrizia Donato (Univ Rouen Normandie, France)

Abstract : The homogenization of an elliptic boundary value problem is considered in a finite cylindrical domain that consists of two components separated by a periodically oscillating thick interface. On the interface, the flux is assumed to be continuous, and the jump of the solution to be proportional to the flux through the interface. By means of the periodic unfolding method, we derive the homogenized system, and prove the convergence of the solutions and their energies.

00154 (2/2) : 2E @F312 [Chair: Akambadath K. Nandakumaran]

[00402] Heat conduction in composite media involving imperfect contact conditions

Format : Online Talk on Zoom

Author(s) : Micol Amar (Sapienza Università di Roma)Daniele Andreucci (Sapienza Università di Roma)Claudia Timofte (University of Bucharest)

Abstract : We present a model which exhibit simultaneously jumps in the solution and in the flux, involving also the mean average of the physical fields representing the different phases. The starting model is a composite made by a hosting medium containing a periodic array of inclusions of small size, coated by a thin layer made by two different materials, one encapsulated in the other. The smallness of the thin layer leads us to perform first a two-step concentration procedure. The periodic structure leads to a homogenization limit, in order to achieve a macroscopic description.

[00399] Homogenization by unfolding of a Bingham fluid in a thin domain with rough boundary

Format : Online Talk on Zoom
Author(s) : Carmen Perugia (Department of Science and Technology, University of Sannio)Manuel Villanueva-Pesqueira (Universidad Pontificia Comillas)Giuseppe Cardone (University of Naples "Federico II")
Abstract : We consider a Bingham flow in a thin domain with rough boundary and with no-slip boundary condition on the whole boundary of the domain. By using an adapted linear unfolding operator we perform a detailed analysis of the asymptotic behavior of the Bingham flow when thickness of the domain and roughness periodicity tends to zero. We obtain the homogenized problem for the velocity and the pressure, which preserves the nonlinear character of the flow.

[00401] Homogenization of Stokes system with Neumann condition on highly oscillating boundary

Format : Talk at Waseda University
Author(s) : Bidhan Chandra Sardar (Indian Institute of Technology Ropar)
Abstract : We consider the steady Stokes system in a n-dimensional domain Ω_ε with a rapidly oscillating $(n-1)$ dimensional boundary prescribed with Neumann boundary condition and periodicity along the lateral sides is considered. We aim to study the limiting analysis $(as\ \varepsilon \to 0)$ of the steady Stokes problem and identify the limit problem in a fixed domain. Finally, show the weak convergences of velocities are improved to strong convergence by introducing corrector terms.

[00407] Fluids with a non-slip condition on a non-periodic oscillating boundary

Format : Talk at Waseda University
Author(s) : Juan Casado-Díaz (University of Seville)Manuel Luna-Laynez (University of Seville)
Abstract : It is known that a viscous fluid with a non-slip condition on a rough boundary behaves as if an adherence condition is imposed. This is the case for a boundary given by $x_3 = \delta_\varepsilon \psi(x_1/\varepsilon, x_2/\varepsilon)$, ψ periodic, and $\delta_\varepsilon/\varepsilon^{\frac{3}{2}}$ tending to infinity. The rugosity has not effect if it tends to zero. In the critical case a new zero order term appears in the boundary condition. Here, we extend these results to non-periodic boundaries.

Session Time & Room :

00164 (1/3) : 2C (Aug.22, 13:20-15:00) @G801

00164 (2/3) : 2D (Aug.22, 15:30-17:10) @G801

00164 (3/3) : 2E (Aug.22, 17:40-19:20) @G801

Type : Proposal of Minisymposium
Abstract : In recent years, there has been a tremendous growth of activity in developing methods for materials-related phenomena occurring over multiple scales in time and space. This minisymposium focuses on multiscale modeling, analysis, and simulation of the problems arising in composites and other heterogeneous media. In particular, topics that will be discussed include but are not limited to asymptotic analysis such as homogenization, modeling of new materials, inverse problems, and computational tools. The purpose of this minisymposium is to encourage the exchange of ideas and networking among researchers working on the topics mentioned above.

Organizer(s) : Lyudmyla Barannyk, Silvia Jimenez Bolanos, Yvonne OuSponsor : This session is sponsored by the SIAM Activity Group on Mathematical Aspects of Materials Science.
Classification : 35Qxx, 74Qxx, 74Rxx, 80Axx, 78Mxx
Minisymposium Program :

00164 (1/3) : 2C @G801 [Chair: Lyudmyla Barannyk]

[00473] Bloch Waves in High Contrast Electromagnetic Crystals

Author(s) : Silvia Jimenez Bolanos (Colgate University)Robert Lipton (Louisiana State University)Robert Viator (Swarthmore College)Abiti Adili (University of Massachusetts Lowell)
Abstract : In this talk, we present the derivation of analytic representation formulas and power series describing the band structure inside non-magnetic periodic photonic crystals, made from high dielectric contrast inclusions. We identify a resonance spectrum for quasi-periodic source-free modes, which are used to represent solution operators associated with electromagnetic and acoustic waves inside periodic high-contrast media. A convergent power series for the Bloch wave spectrum is obtained from the representation formulas and explicit conditions on the contrast are found that provide lower bounds on the convergence radius. These conditions are sufficient for the separation of spectral branches of the dispersion relation for any fixed quasi-momentum.

[00483] An axisymmetric problem for a nano-sized material surface on a boundary of an elastic semi-space

Author(s) : Anna Zemlyanova (Kansas State University)
Abstract : An axisymmetric problem for a nano-sized penny-shaped material surface attached to the boundary of an elastic isotropic semi-space is considered. The surface is modeled using the Steigmann-Ogden form of surface energy. The problem is solved by using the Boussinesq potentials and Hankel transforms. The problem can be reduced to a system of two singular integral equations. This is a joint work with Lauren M. White.

[00569] Clusters of Bloch waves in three-dimensional periodic media

Author(s) : Yuri Godin (University of North Carolina at Charlotte)
Abstract : We consider acoustic wave propagation through a periodic array of small inclusions of arbitrary shape. The inclusion size is much smaller than the array period while the wavelength is fixed. We derive and rigorously justify the dispersion relation for general frequencies and show that there are exceptional frequencies for which the solution is a cluster of waves propagating in different directions with different frequencies so that the dispersion relation cannot be defined uniquely. The results are illustrated by an example of a medium with a simple cubic lattice of spherical inclusions where we derived the dispersion relation, determine the parameters of the effective medium, and provided examples of some clusters. This is joint work with B. Vainberg.

[00588] Modeling sea ice as a multiscale composite material

Author(s) : Kenneth Morgan Golden (University of Utah)
Abstract : Sea ice exhibits composite structure on length scales ranging over many orders of magnitude. Forward and inverse homogenization are central to modeling sea ice and its role in climate and ecosystems. We'll tour recent advances, from the fractal geometry of millimeter-scale brine inclusions and meter-scale melt ponds, to the homogenized dynamics of the marginal ice zone on the scale of the Arctic Ocean. We'll also explore spectral representations for effective parameters in several contexts.

00164 (2/3) : 2D @G801 [Chair: Yvonne Ou]

[00596] Forward and inverse homogenization for quasiperiodic composites

Author(s) : Elena Cherkaev (University of Utah)Sébastien Guenneau (Imperial College London)Niklas Wellander (Swedish Defence Research Agency)
Abstract : From quasicrystalline alloys to twisted bilayer graphene, materials with a quasiperiodic structure exhibit unusual properties that drastically differ from those with periodic structures. Quasiperiodic geometries can be modeled using the cut-and-projection method restricting a periodic function in a higher-dimensional space to a lower-dimensional subspace cut at an irrational projection angle. The talk will discuss the homogenized equations for quasiperiodic materials and an inverse problem of recovering information about microstructural parameters from known effective properties.

[00609] Studying Stefan problems with internal heat generation using sharp interface models

Format : Talk at Waseda University
Author(s) : Lyudmyla L. Barannyk (University of Idaho)John C. Crepeau (University of Idaho)Patrick Paulus (University of Idaho)Alexey Sakhnov (Kutateladze Institute of Thermophysics SB RAS)Sidney D. V. Williams (Georgia Institute of Technology)
Abstract : We study the evolution of the solid-liquid interface during melting and solidification of a material with constant internal heat generation with prescribed temperature and heat flux conditions at the boundary of an infinite

cylinder. We derive a nonlinear differential equation for the motion of the interface, which involves Fourier-Bessel series. The problem is also solved numerically by the front catching into a space grid node method as well as the enthalpy-porosity method to validate results.

[00623] Capturing Quasistatic Fracture Evolution with Nonlocal Models

Author(s) : Robert Lipton (Louisiana State University)Debdeep Bhattacharya (Louisiana State University)
Abstract : Nonllocal quasistatic fracture evolution for interacting cracks is developed. The approach is implicit and based on local stationarity and fixed point methods. It is proved that the fracture evolution decreases the stored elastic energy with each load step; provided the load increments are taken sufficiently small. Existence theory for the fracture evolution is proved rigorously. Numerical examples include capturing the crack path propagating inside an L-shaped domain, and two offset inward propagating cracks.

[00631] The Lippmann Schwinger Lanczos algorithm for inverse scattering problems

Author(s) : Shari Moskow (Drexel University)Vladimir Druskin (WPI)Mikhail Zaslavsky (Southern Methodist University)
Abstract : We combine data-driven reduced order models with the Lippmann- Schwinger integral equation to produce a direct nonlinear inversion method. The ROM is viewed as a Galerkin projection and is sparse due to Lanczos orthogonalization. Embedding into the continuous problem, a data-driven internal solution is produced. This internal solution is then used in the Lippmann-Schwinger equation, in a direct or iterative framework. The approach also allows us to process more general transfer functions, i.e., to remove the main limitation of the earlier versions of the ROM based inversion algorithms. We also describe how the generation of internal solutions simplifies in the time domain and give examples of its use given mono static data, targeting synthetic aperture radar.

00164 (3/3) : 2E @G801 [Chair: Silvia Jimenez Bolanos]

[00647] Uncertainty quantification for stochastic models of damage mechanics

Author(s) : Petr Plechac (University of Delaware)Gideon Simpson (l University)Jerome R Troy (University of Delaware)
Abstract : We study models used for describing brittle materials which exhibit linear elastic behavior until an applied load reaches a critical yield stress at which point a damage/fracture occurs . The underlying visco-elasto dynamics PDEs are characterized by a non-monotone stress-strain relation with a non-linearity linked to the critical yield stress. We study these equations in the presence of random yield stress field. The developed computational techniques will be demonstrated in numerical examples.

[00649] On the governing equations of poro-piezoelectric composite materials

Author(s) : Miao-Jung Yvonne Ou (University of Delaware)
Abstract : Materials such as quartz, cortical bones and cancellous bones exhibit piezo-electric behaviors, for which a mechanical wave such as ultrasound can trigger electro-magnetic waves. In this talk, we consider a porous material made of piezo-electric solid with pores saturated with conducting fluid, a model mimicking in vivo bones. The focus is to understand how the microstructure is encoded in the effective piezoelectric properties of these porous composites by using the two-scale convergence homogenization approach.

[01237] Homogenization of a suspension of viscous fluid with magnetic particles

Author(s) : Yuliya Gorb (NSF)Thuyen Dang (University of Chicago)Silvia Jimenez Bolanos (Colgate University)
Abstract : In this talk, the rigorous periodic homogenization for a coupled system, which models a suspension of magnetizable rigid particles in a non-conducting carrier viscous Newtonian fluid is discussed. Both one-way and two-way coupling between the fluid and particles are considered. As the size of the particles approaches zero, it is shown that the suspension’s behavior is governed by a generalized homogenized magnetohydrodynamic system, whose parameters are explicitly derived. The two-scale convergence is utilized to justify obtained homogenized behavior of the original heterogeneous system.

[05177] Energy-efficient flocking of particle systems

Author(s) : Alexander Panchenko (Washington State University)
Abstract : The talk explores the problem of achieving flocking in multi-agent systems using minimal amount of on-board energy.
We also assume that censor capacity is limited. Starting from a model reminiscent of Dissipative Particle Dynamics augmented with self-propulsion forces, we prove existence of an attractor for certain non-dissipative systems. Computer simulations show that velocity alignment is more energy efficient than formation control.

[00168] Applications of evolutionary algorithms in differential equation models

Session Time & Room :

00168 (1/2) : 1C (Aug.21, 13:20-15:00) @E811

00168 (2/2) : 1D (Aug.21, 15:30-17:10) @E811

Type : Proposal of Minisymposium
Abstract : Evolutionary algorithms (EAs) have been at the forefront of computational science in solving optimization problems arising from science and engineering. EAs gained popularity because of their capability to obtain global minimizers of non-smooth objective functions. In this minisymposium, we explore the applications of EAs in solving optimization problems arising from differential equation models. Recent techniques in unconstrained, constrained, and multi-objective EAs will be presented along with applications in parameter estimation and control of infectious disease models, medical image reconstruction in electrical impedance tomography, optimal placement of sensors of tsunami sensors, and other applications in engineering.

00168 (1/2) : 1C @E811

[03121] Spherical search with multi-operator differential evolution for constrained optimization problems

Format : Talk at Waseda University
Author(s) : Renier Mendoza (Institute of Mathematics, University of the Philippines Diliman)Jongmin Lee (Konkuk University)Victoria May Paguio Mendoza (University of the Philippines Diliman)Eunok Jung (Konkuk University)
Abstract : We propose a new method, SASS-MODE, for solving constrained optimization problems by combining the self-adaptive spherical search (SASS) with the improved multi-operator differential evolution (IMODE). We adapted IMODE to handle constraints with three modifications and tested our method on 57 benchmark problems and an optimal control problem from an infectious disease model. SASS-MODE outperforms recent algorithms and achieves state-of-the-art results.

[02925] Minimizing infections and intervention cost: multi-objective approach with user-friendly dashboard

Format : Talk at Waseda University
Author(s) : Jongmin Lee (Department of Mathematics, Konkuk University)Renier Mendoza (Institute of Mathematics, University of the Philippines Diliman)Victoria May P. Mendoza (Institute of Mathematics, University of the Philippines Diliman)Eunok Jung (Department of Mathematics, Konkuk University)
Abstract : During the COVID-19 pandemic, the world faces the challenge of reducing the number of infections while simultaneously minimizing the cost of intervention policies. This study proposes a deterministic model and multi-objective optimization approach that balances these conflicting objectives. Metropolis-Hastings algorithm estimated parameters, and the genetic algorithm found multi-objective optimization solutions. From Pareto solutions, users can select the most suitable solution by considering economic-related parameters. Additionally, we develop a user-friendly, web-based dashboard for ease of use.

[02755] Comparative Study of Heuristic Algorithms for Electrical Impedance Tomography

Format : Talk at Waseda University
Author(s) : Arrianne Crystal Velasco (Institute of Mathematics, University of the Philippines Diliman)Renier Mendoza (Institute of Mathematics, University of the Philippines Diliman)Marion Darbas (LAGA CNRS UMR 7539, University Sorbonne Paris Nord)Monica Bacon (Institute of Mathematics, University of the Philippines Diliman)Johm Cedrick de Leon (Institute of Mathematics, University of the Philippines Diliman)
Abstract : Based on electrical measurements from electrodes placed around the boundary of a body, electrical impedance tomography (EIT) is an imaging procedure that recovers the spatial distribution of the conductivities in the interior of a body. This work presents a study of the applicability of six heuristic algorithms for the EIT image reconstruction problem.

[03163] Bi-objective optimization considering bed capacity and timing of interventions

Format : Talk at Waseda University
Author(s) : Victoria May Paguio Mendoza (University of the Philippines Diliman)Renier Mendoza (Institute of Mathematics, University of the Philippines Diliman)Youngsuk Ko (Department of mathematics, Konkuk university)Jongmin Lee (Konkuk University)Eunok Jung (Konkuk University)
Abstract : Without vaccines and medicine, non-pharmaceutical interventions are the main strategy for controlling the spread of diseases. A bi-objective optimization problem is formulated that allows for the easing of restrictions at an earlier time and minimizes the number of additional beds ensuring sufficient capacity in healthcare facilities. We utilize a compartmental model that distinguishes mild from severe cases. The multiple optimal solutions of the bi-objective problem offer trade-off solutions that can be useful decision-support tools.

00168 (2/2) : 1D @E811 [Chair: Arrianne Crystal Velasco]

[00170] Integrable systems, orthogonal polynomials and asymptotics

Session Time & Room :

00170 (1/3) : 2C (Aug.22, 13:20-15:00) @G401

00170 (2/3) : 2D (Aug.22, 15:30-17:10) @G401

00170 (3/3) : 2E (Aug.22, 17:40-19:20) @G401

Type : Proposal of Minisymposium
Abstract : Interest in nonlinear dynamical systems has grown dramatically over the past half century. Profound advances have been fueled by the discovery of integrable systems that are applicable in a wide range of applications. In particular, nonlinear ODEs called the Painlev' equations model applications in many fields, in particular in random matrix theory and growth processes. Their appearance in quantum gravity and orthogonal polynomial theory has led to widening interest in integrable discrete versions of these equations. This minisymposium will bring together recent developments in integrable systems, orthogonal polynomials and asymptotics with a view to describing new special functions.

[05493] Welcome and Introduction

Format : Talk at Waseda University
Author(s) : Nalini Joshi (The University of Sydney)
Abstract : This talk will provide an overview of recent developments in integrable systems, orthogonal polynomials and asymptotics and the topics underlying the talks in this minisymposium.

[02937] Lagrangian multiform structure of discrete and semi-discrete KP typequations

Format : Talk at Waseda University
Author(s) : Frank Willem Nijhoff (University of Leeds)
Abstract : A brief review of of Lagrangian multiform theory for integrable discrete and continuous equations will be presented. As specific examples I will discuss the recently established 3-form structure of the KP hierarchy, and its discrete and semi-discrete counterparts.

[03500] Charge-conserving solutions to the constant Yang-Baxter equations

Format : Talk at Waseda University
Author(s) : Jarmo Hietarinta (University of Turku)Paul Martin (University of Leeds)Eric C. Rowell (Texas A&M University)
Abstract :
The Yang-Baxter equation is difficult to solve even in the constant form $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$ and a complete solution is known only for rank two. For further progress it is important to make a meaningful ansatz. Recently Martin and Rowell proposed charge-conservation as an effective constraint (arXiv:2112.04533). We explore the results obtained by a slightly different charge-conservation rule.

[03983] Stokes' phenomenon, discretization, and discrete integrability

Format : Talk at Waseda University
Author(s) : Christopher Lustri (Macquarie University)
Abstract : This talk is concerned with integrability in discrete systems, and its relationship with Stokes' phenomenon. Discrete equations such as the discrete Painleve I equation can be written in terms of an infinite-order differential equation. We will consider a family of equations obtained by truncating this infinite-order differential equation at different orders. In this talk we will answer two questions: (1) How does discretization connect the Stokes' phenomenon in continuous and discrete Painleve I? (2) How does integrability emerge in this family of equations in the discrete limit?

00170 (2/3) : 2D @G401 [Chair: Nalini Joshi]

[04872] On q-Painlevé VI and the geometry of affine Segre surfaces

Format : Talk at Waseda University
Author(s) : Pieter Roffelsen (University of Sydney)
Abstract : A famous result by M. Jimbo (1982) relates Painlevé VI to a family of affine cubic surfaces via the Riemann-Hilbert correspondence. In recent work with Nalini Joshi, a q-analog of this result was obtained, relating q-Painlevé VI to a family of affine Segre surfaces. I will explain this result and show how the geometry of these surfaces is reflected in the asymptotic expansions of solutions around the two critical points of q-Painlevé VI.

[04990] Deformed orthogonal functions and integrable lattices

Format : Talk at Waseda University
Author(s) : Xiangke Chang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Since the 1990s, the theory of orthogonal polynomials has been increasingly playing an important role in the studies of Toda type lattices, peakon dynamical systems of the Camassa-Holm type, as well as specific Painlevè equations. These integrable lattices can be derived according to deformations of orthogonal functions, directly or indirectly. This talk is devoted to exploring some of related works with focus on our recent results for some new orthogonality.

[05269] Borel analysis for the first difference q-Painlevé equation

Format : Talk at Waseda University
Author(s) : Adri Olde Daalhuis (The University of Edinburgh)
Abstract : We discuss the asymptotics of solutions of the first -difference q-Painlevé equation $w(qt)w^2(t)w(t/q) = w(t) - t$. Via the q-Borel transform we obtain an interesting singularity distribution in the Borel plane.

[05326] Non-linear Stokes phenomenon for Painleve transcendents and topological recursion

Format : Talk at Waseda University
Author(s) : Kohei Iwaki (The University of Tokyo)
Abstract : I will propose a conjectural statement on the Stokes phenomenon for the topological recursion partition function. Our claim is based on a relation between the topological recursion and the Painleve tau-function through the exact WKB analysis.

00170 (3/3) : 2E @G401 [Chair: Nobutaka Nakazono]

[05494] Orthogonal polynomials on elliptic curves and Painlevé VI equation.

Author(s) : Harini Desiraju (University of Sydney)Pieter Roffelsen (University of Sydney)Tomas Latimer (University of Sydney)
Abstract : Elliptic orthogonal polynomials are a family of special functions that satisfy certain orthogonality condition with respect to a weight function on an elliptic curve. Building up on several recent works on the topic, we establish a framework using Riemann-Hilbert problems to study such polynomials. When the weight function is constant, these polynomials relate to the elliptic form of the sixth Painleve equation. This talk is based on a recent work with Tomas Latimer and Pieter Roffelsen (arXiv: 2305.04404).

[05496] Asymptotic prediction of tau-function zeros of Painlevé equations

Author(s) : Ines Varela Aniceto (University of Southampton)
Abstract : Transseries solutions of Painlevé I and II equations include both algebraic asymptotic expansions and exponentially small corrections, valid in pole-free regions. In this talk I will show how summing all exponential terms at each algebraic order provides an analytic continuation into the pole-filled regions of the solutions, where exponentials are no longer suppressed. The same can done for the respective tau-functions to obtain asymptotic predictions for all the arrays of the tau-function zeros.

[05564] Riemann-HIlbert problem on the q-Painleve equations

Author(s) : Yousuke Ohyama (Tokushima University)
Abstract : We study monodromy spaces of q-Painleve equations. We apply the Riemann-Hilbert correspondence to analytic studies on q-Painleve equations.

[05591] A 3×3 Lax form for the q-P(E_6^{(1)})

Author(s) : Kanam Park (Toba college)
Abstract : For the q-Painlevé equation with the affine Weyl group symmetry of type E_6^{(1)}, a 2×2 matrix Lax form and a second order scalar lax form were known.
In this talk, we give a 3×3 matrix Lax form and a third order scalar equation related to it. We also give its continuous limit.
These Lax form and a scalar equation seems to be new.

[00172] On application of principle curvature distribution in local differential geometry

Session Time & Room : 1C (Aug.21, 13:20-15:00) @A508

Type : Proposal of Minisymposium
Abstract : Recently, shape has become increasingly crucial in device and materials science. In this symposium, we will focus on principal curvature distributions in differential geometry and discuss examples where the principal curvature distributions play a crucial role. We take particular note of the curved carbon nanotubes discovered in the 2000s, and the manufacturing methods of curved surfaces in shipbuilding and other applications. Both seem unrelated at first glance, but from an applied mathematical point of view, the principal curvature distribution is analyzed by utilizing common mathematics. This symposium aims to discuss these issues from the standpoint of local differential geometry.

[04166] Fullerene and discrete principal curvature

Format : Talk at Waseda University
Author(s) : Shigeki Matsutani (Kanazawa University)Yusuke Noda (Okayama Prefectural University)
Abstract : Due to geometrical investigations of the carbon configurations of the first principle computations, the novel symmetry in the fullerenes, i.e., the pre-constant discrete principal curvature (pCDPC) structure, was recently found.
In this talk, we show the symmetry mainly on the C60 polymers and related fullerenes from geometrical viewpoints.

[03759] Interplay between topology-induced geometry and the electronic properties of nanocarbon materials

Format : Talk at Waseda University
Author(s) : Jun Onoe (Nagoya University)
Abstract : The quantum mechanics in curved surface has been studied in 1950s and predicted that the electron behaviors are affected by Gaussian and average curvatures theoretically in 1980s. We have first demonstrated the quantum mechanics in submanihold experimentally using one-dimensional periodic uneven structured C60 polymer formed by electron-beam irradiation of C60 film.

[04350] On discrete constant principal curvature surfaces

Format : Online Talk on Zoom
Author(s) : Yuta Ogata (Kyoto Sangyo University)
Abstract : In this talk, we will study the discrete surface theory on a full 3-ary oriented tree and introduce the notion of discrete principal curvatures on them. In order to investigate the geometric meaning of discrete principal curvatures, we will also define a discrete analog of curvature lines on discrete surfaces, called weak-curvature lines. At the end of the talk, we also show some examples of discrete constant principal curvature surfaces.

[04368] Surface parametrization for manufacturing by principal curvature integral

Format : Online Talk on Zoom
Author(s) : Yutaro Kabata (Nagasaki University)
Abstract : The choice of coordinates is crucial in the theory of curves and surfaces. In this presentation, we discuss the appropriate way to choose coordinates for curves and surfaces from a manufacturing perspective. Specifically, we define coordinates obtained from the integration of curvature for curves and principal curvatures for surfaces, and present results related to the stratification of curves and surfaces obtained from these coordinates.

[00176] Hyperbolic PDEs modelling non-Newtonian fluid flows

Session Time & Room : 5B (Aug.25, 10:40-12:20) @G605

Type : Proposal of Minisymposium
Abstract : Since the beginning of continuum mechanics, the need to improve quantitative predictions of non-Newtonian flows continues.
The simulation of turbulence or of complex (non-homogeneous) fluids using good PDEs, in particular, remains an unsatisfied goal.
A major challenge is how to conciliate the conservation principles funding physics with quantitative observations.
A natural approach is to add dissipative relaxation terms in the hyperbolic PDEs resulting of conservation laws.
The goal of the minisymposium is to confront recent advances, with promising theoretical or numerical results, regarding hyperbolic PDEs plus relaxation sources for various non-Newtonian fluid flows.

[00332] Well-posedness and asymtotic behavior for hyperbolized compressible Navier-Stokes equations

Author(s) : Yuxi Hu (China University of Mining and Technology, Beijing)
Abstract : We consider the non-isentropic compressible Navier-Stokes equations (CNS) for which the heat conduction of Fourier's law is replaced by Cattaneo's law and the classical Newtonian flow is replaced by a revised Maxwell flow. We shall present our recent results on global well-posedness, finite time blow-up and asymptotic behaviour of solutions. Some quality behaviour of solutions are shown to be changed, i.e., Global existence VS blowup in finite time, between the classical CNS and the studied hyperbolized model, although the solutions of two system are quite close to each other for small relaxation parameter.

[00503] Structure preserving finite element schemes for a non-Newtonian flow

Author(s) : Gabriel R. Barrenechea (University of Strathclyde, Glasgow, UK)Tristan Pryer (University of Bath)Emmanuil Georgoulis (Heriot-Watt University)
Abstract : We propose a finite element discretisation of a three-dimensional non-Newtonian flow whose dynamics are described by an Upper Convected Maxwell model. The scheme preserves structure in the sense that the velocity is divergence-free and the overall discretisation is energy consistent with the underlying problem. We investigate the problem's complexity and devise relevant timestepping strategies for effcient solution realisation. We showcase the method with several numerical experiments, confirm the theory and demonstrate the efficiency of the scheme.

[00918] Temporal discretisation of non-Newtonian fluid flows

Author(s) : Ben Ashby (Heriot-Watt University, Edinburgh, UK)Tristan Pryer (University of Bath)Gabriel Barrenechea (University of Strathclyde, Glasgow)Emmanuil Georgoulis (Heriot-Watt University, UK & National Technical University of Athens, Greece)
Abstract : Choice of discretisation of the constitutive law for the stress in a non-Newtonian fluid is crucial for the success of any numerical method. We propose a new methodology for temporal discretisations of some non-Newtonian flows with the aim of preserving flow structure. We show that for models where both differential and integral constitutive laws are available, such as Oldroyd-B, a correspondence can be found between discretisations of both.

[04850] New symmetric-hyperbolic PDEs for viscoelastic fluid flows

Author(s) : Sébastien Julien Boyaval (Ecole des Ponts ParisTech)
Abstract : Many Partial Differential Equations (PDEs) have been proposed to model viscoelastic flows, in between fluids and solids.
Seminal hyperbolic PDEs with stress relaxation have been proposed by Maxwell in 1867 to ensure propagation of 1D shear waves at finite-speed while capturing the viscosity of real fluid continua.
But actual computations of multi-dimensional viscoelastic flows using Maxwell's PDEs have remained limited,
at least without additional diffusion that blurs the hyperbolic character of Maxwell's PDEs.
We propose a new system of PDEs to model 3D viscoelastic flows of Maxwell fluids.
Our system, quasilinear and symmetric-hyperbolic, unequivocally models smooth flows on small times, while ensuring propagation of waves at finite-speed.
Our system rigorously unifies fluid models with elastodynamics for compressible solids,
and it can be extended for applications in environmental hydraulics (shallow-water flows) or materials engineering (non-isothermal flows).

[00178] Theoretical and Computational Progress on PDE-based Inverse Problems with Applications

Session Time & Room :

00178 (1/3) : 2C (Aug.22, 13:20-15:00) @G808

00178 (2/3) : 2D (Aug.22, 15:30-17:10) @G808

00178 (3/3) : 2E (Aug.22, 17:40-19:20) @G808

Type : Proposal of Minisymposium

Abstract : Inverse problems for partial differential equations (PDEs) concern recovery of unknown coefficients or geometries/topologies within the equations by knowledge of certain observables. These problems sit at the intersection of mathematical analysis, PDE theory, and scientific computing, with broader application to modern imaging science and technology.

This minisymposium aims to highlight recent advances in inverse problems for PDEs. It will bring together international scientific researchers to discuss recent developments and emerging challenges in this fast-evolving field. Major topics include (1) inverse problems in wave-based imaging; (2) inverse scattering theory; (3) data-driven inverse methods, and their applications to medical and geophysical imaging.

[00556] Deterministic-Statistical Approach for Inverse Problems with Partial Data

Format : Online Talk on Zoom
Author(s) : Jiguang Sun (Michigan Technological University)
Abstract : We propose a deterministic-statistical approach for inverse problems with partial data. Certain deterministic method is first used to obtain useful (qualitative) information for the unknowns. Then the inverse problem is recast as a statistical inference problem and the Bayesian inversion is employed to obtain more (quantitative) information of the unknowns. Several examples are presented for demonstration. Furthermore, we introduce new statistical estimators to characterize the non-unique solutions of several inverse problems.

[00553] Quantitative PAT with simplified PN approximation

Format : Online Talk on Zoom
Author(s) : Yimin Zhong (Auburn University)Hongkai Zhao (Duke University)
Abstract : The photoacoustic tomography (PAT) is a hybrid modality that combines the optics and acoustics to obtain high resolution and high contrast imaging of heterogeneous media. In this work, our objective is to study the inverse problem in the quantitative step of PAT which aims to reconstruct the optical coefficients of the governing radiative transport equation from the ultrasound measurements. In our analysis, we take the simplified P N approximation of the radiative transport equation as the physical model and then show the uniqueness and stability for this modified inverse problem. Numerical simulations based on synthetic data are presented to validate our analysis.

[02856] Adaptive Mesh-free Approach for Gravity Inversion

Format : Talk at Waseda University
Author(s) : Yan Liu (Chinese Academy of Geological Sciences)
Abstract : We proposes a method of gravity inversion based on an adaptive mesh-free approach by using a modified radial basis function. As the subsurface space is generally discretized into regular grid cells, and this unstructured nodal discretization bring the expensive mesh generation and manipulation, we use a mesh-free discretization strategy to establish a mapping of subsurface grid cells to a cloud of discrete points. The nodes are adaptively refined during the inversion process to better recover abnormal bodies. In addition, the hybrid basis function and the modified radial basis function are used to improve the accuracy and stability of the solution.

[00358] A neural network method for inverse source problem with limited-aperture data

Format : Talk at Waseda University
Author(s) : Weishi Yin (Changchun University of Science and Technology)Ping Zhang (Changchun University of Science and Technology)Pinchao Meng (Changchun University of Science and Technology)Hongyu Liu (City University of Hong Kong)
Abstract : This talk is concerned with an inverse moving source problem, that is, one identifies and predicts
the trajectory of a moving point source by measuring the corresponding wave field. First, for the practical consideration,the dynamical wave field data are collected in a limited aperture and full aperture respectively. Second, we design a parameter inversion model by neural network to reconstruct the trajectory of the moving point source. This model solves the problem of information loss caused by data acquisition in limited aperture and has certain robustness with respect to noise. Third, we consider the trajectory prediction of the moving point source for the inverse source problem associated with the novel input/instruction approach, and construct a trajectory prediction model by neural

network to predict the trajectory of the moving point source. Numerical experiments show that the proposed device works effectively and efficiently in some practical scenarios.

00178 (2/3) : 2D @G808 [Chair: Hongyu Liu]

[00236] On plasmon modes in multi-layer structures

Format : Talk at Waseda University
Author(s) : Youjun Deng (Central South University)
Abstract : We consider the plasmon resonances in multi-layer structures. We show the plasmon modes are equivalent to the eigenvalue problem of a matrix, whose order is the same to the number of layers. For any number of layers, the exact characteristic polynomial is derived by a conjecture, which is verified by using induction. It is shown that all the solutions to the characteristic polynomial are real and exist in the span [-1, 2]. Numerical examples are presented for finding all the plasmon modes.

[00405] Uniqueness and non-uniqueness for inverse source problems of elliptic equations

Format : Talk at Waseda University
Author(s) : Yi-Hsuan Lin (Department of Applied Mathematics, National Yang Ming Chiao Tung University)
Abstract : We study inverse source problems associated to second order elliptic equations on a bounded domain. We demonstrate both uniqueness and non-uniqueness for inverse source problems of different type elliptic equations.

[00361] Mathematical analysis of microscale hydrodynamic cloaking and shielding using electro-osmosis

Format : Talk at Waseda University
Author(s) : Guang-Hui Zheng (Hunan University)
Abstract : Rendering objects invisible by cloaking them with metamaterials have made rapid progress in the past decade. However, the difficulties of metamaterials manufacturing have limited its development. In this talk, we discuss the mathematical analysis of hydrodynamic cloaking and shielding via electro-osmosis in a microfluidic chamber that does not rely on metamaterials. Based on layer potential technique, the conditions that can ensure the occurrence of the microscale hydrodynamic cloaking and shielding are established. Finally, several numerical examples are served to validate our theoretical analysis. (joint works with Hongyu Liu (CityU) and Zhiqiang Miao (HNU))

[00920] Regularizing Effect of Damping Mechanisms in Inverse Problems of Evolution Equations

Format : Talk at Waseda University
Author(s) : Sakthivel Kumarasamy (Indian Institute of Space Science and Technology)Alemdar Hasanov Hasanoglu (Kocaeli University, Turkey)Anjuna Dileep (Indian Institute of Space Science and Technology)
Abstract : It is known that the undamped evolution models, such as the Euler-Bernoulli beam, and Kirchhoff-Love plate, don't support the unique determination of unknown spatial load from the measured displacement at the final time. We solve this issue by introducing the viscous external damping and Kelvin-Voigt damping effects in the basic governing equations. The damping terms play a pivotal role in getting more regular solutions with less regular data on the direct problem, while in the context of inverse problems, it has a similar effect to a regularization term in the Tikhonov functional of the quasi-solution approach.

00178 (3/3) : 2E @G808 [Chair: Yang Yang]

[00359] A NOVEL QUANTITATIVE INVERSE SCATTERING SCHEME USING INTERIOR RESONANT MODES

Format : Talk at Waseda University
Author(s) : Xianchao Wang (Harbin Institute of Technology)
Abstract : In this talk, we introduce a novel quantitative imaging scheme to identify impenetrable obstacles in time-harmonic acoustic scattering from the associated far-field data. The proposed method consists of two phases. In the first phase, we determine the interior eigenvalues of the underlying unknown obstacle from the far-field data via the indicating behaviour of the linear sampling method. Then we further determine the associated interior eigenfunctions by solving a constrained optimization problem, again only involving the far-field data. In the second phase, we propose a novel iteration scheme of Newton's type to identify the boundary surface of the obstacle. By using the interior eigenfunctions determined in the first phase, we can avoid computing any direct scattering problem at each Newton's

iteration. The proposed method is particularly valuable for recovering a sound-hard obstacle, where the Newton's formula involves the geometric quantities of the unknown boundary surface in a natural way.

[00333] Simultaneous recovery of a scattering cavity and its internal sources

Format : Talk at Waseda University
Author(s) : Deyue Zhang (Jilin University)Yukun Guo (Harbin Institute of Technology)Yinglin Wang (Jilin University)Yan Chang (Harbin Institute of Technology)
Abstract : We consider the simultaneous reconstruction of a sound-soft cavity and its excitation sources from the total-field data. Using the single-layer potential representations on two measurement curves, this problem can be decoupled into an inverse cavity scattering problem and an inverse source problem. Then the uncoupled subproblems are respectively solved by the modified optimization and sampling method. Numerical examples will be presented to demonstrate the effectiveness of the method.

[00259] The anisotropic Calderón problem at large fixed frequency on manifolds with invertible ray transform

Format : Talk at Waseda University
Author(s) : Shiqi Ma (Jilin University)
Abstract : We consider the inverse problem of recovering a potential from the Dirichlet to Neumann map at a large fixed frequency on certain Riemannian manifolds. We extend the earlier result of [G. Uhlmann and Y. Wang, arXiv:2104.03477] to the case of simple manifolds, and more generally to manifolds where the geodesic ray transform is stably invertible.

[00245] Minnaert resonances for bubbles in soft elastic materials

Format : Online Talk on Zoom
Author(s) : Hongjie LI (The Chinese University of Hong Kong)
Abstract : In this talk, the low-frequency resonance for acoustic bubbles embedded in soft elastic materials is discussed. This is a hybrid physical process that couples the acoustic and elastic wave propagations. By delicately and subtly balancing the acoustic and elastic parameters as well as the geometry of the bubble, we show that Minnaert resonance can occur for rather general constructions. This study poses a great potential for the effective realisation of negative elastic materials by using bubbly elastic media.

[00179] Advances in forward and inverse problems of wave equations

Session Time & Room :

00179 (1/3) : 3C (Aug.23, 13:20-15:00) @E709

00179 (2/3) : 3D (Aug.23, 15:30-17:10) @E709

00179 (3/3) : 3E (Aug.23, 17:40-19:20) @E709

Type : Proposal of Minisymposium
Abstract : The recent advances in wave equations and its fast numerical methods have provided useful tools for many applications ranging from nano-optics to medical imaging and geosciences. This mini-symposium will discuss the challenges in the formulations of forward and inverse problems, cutting edge fast algorithms and their efficient implementation and applications in various fields. At the same time, it will provide opportunities to promote interdisciplinary research collaboration between computational scientists and other fields.
Organizer(s) : Carlos Borges, Jun Lai
Classification : 65N21, 45Q05, 31A10, 31B10, 78M99
Minisymposium Program :

00179 (1/3) : 3C @E709 [Chair: Jun Lai]

[00347] Accurate evaluation of Helmholtz layer potentials using Quadrature by two expansions

Format : Talk at Waseda University
Author(s) : Min Hyung Cho (University of Massachusetts Lowell)Jared Weed (University of Massachusetts Lowell)Lingyun Ding (University of California Los Angeles)Jingfang Huang (University of North Carolina at Chapel Hill)
Abstract : The Helmholtz layer potentials are evaluated using the Quadrature by two expansions (QB2X). The QB2X method uses local complex Taylor expansion and planewave-type expansions to achieve a representation that is numerically accurate at all target points inside the leaf box in the hierarchical tree structure. Compared with the original quadrature by the expansion that uses only the local expansion, the QB2X includes explicit nonlinearity from the boundary geometry in the planewave type expansions and it follows standard fast multipole method error analysis. Therefore, QB2X overcomes many challenges quadrature by expansion has and is suitable for complex geometry. The main ideas of the derivation of QB2X using Fourier extension and contour integrals, and numerical results showing the efficiency of QB2X compared with the quadrature by expansion will be presented for both flat and curved boundaries.

[00411] On the Robustness of Inverse Scattering for Penetrable, Homogeneous Objects

Format : Talk at Waseda University
Author(s) : Borges Carlos (University of Central Florida)Manas Rachh (Flatiron Institute)Leslie Greengard (New York University and Flatiron Institute)
Abstract : In the inverse obstacle scattering problem, one determines the shape of a domain from measurements of the scattered field due to a set of incident fields. For a penetrable obstacle with known sound speed, this can be accomplished by treating the boundary alone as an unknown curve. Alternatively, one can treat the entire object as an unknown and use a volumetric representation, without making use of the known sound speed. Both lead to strongly nonlinear and nonconvex optimization problems for which recursive linearization provides a useful framework. After extending our shape optimization approach developed earlier for impenetrable bodies to penetrable obstacles, we carry out a systematic study of both methods and compare their performance on a variety of examples. Our findings indicate that the volumetric approach is more robust, even though the number of degrees of freedom is significantly larger.

[00490] A Neural Network Warm-Start Approach for the Inverse Acoustic Obstacle Scattering Problem

Format : Talk at Waseda University
Author(s) : Manas Rachh (Flatiron Institute)Mo Zhou (Duke University)Jiequn Han (Flatiron Institute)Borges Carlos (University of Central Florida)
Abstract : We consider the inverse acoustic obstacle problem for sound-soft star-shaped obstacles in two dimensions. The inverse problem is computationally challenging since the local set of convexity shrinks with increasing frequency and results in an increasing number of local minima in the vicinity of the true solution. In this talk, we present a neural network warm-start approach for solving the inverse scattering problem, where an initial guess is obtained using a trained neural network.

[04073] Optimal Transportation for Electrical Impedance Tomography

Format : Talk at Waseda University
Author(s) : Gang BAO (Zhejiang University)Yixuan Zhang (Zhejiang University)
Abstract : A new framework is introduced for solving inverse boundary problems with the geodesic based quadratic Wasserstein distance. A general form of the Fréchet gradient is systematically derived by optimal transportation (OT) theory. A fast algorithm based on the new formulation of OT is developed to solve the corresponding optimal transport problem with much improved computational complexity. This framework provides a new computational approach for solving the challenging electrical impedance tomography problem.

00179 (2/3) : 3D @E709 [Chair: Carlos Borges]

[03446] A high-accuracy boundary integral equation method for wave scattering by 3D analytic surfaces

Format : Talk at Waseda University
Author(s) : Wangtao Lu (Zhejiang University)Jun Lai (Zhejiang University)
Abstract : In this talk, we present a high accuracy boundary integral equation method for wave scattering by a closed analytic surface. The surface is assumed to parameterize in earth-like latitude and longitude coordinates. Any analytic function on it can be firstly approximated by its Fourier series in the latitude variable, and then piecewise Legendre

polynomials in the longitude variable. By doing so, we can accurately approximate the standard single-, double-, and adjoint double-layer integral operators in two stages. First, the integrals in the latitude direction are approximated by a nearly optimal algorithm for computing the Fourier transforms of the related kernel functions. Second, the resulting single-variable integrals in the latitude direction have weakly singular kernels, and can be spectrally discretized by pre-designed high-accuracy quadrature rules. We study exterior and interior boundary value problems to validate efficiency and accuracy of the proposed method.

[03520] Fast algorithms for multiple elastic obstacles scattering and inverse scattering

Format : Talk at Waseda University
Author(s) : Jun Lai (Zhejiang University)
Abstract : Elastic wave scattering and inverse scattering have been appeared in a lot of important applications, including non-destructive testing, seismic inversion, and medical imaging, etc. Integral equation method provides an effective tool for solving elastic wave scattering and inverse scattering problems. In this talk, fast and high order numerical methods based on integral equations will be presented for elastic wave equations in the presence of multiple obstacles. In particular, I will talk about the numerical algorithms using high order discretization of singular integrals and the fast multipole method for evaluating the multiple elastic scattering problem, as well as their applications in the inverse elastic wave scattering based on the time reversal method.

[05069] Exploring inverse obstacle scattering with an impedance model

Format : Talk at Waseda University
Author(s) : Travis Askham (New Jersey Institute of Technology)Manas Rachh (Flatiron Institute)Carlos Borges (University of Central Florida)Jeremy Hoskins (University of Chicago)
Abstract : It is well known that in certain limits the impedance boundary condition can mimic the sound hard, sound soft, and transmission boundary conditions. Here we explore the performance of this approximation in inverse obstacle scattering problems. We find that for certain problems a relaxation of the usual measurement of scattering error improves the quality of obstacle recovery.

[03858] Hybrid methods for the application of singular integral operators

Format : Talk at Waseda University
Author(s) : Leslie Greengard (New York University and Flatiron Institute)Shidong Jiang (Flatiron Institute)Jun Wang (Tsinghua University)Fredrik Fryklund (Courant Institute, NYU)Samuel F Potter (Courant Institute, NYU)
Abstract : We present hybrid asymptotic/numerical methods for the accurate computation of elliptic and parabolic volume and layer potentials in two and three dimensions.

00179 (3/3) : 3E @E709 [Chair: Carlos Borges]

[04029] Obstacles and interfaces composite scattering in a multilayered medium

Format : Talk at Waseda University
Author(s) : Lei Zhang (Zhejiang University of Technology)
Abstract : This talk will focus on the mathematical analysis and numerical methods for the composite scattering problem from obstacles and interfaces in a multilayered medium. We will highlight some recent progress in this area. Specifically, we will address how to handle obstacles and rough surfaces, and how to model scattering from unbounded surfaces. We will also discuss the well-posedness and numerical methods for solving these problems based on the characteristic of the scattering problems.

[04887] Lippmann Schwinger integral equation for fiber optics analysis

Format : Talk at Waseda University
Author(s) : Felipe Vico (UPV)Miguel Ferrando-Bataller (UPV)Eva Antonino-Daviu (UPV)Marta Cabedo-Fabrés (UPV)
Abstract : In this talk, we will present a Limpann-Schwinger integral formulation for accurately calculating the propagating modes in fiber optics. Our formulation is based on a second-kind integral equation, which ensures stability in the presence of noise and uncertainties. Furthermore, our discretization scheme exhibits superalgebraic convergence for smooth refractive index fibers, making it suitable for graded-index fibers.

[05178] Single-excitation quantum optics: analysis and algorithms

Format : Talk at Waseda University
Author(s) : Jeremy Graeme Hoskins (University of Chicago)Jeremy Hoskins (University of Chicago)Manas Rachh (Flatiron Institute)John Schotland (Yale University)Jason Kaye (Flatiron Institute, Simons Foundation)
Abstract : Recent progress in experimental quantum optics has facilitated the physical construction of systems of increasing complexity. Of particular importance are experiments involving the scattering of one or two photons from a collection of atoms. In this context, a central question is to understand the time evolution of the entanglement between atoms, mediated by the field. In this talk we will discuss analytical results on the properties of these systems, and how those properties depend on disorder or distribution of the locations of the atoms.

[05639] Poisson Solver for Complicated Geometries in R3 Using Function Extension

Author(s) : Fredrik Fryklund (New York University)Charles Epstein (Flatiron Institute, Simons Foundation)Shidong Jiang (Flatiron Institute, Simons Foundation)Leslie Greengard (Flatiron Institute, Simons Foundation)
Abstract : We describe a new, adaptive solver for the three-dimensional Poisson equation in complicated geometries. The solution is represented as the sum of a volume potential and a double layer potential. The source data is extended with high order accuracy along the normals to the surface, to a geometrically simpler region. This allows us to accelerate the evaluation of the volume potential using an FMM.

[00184] Recent advances in data-driven methods for inverse problems

Session Time & Room :

00184 (1/4) : 4C (Aug.24, 13:20-15:00) @E811

00184 (2/4) : 4D (Aug.24, 15:30-17:10) @E811

00184 (3/4) : 4E (Aug.24, 17:40-19:20) @E811

00184 (4/4) : 5B (Aug.25, 10:40-12:20) @E811

Type : Proposal of Minisymposium
Abstract : The remarkable success of deep learning has led to a transformative impact on the research landscape of inverse problems in imaging. This mini-symposium aims to bring together researchers who have made exciting contributions to understanding the theoretical foundations and empirical performance of deep learning in various imaging applications. The talks will cover a wide range of topics such as deep regularization, Bayesian methods, microlocal analysis, learned optimization solvers, and robustness of reconstruction methods to distribution shift and adversarial attacks, making the sessions of sufficient interest to a broad audience, while encouraging an exchange of ideas to advance the state-of-the-art.

[05418] Machine learned regularization for inverse problems - the dos and don‘ts

Format : Online Talk on Zoom
Author(s) : Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : Inverse problems are about the reconstruction of an unknown physical quantity from indirect measurements. They appear in a variety of places, from medical imaging, for instance MRI or CT, to remote sensing, for instance Radar, to material sciences and molecular biology, for instance electron microscopy. Here, inverse problems is a tool for looking inside specimen, resolving structures beyond the scale visible to the naked eye, and to quantify them. It is a mean for diagnosis, prediction and discovery.
Most inverse problems of interest are ill-posed and require appropriate mathematical treatment for recovering

meaningful solutions. Classically, such approaches are derived almost conclusively in a knowledge driven manner, constituting handcrafted mathematical models. Examples include variational regularization methods with Tikhonov regularization, the total variation and several sparsity-promoting regularizers such as the L1 norm of Wavelet coefficients of the solution. While such handcrafted approaches deliver mathematically rigorous and computationally robust solutions to inverse problems, they are also limited by our ability to model solution properties accurately and to realise these approaches in a computationally efficient manner.
Recently, a new paradigm has been introduced to the regularization of inverse problems, which derives solutions to inverse problems in a data driven way. Here, the inversion approach is not mathematically modelled in the classical sense, but modelled by highly over-parametrised models, typically deep neural networks, that are adapted to the inverse problems at hand by appropriately selected training data. Current approaches that follow this new paradigm distinguish themselves through solution accuracies paired with computational efficieny that were previously unconceivable.
In this talk I will give an introduction to this new data-driven paradigm for inverse problems. Presented methods include data-driven variational models and plug-and-play approaches, learned iterative schemes aka learned unrolling, and learned post-processing. Throughout presenting these methodologies, we will discuss their theoretical properties and provide numerical examples for image denoising, deconvolution and computed tomography reconstruction. The talk will finish with a discussion of open problems and future perspectives.

[04644] Data-driven Regularization based on Diagonal Frame Decompostion

Format : Talk at Waseda University
Author(s) : Yunseok Lee (Ludwig Maximilian University Munich)Samira Kabri (Deutsches Elektronen-Synchrotron (DESY) Hamburg)Martin Burger (Deutsches Elektronen-Synchrotron (DESY) Hamburg and University of Hamburg)Gitta Kutyniok (Ludwig Maximilian University Munich)
Abstract : In this talk, we propose a data-driven framework to design optimal filters for inverse problems using frame decompositions, which generalize classical spectral filters. Frames are sets of vectors that allow for stable and redundant representations of signals in a Hilbert space. Our framework works by learning a linear transformation that modifies the frame coefficients of a measured signal to enhance or suppress certain features. This is achieved by formulating this as an optimization problem with a data-driven regularizer that incorporates prior knowledge from noise and ground truth data. Our approach comes with theoretical guarantees in terms of convergence as well as in terms of generalization to unseen data. We also illustrate its effectiveness on several numerical experiments using the Wavelet-Vaguelette decomposition as an example.

[03944] Fourier Neural Operators for data-driven regularization

Format : Talk at Waseda University
Author(s) : Samira Kabri (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : In this talk we investigate the use of Fourier Neural Operators (FNOs) for image processing in comparison to standard Convolutional Neural Networks (CNNs). FNOs - which are so-called neural operators with a specific parametrization - have been applied successfully in the context of parametric PDEs. We derive the FNO architecture as an example for continuous and Fréchet-differentiable neural operators on Lebesgue spaces and show how CNNs can be converted into FNOs and vice versa. Based on these insights, we explore possibilities of incorporating the ideas of FNOs into the data-driven regularization of inverse problems in imaging.

[05027] Data-driven regularization theory of invertible ResNets for solving inverse problems

Format : Online Talk on Zoom
Author(s) : Clemens Arndt (ZeTeM University of Bremen)Alexander Denker (ZeTeM University of Bremen)Sören Dittmer (ZeTeM University of Bremen)Nick Heilenkötter (ZeTeM University of Bremen)Meira Iske (ZeTeM University of Bremen)Tobias Kluth (University of Bremen)Judith Nickel (ZeTeM University of Bremen)
Abstract : Data-driven solution techniques for inverse problems, typically based on specific learning strategies, exhibit remarkable performance in image reconstruction tasks. These learning-based reconstruction strategies often follow a two-step scheme. First, one uses a given dataset to train the reconstruction scheme, which one often parametrizes via a neural network. Second, the reconstruction scheme is applied to a new measurement to obtain a reconstruction. We follow these steps but specifically parametrize the reconstruction scheme with invertible residual networks (iResNets). We demonstrate that the invertibility opens the door to new investigations into the influence of the training and the architecture on the resulting reconstruction scheme. To be more precise, we analyze the effect of different iResNet architectures, loss functions, and prior distributions on the trained network. The investigations reveal a formal link to the regularization theory of linear inverse problems for shallow network architectures. Moreover, we analytically optimize the parameters of specific classes of architectures in the context of Bayesian inversion, revealing the influence of the prior and noise distribution on the solution.

00184 (3/4) : 4E @E811 [Chair: Martin Burger]

[05430] Are neural operators really neural operators?

Format : Online Talk on Zoom
Author(s) : Rima Alaifari (ETH Zurich)
Abstract : In operator learning, it has been observed that proposed models may not behave as operators when implemented, questioning the very essence of what operator learning should be. We contend that some form of continuous-discrete equivalence is necessary for an architecture to genuinely learn the underlying operator, rather than just discretizations of it. Employing frames, we introduce the framework of Representation equivalent Neural Operator (ReNO) to ensure operations at the continuous and discrete level are equivalent.

[04722] Plug-and-Play Models for Large-Scale Computational Imaging

Format : Talk at Waseda University
Author(s) : Ulugbek Kamilov (Washington University in St. Louis)
Abstract : Computational imaging is a rapidly growing area that seeks to enhance the capabilities of imaging instruments by viewing imaging as an inverse problem. Plug-and-Play Priors (PnP) is one of the most popular frameworks for solving computational imaging problems through integration of physical and learned models. PnP leverages high-fidelity physical sensor models and powerful machine learning methods to provide state-of-the-art imaging algorithms. PnP models alternate between minimizing a data-fidelity term to promote data consistency and imposing a learned image prior in the form of an "image denoising" deep neural network. This talk presents a principled discussion of PnP, its theoretical foundations, its implementations for large-scale imaging problems, and recent results on PnP for the recovery of continuously represented images. We present several applications of our theoretical and algorithmic insights in bio-microscopy, computerized tomography, and magnetic resonance imaging.

[02097] Learned proximal operators meets unrolling for limited angle tomography

Format : Online Talk on Zoom
Author(s) : Tatiana Alessandra Bubba (University of Bath)Subhadip Mukherjee (University of Bath)Luca Ratti (University of Genoa)Andrea Sebastiani (University of Bologna)
Abstract : In recent years, limited angle tomography has become a challenging testing ground for several theoretical and numerical studies, where both variational regularisation and data-driven techniques have been investigated extensively. I will present a hybrid reconstruction framework where the proximal operator of an accelerated unrolled scheme is learned to ensure suitable theoretical guarantees. The recipe relays on the interplay between sparse regularisation, harmonic analysis, microlocal analysis and Plug and Play methods.

[04626] Plug-and-Play sampling for inverse problems in imaging

Format : Talk at Waseda University
Author(s) : Julie Delon (Université Paris Cité)Rémi Laumont (Technical University of Denmark,)Marcelo Pereyra (Heriot-Watt University)Andrés Almansa (Université Paris Cité)Valentin De Bortoli (Ecole Normale Supérieure)
Abstract : In a Bayesian framework, image models are used as priors or regularisers and combined to explicit likelihood functions to define posterior distributions. These posterior distributions can be used to derive Maximum A Posteriori (MAP) estimators, leading to optimization problems that are generally well studied and understood. Sampling schemes can also be used to explore more finely these posterior distributions, derive other estimators, quantify uncertainties or perform other advanced inferences. In a manner akin to Plug & Play (PnP) methods in optimization, these sampling schemes can be combined with denoising neural networks approximating the gradient of a log-prior on images. In this talk, we will focus on these PnP sampling schemes, which raise important questions concerning the correct definition of the underlying Bayesian models or the computed estimators, as well as their regularity properties, necessary to ensure the stability of the numerical schemes.

00184 (4/4) : 5B @E811 [Chair: Subhadip Mukherjee]

[03828] Recent advance of diffusion models in inverse problems

Format : Talk at Waseda University
Author(s) : Jong Chul YE (KAIST)
Abstract : Recently, diffusion models have been used to solve various inverse problems for medical imaging applications in an unsupervised manner. In this talk, we propose an additional correction term inspired by the manifold constraint, which can be used synergistically with the previous solvers to make the iterations close to the manifold.

[04409] Conditional Image Generation with Score Based Models

Format : Talk at Waseda University
Author(s) : Jan Pawel Stanczuk (University of Cambridge)Georgios Batzolis (University of Cambridge)
Abstract : Score-based diffusion models have emerged as one of the most promising frameworks for deep generative modelling. In this work we conduct a systematic comparison and theoretical analysis of different approaches to learning conditional probability distributions with score-based diffusion models. In particular, we prove results which provide a theoretical justification for one of the most successful estimators of the conditional score. Moreover, we introduce a multi-speed diffusion framework, which leads to a new estimator for the conditional score, performing on par with previous state-of-the-art approaches.

[01555] Data-Driven Convex Optimization via Mirror Descent

Format : Talk at Waseda University
Author(s) : Hong Ye Tan (University of Cambridge)Subhadip Mukherjee (University of Bath)Junqi Tang (University of Cambridge)Carola Bibiane Schoenlieb (University of Cambridge)Andreas Hauptmann (University of Oulu)
Abstract : Learning-to-optimize is an emerging framework that seeks to speed up the solution of certain optimization problems by leveraging training data. We propose a provably approximately convergent learning-to-optimize scheme for convex optimization based on a functional parameterization of the classical mirror descent algorithm. In particular, we model the underlying convex function with an input-convex neural network and derive corresponding convergence rate bounds. We demonstrate improved convergence rates on various convex image processing examples.

[03784] Multi-Modal Hypergraph Diffusion Network with Dual Prior for Alzheimer Classification

Format : Talk at Waseda University
Author(s) : Angelica Aviles-Rivero (University of Cambridge)
Abstract : The automatic early diagnosis of prodromal stages of Alzhei-mer's disease is of great relevance for patient treatment to improve quality of life. We address this problem as a multi-modal classification task. Multi-modal data provides richer and complementary information. However, existing techniques only consider lower order relations between the data and single/multi-modal imaging data. In this work, we introduce a novel semi-supervised hypergraph learning framework for Alzheimer’s disease diagnosis. Our framework allows for higher-order relations among multi-modal imaging and non-imaging data whilst requiring a tiny labelled set. Firstly, we introduce a dual embedding strategy for constructing a robust hypergraph that preserves the data semantics. We achieve this by enforcing perturbation invariance at the image and graph levels using a contrastive based mechanism. Secondly, we present a dynamically adjusted hypergraph diffusion model, via a semi-explicit flow, to improve the predictive uncertainty.

[00185] AAA rational approximation: extensions and applications

Session Time & Room :

00185 (1/2) : 4C (Aug.24, 13:20-15:00) @F310

00185 (2/2) : 4D (Aug.24, 15:30-17:10) @F310

Type : Proposal of Minisymposium
Abstract : The numerical computation of rational approximations has become much easier since the appearance of the AAA
algorithm in 2018. This minisymposium will explore some of the many things that have happened since then.

Organizer(s) : Lloyd N. Trefethen
Classification : 41A20, 65D15
Minisymposium Program :

00185 (1/2) : 4C @F310 [Chair: Nick Trefethen]

[02196] Review of AAA approximation

Format : Talk at Waseda University
Author(s) : Lloyd Nicholas Trefethen (University of Oxford)
Abstract : The AAA ("triple A") algorithm is a fast and reliable black box algorithm for computing rational approximations to real or complex functions. It has been used by many people since its publication in 2018. This talk will be an introduction to to AAA and its applications.

[05528] pAAA for multivariate functions and AAA-LQO for systems with quadratic outputs

Format : Online Talk on Zoom
Author(s) : Serkan Gugercin (Virginia Tech)
Abstract : We first introduce the parametric-AAA (pAAA) algorithm for approximating multivariate functions, such as the transfer functions of parametric dynamical systems, where the approximant is constructed in the multivariate barycentric form. We then develop the barycentric form for linear dynamical systems with quadratic outputs (LQO). This new formulation leads to the AAA-LQO algorithm.

[02708] Rational approximation for noisy data

Format : Talk at Waseda University
Author(s) : Anil Damle (Cornell University)
Abstract : Approximation of data by rational functions has many clear upsides over other representational forms. However, even if a rational function provides an effective underlying model for a given task the data it must be built from is often corrupted by noise. In this talk we will explore how existing rational approximation algorithms are impacted by noise, and discuss algorithms that are specifically tailored to effectively and efficiently build rational approximations of noisy data.

[03138] SO-AAA: learning systems with second-order dynamics

Format : Talk at Waseda University
Author(s) : Ion Victor Gosea (Max Planck Institute for Dynamics of Complex Technical Systems)Serkan Gugercin (Virginia Tech University)Steffen W. R. Werner (New York University)
Abstract : The AAA (Adaptive Antoulas Anderson) algorithm is a rational approximation tool used to fit rational functions to data measurements. We present here an extension of AAA to fitting systems with second-order dynamics (structured case). Toward this goal, the development of structured barycentric forms associated with the transfer function of second-order systems is needed. These allow the iterative construction of reduced-order models from given frequency domain data, by combining interpolation and least-squares fit.

00185 (2/2) : 4D @F310 [Chair: Nick Trefethen]

[02698] Linearization of dynamical systems using the AAA algorithm

Format : Talk at Waseda University
Author(s) : Karl Meerbergen (KU Leuven)
Abstract : We provide an overview of the use of AAA for the linearization of all kinds of nonlinear equations arising from dynamical systems. This includes nonlinear eigenvalue problems, nonlinear frequency dependent dynamical systems and nonlinear time dependent systems. The concept linearization is key for these problems, since linear problems are usually easier to handle in numerics.

[02371] Time-domain model reduction in the Loewner framework

Format : Talk at Waseda University
Author(s) : Athanasios Antoulas (Rice University)
Abstract : In this talk we will present the main features of the Loewner Framework for rational approximation and model reduction. In particular, time domain methods will be of central importance.

[05435] AAA and numerical conformal mapping

Format : Online Talk on Zoom
Author(s) : Olivier Sète (University of Greifswald)
Abstract : In this talk, we explore applications of AAA rational approximation in numerical conformal mapping.

[05536] AAA rational approximation on a continuum

Format : Talk at Waseda University
Author(s) : Yuji Nakatsukasa (University of Oxford)
Abstract : AAA has normally been applied on a discrete set, typically hundreds or thousands of points in a (real or complex) domain. Here we introduce a continuum AAA algorithm that discretizes a domain adaptively as it goes, which often also reduces the number of samples required. The key idea is that the support points tend to indicate where more samples are required. Execution is fast since SVDs are computed only for matrices that are nearly square.

[00187] Analysis and geometry of inextensible materials

Session Time & Room : 3C (Aug.23, 13:20-15:00) @G801

Type : Proposal of Minisymposium
Abstract : There are many objects in the world around us that can be modeled as inextensible: pipes, chains, ribbons, cloth, whips, flagella, filaments, macromolecules, soft robot links, yarn, flags, cables in the ocean, galactic motion and octopus tentacles. In a certain sense, the inextensibility interpolates between rigid bodies and incompressible fluids but in comparison to them has many genuinely new difficulties due to the presence of unknown Lagrange multipliers. We intend to bring together some of the leading experts to discuss the modern ways to handle the analytical complexity of the PDE related to inextensible materials and the beautiful underlying geometry.
Organizer(s) : Dmitry Vorotnikov
Classification : 35Qxx, 58Exx, 74Hxx
Minisymposium Program :

00187 (1/1) : 3C @G801 [Chair: Dmitry Vorotnikov]

[02002] Modeling and Simulation of Thin Sheet Folding

Format : Talk at Waseda University
Author(s) : Soeren Bartels (University of Freiburg)
Abstract : The folding of a thin elastic sheet along a curved arc has various applications including the construction of bistable devices. We discuss the derivation of a plate model from three-dimensional hyperelasticity and rigidity properties of admissible deformations and minimizers. The numerical solution is based on an isoparametric discontinuous Galerkin finite element method that provides a suitable geometric approximation of the folding arc. Error estimates are presented for a linearized version of the model problem.

[02066] Periodic partitions with minimal perimeter

Format : Talk at Waseda University
Author(s) : Matteo Novaga (University of Pisa)Annalisa Cesaroni (University of Padova)
Abstract : I will discuss existence and regularity of fundamental domains which minimize a general perimeter functional in a homogeneous metric measure space. In the planar case I will give a detailed description of the domains which are minimal for a general anisotropic perimeter.

[02439] Inextensible elastic curves and subriemannian maniflods

Format : Talk at Waseda University
Author(s) : Chun-Chi Lin (National Taiwan Normal UniversiNational Taiwan Normal University)
Abstract : Elastic curves are relatively simple geometric objects in differential geometry but are related to many applications in image sciences and geometric control theory.
These curves are characterized the equilibrium configurations to the energy functional,
$\int (a + b \cdot |\vec{\kappa}|^2)\, ds$,
where a, b are positive constants, $\vec{\kappa}$ is the curvature vector of curves and s is the arclength of curves.
The Euler-Lagrange equations are fourth-order differential equations of the curves.
On the other hand, an energy decreasing flow of inextensible elastic curves in the plane can be formulated by a second-order parabolic equation with Lagrange multipliers.
However, difficulties come out as one generalizes this approach to curves in higher dimensional Euclidean spaces or Riemannian manifolds.
In this talk, we are interested in relating inextensible elastic curves to geometric analysis of curves in subriemannian

manifolds.
We will introduce a different approach for problem and demonstrate our progress and results.

[02016] Gradient flows of inextensible networks

Format : Talk at Waseda University
Author(s) : Dmitry Vorotnikov (Universidade de Coimbra)
Abstract : We address solvability of equations of overdamped motion of inextensible networks. Problems of this kind can be expressed as PDE that involve unknown Lagrange multipliers and non-standard boundary conditions related to the moving junctions. They can also be interpreted as gradient flows on certain "manifolds" of probability measures. We also discuss the geometry of these manifolds as well as links of our equations to the mean curvature flow and to fluid dynamics.

[00193] Adversarial robustness at the interface of analysis, geometry and statistics

Session Time & Room :

00193 (1/3) : 5B (Aug.25, 10:40-12:20) @E503

00193 (2/3) : 5C (Aug.25, 13:20-15:00) @E503

00193 (3/3) : 5D (Aug.25, 15:30-17:10) @E503

Type : Proposal of Minisymposium
Abstract : Stability and robustness have emerged as essential properties for modern machine learning methods. In this three-part minisymposium, we gather researchers from mathematics, statistics, and computer science that have been driving the research in this field in a variety of directions, offering a platform for scientific exchange and aiming at sparking new collaborations in this vibrant and important field.

Some of the topics that will be covered by this mini-symposium include regularization methods and insights from variational calculus for training robust models, numerical methods for solving min-max problems, distributionally robust optimization, GANs, geometric insights on adversarial robustness, among others.
Organizer(s) : Tim Roith, Nicolás García Trillos, Martin Burger
Classification : 62Gxx, 68Q32, 49Qxx
Minisymposium Program :

00193 (1/3) : 5B @E503 [Chair: Nicolás García Trillos]

[00265] Distributionally Robust Gaussian Process Regression and Bayesian Inverse Problems

Format : Talk at Waseda University
Author(s) : Jose Blanchet (Stanford)
Abstract : We study a distributionally robust optimization formulation (i.e., a min-max game) for two representative problems in Bayesian nonparametric estimation: Gaussian process regression and, more generally, linear inverse problems. Our formulation seeks the best mean-squared error predictor, in an infinite-dimensional space, against an adversary who chooses the worst-case model in a Wasserstein ball around a nominal infinite-dimensional Bayesian model. The transport cost is chosen to control features such as the degree of roughness of the sample paths that the adversary is allowed to inject. We show that the game has a well-defined value (i.e., strong duality holds in the sense that max-min equals min-max) and that there exists a unique Nash equilibrium which can be computed by a sequence of finite-dimensional approximations. Crucially, the worst-case distribution is itself Gaussian. We explore properties of the Nash equilibrium and the effects of hyperparameters through a set of numerical experiments, demonstrating the versatility of our modeling framework.

[01932] Adversarial distributional robustness from Wasserstein ascent-descent particle dynamics

Format : Talk at Waseda University
Author(s) : Camilo García Trillos (University College London)Nicolas Garcia Trillos (University of Wisconsin Madison)
Abstract : We propose iterative algorithms to solve adversarial problems in a variety of supervised learning settings. Our algorithms, suggested by ascent-descent dynamics in a projected Wasserstein space, take the form of a system of

interacting particles. We show the particle dynamics converge toward mean-field limit equations as the number of particles grows. In turn, the mean-field dynamics converge, as time goes to infinity, to epsilon-Nash equilibria of the original adversarial learning problem. We study, moreover, some advantages found on a nonconvex- strongly concave case -in a sense to be made precise in the talk-. Joint work with Nicolás García Trillos.

[00273] Optimal Algorithms for Stochastic Nested Composition Optimization with Applications to Robust Training

Format : Talk at Waseda University
Author(s) : Krishnakumar Balasubramanian (UC DavisUC Davis)
Abstract : Many robust training problems could be cast in the form of optimizing a nested composition of T functions. Examples include distributionally robust optimization, risk-averse learning, robust meta learning, etc. In this talk, I will discuss stochastic optimization algorithms for minimizing nested composition of T functions with and without bi-level structures. Assuming access to noisy evaluations of the functions and their gradients through a stochastic first-order oracle, I will present an algorithm using moving-average stochastic estimates for solving the above problem. We show that the proposed algorithm can achieve a sample complexity of $\mathcal{O}(1/\epsilon^4)$ for converging to an ϵ-stationary point of the problem. To the best of our knowledge, this is the first time that such an online algorithm designed for the (un)constrained multi-level setting, obtains the optimal sample complexity of the smooth single-level setting, under mild assumptions on the stochastic first-order oracle.

[00274] Convergence of GDA for mean field two-player zero-sum games

Format : Talk at Waseda University
Author(s) : Yulong Lu (University of Massachusetts Amherst)
Abstract : Min-max optimization problems arise from many problems in machine learning ,such as generative modeling and adversarial learning. In general, finding the global Nash-equilibrium of a two-player zero-sum game is difficult when the objective function lacks convexity and concavity assumptions. In this talk, I will introduce a mean-field setting of the game problem and discuss some global convergence results of GDA for finding mixed equilibria on the space of probability measures.

00193 (2/3) : 5C @E503 [Chair: Tim Roith]

[00292] Gamma convergence of a nonlocal perimeter from adversarial machine learning

Format : Talk at Waseda University
Author(s) : Leon Bungert (University of Bonn)Kerrek Stinson (University of Bonn)
Abstract : Adversarial training is a robust machine learning method which seeks to compute a classifier which is stable with respect to adversarial attacks. Recent analysis has shown that adversarial training admits different reformulations, e.g., as distributionally robust optimization, multi-marginal optimal transport, or geometric regularization problem. In this last context, adversarial training is equivalent to regularized empirical risk minimization $\min_{A\subset\mathbb{R}^d}\mathcal{R}_{\mathrm{emp}}(A)+\varepsilon\,\mathrm{Per}_\varepsilon(A)$ where a nonlocal perimeter Per_ε of the classifier is penalized. The nonlocality is parametrized with the so-called "adversarial budget" $\varepsilon>0$ which models the strength of the adversary. In this talk I will discuss local limits of this nonlocal perimeter as the adversarial budget goes to zero. Under generic conditions we prove Gamma convergence of Per_ε to a weighted local perimeter as $\varepsilon\to 0$. This is joint work with Kerrek Stinson from the University of Bonn.

[00313] Provable Adversarial Robustness via Optimal Transport

Format : Talk at Waseda University
Author(s) : Muni Sreenivas Pydi (Université Paris Dauphine-PSL)
Abstract : In this talk, we explore the fundamental limits of adversarially robust classification using optimal transport. We give two characterizations of the best error: as an optimal transport cost between the true data distributions, and as the Bayes error of a minimax hypothesis test involving Wasserstein uncertainty sets. The first characterization leads to a recipe for finding the optimal classifier, and the second leads to the existence of a Nash equilibrium.

[00277] Adversarial learning and the Wasserstein barycenter problem

Format : Talk at Waseda University
Author(s) : Matt Jacobs (Purdue University)
Abstract : In this talk, I will show that the adversarial training problem is equivalent to a generalized version of the Wasserstein barycenter problem. The connection between these problems allows us to completely characterize the optimal adversarial strategy and to bring in tools from optimal transport to analyze and compute optimal classifiers. We will then use these tools to better understand the regularizing effect of adversarial training.

[00299] Optimal Adversarial Classification: geometry, regularity, and topology

Format : Talk at Waseda University
Author(s) : Ryan Murray (North Carolina State University)
Abstract : Classification is a fundamental task in data science and machine learning, and in the past ten years there have been significant improvements on classification tasks (e.g. via deep learning). However, recently there have been a number of works demonstrating that these improved algorithms can be "fooled" using specially constructed adversarial examples. In turn, there has been increased attention given to creating machine learning algorithms which are more robust against adversarial attacks.

In this talk I will discuss delicate mathematical and geometric information which can inferred about optimal adversarial classifiers. In particular, I will describe types of available regularity theory, and draw connections with non-local isoperimetric problems which have been popular in the variational community. Time permitting, I will also discuss recent algorithmic advances which can detect and track topological changes induced by the presence of an adversary.

00193 (3/3) : 5D @E503 [Chair: Tim Roith]

[00330] Adversarial flows

Format : Talk at Waseda University
Author(s) : Lukas Weigand (Friedrich-Alexander-Universität Erlangen-Nürnberg)Tim Roith (Friedrich-Alexander-Universität Erlangen-Nürnberg)Martin Burger (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : The fast gradient method and the fast gradient sign method are two popular methods to generate adversaries of neural networks. Iterative applications of those methods yield differential equations, corresponding to p-curves of maximum slope in $\mathbb{R}^d$ for the limit case $p = \infty$. We extend current analysis to this limit case, which allow us to generate distributional adversaries by corresponding ∞-curves of maximum slope in the ∞-Wasserstein space.

[02000] Distributionally Robust Linear Predictors using the Max-Sliced Wasserstein Metric

Format : Talk at Waseda University
Author(s) : Cynthia Rush (Columbia University)
Abstract : We study the classical problem of predicting an outcome variable, Y, using a linear combination of a d-dimensional covariate vector, X. We provide conditions under which linear predictors that minimize the worst-case prediction error over a ball of distributions determined by a type of max-sliced Wasserstein metric are equivalent to linear predictors whose coefficients solve: inf_β (E[(Y - < β, X >)^r])^(1/r) + δ || β ||, where r >1 and $\delta > 0$ is a regularization parameter. A detailed analysis of the statistical properties of this metric yields a simple recommendation for the choice of regularization parameter. The suggested order of δ, after a suitable normalization of the covariates, is typically d/n, up to logarithmic factors. Our recommendation is computationally straightforward to implement, pivotal, has provable out-of-sample performance guarantees, and does not rely on sparsity assumptions about the true data generating process.

This is joint work with Jose Montiel Olea, Amilcar Velez and Johannes Wiesel.

[00352] Minimax results for Surrogate risks in Adversarial Learning

Format : Talk at Waseda University
Author(s) : Natalie Frank (NYU)
Abstract : Robustness to adversarial perturbations is of paramount concern in modern machine learning. One of the state-of-the-art methods for training robust classifiers is adversarial training, which involves minimizing a supremum-based surrogate risk. We prove a minimax theorem for this adversarial surrogate risk and discuss some of the algorithmic implications. Specifically, we use this minimax result to characterize the statistical consistency of surrogate risks in the adversarial setting.

[00349] Robust second-order estimation algorithms

Format : Online Talk on Zoom
Author(s) : Po-Ling Loh (University of Cambridge)
Abstract : We provide a new computationally-efficient algorithm that finds estimators for the empirical risk minimization problem. We show that these estimators are robust for general statistical models. Our workhorse is a novel robust variant of Newton's method, and we provide conditions under which our version of Newton's method variant provides accurate estimators for general convex objectives.

[00194] Recent Progress of Computational Electromagnetics

Session Time & Room : 1E (Aug.21, 17:40-19:20) @E705

Type : Proposal of Minisymposium
Abstract : This minisymposium will feature the recent advances and challenges in the field of computational electromagnetics. The topics covered in the minisymposium will include (but be not limited to) novel numerical methods and techniques for solving electromagnetic partial differential equations, e.g., use of the extended finite element methods in eddy-current problem, and balancing domain decomposition method for large-scale parallel computation for electromagnetic fields.
Organizer(s) : Takeshi Mifune, Tetsuji Matsuo, Takeshi Iwashita
Classification : 65Mxx, 65Fxx
Minisymposium Program :

00194 (1/1) : 1E @E705 [Chair: Takeshi Mifune]

[03979] Application of POD to solve non linear magnetoquasistatic FE problems

Format : Online Talk on Zoom
Author(s) : Stephane Clenet (AMValorArts et Métiers Science and Technology)Thomas Henneron (University of Lille)Theo Delagnes (EdF R&D)
Abstract : The Finite Element (FE) method is widely used to build accurate models of electrical devices but leads to the solution of large scale equation systems. To overcome this issue, model order reduction methods, like Proper Orthogonal Decomposition (POD), can significantly reduce the size of the equation system. In the presentation, the principles of POD method will be presented and how it can be applied to reduce FE model of non linear magnetoquasistatics problems. Application examples (transformers, electrical machines....) are given to illustrate the effectiveness of the POD method and also its limitations.

[04030] BDD-DIAG Preconditioner of the Interface Problem for Magnetostatic Domain Decomposition Analysis

Format : Online Talk on Zoom
Author(s) : Hiroshi Kanayama (Japan Women's University)Masao Ogino (Daido University)Shin-ichiro Sugimoto (Hachinohe Institute of Technology)Kaworu Yodo (Insight Inc.)
Abstract : An iterative domain decomposition method is proposed for numerical analysis of 3-Dimensional linear magnetostatic problems taking the magnetic vector potential as an unknown function. The iterative domain decomposition method is combined with the Preconditioned Conjugate Gradient procedure and the Hierarchical Domain Decomposition Method which is adopted in parallel computing. Our previously employed preconditioner was the Neumann-Neumann preconditioner. Numerical results showed that the method was only effective for smaller problems. In this paper, we consider its improvement with the Balancing Domain Decomposition DIAGonal scaling (BDD-DIAG) preconditioner.

[04666] Reduced Order Modeling of a Cage Induction Motor with Skewed Rotor Slots

Format : Online Talk on Zoom
Author(s) : Yasuhito Takahashi (Doshisha University)Koji Fujiwara (Doshisha University)Kengo Sugahara (Kindai University)Tetsuji Matsuo (Kyoto University)
Abstract : A method for deriving a reduced-order model of cage induction motors with skewed rotor slots is investigated based on the multiport Cauer ladder network method. The features of the several formulations for the skewed rotor are discussed, in which the continuity of the bar currents and the space harmonics included in the air-gap flux density waveform are treated differently. The effectiveness of the developed methods is verified from the viewpoints of computational accuracy and cost.

[05040] Introducing extended finite element approaches in eddy currents analysis

Format : Talk at Waseda University
Author(s) : Shingo Hiruma (Kyoto University)
Abstract : In recent years, the evaluation of eddy current losses caused by harmonic components in power supplies has become increasingly important. However, the conventional finite element method requires the conductor region to be divided into fine elements, which results in high computational cost. In this study, we apply the extended finite element approach to high-frequency eddy current analysis and show that accurate analysis can be performed with low computational cost.

[00196] Recent development of mathematical geophysics

Session Time & Room : 3D (Aug.23, 15:30-17:10) @G710

Type : Proposal of Minisymposium
Abstract : The purpose of this minisymposium is to interact with mathematicians working on geophysics with various recent topics: large time behavior of solutions, machine learning approach, flow behavior on manifolds and meteorological analysis. These each topics have long research history. However, the tendency of the recent studies seems to be a broader point of view, not only from each own research field but also from an interdisciplinary perspective.

00196 (1/1) : 3D @G710 [Chair: Tsuyoshi Yoneda]

[01262] Global solutions for rotating MHD equations in the critical space

Format : Talk at Waseda University
Author(s) : Ryo Takada (The University of Tokyo)Keiji Yoneda (Kyushu University)
Abstract : We consider the initial value problem for the incompressible rotating magnetohydrodynamics equations in $\mathbb{R}^3$. We prove the unique existence of global solutions for large initial data in the scaling critical space $\dot{H}^{\frac{1}{2}}(\mathbb{R}^3)$ when the rotation speed is sufficiently high. In order to control large magnetic fields, we introduce a modified linear solution for the velocity, and show its smallness in a suitable space-time norm by means of the dispersive effect of the Coriolis force.

[02684] Multi-scale interaction of tropical weather in a simplified three-dimensional model

Format : Talk at Waseda University
Author(s) : Daisuke Takasuka (University of Tokyo)
Abstract : In the tropics, various kinds of weather systems are spontaneously realized, as represented by mesoscale convective systems, equatorial waves, the Madden–Julian oscillation ((\rm{MJO})). They interact with each other through moist processes, wave–mean-flow interaction, and so on. As an example of this, we will present a non-linear multi-scale process in the MJO initiation, which involves the mean tropical circulations and equatorial waves, using a simplified three-dimensional fluid dynamical model.

[00606] Eigenvalue Problem for Perturbation Operator of Two-jet Kolmogorov Type Flow

Format : Talk at Waseda University
Author(s) : Tatsu-Hiko Miura (Hirosaki University)
Abstract : We consider the linear stability of the two-jet Kolmogorov type flow which is a stationary solution to the vorticity equation on the unit sphere given by the zonal spherical harmonic function of degree two. Using the mixing structure of the two-jet Kolmogorov type flow, we show that the perturbation operator does not have eigenvalues except for zero. As an application, we also prove the occurrence of the enhanced dissipation in the linearized setting.

[00377] On the physics-informed neural networks approximating the primitive equations

Format : Online Talk on Zoom
Author(s) : Quyuan Lin (University of California, Santa Barbara)Ruimeng Hu (University of California, Santa Barbara)Alan Raydan (University of California, Santa Barbara)Sui Tang (University of California, Santa Barbara)
Abstract : Large scale dynamics of the oceans and the atmosphere are governed by the primitive equations (PEs). Due to the nonlinearity and nonlocality, the numerical study of the PEs is in general a hard task. In this talk, I will introduce physics-informed neural networks (PINNs) to tackle this challenge, and show the theoretical error estimates and the results from numerical experiments that confirm the reliability of PINNs.

[00201] Data-Driven Methods for Rough PDEs

Session Time & Room :

00201 (1/3) : 2C (Aug.22, 13:20-15:00) @E705

00201 (2/3) : 2D (Aug.22, 15:30-17:10) @E705

00201 (3/3) : 2E (Aug.22, 17:40-19:20) @E705

Type : Proposal of Minisymposium
Abstract : Recently there has been an increased interest in applying data driven methods to learn partial differential equations (PDEs). For example, operator learning has been developed to learn maps between infinite-dimensional function spaces and has shown success in the context of smooth PDEs. However, these methods perform poorly in areas where PDEs are less well-behaved; for instance, when equations are parameterized by non-smooth functions or when the PDE involves stochasticity. This mini-symposium invites experts on novel methods for learning stochastic and ill-conditioned multiscale PDEs. Topics will include numerical methods for SPDEs, learning in multiscale settings, and advances in operator learning.

[04969] Operator Learning by Regressing PDEs

Format : Talk at Waseda University
Author(s) : Bamdad Hosseini (University of Washington)
Abstract : In this talk we will discuss a new approach towards operator learning by regression or discovery of the functional form the PDE. A simple, three step approach will be discussed that can be implemented using convenient, off-the-shelf kernel regression tools. Our approach naturally includes PDEs with unknown and variable coefficients and obtains competitive accuracy when training data is very scarce.

[05235] Neural Operator for Discovering Physical Equations

Format : Talk at Waseda University
Author(s) : Paul Bogdan (USC)Xiongye Xiao (USC)Gaurav Gupta (USC)Radu Victor Balan (UMD)
Abstract : We develop a multiwavelet-based neural operator learning architecture that compresses the associated operator's kernel using fine-grained multiwavelets. For the initial value problems, we propose an exponential neural operator scheme for efficiently learning the map between the initial condition and the activities at later times. To solve coupled partial differential equations, we propose the coupled multiwavelets operator learning scheme by decoupling the coupled integral kernels during the decomposition and reconstruction procedures in the Wavelet space.

[05013] Neural Option Pricing for Rough Bergomi Model

Format : Talk at Waseda University
Author(s) : Guanglian Li (HKU)
Abstract : This research investigates pricing financial options based on the rough Bergomi model by neural SDEs. We propose an efficient approximation of sample paths using the sum of exponentials and implement the Wasserstein distance as a loss function for network training. The option pricing is entirely based on the traditional martingale theory.

Our experimental results indicate that the error of the option price can be bounded by the very Wasserstein distance attained during training.

[05221] One shot learning of stochastic differential equations with kernel methods

Format : Talk at Waseda University
Author(s) : Matthieu Darcy (California Institute of Technology)Boumediene Hamzi (Johns Hopkins University)Giulia Livieri (Scuola Normale Superiore)Houman Owhadi (California Institute of Technology)Peyman Tavallali (Jet Propulsion Lab, NASa)
Abstract : We consider the problem of learning a Stochastic Differential Equations from one sample trajectory, a challenging problem as a single trajectory only provides indirect information on the unknown functions. We propose a kernel-based method that recovers the drift function f and the diffusion function σ via Maximum a Posteriori Estimation given the data. Additionally, we learn the kernels from data with randomized cross-validation. Numerical examples illustrate the efficacy and robustness of our method.

00201 (2/3) : 2D @E705 [Chair: Matthieu Darcy]

[03744] GMsFEM based multiscale model learning

Format : Talk at Waseda University
Author(s) : Eric Chung (The Chinese University of Hong Kong)Yiran Wang (Purdue University)Shubin Fu (Eastern Institute for Advanced Study)
Abstract : In this talk, we present a deep learning based reduced order modeling method for stochastic flow problems in highly heterogeneous media. We aim to utilize supervised learning to build a reduced surrogate mapping from the stochastic parameter space that characterizes the possible highly heterogeneous media to the solution space of a stochastic flow problem. The research of Eric Chung is partially supported by the Hong Kong RGC General Research Fund (Projects: 14305222 and 14304021).

[03131] Multilevel Picard Approximation Algorithm for Semi-linear Integro-differential Equations

Format : Talk at Waseda University
Author(s) : Ariel Neufeld (Nanyang Technological University)Sizhou Wu (Nanyang Technological University)
Abstract : We introduce a multilevel Picard approximation algorithm for semi-linear parabolic partial integro-differential equations (PIDEs). We prove that the numerical approximation scheme converges to the unique viscosity solution of the PIDE under consideration. To that end, we derive a nonlinear Feynman-Kac formula. Furthermore, we show that the algorithm does not suffer from the curse of dimensionality, i.e., the computational complexity of the algorithm is bounded polynomially in the dimension and the reciprocal of the prescribed accuracy.

[03090] Exponentially Convergent Multiscale Finite Element Method

Format : Talk at Waseda University
Author(s) : Yixuan Wang (California Institute of Technology)
Abstract : Exponentially convergent multiscale finite element method (ExpMsFEM) for efficient model reduction of PDEs in heterogeneous media without scale separation and in high-frequency wave propagation is proposed. ExpMsFEM is built on the non-overlapped domain decomposition in the classical MsFEM while enriching the approximation space systematically to achieve a nearly exponential convergence rate regarding the number of basis functions.

[05179] Learning Solutions to Elliptic PDEs with Discontinuous Multiscale Parameters

Format : Talk at Waseda University
Author(s) : Margaret Katherine Trautner (California Institute of Technology)
Abstract : Elliptic partial differential equations with discontinuous coefficients arise in modeling dynamics of solid materials. When these coefficients are also multiscale, homogenization theory eliminates the rapidly-varying stiff variable. The bottleneck of this approach is solving an associated cell problem whose discontinuous parameters make solving computationally expensive. Thus, we aim to learn the cell problem solution via data-driven means. In this talk, we describe rigorous theory underpinning these learning methods and numerical experiments that validate the theory.

00201 (3/3) : 2E @E705 [Chair: Edoardo Calvello]

[04555] Recent Advances in Rigorous Koopmanism

Format : Talk at Waseda University
Author(s) : Matthew Colbrook (University of Cambridge)Qin Li (UW-Madison)Ryan Raut (University of Washington)Alex Townsend (Cornell University)
Abstract : Koopman operators are infinite-dimensional operators that globally linearize nonlinear dynamical systems, making their spectral information valuable for understanding dynamics. They have received considerable attention over the last decade, yet computing their spectral properties is a major challenge. I will present some recent advances in data-driven computation of Koopman spectral properties, including ResDMD and its analogue for stochastic dynamical systems. These new algorithms verifiably converge to the correct spectral properties (avoiding issues such as spectral pollution).

[05147] Solving path-dependent PDEs with signature kernels

Format : Talk at Waseda University
Author(s) : Cristopher Salvi (Imperial College London)
Abstract : In talk I will introduce a kernel framework for solving path-dependent PDEs (PPDEs) leveraging signature kernels, a recently introduced class of kernels indexed on path space. The proposed method recast the original infinite dimensional optimsation problem to an optimal recovery problem that approximates the solution of a PPDE with an element of minimal norm in the (signature) reproducing kernel Hilbert space constrained to satisfy the PPDE at a finite collection of collocation paths. By the representer theorem, the optimisation has a unique, analytic solution expressed entirely in terms of simple linear algebra operations. I will will discuss some motivating examples from rough volatility and present numerical results on option pricing under a rough Bergomi model.

[05248] Kernel Methods for Rough PDEs

Format : Talk at Waseda University
Author(s) : Edoardo Calvello (California Institute of Technology)Ricardo Baptista (California Institute of Technology)Matthieu Darcy (California Institute of Technology)Houman Owhadi (California Institute of Technology)Andrew Stuart (California Institute of Technology)Xianjin Yang (California Institute of Technology)
Abstract : Following the promising success of kernel methods in solving non-linear partial differential equations (PDEs), we investigate the application of Gaussian process methods to solve PDEs with rough right-hand side. We introduce an optimal recovery scheme defined by a Reproducing Kernel Hilbert Space (RKHS) of functions of greater regularity than that of the PDE's solution. We illustrate the resulting theoretical framework for the recovery of solutions to the PDE and related numerical experiments.

[00211] Mathematics of Geometric Deep Learning

Session Time & Room :

00211 (1/4) : 1C (Aug.21, 13:20-15:00) @E812

00211 (2/4) : 1D (Aug.21, 15:30-17:10) @E812

00211 (4/4) : 2C (Aug.22, 13:20-15:00) @E812

Type : Proposal of Minisymposium
Abstract : Geometric deep learning has important applications in the fields of quantum computing, 3D perception, molecular designs, and the discovery of mathematical theorems. It takes account of properties such as invariance and equivariance. Many existing structure-aware deep networks lack rigorous theoretical foundations of desired properties in modeling, such as network stability, interpretability, and efficient computation. This workshop will gather researchers from mathematics and computer sciences to provide a forum to establish diverse mathematical theories for geometric deep learning, such as harmonic analysis, algebraic topology, algebraic geometry, combinatorics, differential geometry, differential equations, graph theory, approximation theory, statistics, and theoretical computer science.

[01563] Negative sampling for graph neural networks based on determinantal point processes

Author(s) : Junyu Xuan (University of Technology Sydney)
Abstract : Graph neural networks (GNNs) have become the de facto standard of a variety of graph-based applications. Most GNNs are built on a message-passing mechanism and only aggregate information from the first-order neighbours (positive samples), which may lead to over-smoothing, limited expressive power and over-squashing. However, beyond these neighbouring nodes, graphs have a large, dark, all-but forgotten world in which we find the non-neighbouring nodes (negative samples) that are helpful for representation learning.

[01565] Spherical Framelets with Directionality for Spherical Neural Networks

Author(s) : Jianfei Li (City University of Hong Kong)Han Feng (City University of Hong Kong)Xiaosheng Zhuang (City University of Hong Kong)
Abstract : In this talk, we shall focus on the constructions and applications of directional framelets beyond the Euclidean domain, i.e., on the 2-sphere. We shall discuss their characterizations in terms of the affine systems. Fast algorithmic framelet transforms associated with the underlying filter banks or multiscale structures will be investigated. Moreover, based on our spherical framelets with directionality, we shall consider the development of spherical convolutional neural network (SNN) model for deep learning tasks.

[01568] Some Applications of Hyperplane Arrangements in Deep Learning

Author(s) : Huan Xiong (HIT and MBZUAI)
Abstract : In this talk, we build some connections between hyperplane arrangements and Piecewise Linear Convolutional Neural Networks (PLCNNs), and use them to derive maximal and average numbers of linear regions for one-layer PLCNNs. Furthermore, we obtain upper and lower bounds for the number of linear regions of multi-layer PLCNNs. Our results suggest that deeper ReLU CNNs have more powerful expressivity than their shallow counterparts, while ReLU CNNs have more expressivity than fully-connected ReLU NNs per parameter.

[01769] Machine Learning in Banach Spaces: A Black-box or White-box Method?

Author(s) : Qi Ye (South China Normal University)
Abstract : In this talk, we study the whole theory of regularized learning for generalized data in Banach spaces including representer theorems, approximation theorems, and convergence theorems. Specially, we combine the data-driven and model-driven methods to study the new algorithms and theorems of the regularized learning. Usually the data-driven and model-driven methods are used to analyze the black-box and white-box models, respectively. With the same thought of the Tai Chi diagram, we use the discrete local information of the black-box and white-box models to construct the global approximate solutions by the regularized learning. Our original ideas are inspired by the eastern philosophy such as the golden mean. The work of the regularized learning for generalized data provides another road to study the algorithms of machine learning including: 1. the interpretability in approximation theory, 2. the nonconvexity and nonsmoothness in optimization theory, 3. the generalization and overfitting in regularization theory. Moreover, based on the theory of the regularized learning, we will construct the composite algorithms combining the model-driven and data-driven methods for our current research projects of the big data analytics in education and medicine.

00211 (2/4) : 1D @E812

[01857] Stable Hyperbolic Neural Networks for Graph Generation and Classification

Author(s) : Eric Qu (Duke Kunshan University)Dongmian Zou (Duke Kunshan University)
Abstract : The past few years have witnessed successful development of hyperbolic neural networks. However, they are known to suffer from instability in training. In this talk, we present two recent works that build novel hyperbolic layers for generation and classification tasks on tree-like and hierarchical-structured data. The first defines a stable hybrid AE-GAN model; the second defines a hyperbolic convolutional layer built upon pre-defined kernel points. We illustrate their competitiveness by showing extensive numerical results.

[02110] Spectral-Inspired Graph Neural Networks

Author(s) : Teresa Huang (Johns Hopkins University)

Abstract : Message Passing Neural Networks (MPNNs) can suffer from expressivity issues like over-smoothing and over-squashing. To mitigate such issues, we propose PowerEmbed -- a simple layer-wise normalization technique to boost MPNNs. We show PowerEmbed can provably express the top-k leading eigenvectors of the graph operator, which prevents over-smoothing and is agnostic to the graph topology; meanwhile, it produces a list of representations ranging from local features to global signals, which avoids over-squashing.

[02341] Generalization Capabilities of Graph Neural Networks

Author(s) : Gitta Kutyniok (LMU Munich)Sohir Maskey (LMU Munich)Ron Levie (Technion)Yunseok Lee (LMU Munich)

Abstract : The tremendous importance of graph structured data due to recommender systems, social networks, or biological applications led to the introduction of graph neural networks. One key question in machine learning is the ability of a learnt model to generalize to unknown data sets. In this talk, we will present several results on the generalization capabilities of graph neural networks, focussing on both message passing and spectral graph neural networks.

[03411] On the stability of spectral graph filters and beyond

Author(s) : Xiaowen Dong (University of Oxford)

Abstract : Data collected in network domains, hence supported by an (irregular) graph rather than a (regular) grid-like structure, are becoming pervasive. Typical examples include gene expression data associated with a protein-protein interaction graph, or behaviours of a group of individuals in a social network. Graph-based signal processing and machine learning are recent techniques that have been developed to handle such graph-structured data and have seen applications in such diverse fields as drug discovery, fake news detection, and traffic prediction. However, a theoretical understanding of the robustness of these models against perturbation to the input graph domain has been lacking. In this talk, I will present our results on the stability bounds of spectral graph filters as well as other recent work on the robustness of graph machine learning models, which together will contribute to the deployment of these models in real-world scenarios.

00211 (3/4) : 1E @E812

[03588] Geometric Diffusion Generative model for protein sequence design

Author(s) : Kai Yi (UNSW)

Abstract : Propose a new approach to protein sequence design using a diffusion generative model in geometric. This approach has the potential to improve protein properties and has implications for biotechnology and medicine. The method outperforms state-of-the-art methods on benchmark datasets.

[03727] FoSR: First-order spectral rewiring for addressing oversquashing in GNNs

Author(s) : Guido Montufar (UCLA and MPI MiS)

Abstract : Graph neural networks (GNNs) are able to leverage the structure of graph data by passing messages along the edges of the graph. While this allows GNNs to learn features depending on the graph structure, for certain graph topologies it leads to inefficient information propagation and a problem known as oversquashing. This has recently been linked with the curvature and spectral gap of the graph. On the other hand, adding edges to the message-passing graph can lead to increasingly similar node representations and a problem known as oversmoothing. We propose a computationally efficient algorithm that prevents oversquashing by systematically adding edges to the graph based on spectral expansion. We combine this with a relational architecture, which lets the GNN preserve the original graph structure and provably prevents oversmoothing. We find experimentally that our algorithm outperforms existing graph rewiring methods in several graph classification tasks. This is work with Kedar Karhadkar and Pradeep Kr. Banerjee.

[04482] DynG2G: An Efficient Stochastic Graph Embedding Method for Temporal Graphs

Author(s) : Mengjia Xu (Brown University & MIT)Apoorva Vikram Singh (National Institute of Technology)George Em Karniadakis (Brown University)

Abstract : Dynamic graph embedding has gained great attention due to its capability of learning low-dimensional graph embeddings for complex temporal graphs with high accuracy. However, recent advances mostly focus on learning node embeddings as deterministic ``vectors'' for static graphs, hence disregarding the key graph temporal dynamics and the

evolving uncertainty associated with node embedding in the latent space. We propose an efficient stochastic dynamic graph embedding method (DynG2G) that applies an inductive feed-forward encoder trained with node triplet energy-based ranking loss. Every node per timestamp is encoded as a time-dependent probabilistic multivariate Gaussian distribution in the latent space. We adopted eight benchmarks of different sizes and evolving dynamics (from slowly changing dynamics to rapidly varying multi-rate dynamics). Our experiments indicate that DynG2G achieves new state-of-the-art performance in capturing the temporal node embeddings and simultaneously predicting the evolving node embedding uncertainty, which plays a crucial role in quantifying the intrinsic dimensionality of the dynamical system over time. We also obtain a “universal” relation of the optimal embedding dimension L versus the effective dimensionality of uncertainty (D). The L - D correlation provides a clear path for selecting the optimum embedding size adaptively per timestamp by $L \geq D$.

[04999] On oversquashing and expressivity: can GNNs mix variables?

Author(s) : Francesco Di Giovanni (University of Cambridge)
Abstract : I discuss how Message Passing Neural Networks (MPNNs) model mixing among features in a graph. As a consequence of this approach, I show that MPNNs may need as many layers as the (largest) commute time to model strong mixing of distant nodes in a graph. This allows to derive a measure for over-squashing and to clarify how the latter limits the expressivity of MPNNs to learn functions with long-range interactions.

00211 (4/4) : 2C @E812

[05074] Applied harmonic analysis and particle dynamics for designing neural message passing on graphs

Author(s) : Yuguang Wang (Shanghai Jiao Tong University)
Abstract : Graph representation learning has broad applications applications from recommendation systems to drug and protein designs. In this talk, I will talk about using harmonic analysis and particle systems to design useful neural message passing with theoretically guaranteed separability and efficient computation. These message passings are proved to have strictly positive lower bounded Dirichlet energy and thus to circumvent the oversmoothing problem appearing in many spatial GNNs, when the node features are indistinguishable as the network deepens.

[05109] Geometric Deep Learning from a Topological Viewpoint

Author(s) : Cristian Bodnar (Microsoft Research)
Abstract : The multitude of applications where data is attached to spaces with non-Euclidean structure has driven the rise of the field of Geometric Deep Learning (GDL). Nonetheless, from many points of view, geometry does not always provide the right level of abstraction to study all the spaces that commonly emerge in such settings. For instance, graphs, by far the most prevalent type of space in GDL, do not even have a geometrical structure in the strict sense. In this talk, I will explore how we can take a (more general) topological perspective of the field with a focus on understanding and developing Graph Neural Network models.

[05231] Ridgelet Transforms of Neural Network on Manifolds and Hilbert Spaces

Author(s) : Sho Sonoda (RIKEN AIP)
Abstract : Ridgelet transform is a pseudo-inverse operator of neural networks. Namely, given a function $f \in L^2(\mathbb{R}^m)$, the ridgelet transform $R[f]$ describes how the network parameters should be distributed for the network to represent f. In this talk, I will explain a systematic scheme to derive the ridgelet transform by turning the network into a Fourier expression. As applications, we extend the scheme to networks on manifolds G/K and Hilbert spaces H, and derive their associated ridgelet transforms.

[05341] Scattering Message Passing

Author(s) : Yuanhong Jiang (Shanghai JiaoTong University)
Abstract : Graph neural network (GNN) with message Passing scheme provides an elegant way to process graph data. However, the stability, oversmoothing and oversquashing problems commonly exist in current GNN models. We propose the message passing scheme with scattering transform which is proved theoretically to solve the above problems. In the numerical experiments, the scattering message passing has been validated to be effective compared to SOTA GNN models.

[00215] Mathematical Advances in the nonlinear PDEs from physics

Session Time & Room :

00215 (1/3) : 4E (Aug.24, 17:40-19:20) @G702

00215 (2/3) : 5B (Aug.25, 10:40-12:20) @G702

00215 (3/3) : 5C (Aug.25, 13:20-15:00) @G702

Type : Proposal of Minisymposium
Abstract : The aim of this mini-symposium is to bring together experts in the area of nonlinear PDEs from physics, such as Euler-type equations and Boltzmann equation, to present their recent research results in theoretical analysis and applications in physics. In this mini-symposium, people are expected to exchange new ideas, to discuss challenging issues, to explore new directions and topics, and to foster new collaborations and connections.

[04052] Wave propagation and stabilization in the Boussinesq–Burgers system

Format : Talk at Waseda University
Author(s) : Zhi-An Wang (The Hong Kong Polytechnic University)
Abstract : This talk will discuss the existence and stability of traveling wave solutions of the Boussinesq–Burgers system describing the propagation of bores. Assuming the fluid is weakly dispersive, we establish the existence of three different wave profiles by the geometric singular perturbation theory alongside phase plane analysis. We further employ the method of weighted energy estimates to prove the nonlinear asymptotic stability of the traveling wave solutions against small perturbations. The technique of taking antiderivative is utilized to integrate perturbation functions because of the conservative structure of the Boussinesq–Burgers system. Using a change of variable to deal with the dispersion term, we perform numerical simulations for the Boussinesq–Burgers system to showcase the generation and propagation of various wave profiles in both weak and strong dispersions. The numerical simulations not only confirm our analytical results, but also illustrate that the Boussinesq–Burgers system can generate numerous propagating wave profiles depending on the profiles of initial data and the intensity of fluid dispersion, where in particular the propagation of bores can be generated from the system in the case of strong dispersion.

[03930] Hypersonic similarity for steady potential flows over a two dimensional wedge

Format : Talk at Waseda University
Author(s) : jie kuang (Academy of Mathematics and Systems Science)wei xiang (city university of hong kong)Yongqian Zhang (Fudan University)
Abstract : We will talk about our recent results on the hypersonic similarity for the potential flow over a two-dimensional wedge. The convergence is obtained in BV\cap L^1 spaces. Progress on related problems will be presented too.

[05017] Stability theory for the linear symmetric hyperbolic system with general relaxation

Format : Talk at Waseda University
Author(s) : Yoshihiro Ueda (Kobe University)
Abstract : In this talk, we study the dissipative structure for the linear symmetric hyperbolic system with general relaxation. If the relaxation matrix of the system has symmetric properties, Shizuta and Kawashima(1985) introduced the suitable stability condition, and Umeda, Kawashima and Shizuta(1984) analyzed the dissipative structure. On the other hand, Ueda, Duan and Kawashima(2012,2018) focused on the system with non-symmetric relaxation and got partial results. Furthermore, they argued the new dissipative structure called the regularity-loss type. In this situation, this talk aims to extend the stability theory introduced by Shizuta and Kawashima(1985) and Umeda, Kawashima and

Shizuta(1984) to our general system. Furthermore, we will consider the optimality of the dissipative structure. If we have time, I would like to discuss some physical models for its application and new dissipative structures.

[00454] Stability of Riemann shock wave via the method of a-contraction of shifts

Format : Talk at Waseda University
Author(s) : Moon-Jin Kang (KAIST)
Abstract : I will present the so-called "a-contraction with shifts" method.
This method is quite useful in studying the stability of Navier-Stokes and Euler flows perturbed from Riemann solution containing a shock wave.
First, this method is energy based, and so allows us to seamlessly handle the composite wave of a viscous shock and rarefaction for its long-time behavior.
On the other hand, since the method can handle large perturbations of a viscous shock, and so provides the uniform stability of the shock w.r.t. the strength of viscosity, we can prove that the Riemann solution composed of a shock is stable and unique in the class of inviscid limits of solutions to the associated Navier-Stokes system.

00215 (2/3) : 5B @G702 [Chair: Xianpeng Hu]

[03959] Polynomial tail solutions for Boltzmann equation in the whole space

Format : Talk at Waseda University
Author(s) : Renjun Duan (The Chinese University of Hong Kong)
Abstract : We are concerned with the Cauchy problem on the Boltzmann equation in the whole space. The goal is to construct global-in-time bounded mild solutions near Maxwellians with the perturbation admitting a polynomial tail in large velocities. The main difficulty to be overcome in case of the whole space is the polynomial time decay of solutions which is much slower than the exponential rate in contrast with the torus case.

[02793] Analytic regularization effect for the spatially inhomogeneous Boltzmann equation

Format : Talk at Waseda University
Author(s) : Wei-Xi LI (Wuhan University)
Abstract : We verify in this work the spatially inhomogeneous Boltzmann equation with strong angular singularity will admit the analytic smoothing effect, just like its diffusive models such as the Landau and Fokker-Planck equations. To overcome the degeneracy in the spatial variable, a family of well-chosen vector fields with time-dependent coefficients will play a crucial role in the proof

[04010] Dispersive limit of kinetic models for collisional plasma

Format : Talk at Waseda University
Author(s) : Zhu Zhang (The Hong Kong Polytechnic University)Tong Yang (The Hong Kong Polytechnic University)
Abstract : The motion of charged particles can be described by the Vlasov-Poisson-Boltzmann (VPB) system. Compared to the classical Boltzmann equation for dilute gases, solutions to VPB are expected to have dispersive behavior because of the dispersion mechanism on the dynamics of plasma in different scales of physical interest. By a formal spectrum analysis, we can observe asymptotic relations between VPB and some limiting dispersive equations in a suitable regime. Then we justify that the propagation of non-linear ions-acoustic waves are governed by the KdV equation. This is a joint work with T. Yang.

[04067] Wave propogation and stabilization in the Boussinesq-Burgers system

Format : Talk at Waseda University
Author(s) : Xianpeng Hu (City University of Hong Kong)Anita Yang (The Chinese University of Hong Kong)
Abstract : In this talk, we will present the existence and stability of traveling wave solutions of the Boussinesq–Burgers system describing the propagation of bores. Assuming the fluid is weakly dispersive, we establish the existence of three different wave profiles by the geometric singular perturbation theory alongside phase plane analysis. We further employ the method of weighted energy estimates to prove the nonlinear asymptotic stability of the traveling wave solutions against small perturbations. The technique of taking antiderivative is utilized to integrate perturbation functions because of the conservative structure of the Boussinesq–Burgers system. Using a change of variable to deal with the dispersion term, we perform numerical simulations for the Boussinesq–Burgers system to showcase the generation and propagation of various wave profiles in both weak and strong dispersions. The numerical simulations not only confirm our analytical results, but also illustrate that the Boussinesq–Burgers system can generate numerous propagating wave profiles depending on the profiles of initial data and the intensity of fluid dispersion, where in particular the propagation of bores

can be generated from the system in the case of strong dispersion. The talk is based on a recent joint work with Prof. Zhian Wang and Prof. Kun Zhao.

00215 (3/3) : 5C @G702 [Chair: Renjun Duan]

[04667] Vacuum free boundary problems in ideal compressible MHD

Format : Talk at Waseda University
Author(s) : Tao Wang (Wuhan University)
Abstract : We present the joint works with Professor Yuri Trakhinin on the local well-posedness of vacuum free boundary problems in ideal compressible magnetohydrodynamics (MHD) with or without surface tension.

[01253] Well-posedness of some free boundary problems in compressible fluids

Format : Talk at Waseda University
Author(s) : Wenbin Zhao (Peking University)
Abstract : In this talk, we will discuss some free boundary problems in compressible fluids. We derive the evolution equation of the free surface and identify the stability condition of the problem. This method gives a unified approach to treat both incompressible and compressible fluids.

[04043] Long time instability of compressible symmetric shear flows

Format : Talk at Waseda University
Author(s) : Xianpeng Hu (City University of Hong Kong)Andrew Yang (City University of Hong Kong)
Abstract : It is well-known that at high Reynolds numbers, the linearized Navier-Stokes equations around the inviscid stable shear profile admit growing mode solutions due to the destabilizing effect of small viscosities. This phenomenon, which is related to Tollmien-Schlichting instability, has been rigoriously justified by Grenier-Guo-Nguyen [Adv. Math. 292 (2016); Duke J. Math. 165 (2016)] on incompressible Navier-Stokes equations. In this work, we aim to construct the Tollmien-Schlichting waves for the compressible Navier-Stokes equations over symmetric shear flows in a channel. We will also discuss the effect of temperature fields on the stability of these shear flows.

[00216] Recent Advances on interfaces dynamics modeling and simulation

Session Time & Room :

00216 (1/3) : 5B (Aug.25, 10:40-12:20) @A601

00216 (2/3) : 5C (Aug.25, 13:20-15:00) @A601

00216 (3/3) : 5D (Aug.25, 15:30-17:10) @A601

Type : Proposal of Minisymposium
Abstract : Dynamics of the interface, like deformation and reaction, play an important role in biology like cell aggregation, and industry like water-proof material. Modeling and simulation of the dynamics of the interface are challenging since multiphase-flow and multiphysics fields are evolved. Recently, machine learning-based methods like Neural networks are introduced to solve the obtained nonlinear coupled system more efficiently. The purpose of this symposium is to bring together researchers working on modeling, theory, and numerics for interface problems, to share the latest advances in the field, and to provide a forum for joint collaborations.

[01225] Solving elliptic interface problems using neural networks

Format : Talk at Waseda University
Author(s) : Ming-Chih Lai (National Yang Ming Chiao Tung University)
Abstract : In this talk, we shall introduce a series of neural network methodology for solving elliptic interface problems that comprise of variable-coefficient Poisson equation and Stokes equations with interfaces. There are three novel features in the present network; namely, (i) jump discontinuities are accurately captured, (ii) it is completely

shallow, comprising only one hidden layer, (iii) it is completely mesh-free so the problems in irregular domains with irregular interfaces can be handled easily. Numerical results show better accuracy than the traditional finite difference method such as the immersed interface method.

[01276] Role of Cohesive Fiber-Fiber Interactions in Fibrin Networks

Format : Online Talk on Zoom

Author(s) : Zhiliang Xu (University of Notre Dame)

Abstract : A novel structural mechanism of fibrin clots' mechanical response to external tensile loads is tested using newly developed three-dimensional computational model. This mechanism, underlying local strain-stiffening of individual fibers as well as global stiffening of the entire network, is based on previously neglected nascent cohesive pairwise interactions between individual fibers (crisscrossing) in fibrin networks formed under tensile load. The computational model enabled us to study structural details and quantify mechanical effects of the fiber-fiber cohesive crisscrossing during stretching of fibrin gels at various spatial scales. The results show that the nascent cohesive crisscrossing of fibers in stretched fibrin networks comprise an underappreciated important structural mechanism underlying the mechanical response of fibrin to (patho)physiological stresses that determine the course and outcomes of thrombotic and hemostatic disorders.

[01217] Variational Lagrangian schemes for interface problems

Format : Online Talk on Zoom

Author(s) : Yiwei Wang (University of California, Riverside)Chun Liu (Illinois Institute of Technology)

Abstract : In this talk, we present a systematic framework for deriving variational numerical methods for generalized diffusions and gradient flows. The numerical framework is based on the energy-dissipation law, which describes all the physics and the assumptions in each system and can combine different types of spatial discretizations including Eulerian, Lagrangian, and particle-based approaches. The resulting semi-discrete equation inherits the variational structures from the continuous energy-dissipation law. We apply such an approach to construct variational Lagrangian schemes to several interface problems, including the Allen-Cahn type phase-field models and the porous medium equation. Numerical examples show the advantages of the variational Lagrangian schemes in capturing thin diffuse interfaces and free boundaries. This is joint work with Professor Chun Liu.

[01256] Helical organization of DNA-like liquid crystal filaments in cylindrical viral capsids

Format : Online Talk on Zoom

Author(s) : Pei Liu (Florida Institute of Technology)

Abstract : We study equilibrium configurations of ds-DNA in a cylindrical viral capsid. The state of the encapsidated DNA consists of a disordered inner core enclosed by an ordered outer region, next to the capsid wall. The DNA configuration is described by a unit helical vector field, tangent to an associated center curve, passing through properly selected locations. We postulate an expression for the energy of the encapsulated DNA based on that of columnar chromonic liquid crystals. A thorough analysis of the Euler--Lagrange equations yields multiple solutions. We demonstrate that there is a trivial, non-helical solution, together with two solutions with nonzero helicity of opposite sign. Using bifurcation analysis, we derive the conditions for local stability and determine when the preferred coiling state is helical. The bifurcation parameters are the ratio of the twist versus the bend moduli of DNA and the ratio between the sizes of the ordered and the disordered regions.

00216 (2/3) : 5C @A601 [Chair: Ming-Chih Lai]

[01231] A phase-field model and an energy-law preserving method for vesicles

Format : Talk at Waseda University

Author(s) : Ping Lin (University of Dundee)

Abstract : We will first show how to develop a thermodynamically consistent phase field model for the binary incompressible (quasi-incompressible) fluid. We then show how to apply the idea to model vesicle motions and deformations through a narrowed channel. We will also introduce a Lennard-Jones type of interaction potential for vesicle-vesicle and vesicle-channel wall interactions. An energy law preserving computational method is then developed for the model. A few computational examples including vesicle-wall and multi-vesicle interactions will be presented to demonstrate the model and the computational method.

[01214] Free boundary problems in cardiovascular diseases

Format : Talk at Waseda University
Author(s) : Wenrui Hao (Penn State University)
Abstract : I will present several free boundary problems based on the pathophysiology of cardiovascular disease. As an example, a mathematical model of atherosclerosis, based on this modeling approach, provides a personalized cardiovascular risk by solving a free boundary problem. Some interesting mathematical problems are also introduced by this new model to help us understand cardiovascular risk.

[05636] Buckling on Erythrocyte Membranes in Narrow Capillary Flows

Author(s) : Deyun Liu (Shanghai Jiao Tong University)Kazuyasu Sugiyama (Osaka University)Xiaobo Gong (Shanghai Jiao Tong University)
Abstract : Experiments and numerical simulations are conducted to understand the non-axisymmetric deformation of a single RBC in narrow tubes and the hydrodynamics associated. With decreasing capillary numbers, the stable deformation shapes of RBCs change from axisymmetric bullet shape to asymmetric deformation with buckling under the major effect of the negative pressure difference across cell membrane at the rear part of the deformed RBCs.

[01394] Machine Learning of Self Organization from Observation

Format : Online Talk on Zoom
Author(s) : Ming Zhong (Illinois Institute of Technology)
Abstract : Self organization (also known as collective behaviors) can be found in studying crystal formation, aggregation of cells/animals, social behaviors of insects and humans, etc. It is a challenging task to understand such behaviors from the mathematical point of view. We offer a statistical/machine learning approach to understand these behaviors quantitatively from observation data; moreover, our learning approach can aid in validating and improving the modeling of collective behaviors.

We develop a learning framework to derive physically meaningful models to explain self organization from observation. We also investigate the stead state properties of our learned models, and extend the learning framework to include more complicated structures. We extend the learning approach to infer dynamical models for agents constrained on Riemannian manifolds. We further improve our learning capability to infer interaction feature variables as well as interaction kernels. We even study the effectiveness of our learning method on the NASA Jet Propulsion Laboratory's modern Ephemerides. Upon careful inspection of our model, we discover that it even captures potion of the general relativity effects. A complete learning theory on second-order systems is presented, as well as two new models on emergence of social hierarchy and combination of flocking and synchronization.

00216 (3/3) : 5D @A601 [Chair: Shixin Xu]

[01249] A phase field model for droplets suspended in electrolyte solution

Format : Talk at Waseda University
Author(s) : Yuzhe Qin (Shanxi University)Huaxiong Huang (Beijing Normal University, Zhuhai)Shixin Xu (Duke Kunshan Univeristy)Zilong Song (Utah State University)
Abstract : In this talk, we consider modeling the deformation of droplets suspended in electrolyte solution with the phase field method. Firstly, we derive the Poisson-Nernst-Planck-Navier-Stokes phase field model based on energy variational approach method. Secondly, we accomplish the asymptotic analysis for our model after nondimensionalizing the system and the sharp interface limits of our proposed model is consistent to the sharp interface model. We take a series of numerical experiments to validate the correctness and effectiveness about our model.

[01220] A deterministic particle simulation for micro-macro viscoelastic flows

Format : Talk at Waseda University
Author(s) : Xuelian Bao (Beijing Normal University)Chun Liu (Illinois Institute of Technology)Yiwei Wang (University of California, Riverside)
Abstract : We propose a deterministic particle-FEM discretization to micro-macro models of dilute polymeric fluids, which combines a finite element discretization to the macroscopic fluid dynamic equation with a variational particle scheme to the microscopic Fokker-Planck equation. The discretization is constructed by a discrete energetic variational approach, and preserves the microscopic variational structure in the semi-discrete level. All numerical examples demonstrate the accuracy and robustness of the proposed deterministic particle-FEM approach.

[01227] A Bubble Model for the Gating of Kv Channels

Format : Online Talk on Zoom
Author(s) : zilong song (Utah State University)ROBERT EISENBERG (Illinois Institute of Technology)Shixin Xu (Duke Kunshan Univeristy)Huaxiong Huang (York University)
Abstract : Voltage-gated Kv channels play fundamental roles in many biological processes. In this talk, we propose a bubble model coupled with a Poisson-Nernst-Planck (PNP) system to capture the key characteristics, particularly the delay in the opening of channels. The coupled PNP system is solved numerically by a finite-difference method and the solution is compared with an analytical approximation. The predicted ensemble average of the currents and the Cole-Moore delay is consistent with experimental observations.

[00217] Integration of modeling and data analysis on molecular, cellular, and population dynamics in the life sciences

Session Time & Room :

00217 (1/3) : 2C (Aug.22, 13:20-15:00) @A511

00217 (2/3) : 2D (Aug.22, 15:30-17:10) @A511

00217 (3/3) : 2E (Aug.22, 17:40-19:20) @A511

Type : Proposal of Minisymposium
Abstract : Systems biology approaches that integrate heterogeneous biological data in quantitative mathematical models are expected to facilitate a comprehensive understanding of complex biological systems. This A3 (China-Japan-Korea) mini-symposium will bring together Asian mathematicians working in the field of mathematical modeling and data analysis to share their cutting-edge research results on dynamic phenomena at all levels from molecular and cellular to population.
Organizer(s) : Jae Kyoung Kim, Sungrim Seirin-Lee, Lei Zhang

[01180] Mathematical Models of Plasmid Loss

Author(s) : Kresimir Josic (University of Houston)Jayson Cortez (University of Philippines at Los Banos)Amanda Alexander (University of Houston)Charilaos Giannitsis (Rice University)Oleg Igoshin (Rice University)
Abstract : Plasmids, extrachromosomal DNA elements, are found in most bacteria and confer benefits to their hosts. Most models suggest that plasmids are lost in barring strong selection. The ubiquity of plasmids thus presents a paradox. We developed a mathematical model of ColE1 plasmid copy number based on experimental findings. This allows us to relate the probability of plasmid loss to properties of the population and provide testable predictions about conditions under which plasmids are lost.

[00813] Morphology of organoids using a multicellular phase-field model

Author(s) : Sakurako Tanida (The University of Tokyo)Kana Fuji (The University of Tokyo)Tetsuya Hiraiwa (The University of Tokyo, National University of Singapore)Makiko Nonomura (Nihon University)Masaki Sano (The University of Tokyo, Shanghai Jiaotong University)
Abstract : Organoids are self-organizing cells grown from stem cells in vitro. The organoid morphology is affected not only by genes but also by mechanical constrained due to the geometrical requirements to maintain the cell cluster. In this study, using a multicellular phase-field model, we examined the morphology when changing luminal fluid pressure and the minimum time of the cell cycle. Classifying the patterns by several indices, we discuss the mechanisms which generate the different patterns.

[00720] Mind the gap:The extra-embryonic space is crucial geometric constraints regulating cell arrangement.

Author(s) : Sungrim Seirin-Lee (Kyoto University)Kazunori Yamamoto (Kanagawa Institute of Technology)Akatsuki Kimura (National Institute of Genetics)
Abstract : Imagine sitting at a meeting where the shape of the table and your place at it might impact how you get along with the other members. In multicellular systems, cells also communicate with adjacent cells to decide their positions and fates. Cellular arrangement in space is thus important for development. Orientation of cell division, cell-cell interaction, and geometric constraints are the three major factors that define cell arrangement. In particular, the details of geometric constraints are difficult to be revealed only in experiments and the contribution of local contour has been remained elusive. Here we developed a multicellular morphology model based on the phase-field method so that we can incorporate precise geometric constrains. We applied the model to examine cell arrangement in the 4-cell stage embryo of nematodes, and succeeded in reproducing cell arrangements observed in vivo, including an arrangement which has not been explained before. Our cell morphology model predicted that the amount of extra-embryonic space (ES), the empty space within the eggshell not occupied by embryonic cells, affects cell arrangement in a manner dependent on the local contour and the aspect ratio of the eggshell as well as the strength of cell adhesion. The prediction was validated experimentally as increasing the (ES) did change the cell arrangement in the Cenorhabditis elegans embryo. Overall, our analyses characterized the roles of new geometrical contributors, namely the amount of (ES) and the local contour, to cell arrangements. These factors should be considered in all multicellular systems, including human being.

[03207] Test three different models for the Chlamydia developmental cycle with intrinsic noise

Author(s) : Jinsu Kim (POSTECH)
Abstract : Chlamydia is an intracellular bacterium that reproduces via an unusual developmental cycle such as late RB-EB conversion and heterogeneity of individual Chlamydia size. A key step is a conversion from a replicating form (RB) to an infectious form (EB), which occurs in a delayed and asynchronous manner. The regulatory mechanisms that control this developmental switch are unknown, but could potentially include extrinsic signals from the host cell or from other chlamydiae, or an intrinsic signal such as chlamydial cell size. In this presentation, we introduce three stochastic models, each based on a different regulatory mechanism. To test the models, we use the intrinsic noise of each model that can be estimated with statistical quantities measured experimentally. We found that all three models successfully reproduced the observed timing of RB-to-EB conversion and the growth curves of the developmental forms within an inclusion. However, only one model, based on the regulation of RB-to-EB conversion by RB size, was able to produce the positive correlation between the number of RBs and EBs and the monotonic time evolution of the coefficient of variation in the RB population.

00217 (2/3) : 2D @A511

[03206] Network design principle for biological dual functions

Author(s) : Lei Zhang (Peking University)
Abstract : Biological systems are capable of performing complex functions with a remarkable degree of accuracy, reliability, and robustness. We postulate that behind the celebrated diversity of the biological world lie “universal” principles that emerge at various levels of organization. For example, many signaling systems execute adaptation under noisy circumstances, and transcriptional regulatory networks can robustly achieve accurate oscillation in the presence of biological noise. In this talk, we will explore two dual functions: one is adaptation and noise attenuation, and the other one is oscillation and noise attenuation. By analyzing and computing three-node or four-node networks, we reveal essential network design principles for biological dual functions, which can be utilized in synthetic biology.

[03385] Density Physics-Informed Neural Network infers an arbitrary density distribution for non-Markovian system

Author(s) : Hyeontae Jo (Institute for Basic Science)Hyukpyo Hong (KAIST)Hyung Ju Hwang (Pohang University of Science and Technology)Won Chang (University of Cincinnati)Jae Kyoung Kim (KAIST)
Abstract : In this talk, we developed Density-PINN (Physics-Informed Neural Networks), a method capable of estimating the probability density function embedded within a differential equation. While conventional PINNs have focused on determining the solutions or parameters of differential equations that can explain observed data, we introduce a specialized approach for estimating the probability density function contained within the equation. Specifically, when dealing with a limited number of stochastic time series as observed data, and where only the average of the data satisfies the solution of the differential equation, we have constructed a mean-generating model using

Variational Autoencoders. By applying our method to single-cell gene expression data from 16 promoters in response to antibiotic stress, we discovered that promoters with slower signaling initiation and transduction exhibit greater cell-to-cell heterogeneity in response intensity.

[02263] Integrating different layers of biological data to enhance prediction

Author(s) : Suoqin Jin (Wuhan University)

Abstract : The rapid advances of single-cell technologies have been attracting more attention. Recently we made some efforts to enhance biological prediction and discovery from single-cell RNA sequencing. By integrating single-cell RNA-seq with single-cell epigenomic data, bulk data or prior knowledge, we were able to dissect cellular heterogeneity and communication more comprehensively, and prioritize clinically-relevant cell subsets and prognostic signatures, which cannot be fully explained by single-cell genomics only, and highlights the valuable role of data integration.

[03677] Physics of Furrow Ingression in C. elegans Zygote

Author(s) : Masatoshi Nishikawa (Hosei University)

Abstract : Cleavage furrow ingression is asymmetric in the first cleavage of Caenorhabditis elegans zygote. The asymmetric ingression gives rise to the symmetry breaking in terms of dorsal-ventral axis establishment, but its underlying mechanisms are largely unexplored. We will demonstrate that the distribution of cortical tension generator in the contractile ring becomes asymmetric as the curvature change at the ingression site and cortical flow toward the ring, suggesting the feedback between cell shape, contractility and flow.

00217 (3/3) : 2E @A511

[01465] Screening cell-cell communication in spatial transcriptomics via collective optimal transport

Author(s) : Yanxiang Zhao (George Washington University)

Abstract : Spatial transcriptomic technologies and spatially annotated single cell RNA-sequencing (scRNA-seq) datasets provide unprecedented opportunities to dissect cell-cell communication (CCC). How to incorporate the spatial constraints and other physical processes when inferring CCC computationally remains a major challenge. Here we present COMMOT to infer CCC in spatial transcriptomics accounting for the competition among different ligand and receptor species and cells or spots, and enforcing spatial constraints. A novel collective optimal transport method is developed to handle these complex interactions and constraints. Further downstream analysis tools on spatial signaling directions and signaling-regulated genes are then developed using machine learning models. We validate the method with simulation data and one spatially annotated scRNA-seq dataset. We show that COMMOT effectively infers spatial CCC using datasets by three popular spatial transcriptomic technologies. Finally, COMMOT reveals connections between CCC and skin development in a case study of human epidermal development. The method will have broad application in uncovering ligand-receptor mediated CCC using spatial genomics datasets.

[04188] A Novel Tool for Enhanced Single-cell RNA Sequencing Data Preprocessing and Dimensionality Reduction

Author(s) : Hyun Kim (Institute for basic science)JaeKyoung Kim (Korea Advanced Institute of Science and Technology, Institute for basic science)Jong-Eun Park (Korea Advanced Institute of Science and Technology)Minseok Seo (Korea University)

Abstract : Single-cell RNA sequencing (scRNA-seq) has revolutionized various cellular research applications, including cellular phenotyping and gene regulatory network reconstruction. However, data analysis remains challenging due to sparsity, high dimensionality, bias, skewed data distribution, and technological noise. In addition, conventional preprocessing methods, such as log-normalization and user-driven dimensionality reduction techniques, often introduce subjectivity and signal distortion, leading to decreased data dimension accuracy. To address these limitations, we developed a novel tool that effectively filters out data noise and corrects signal distortion during preprocessing. This approach significantly improves the accuracy of dimensionality reduction and overcomes the drawbacks associated with current methodologies. Our solution was tested on 53 real and simulated datasets and demonstrated superior performance compared to ten widely-used tools, including Seurat, Scanpy, and Monocle3. The enhanced performance of our tool offers promise for advancing scRNA-seq data analysis and facilitating more accurate downstream analyses.

[00602] Adaptive immune discrimination of antigen risks by predictive coding

Author(s) : Kana Yoshido (Graduate School of Biostudies, Kyoto University)Honda Naoki (Graduate School of Integrated Sciences for Life, Hiroshima University)

Abstract : Immune system induces appropriate responses depending on the risk of antigens: Strong responses to harmful antigens and weak or no responses to harmless antigens. To reveal the mechanism, we modeled T cell population dynamics with memory formation based on predictive coding. By the simulation, we found antigen

concentration- and input rapidness- dependent discrimination between harmful and harmless antigens. Furthermore, we reproduced temporal change of discrimination as seen in the onset and therapy of allergy.

[00220] Reaction-Diffusion Systems and Applications in life Sciences

Session Time & Room :

00220 (1/3) : 5B (Aug.25, 10:40-12:20) @G601

00220 (2/3) : 5C (Aug.25, 13:20-15:00) @G601

00220 (3/3) : 5D (Aug.25, 15:30-17:10) @G601

Type : Proposal of Minisymposium
Abstract : In this minisymposium we will focus on recent progress about the theory and applications of reaction-diffusion systems. A special focus will on the mathematical modelling and analysis for evolution systems with applications in biological, ecological, health and medical sciences such as modelling infectious diseases and tumor growth in life sciences. The minisymposium will invite experts in the field to report their recent results on these subjects.

[01711] Propagation dynamics of the Fisher-KPP nonlocal diffusion equation with free boundary

Format : Talk at Waseda University
Author(s) : Yihong Du (University of New England)
Abstract : Propagation has been modelled by reaction-diffusion equations since the pioneering works of Fisher and Kolmogorov-Peterovski-Piskunov (KPP). Much new developments have been achieved in the past several decades on the modelling of propagation, with traveling wave and related solutions playing a central role. In this talk, I will report some recent results obtained with several collaborators on the Fisher-KPP equation with free boundary and "nonlocal diffusion", where the diffusion operator is given by a convolution integral instead of the traditional Laplacian operator. A key feature of this nonlocal equation is that the propagation may or may not be determined by traveling wave solutions. There is a threshold condition on the kernel function in the diffusion operator which determines whether the propagation rate is linear or superlinear in time, also known as accelerated spreading in the latter case, where the rate of spreading is not determined by traveling waves. For some typical kernel functions, sharp spreading rates will be presented.

[03297] propagation phenomena of fractional diffusion equations

Format : Talk at Waseda University
Author(s) : Xing Liang (University of Science and Technology of China)
Abstract : In this talk, I will introduce our works on the propagation phenomena of fractional diffusion equations. The first part is about KPP-type equations in almost periodic media. We will show the existence of exponential speeds of propagation and a counterintuitive conclusion that faster diffusion yields slower propagation. The second part is about bistable and multi-stable equation in periodic media. We will show the existence of the traveling terrace and when the traveling terrace becomes a traveling wave.

[02984] Sharp traveling waves for degenerate equations with time-delay: Fisher-KPP equations and Burgers equations

Format : Talk at Waseda University
Author(s) : Ming Mei (McGill University & Champlain College)
Abstract : In this talk, we are concerned with the degenerate diffusion equations with time-delay. The typical examples include Fisher-KPP equations and Burgers equations. The main issue is to investigate the structure of traveling waves, which are the sharp traveling waves with oscillations. The sharpness is caused by the degeneracy of diffusion, and oscillation is caused by the large time-delay.

[03485] Accelerating propagation in a nonlocal model with periodic time delay

Format : Talk at Waseda University
Author(s) : Jian Fang (Harbin Institute of Technology)
Abstract : In this talk, we investigate the accelerating propagation dynamics of a nonlocal population model with periodic time delay, which may arise from the study of stage-structured invasive species subject to seasonal successions. After establishing the fundamental solution of related linear equation, we obtain a sharp estimate for the solution level set.

00220 (2/3) : 5C @G601 [Chair: Yihong Du]

[01484] Recent Progress on Reaction-Diffusion Systems and Applications in Life Sciences

Format : Talk at Waseda University
Author(s) : Hong-Ming Yin (Washington State University)
Abstract : Reaction-diffusion equations and systems are the backbone of many mathematical models in biological, ecological, health and medical sciences. In this talk I will first give a short survey on some recent progress about the global solvability for general reaction-diffusion systems. Then I will focus on a class of nonlinear reaction-diffusion systems with balanced mass. Some new results will be reported in the talk. Finally, I will show how the general result is used to establish the global solvability for two models arising from life sciences.

[04053] Effect of density-dependent dispersal on the predator-prey system

Format : Talk at Waseda University
Author(s) : Zhi-An Wang (The Hong Kong Polytechnic University)
Abstract : This talk is concerned with existence, non-existence and uniqueness of positive (coexistence) steady states to a predator-prey system with density-dependent dispersal. By our analysis results, we pinpoint the positive role of density-dependent dispersal on the predator-prey dynamics for the first time and show that the density-dependent dispersal is a beneficial strategy promoting the coexistence of species in the predator-prey system by increasing the chance of predator's survival.

[04100] Nonlinear Stefan problem with a certain class of multi-stable nonlinearity

Format : Talk at Waseda University
Author(s) : Hiroshi Matsuzawa (Kanagawa University)Yuki Kaneko (Kanto Gakuin University)Yoshio Yamada (Waseda University)
Abstract : I will discuss the long-time dynamical behavior of solutions to a nonlinear Stefan problem for a reaction-diffusion equation with a positive bistable type nonlinearity. I will show that the asymptotic behavior of the solutions is classified into four cases: vanishing, small spreading, big spreading, and transition. In particular, I will show that for transition occurs, the solution converges to an equilibrium solution that is radially symmetric, radially decreasing, and centered at some point as $t \to \infty$.

[01531] Some results on a haptotaxis model of cancer invasion

Format : Online Talk on Zoom
Author(s) : Feng Dai (Huazhong University of Science and Technology)
Abstract : In this talk, we will report some results on a haptotaxis model of cancer invasion. Under appropriate regularity assumptions on initial data, the global solvability of the corresponding homogeneous Neumann initial-boundary value problem is established. In addition, an optimal control problem for this cancer invasion model with chemotherapy is investigated to balance the therapeutic benefits with its side effects.

00220 (3/3) : 5D @G601 [Chair: Zhi-an Wang]

[05208] Basic Propagation Number

Format : Talk at Waseda University
Author(s) : Juan B Gutierrez (University of Texas at San Antonio)
Abstract : In this talk, I present a framework that describes the necessary and sufficient conditions for propagation of one or more undesirable species, named here the nonconformist species, in a given environment when there is an intervention trying to counter their propagation. We assume that the dispersal of the nonconformist could be characterized by a reaction-diffusion process, whereas there is no spatial dependence for the action of the

countermeasures. I present a generalized method that can analyze an arbitrary number of nonconformist species and countermeasures.

[00221] Analysis of Fluid Dynamics and Free Boundary Problems

Session Time & Room :

00221 (1/3) : 1C (Aug.21, 13:20-15:00) @D404

00221 (2/3) : 1D (Aug.21, 15:30-17:10) @D404

00221 (3/3) : 1E (Aug.21, 17:40-19:20) @D404

Type : Proposal of Minisymposium
Abstract : This mini-symposium will focus on the analysis of fluid dynamics and free boundary problems including the geometric evolution equations. We will put particular emphasis on the study of existence, uniqueness, regularity, global existence and stability, singularity formation of the modeling equations and the motion of free interfaces in Euclidean spaces or on manifolds. The study of fluid dynamics and free boundary problems have profoundly impacted many applied fields such as physics, biology and material sciences. Thus the analysis of these problems provides a critical and rigorous mathematical descriptions of the corresponding physical phenomena.
Organizer(s) : Changyou Wang, Yuanzhen Shao
Classification : 76N10, 35R35
Minisymposium Program :

00221 (1/3) : 1C @D404 [Chair: Yuanzhen Shao]

[03643] Transonic flows and free boundary problems in gas dynamics

Format : Talk at Waseda University
Author(s) : Dehua Wang (University of PittsburghUniversity of Pittsburgh)
Abstract : In this talk, the transonic flows and free boundary problems in gas dynamics will be considered. The existence and stability of solutions will be presented for transonic flows past an obstacle and in a nozzle.

[03380] Regularity and asymptotics for porous medium equations in bounded domains

Format : Talk at Waseda University
Author(s) : Tianling Jin (The Hong Kong University of Science and Technology)Xavier Ros-Oton (Universitat de Barcelona)Jingang Xiong (Beijing Normal University)
Abstract : We prove the optimal global regularity of nonnegative solutions to the porous medium equation in smooth bounded domains with the zero Dirichlet boundary condition after certain waiting time. This allows us to refine the asymptotics of solutions for large times. We establish faster rate of convergence and prove that the convergence holds in the regular topology.

[03966] Energy concentration and weak stability in fluid dynamics

Format : Talk at Waseda University
Author(s) : Xianpeng Hu (City University of Hong Kong)
Abstract : The weak stability is an important issue in fluid dynamics. We will discuss the mathematical understudying of concentration phenomena in the framework of weak solutions with either critical or subcritical energy. Two typical examples, including two dimensional incompressible Euler equations and compressible Navier-Stokes equations, will be discussed.

[03949] On Ericksen-Leslie system with free boundary

Format : Talk at Waseda University
Author(s) : Yong Yu (The Chinese University of Hong Kong)Chenyun Luo (The Chinese University of Hong Kong)Kaihui Luo (The Chinese University of Hong Kong)
Abstract : In this talk, we discuss a 3D simplified Ericksen-Leslie system subjected to the free boundary condition with surface tension. Dynamical stability of the classical planar wave solutions will also be addressed when the liquid crystal droplet is thin.

00221 (2/3) : 1D @D404 [Chair: Changyou Wang]

[00618] L1 maximalr regularity and its application to the Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Yoshihiro Shibata (Department of Mathematics, Waseda University)
Abstract : I will talk about the L1 maximal regularity theorem to the Stokes equations and its application to free boundary problem for the Navier-Stokes equations.

[03780] Fluid flow on surfaces

Format : Talk at Waseda University
Author(s) : Gieri Simonett (Vanderbilt University)Mathias Wilke (Martin-Luther-Universität Halle-Wittenberg)
Abstract : I will consider the motion of an incompressible viscous fluid on compact surfaces without boundary.
Local in time well-posedness is established in the framework of L_p-L_q maximal regularity for initial values in critical spaces.
It will be shown that the set of equilibria consists exactly of the Killing vector fields. Each equilibrium is stable and any solution starting close to an equilibrium converges at an exponential rate to a (possibly different) equilibrium. In case the surface is two-dimensional, it will be shown that any solution with divergence free initial value in L_2 exists globally and converges to an equilibrium.

[04880] The Curve Shortening Flow for Immersed Curves

Format : Talk at Waseda University
Author(s) : Patrick Guidotti (UC Irvine)
Abstract : We will revisit and study the curve shortening flow for immersed curves and its numerical computation.

[03690] On a thermodynamically consistent model for magnetoviscoelastic fluids in 3D

Format : Talk at Waseda University
Author(s) : Hengrong Du (Vanderbilt University)Yuanzhen Shao (University of Alabama)Gieri Simonett (Vanderbilt University)
Abstract : In this talk, we consider a system of equations that model a non-isothermal magnetoviscoelastic fluid, which is thermodynamically consistent. The system is analyzed by means of the Lp-maximal regularity theory. First, we will discuss the local existence and uniqueness of a strong solution. Then it will be shown that a solution initially close to a constant equilibrium exists globally and converges to a (possibly different) constant equilibrium. Finally, we will show that that every solution that is eventually bounded in the topology of the natural state space exists globally and converges to the set of equilibria.

00221 (3/3) : 1E @D404 [Chair: Yuanzhen Shao]

[04664] On some contact angle problems in fluid dynamics

Format : Online Talk on Zoom
Author(s) : Mathias Wilke (Martin-Luther-University Halle-Wittenberg)
Abstract : In this talk, we consider some contact angle problems for the dynamic of fluids and discuss several topics such as existence and uniqueness of solutions as well as their qualitative behaviour.

[00258] The relativistic Euler equations with a physical vacuum boundary

Format : Talk at Waseda University
Author(s) : Marcelo Mendes Disconzi (Vanderbilt University)
Abstract :
We consider the relativistic Euler equations with a physical vacuum boundary and an equation of state $p(\varrho) = \varrho^\gamma, \gamma > 1$
. We establish the following results. i. local well-posedness in the Hadamard sense, i.e., local existence, uniqueness, and continuous dependence on the data; ii. low regularity solutions: our uniqueness result holds at the level of Lipschitz velocity and density, while our rough solutions, obtained as unique limits of smooth solutions, have regularity only a half derivative above scaling; iii. stability: our uniqueness in fact follows from a more general result, namely, we show that a certain nonlinear functional that tracks the distance between two solutions, in part by measuring the distance between their respective boundaries, is propagated by the flow; iv. we establish sharp, essentially scale invariant energy estimates for solutions; v. we establish a sharp continuation criterion, at the level of scaling, showing that solutions can be

continued as long as the velocity is in $L^1_t Lip_x$ and a suitable weighted version of the density is at the same regularity level. This is joint work with Mihaela Ifrim and Daniel Tataru.

[00223] Stochastic optimization and stochastic variational inequalities

Session Time & Room : 3D (Aug.23, 15:30-17:10) @A201

Type : Proposal of Minisymposium
Abstract : Stochastic optimization and stochastic variational inequalities are important mathematical tools for decision-making problems and equilibrium problems under uncertainty. This mini-symposium brings several researchers in stochastic optimization and stochastic variational inequalities together and offers an opportunity to discuss the latest developments.
Organizer(s) : Hailin Sun, Chao Zhang
Classification : 90C15, 90C33
Minisymposium Program :

00223 (1/1) : 3D @A201 [Chair: Chao Zhang]

[02880] Dynamic Stochastic Projection Method for Multistage Stochastic Variational Inequalities

Format : Talk at Waseda University
Author(s) : Hailin Sun (Nanjing Normal University)Bin Zhou (Nanjing Normal University)Jie Jiang (Chongqing University)
Abstract : Stochastic approximation (SA) type methods have been well studied for solving single-stage stochastic variational inequalities (SVIs). This paper proposes a dynamic stochastic projection method (DSPM) for solving multistage SVIs. In particular, we investigate an inexact single-stage SVI and present an inexact stochastic projection method (ISPM) for solving it. Then we give the DSPM to a three-stage SVI by applying the ISPM to each stage. We show that the DSPM can achieve an $\mathcal{O}(\frac{1}{\epsilon^2})$ convergence rate regarding the total number of required scenarios for the three-stage SVI. We also extend the DSPM to the multistage SVI when the number of stages is larger than three. The numerical experiments illustrate the effectiveness and efficiency of the DSPM.

[02891] A two-stage stochastic variational inequality model

Format : Talk at Waseda University
Author(s) : Min Li (Beijing Jiaotong University)Chao Zhang (Beijing Jiaotong University)Mingxv Ding (Beijing Jiaotong University)Ruipu Lv (Beijing Jiaotong University)
Abstract : This paper first proposes a new nonsmooth two-stage stochastic equilibrium model of medical supplies in epidemic management. The first stage addresses the storage in the pre-disaster phase, and the second stage focuses on the dynamic distribution in the post-disaster phase. The uncertainties are the numbers of infected people treated in multiple hospitals. The model is further approximated and transformed to a monotone two-stage stochastic variational inequality (SVI) model that is computationally tractable.

[02899] Discrete approximation for two-stage stochastic variational inequalities

Format : Talk at Waseda University
Author(s) : Jie Jiang (Chongqing University)Hailin Sun (Nanjing Normal University)
Abstract : In this paper, the discrete approximation of two-stage stochastic variational inequalities has been investigated when the second stage problem has multiple solutions. First, a discrete approximation scheme is given by a series of models with the aid of merit functions. After that, the convergence relationships between these models are analysed, which therefore yields the convergence guarantee of the proposed discrete approximation scheme. Finally, we use the well-known progressive hedging algorithm to report some numerical results and to validate the effectiveness of the discrete approximation approach.

[05136] Iteratively sampling scheme for stochastic optimization with variable number sample path

Format : Online Talk on Zoom
Author(s) : Dali ZHANG (Shanghai Jiao Tong University)Shuang HAO (Shanghai Jiao Tong University)Ming Dong (Shanghai Jiao Tong University)
Abstract : Optimal search methods are proposed for solving optimization problems with analytically unobtainable objectives. This paper proposes a method by incorporating sampling schemes into the directional direct search with variable number sample path and investigates its effectiveness in solving stochastic optimization problems. We also explore the conditions on sample sizes at each iteration under which the convergence in probability can be guaranteed. Finally, a set of benchmark problems are numerically tested to show the effectiveness in different sampling schemes.

[00232] Theoretical foundations and algorithmic innovation in operator learning

Session Time & Room :

00232 (1/3) : 2C (Aug.22, 13:20-15:00) @E704

00232 (2/3) : 2D (Aug.22, 15:30-17:10) @E704

00232 (3/3) : 2E (Aug.22, 17:40-19:20) @E704

Type : Proposal of Minisymposium
Abstract : Many interesting phenomena in science and engineering involve operators mapping functions to functions. The application of data-driven tools from machine learning to scientific computing has thus given rise to the rapidly emerging field of operator learning. Despite encouraging practical successes, our understanding of these methods is still in its infancy, leaving important open questions to be addressed, including approximation guarantees, learning in data-scarce regimes, and understanding the limitations of current approaches and overcoming them. This minisymposium brings together researchers at the intersection of machine learning, approximation theory and PDEs to discuss theoretical foundations and recent algorithmic developments in this field.

[03323] BelNet: basis enhanced learning, a mesh-free neural operator

Format : Online Talk on Zoom
Author(s) : zecheng zhang (Carnegie Mellon University)Wing Tat Leung (City University Hong Kong)Hayden Schaeffer (UCLA)
Abstract : Operator learning trains a neural network to map functions to functions. An ideal operator learning framework should be mesh-free in the sense that the training does not require a particular choice of discretization for the input functions, allows for the input and output functions to be on different domains, and is able to have different grids between samples. We propose a mesh-free neural operator for solving parametric partial differential equations. The basis enhanced learning network (BelNet) projects the input function into a latent space and reconstructs the output functions. In particular, we construct part of the network to learn the ``basis'' functions in the training process. This generalized the networks proposed in Chen and Chen's universal approximation theory for the nonlinear operators to account for differences in input and output meshes. Through several challenging high-contrast and multiscale problems, we show that our approach outperforms other operator learning methods for these tasks and allows for more freedom in the sampling and/or discretization process.

[01354] The curse of dimensionality in operator learning

Format : Talk at Waseda University
Author(s) : Samuel Lanthaler (California Institute of Technology)
Abstract : Neural operator architectures employ neural networks to approximate operators between Banach spaces of functions. We show that for general classes of operators, which are characterized only by their Lipschitz- or C^r-regularity, operator learning with neural operators suffers from a curse of dimensionality related to the infinite-dimensional input and output function spaces. This curse, made rigorous in this work, is characterized by an exponential lower complexity bound: in order to achieve approximation accuracy ϵ, the number of tunable parameters generally has

to scale exponentially in ϵ^{-1}. This negative result is applicable to a wide variety of existing neural operators, including DeepONet, the Fourier neural operator and PCA-Net. It is then shown that the general curse of dimensionality can be overcome for operators possessing additional structure, going beyond regularity. This is illustrated for the solution operator of the Hamilton-Jacobi equation.

[05247] Score-based Diffusion Models in Function Space

Format : Talk at Waseda University
Author(s) : Nikola Kovachki (NVIDIA)
Abstract : We present a generalization of score-based diffusion models to function space by perturbing functional data via a Gaussian process at multiple scales. We obtain an appropriate notion of score by defining densities with respect to Guassian measures and generalize denoising score matching. We then define the generative process by integrating a function-valued Langevin dynamic. We show that the corresponding discretized algorithm generates accurate samples at a fixed cost that is independent of the data discretization.

[04771] Deep Learning Theories for Problems with Low–Dimensional Structures

Format : Talk at Waseda University
Author(s) : Hao Liu (Hong Kong Baptist University)Minshuo Chen (Princeton University)Siawpeng Er (Georgia Institute of Technology)Haizhao Yang (University of Maryland College Park)Tong Zhang (he Hong Kong University of Science and Technology)Tuo Zhao (Georgia Institute of Technology)Wenjing Liao (Georgia Institute of Technology)
Abstract : Deep neural networks have demonstrated a great success on many applications, especially on problems with high-dimensional data sets. However, most existing theories are cursed by data dimension. To mitigate the curse of dimensionality, we exploit the low-dimensional structures of data set and establish theoretical guarantees with a fast rate that is only cursed by the intrinsic dimension of the data set. This presentation addresses our recent work on function approximation and operator learning.

00232 (2/3) : 2D @E704 [Chair: Samuel Lanthaler]

[04076] Local approximation of operators

Format : Talk at Waseda University
Author(s) : HRUSHIKESH N MHASKAR (Claremont Graduate University)
Abstract : We study the question of approximation of an operator $\mathfrak{F}$ from one metric space X to another, Y. The input $f \in X$ and $\mathfrak{F}(f)$ are encoded in terms of a point on a sphere S^d (S^D), Local approximation techniques are developed to achieve approximation of properly defined smooth function in a tractable manner.

[04141] Neural operator surrogates for Gaussian inputs

Format : Talk at Waseda University
Author(s) : Jakob Zech (Universität Heidelberg)
Abstract : In this talk we discuss the use of operator surrogates to approximate smooth maps between infinite-dimensional Hilbert spaces. Such surrogates have a wide range of applications in uncertainty quantification and parameter estimation problems. The error is measured in the L^2-sense with respect to a Gaussian measure on the input space. Under suitable assumptions, we show that algebraic and dimension-independent convergence rates can be achieved.

[03497] Derivative-Informed Neural Operators for Scalable and Efficient UQ

Format : Talk at Waseda University
Author(s) : Thomas O'Leary-Roseberry (The University of Texas at Austin)Omar Ghattas (The University of Texas at Austin)Peng Chen (Georgia Tech)Umberto Villa (The University of Texas at Austin)Dingcheng Luo (The University of Texas at Austin)Lianghao Cao (The University of Texas at Austin)
Abstract : We present a novel operator learning methodology "derivative-informed neural operators" (DINOs) that can accurately represent both operator maps and their derivatives in function spaces. DINOs are built using advanced adjoint methods and dimension reduction techniques, resulting in efficient computation of derivative quantities that can facilitate fast and scalable UQ. We showcase the potential of DINOs in two applications: Bayesian inversion using data from the 2011 Tōhoku earthquake, and optimal control of PDEs under uncertainty.

[05169] Deep Operator Network Approximation Rates for Lipschitz Operators

Format : Online Talk on Zoom
Author(s) : Christoph Schwab (ETH Zurich)
Abstract : We establish expression rate bounds for neural Deep Operator Networks (DON) emulating Lipschitz continuous maps G between (suitable subsets of) separable Hilbert spaces X and Y. The DON architecture uses linear encoders E and decoders D via Riesz bases of X, Y, and an approximator network of a parametric coordinate map that is Lipschitz continuous on the sequence space. The present results require mere Lipschitz (or Holder) continuity of G.

00232 (3/3) : 2E @E704 [Chair: Samuel Lanthaler]

[02675] Transfer Learning Enhanced Physics-informed DeepONets for Long-time Prediction

Format : Talk at Waseda University
Author(s) : wuzhe xu (University of Massachusetts Amherst)
Abstract : Deep operator network (DeepONet) has demonstrated great success in various learning tasks, including learning solution operators of partial differential equations. In particular, it provides an efficient approach to predict the evolution equations in a finite time horizon. Nevertheless, the vanilla DeepONet suffers from the issue of stability degradation in the long-time prediction. This paper proposes a transfer-learning aided DeepONet to enhance the stability. Our idea is to use transfer learning to sequentially update the DeepONets as the surrogates for propagators learned in different time frames. The evolving DeepONets can better track the varying complexities of the evolution equations, while only need to be updated by efficient training of a tiny fraction of the operator networks. Through systematic experiments, we show that the proposed method not only improves the long-time accuracy of DeepONet while maintaining similar computational cost but also substantially reduces the sample size of the training set.

[03360] Generic bounds on the approximation error for physics-informed (and) operator learning

Format : Online Talk on Zoom
Author(s) : Tim De Ryck (ETH Zürich)Siddhartha Mishra (ETH Zürich)
Abstract : We propose a very general framework for deriving rigorous bounds on the approximation error for physics-informed neural networks (PINNs) and operator learning architectures such as DeepONets and FNOs as well as for physics-informed operator learning. These bounds guarantee that PINNs and (physics-informed) DeepONets or FNOs will efficiently approximate the underlying solution or solution operator of generic PDEs.

[03124] Overcoming Fundamental Limitations of Current AI Approaches: From Digital to Analog Hardware

Format : Online Talk on Zoom
Author(s) : Gitta Kutyniok (LMU Munich)Holger Boche (TU Munich)Adalbert Fono (LMU Munich)Aras Bacho (LMU Munich)Yunseok Lee (LMU Munich)
Abstract : Artificial intelligence is currently leading to one breakthrough after the other. However, one current major drawback is the lack of reliability of such methodologies. In this talk, we will discuss fundamental limitations, showing that there do exist severe problems in terms of computability on any type of digital hardware, which seriously affects their reliability. At the same time, we also show that analog hardware such as neuromorphic computing or quantum computing could achieve true reliability.

[00234] Differential Galois Theory and Integrability of Dynamical Systems

Session Time & Room :

00234 (1/2) : 2D (Aug.22, 15:30-17:10) @G404

00234 (2/2) : 2E (Aug.22, 17:40-19:20) @G404

Type : Proposal of Minisymposium
Abstract : The main objective of this minisymposium is to bring together researchers working on differential Galois theory and integrability of dynamical systems and to discuss recent results on the related topics containing the following:

- Developments of differential Galois theory in dynamical systems
- Integrability of dynamical Systems and PDE's
- Integrability in quantum mechanics and spectral theory
- Galois approach to nonintegrability

Organizer(s) : Kazuyuki Yagasaki
Classification : 34M15, 37J30, 12H05, 37J35, 37K10
Minisymposium Program :

00234 (1/2) : 2D @G404 [Chair: Kazuyuki Yagasaki]

[05314] The geodesic deviation equation for null geodesics in the Schwarzschild black-hole

Format : Talk at Waseda University
Author(s) : Juan José Morales-Ruiz (Universidad Politécnica de Madrid)Alvaro Pérez-Raposo (Universidad Politécnica de Madrid)
Abstract : The Schwarzschild black-hole is an integrable Hamiltonian system with four degrees of freedom. The geodesic deviation equations are the variational equations for this Hamiltonian system. By a joint theorem with Ramis, these equations can be solved in closed form in the framework of the differential Galois theory. This talk will be devoted to give the solutions of these equations around some null geodesics. This a joint work with Álvaro Pérez-Raposo.

[03161] Non-integrability of a model of two tethered satellites

Format : Talk at Waseda University
Author(s) : Thierry Combot (Universite de Bourgogne)
Abstract : We study the integrability of a model of two tethered satellites whose centre of mass moves in a circular Keplerian orbit around a gravity centre. When tether rest length is zero, the model is integrable and even superintegrable for selected values of the parameters. For positive rest length, the system is non-integrable. Obstructions to integrability are obtained through study of the differential Galois group of an irreducible symplectic variational equation in dimension 4.

[04393] Obstructions to integrability of nearly integrable dynamical systems

Format : Talk at Waseda University
Author(s) : Shoya Motonaga (Ritsumeikan University)
Abstract : We study necessary conditions for the existence of real-analytic first integrals and real-analytic integrability for perturbations of integrable systems including non-Hamiltonian ones in the sense of Bogoyavlenskij. Moreover, we compare our results with the classical results of Poincar'{e} and Kozlov for systems written in action and angle coordinates and discuss their relationships with the Melnikov methods for periodic perturbations of single-degree-of-freedom Hamiltonian systems. This is joint work with Kazuyuki Yagasaki at Kyoto University.

[04873] A Tale of Two Polytopes related to geodesic flows on spheres

Format : Talk at Waseda University
Author(s) : Holger Rainer Dullin (University of Sydney)Diana Nguyen (University of Sydney)Sean Dawson (University of Sydney)
Abstract : Separation of variables for the geodesic flows on round spheres leads to a large
family of integrable systems whose integrals are defined through the separation constants.
Reduction by the periodic geodesic flow leads to integrable systems on Grassmanians.
Specifically for the geodesic flow on the round S^3 the reduced system defines a family of
integrable systems on $S^2 \times S^2$. We show that the image of these systems under
a continuous momentum map defined through the action variables has a triangle as its image.
The image is rigid and does not change when the integrable system is changed within the family.
Each member of the family can be identified with a point inside a Stasheff polytope.
Corners of the polytope correspond to toric systems (possibly with degenerations),
edges correspond to semi-toric systems (in various meanings of the word),
and the face corresponds to ``generic'' integrable systems.
A fundamental difference of this momentum map to that of a toric or semi-toric system
is that the number of tori in the preimage of a non-critical point may be 1, 2, or 4.
The momentum map is continuous but not smooth along the images of hyperbolic singularities.
The corresponding quantum problem and generalisations to higher dimensional spheres will be discussed.

00234 (2/2) : 2E @G404 [Chair: Juan Jose Morales-Ruiz]

[03566] Local integrability and regularity of autonomous differential systems

Format : Talk at Waseda University
Author(s) : Xiang Zhang (Shanghai Jiao Tong University)
Abstract : For finite dimensional smooth autonomous differential systems, which have a singularity with one zero eigenvalue and the others nonresonant, we present our results on existence of local first integrals at the singularity, with emphasis on the regularity of the local first integrals. We first explore the existence of C^∞ local first integrals for analytic differential systems under the Poincar'e's non-resonant condition. We then show that for the Gevrey class of vector fields, their local first integrals have the same regularity as that of the vector fields provided that the real parts of the nonresonant eigenvalues are all positive or all negative. Lastly, a sharper expression of the loss of the regularity is presented by the lowest order of the resonant terms together with the indices of Gevrey smoothness and the diophantine condition for the case that the Jacobian matrix of the vector field at the singularity is in the diagonal form. The main tools are the homological method, the KAM theory, and the Gevrey normalization theory.

[04369] Singular solitary waves in the KdV equation

Format : Talk at Waseda University
Author(s) : Kazuyuki Yagasaki (Kyoto University)
Abstract : In this talk we consider the KdV equation and discuss its singular solitons which are called rational solitons, positons or negatons. We are especially interested in the solvability by quadrature for Schrodinger equations appearing as one of the related Lax pair. Some formulas for scattering coefficients of positons or negatons are also given. This is joint work with Katsuki Kobayashi.

[04649] Korteweg-de Vries traveling waves and Differential Galois Theory

Format : Online Talk on Zoom
Author(s) : Maria-Angeles Zurro (Autonomous University of Madrid)
Abstract : It was conjectured that the abelianity of the identity component of the Galois group of the variational equation is a necessary condition for the integrability of the non-linear PDE itself. In my lecture I will present an algebraic and spectral study of the variational equation around a KdV solitonic potential from the point of view of Galois differential theory. This is part of an ongoing joint work with J. J. Morales-Ruiz and J.-P. Ramis.

[03529] Real Liouvillian extensions of partial differential fields

Format : Online Talk on Zoom
Author(s) : Zbigniew Hajto (Faculty of Mathematics and Computer Science UJ)
Abstract : I will present Galois theory for partial differential systems defined over formally real differential fields with a real closed field of constants and over formally p-adic differential fields with a p-adically closed field of constants. For an integrable partial differential system, there exists a formally real (resp. formally p-adic) Picard-Vessiot extension. I will explain the applications of this theorem.

[00237] Recent progress in multiscale modeling and computational methods in material sciences

Session Time & Room :

00237 (1/3) : 3D (Aug.23, 15:30-17:10) @G801

00237 (2/3) : 3E (Aug.23, 17:40-19:20) @G801

00237 (3/3) : 4C (Aug.24, 13:20-15:00) @G801

Type : Proposal of Minisymposium
Abstract : Remarkable progress has been made in recent years on multiscale modeling and computational methods for diverse problems in material sciences, including but not limited to fluid mechanics, pattern formation and defects in materials sciences, and soft and active materials in biology.
The research is interdisciplinary, spanning the fields of mathematics, materials science and biology. This minisymposium focuses on the recent progress in the multiscale modeling, mathematical analysis and computational methods of broad

topics in material sciences. We aim to bring together experts from diverse fields to share their interesting research topics and recent progress and to promote interdisciplinary research collaborations.

[05400] Numerical methods for topology optimization and applications

Format : Talk at Waseda University
Author(s) : Xiaoping Wang (Hong Kong university of science and technology)
Abstract : n this talk, I will introduce some numerical methods for topology optimization based on threshold dynamics method. Applications to linear elasticity, fluid network and porous media problems will be discussed.

[05389] Optimal error estimate for the Multiscale Finite Element Method

Format : Talk at Waseda University
Author(s) : Pingbing Ming (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Siqi Song (Academy of Mathematics and Systems Science)
Abstract : We derive the optimal energy error estimate for multiscale finite element method with oversampling technique applying to elliptic systems with rapidly oscillating periodic coefficients that are bounded and measurable, which may admit rough microstructures. As a by-product of the energy estimate, we derive the rate of convergence in $\mathrm{L}^{d/(d-1)}-$norm with d the dimensionality.

[05618] On median filters for motion by mean curvature

Format : Talk at Waseda University
Author(s) : Selim Esedoglu (University of Michigan)
Abstract : The median filter scheme is an elegant, monotone discretization of the level set formulation of motion by mean curvature. It turns out to evolve every level set of the initial condition by another class of methods known as threshold dynamics. Based on this connection, we revisit median filters in light of recent work on the threshold dynamics method.

[02920] Structure-preserving methods based on minimizing movement scheme for gradient flows with respect to transport distances

Format : Talk at Waseda University
Author(s) : Chaozhen Wei (University of Electronic Science and Technology of China)
Abstract : I will present a novel structure-preserving numerical method for gradient flows w.r.t Wasserstein-like transport distances induced by concentration-dependent mobilities, which arise widely in materials science and biology. Based upon the minimizing movement scheme and modern operator-splitting schemes, our method has built-in positivity or boundedness preserving, mass conservation, and energy-dissipative structures. I will show the flexibility and performance of our methods through simulation examples including different free energy functionals, general wetting boundary conditions and degenerate mobilities.

00237 (2/3) : 3E @G801 [Chair: Dong Wang]

[05350] Multi-scale modeling and simulations for two-phase flow with moving contact lines

Format : Talk at Waseda University
Author(s) : Xianmin Xu (Chinese Academy of Sciences)
Abstract : Two phase flow with moving contact lines is very difficult to model and simulate due to its multi-scale nature. The slipness of the fluid molecules on solid substrates must be take into account near the contact line in a continuum model since the standard no slip boundary condition induces infinite energy dissipations. The microscopic roughness and inhomogeneity of the substrates make the problem even more challenging. In this talk, we will present some recent efforts to develop coarse-graining boundary condition and efficient numerical methods on the problem. In particular, we show that the Onsager principle can be used as an approximation tool to derive effective models for the dynamical multiscale problem.

[04103] Energy stable methods for two-phase phase-field surfactant model

Format : Talk at Waseda University
Author(s) : Zhen Zhang (Southern University of Science and Technology)
Abstract : We develop energy stable and bound preserving schemes for phase-field surfactant model with moving contact lines. The desired properties of the schemes are rigorously proved. We numerically validate the accuracies of the schemes and apply them in simulating droplet impact problems. Qualitative agreements with experiments are obtained. Moreover, surfactants are observed to have effects on enhancing droplet deformation and reducing dissipations.

[01396] Construction and Analysis for the Coupling Method of Atomistic and Higher Order Continuum Models

Format : Talk at Waseda University
Author(s) : Hao Wang (Sichuan University)Yangshuai Wang (University of British Columbia)
Abstract : Atomistic to continuum coupling methods have been widely used in the numerical simulation of crystal lattice with defects. In this talk, we present the construction and analysis of a coupling scheme that combines the atomistic model with a higher order continuum with sharp interface. We show that such scheme is of higher order of accuracy compared with existing models that couples the atomistic model with the classic Cauchy-Born model.

[01316] A domain decomposition method for the Poisson-Boltzmann solvation model

Format : Talk at Waseda University
Author(s) : Chaoyu Quan (Southern University of Science and Technology)
Abstract : A nonoverlapping domain decomposition method is studied for the linearized Poisson--Boltzmann equation, which is essentially an interior-exterior transmission problem with bounded interior and unbounded exterior. This problem is different from the classical Schwarz alternating method for bounded nonoverlapping subdomains well studied by Lions in 1990, and is challenging due to the existence of unbounded subdomain. To obtain the convergence, a new concept of interior-exterior Sobolev constant is introduced and a spectral equivalence of related Dirichlet-to-Neumann operators is established afterwards. We prove rigorously that the spectral equivalence results in the convergence of interior-exterior iteration. Some numerical simulations are provided to investigate the optimal stepping parameter of iteration and to verify our convergence analysis.

00237 (3/3) : 4C @G801 [Chair: Chaozhen Wei]

[01430] A Continuum Model for Dislocation Climb Velocity and Numerical Simulations

Format : Talk at Waseda University
Author(s) : Chutian Huang (Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)
Abstract : Dislocations are primary carriers for the crystal plastic deformation. The study of dislocation climb plays an important role in understanding plastic deformation of crystalline deformation at high temperature. In this work, we propose a new continuum formulation for dislocation climb velocity. Numerical simulations are implemented to compare our model with mobility law and discrete model.

[01298] A second-order in time, BGN-based PFEM for solving geometric PDEs

Format : Online Talk on Zoom
Author(s) : Wei Jiang (Wuhan University)Chunmei Su (Tsinghua University)Ganghui Zhang (Tsinghua University)
Abstract : We propose a higher-order in time, BGN-based parametric finite element method for solving geometric flows, e.g., curve shortening flow, area-preserving curve shortening flow and surface diffusion flow.

[00239] Shape and Topology Optimizations

Session Time & Room :

00239 (1/2) : 5C (Aug.25, 13:20-15:00) @E710

00239 (2/2) : 5D (Aug.25, 15:30-17:10) @E710

Type : Proposal of Minisymposium

Abstract : Shape and topology optimizations are widely used in many industries and consider optimal shapes and topologies of materials to maximize desired physical properties. Topological changes also yield extremely high performance, and hence, these optimization methods have attracted much attention in many industries. Furthermore, recent technological innovations in additive manufacturing have made it possible to manufacture optimized materials and even metamaterials that do not exist in nature. Besides, these optimization methods that take manufacturability and practicality into consideration have also been developed and will be expected to be applied in various fields.

Organizer(s) : Takayuki Yamada, Grégoire Allaire, Hideyuki Azegami

Classification : 49-XX

Minisymposium Program :

00239 (1/2) : 5C @E710 [Chair: Takayuki Yamada]

[00244] PDEs for topology optimization considering manufacturability

Format : Talk at Waseda University

Author(s) : Takayuki Yamada (The University of Tokyo)

Abstract : The topology optimization framework is to have the PDEs of the physical field of interest as constraints. In this study, we propose PDEs that expresses target manufacturability in order to consider it in a topology optimization framework.

[00368] Topology optimization of supports for additive manufacturing with accessibility constraints

Format : Talk at Waseda University

Author(s) : Grégoire Allaire (Ecole Polytechnique)Martin Bihr (Safran)Beniamin Bogosel (Ecole Polytechnique)

Abstract : This talk is concerned with an accessibility constraint, for shape and topology optimization of structures built by metallic additive manufacturing. Sacrificial supports are used to maintain a structure, during its building process. Removing them at the end is required but can be very difficult. Our work gives a new mathematical way to evaluate such an accessibility constraint, which is based on distance functions, solutions of eikonal equations. The main advantage is the possibility of computing shape derivatives of such a criterion with respect to both the structure and the support. We implement this accessibility constraint with the level-set method for topology optimization of structures.

[03408] Dehomogenization in stress minimization problems

Format : Talk at Waseda University

Author(s) : Alex Ferrer (CIMNE)Grégoire Allaire (Ecole Polytechnique)Perle Geoffroy-Donders (Ecole Polytechnique)

Abstract : In the last years, additive manufacturing has allowed to build lattice structures with impressive small length scale. This breakthrough has forced the topology optimization community to propose fast multi-scale topology optimization techniques. The dehomogenization method has recently shown very promising results in terms of performance and computational cost for compliance examples. In this work, we extend it to stress minimization problems and by considering singularities in the orientation field.

[03530] The topological ligament: an approach based on thin tubular inhomogeneities

Format : Talk at Waseda University

Author(s) : Charles Dapogny (CNRS & Université Grenoble Alpes)

Abstract : We propose a novel framework to calculate an approximate sensitivity of a functional depending on the domain with respect to the graft of a thin ligament. The resulting formulas are applied to:
• The addition of a thin ligament to a structure in the course of a classical shape optimization process;
• The optimization of the scaffold structure of a 3d printed structure;
• A ``clever'' initialization process for the optimization of a truss structure.

00239 (2/2) : 5D @E710 [Chair: Takayuki Yamada]

[00419] Level set-based topology optimization method with nonlinear diffusion

Format : Talk at Waseda University

Author(s) : Tomoyuki Oka (The University of Tokyo)Takayuki Yamada (The University of Tokyo)

Abstract : In this talk, we shall consider a level set-based topology optimization method with nonlinear diffusion.
Main results consist of the generalization of the method using reaction-diffusion equations, which improves convergence

to optimized designs with the aid of singularity and degeneracy of diffusion coefficients, and therefore, a more practical method can be obtained.

[00247] Interfaces and Free Boundaries in Fluid Mechanics and Materials Science

Session Time & Room :

00247 (1/2) : 3E (Aug.23, 17:40-19:20) @G710

00247 (2/2) : 4C (Aug.24, 13:20-15:00) @G710

Type : Proposal of Minisymposium
Abstract : This minisymposium is focused on recent advances in the analysis of interface evolution problems. A particular
emphasis lies on prominent applications arising in materials science (grain coarsening in polycrystalline materials), fluid mechanics (fluid-structure interaction, viscous surface waves, dynamic wetting) and phase separation models from chemistry. The minisymposium brings together an international group of researchers, new and established, to discuss topics covering a broad range of associated mathematical questions and techniques. These include variational methods for modelling and solution theories, the rigorous derivation of sharp interface limits, and the analysis of evolving networks of branched interfaces.

[02095] On the notion of generalized mean curvature flow

Format : Talk at Waseda University
Author(s) : Yoshihiro Tonegawa (Tokyo Institute of Technology)
Abstract : I describe some new aspects of generalized notion of mean curvature flow which are prompted by various attempts to prove the existence, uniqueness and regularity. The main tool comes from geometric measure theory which allows treatments of singular geometric objects necessary to deal with the weak formulation of mean curvature flow.

[03166] Coarsening phenomena in the network flow

Format : Talk at Waseda University
Author(s) : Alessandra Pluda (University of Pisa)
Abstract : A network is a 1-dimensional connected set in the plane composed of a finite number of curves that meet at their endpoints in junctions. The flow by curvature of networks has been introduced in mathematical materials science to model the evolution of polycrystals. We would like to formalise a coarsening behavior, suggested by numerical simulations. I will present the mathematical tools developed to describe this evolution and an argument which supports the coarsening behavior.

[03048] Uniqueness and stability of multiphase mean curvature flow beyond a singular time: the case of the shrinking circle

Format : Talk at Waseda University
Author(s) : Alice Marveggio (Institute of Science and Technology Austria (ISTA))Julian Fischer (Institute of Science and Technology Austria (ISTA))Maximilian Moser (Institute of Science and Technology Austria (ISTA))Sebastian Hensel (Hausdorff Center for Mathematics, University of Bonn)
Abstract : The evolution of a network of interfaces by mean curvature flow features the occurrence of topology changes and geometric singularities. As a consequence, classical solution concepts for mean curvature flow are in general limited to short-time existence theorems, which include singular times only for some stable shrinkers such as the circle. At the same time, the transition from strong to weak solution concepts (e.g. Brakke solutions) may lead to non-uniqueness of solutions.
Following the relative energy approach à la Fischer-Hensel-Laux-Simon and introducing a suitable notion of gradient-flow calibration for a shrinking circle, we prove a quantitative stability estimate holding up to the singular time. This implies a weak-strong uniqueness principle for weak BV solutions to planar multiphase mean curvature flow beyond a

specific class of singularities.
Furthermore, we expect our method to have further applications to other types of shrinkers, as well as to prove quantitative convergence of diffuse-interface (Allen-Cahn) approximations for mean curvature flow.

[02872] Matrix-valued Allen–Cahn equation and the Keller–Rubinstein–Sternberg problem

Format : Talk at Waseda University
Author(s) : Mingwen Fei Fanghua Lin (Courant Institute of Mathematical Science, New York University)Wei Wang (Zhejiang University)Zhifei Zhang (Peking University)
Abstract : In this talk, we consider the sharp interface limit of a matrix-valued Allen-Cahn equation. We show that the sharp interface system is a two-phases flow system: the interface evolves according to the motion by mean curvature; in the two bulk phase regions, the solution obeys the heat flow of harmonic maps with values in $n \times n$ orthogonal matrices with determinant $+1$ and -1 respectively; on the interface, the phase matrices in two sides satisfy a novel mixed boundary condition. The above result provides a solution to the Keller-Rubinstein-Sternberg's problem in the $O(n)$ setting. Our proof relies on two key ingredients. First, in order to construct the approximate solutions by matched asymptotic expansions, as the standard approach does not seem to work, we introduce the notion of quasi-minimal connecting orbits. They satisfy the usual leading order equations up to some small higher order terms. In addition, the linearized systems around these quasi-minimal orbits needs to be solvable up to some good remainders. These flexibilities are needed for the possible ``degenerations'' and higher dimensional kernels for the linearized operators on matrix-valued functions due to intriguing boundary conditions at the sharp interface. The second key point is to establish a spectral uniform lower bound estimate for the linearized operator around approximate solutions. To this end, we introduce additional decompositions to reduce the problem into the coercive estimates of several linearized operators for scalar functions and some singular product estimates which are accomplished by exploring special cancellation structures between eigenfunctions of these linearized operators.

00247 (2/2) : 4C @G710 [Chair: Alessandra Pluda]

[03054] Variational methods for time-dependent problems on dynamically changing domains

Format : Talk at Waseda University
Author(s) : Malte Kampschulte (Charles University Prague)
Abstract : In this talk I will present a general, energetically consistent method that can be used to show the existence of weak solutions for nonlinear problems in fluid structure-interaction and related fields. Not only can this be done without the need to make simplifying assumptions on domain or equations, in fact it crucially relies on all physical terms being present. This talk is based on several recent results primarily with B.Benesova, S.Schwarzacher but also D.Breit, A.Cesik, G.Gravina and G.Sperone.

[04468] Sharp-interface limit of models with mechanics and contact lines

Format : Talk at Waseda University
Author(s) : Dirk Peschka (WIAS Berlin & Freie Universität Berlin)Leonie Schmeller (Weierstrass Institute)
Abstract : First, we construct gradient structures for free boundary problems including nonlinear elasticity, phase fields and moving contact lines, where the convergence of phase-field models to certain sharp-interface limits is analyzed numerically. Then, in the second part of the talk, it will be shown how shapes of droplets on soft elastic substrates can be predicted by corresponding (sharp-interface) models, and some emergent phenomena - cloaking and phase separation near the contact line - are pointed out.

[03766] Uniform Rectifiability for Minimizers of the Griffith Fracture Energy

Format : Talk at Waseda University
Author(s) : Kerrek Stinson (University of Bonn)Manuel Friedrich (University of Erlangen-Nuremberg)Camille Labourie (University of Erlangen-Nuremberg)
Abstract : Recent studies for minimizers of the Griffith energy, which penalizes elastic energy and fracture, have relied on topological constraints for the (codimension-1) crack. Regularity results effectively say that if the crack locally separates the domain into different connected components, then the crack is in fact a smooth surface. Our analysis looks at minimizers without topological constraints. As a first step, we prove uniform rectifiability, which shows that on sufficiently small scales, the crack is nearly topologically separating. The purpose of this talk is to illuminate the new techniques applied in this setting and discuss how a similar approach can be used to prove a regularity result for the crack.

[00253] Modelling and Simulation of Lithium-Ion Batteries

Session Time & Room :

00253 (1/3) : 4C (Aug.24, 13:20-15:00) @D403

Type : Proposal of Minisymposium
Abstract : Lithium-ion batteries have a very important role to play in the transition to a sustainable future. But despite the current widespread use of batteries, many of the phenomena involved in their functioning are not well understood. Mathematical models can be a fundamental tool to understand batteries and enable better design and management. In this minisymposium we will discuss the latest advances in the development and analysis of continuum models for lithium-ion batteries, with a particular focus on homogenised models and their applications to real-world problems. This minisymposium is part of the ECMI Special Interest Group on Sustainable Energies and Materials.

[03631] Asymptotic methods for lithium-ion battery models

Format : Talk at Waseda University
Author(s) : Ferran Brosa Planella (University of Warwick)
Abstract : Lithium-ion batteries have become an essential in our lives, and to develop better and safer batteries we need accurate and fast models. Current models are often posed in an ad hoc way, which usually leads to inconsistencies. In this talk we will provide an overview of battery modelling, and show how asymptotic methods can help us obtain simple and consistent models that help us design and manage the next generation of batteries.

[05237] Topology Optimization for Li-ion batteries

Format : Talk at Waseda University
Author(s) : Thomas Roy (Lawrence Livermore National Laboratory)Hanyu Li (Lawrence Livermore National Laboratory)Nicholas Brady (Lawrence Livermore National Laboratory)Giovanna Bucci (Lawrence Livermore National Laboratory)Tiras Lin (Lawrence Livermore National Laboratory)Daniel Tortorelli (Lawrence Livermore National Laboratory)Marcus Worsley (Lawrence Livermore National Laboratory)
Abstract : Typical porous electrodes are homogeneous, stochastic collections of small-scale particles offering few opportunities for engineering higher performance. To leverage recent breakthroughs in advanced and additive manufacturing, we use topology optimization to design electrodes for energy storage devices. Energy density is maximized, leading to non-trivial geometries that outperform monolithic electrodes. These geometries facilitate ionic transport and lead to better electrode utilization. We consider simultaneous optimization of cathode and anode, which can lead to interdigitated designs. LLNL-ABS-847750

[04263] Homogenisation and Modelling of a Silicon nanowire Li-ion battery anode

Format : Talk at Waseda University
Author(s) : Emma Elizabeth Greenbank (MACSI, University of Limerick)Michael Vynnycky (MACSI, University of Limerick)Doireann O'Kiely (MACSI, University of Limerick)
Abstract : We consider a battery anode composed of an array of copper nanowires, coated with Li-carrying copper silicide and surrounded by Li-alloying electrolyte. This anode design alleviates degradation arising from extreme volumetric changes of silicon during lithiation. The governing equations for the electric and concentration fields inside the nanowire array structure are homogenised, and solutions of the homogenised problem are used to predict the transport of lithium through the anode.

[02731] A continuum model for lithium plating and dendrite formation in lithium-ion batteries.

Format : Talk at Waseda University
Author(s) : Smita Sahu (University of Portsmouth)
Abstract : This work presents a novel physics-based model for lithium plating and dendrite formation in lithium-ion batteries. The formation of Li metal is an undesirable side-effect of fast charging and a primary contributor to cell degradation and failure. The model distinguishes between three types of plated Li metal, namely: (a) Li metal plated within the pores of the solid electrolyte interphase (assumed to be electronically connected to the anode and therefore recoverable); (b) dendrites protruding outside the SEI that remain electronically connected (and are therefore dangerous, potentially leading to a short circuit), and (c) electronically disconnected/“dead” Li metal outside the SEI contributing to capacity fade. The model is validated against two independent experiments. First, measurements of: (i) the cell voltage and current during a constant-current–constant-voltage charge and subsequent discharge, and (ii) the Li metal intensities (derived from operando NMR) which directly quantifies the time-resolved quantity of Li metal in the cell during use. Second, against voltage measurements during galvanostatic discharge at a range of C-rates and temperatures. Favourable agreement is demonstrated throughout; particularly in terms of the proportions of reversible and irreversible plating. We also demonstrate that the model reproduces the well-documented trends of being more prevalent at increased C-rate and/or decreased temperature.

00253 (2/3) : 4D @D403 [Chair: Ferran Brosa Planella]

[04505] Simulation and analysis of space charge layers in a solid electrolyte

Format : Talk at Waseda University
Author(s) : Laura Marie Keane (York University)Iain Moyles (York University)
Abstract : We consider the zero-charge flux equilibrium problem in a solid electrolyte. We introduce an auxiliary variable to remove singularities from the domain, facilitating robust numerical simulations. We use asymptotic reduction to uncover the true width of the boundary layer of the electrolyte. Exploiting the asymptotic regimes, we generate a nonuniform discretization grid enabling more computationally efficient simulations without sacrificing accuracy as we focus computational power in regions where the solution changes more rapidly.

[03112] Machine Learning of Electrochemistry Battery Models

Format : Talk at Waseda University
Author(s) : Brian Wetton (University of British Columbia)Maricela Best-Mckay (University of British Columbia)
Abstract : We present a surrogate modeling approach that uses synthetic data generated by an electrochemical model to approximate Li-ion battery dynamics using a Deep Neural Network. Our approach uses the Pseudo-Two Dimensional model and a well defined use-cycle, fit to a Network of convolution type for the particle concentrations. The Network is able to accurately predict future behaviour. Extensions to initial State of Charge correction and the identification of a State of Health parameter are given.

[05150] Parameterisation of reduced-order battery models from non-invasive characterisation

Format : Talk at Waseda University
Author(s) : Nicola Courtier (University of Oxford)Ross Drummond (University of Sheffield)David Howey (University of Oxford)
Abstract : Robust parameterisation methods exist for equivalent circuit models of batteries but, to understand the underlying processes and battery design, electrochemical models are needed. Progress is limited by a lack of robust parameterisation methods for nonlinear systems of differential equations, containing parameters which are unidentifiable from non-invasive measurements. Reduced-order modelling offers a pathway to systematically estimate lumped parameters from data using prediction-error minimisation. Furthermore, we apply the measure-moment approach to optimisation to estimate optimal charging profiles.

[05185] Early prediction of battery remaining useful life using AI and physics

Format : Online Talk on Zoom
Author(s) : Edwin Khoo (Institute for Infocomm Research (I2R), Agency for Science, Technology and Research (A*STAR))
Abstract : Accurate prediction of the remaining useful life (RUL) of a lithium-ion battery (LIB) using early cycle data aids in scheduling predictive maintenance, avoiding catastrophic failure during operation and optimizing battery manufacturing. In this talk, we discuss our recent work in building a hybrid deep learning model that combines physics-informed features with statistical features to achieve better generalization performance in early RUL prediction when

benchmarked against several AI models. If time permits, we will also discuss our recent parametric study of LIB capacity fade using a cell OCV model.

00253 (3/3) : 4E @D403

[00255] Recent developments in fast algorithms for inverse problems and imaging

Session Time & Room :

00255 (1/2) : 3D (Aug.23, 15:30-17:10) @E819

00255 (2/2) : 3E (Aug.23, 17:40-19:20) @E819

Type : Proposal of Minisymposium
Abstract : Inverse problems correspond to the reconstruction of hidden objects from possibly noisy indirect measurements and are ubiquitous in a variety of scientific and engineering applications. Since these problems tend to be ill-posed, and real-world applications are often large-scale, this can be a very challenging task. This minisymposium focuses on recent advances in computationally efficient methods for solving large-scale inverse problems in imaging, e.g., those arising in medical, geophysical and industrial applications, covering topics that include advances in iterative methods, regularization, machine learning and novel applications of the previous.

[03339] Streaming Methods for Inverse Problems

Format : Talk at Waseda University
Author(s) : Eric de Sturler (Virginia Tech)
Abstract : We discuss Golub-Kahan type methods for streaming problems. As big data applications become ever more prominent, in many applications we can only solve problems such as linear or nonlinear regression problems in chunks. Data may come in over a larger span of time and we cannot (or prefer not) to wait until all data is available, the problem may be too large to fit in memory, or data is coming in at a rate that we can use only sampled data and use it in chunks. There is a need for methods that can work efficiently under such conditions. We discuss extensions for GKB-type methods that select and build effective search spaces over multiple subsets of data and/or matrix-blocks to compute accurate solutions with limited memory available. Apart from streaming applications this may also be useful for modern computing architectures that have highly non-uniform memory access.
This is joint work with Julianne Chung, Jiahua Jiang, Misha Kilmer, and Mirjeta Pasha.

[03433] Sequential model correction for nonlinear inverse problems

Format : Talk at Waseda University
Author(s) : Arttu Arjas (University of Oulu)Andreas Hauptmann (University of Oulu)Mikko Sillanpää (University of Oulu)
Abstract : Linear inverse problems are usually solved with first-order gradient methods. For nonlinear problems one must resort to second-order methods that are computationally more expensive. In this work we approximate a nonlinear model with a linear one and correct the resulting approximation error. We develop a sequential method that iteratively solves a linear inverse problem and updates the approximation error. We analyze the sequence theoretically and present numerical results.

[02062] Plants, robots and dynamic tomography

Format : Talk at Waseda University
Author(s) : Tommi Heikkilä (University of Helsinki)
Abstract : The need for dynamic tomography can arise from many applications, e.g. imaging nutrient perfusion in plant stems for carbon uptake and metabolism studies. While the measurements may be sparse, obtaining the reconstructions can be computationally intensive, since 3D volumes evolving over time leads to 4D tomography. Thus we need fast and efficient methods: our choice are sparse representation systems such as (complex) wavelets and (cylindrical) shearlets, tested on dynamic data from a motorized phantom.

[04602] Deep learning methods for data-driven uncertainty quantification

Format : Talk at Waseda University
Author(s) : Ling Guo (Shanghai Normal University)
Abstract : In this talk, we will present some recent developments on using Physics-informed neural networks (PINNs) to quantify uncertainty propagation in a unified framework forward, inverse and mixed stochastic problems based on scattered measurements. We will also present generative models for data-driven uncertainty quantification, including physics-informed generative adversarial networks and Normalizing field flows.

00255 (2/2) : 3E @E819 [Chair: Malena Sabaté Landman]

[04412] Exploiting Mixed Precision Arithmetic in Image Reconstruction

Format : Talk at Waseda University
Author(s) : James Nagy (Emory University)
Abstract : Although some work has been done to exploit mixed precision computations for inverse problems arising in image processing, most previous work focuses on extended precision to avoid the influence of rounding errors. We consider a different perspective: because we cannot expect to precisely know data, we develop and analyze solvers that can take advantage of low precision speed of modern computer architectures, and which can be used in a variety of imaging applications.

[03595] Image Quality Assessment for Reconstruction Algorithms

Format : Talk at Waseda University
Author(s) : Anna Breger (University of Cambridge)
Abstract : Assessing digital image quality (IQ) is of high importance in numerous applied research fields, such as image acquisition, reconstruction or processing. Automated evaluation is needed since manual evaluation is too time-consuming and expensive for huge data sets and, furthermore, may be biased or introduce inconsistencies. In this talk I will give a short introduction to IQ assessment and provide examples of failure when applying standard full reference IQ measures in medical imaging reconstruction tasks.

[00260] Statistics for random dynamics

Session Time & Room : 1C (Aug.21, 13:20-15:00) @E504

Type : Proposal of Minisymposium
Abstract : Nowadays, a broad spectrum of large-scale and high-frequency data sets with complex spatiotemporal dependent structures is available; relevant fields of research are wide-ranging, including biology, finance, and actuarial science, to mention just a few. To create white-box models equipped with efficient and practical mechanisms for such data sets, simple combinations of the currently available devices are not enough, and it is therefore urgent and imperative to develop both mathematical statistics for stochastic processes and stochastic analyses synergistically, learning new from the past. Our session is intended to present some state-of-the-art topics in this active area of research.

[03955] Online parametric estimation of stochastic differential equations with discrete observations

Format : Talk at Waseda University
Author(s) : Shogo Nakakita (University of Tokyo)
Abstract : We consider online parametric estimation for stochastic differential equations based on discrete observations. The proposed method uses an online gradient descent method for negative quasi-log-likelihood functions with convexity and achieves low computational complexity. We derive a non-asymptotic uniform upper bound for the risk of the estimation by our results on stochastic optimization and ergodicity.

[03956] Weighted block bootstrap for misspecified ergodic Lévy driven SDE models

Format : Talk at Waseda University
Author(s) : Yuma Uehara (Kansai University)
Abstract : In this talk, we consider possibly misspecified stochastic differential equation models driven by L'{e}vy processes. Under some regularity conditions, Gaussian quasi-likelihood estimator can estimate unknown parameters in the drift and scale coefficients. However, especially in the misspecified case, it is hard to construct a consistent estimator of the asymptotic variance directly. For such a problem, we propose a weighted block bootstrap procedure to evaluate the asymptotic distribution.

[04399] Robustifying Gaussian quasi-likelihood inference for random dynamics

Format : Talk at Waseda University
Author(s) : Shoichi Eguchi (Osaka Institute of Technology)
Abstract : We consider Gaussian quasi-likelihood inference for stochastic differential equations. In this study, suppose that the observations are obtained from the L'{e}vy process with the compound-Poisson jumps and spike noises, and we regard jumps and spike noises as outliers that disturb the parameter estimation. We construct an estimator without reference to the presence of the jump component and some spike noises, in addition to that of the drift term.

[04695] Asymptotic expansion of estimator of Hurst parameter of SDE driven by fractional Brownian motion

Format : Talk at Waseda University
Author(s) : Hayate Yamagishi (University of Tokyo)
Abstract : Asymptotic expansion is presented for an estimator of the Hurst coefficient of a stochastic differential equation driven by a fractional Brownian motion of H>1/2. While applying a recently developed theory of asymptotic expansion of Wiener functionals to the estimator, the main difficulty is to estimate orders of complicated functionals appearing in expanding the estimator and identifying the limit random symbols. To overcome the difficulty, we introduce a theory of an exponent based on weighted graphs.

[00262] numerical analysis, modeling and applications in phase-field its relevant methods

Session Time & Room :

00262 (1/3) : 3C (Aug.23, 13:20-15:00) @E705

00262 (2/3) : 3D (Aug.23, 15:30-17:10) @E705

00262 (3/3) : 3E (Aug.23, 17:40-19:20) @E705

Type : Proposal of Minisymposium
Abstract : The phase field method and its relevant extensions have been widely used in various applications, including phase separations, crystal growth, and solid fracture dynamics. Meanwhile, it is still an active research field to develop thermodynamically consistent phase field models, design accurate, efficient, and stable numerical algorithms for these models, and apply them to various application problems. This mini-symposia brings together experts with diverse backgrounds in numerical analysis, PDE modeling and mathematical biology, machine learning, and data science, but with the same interest in phase field method and its relevant extension. Through this mini-symposia, we aim to foster active interdisciplinary discussions.

[05280] Approximating Structurally Unstable Over-determined Systems of PDEs

Author(s) : Qi Wang (University of South Carolina)
Abstract : Models for nonequilibrium phenomena are normally consisted of differential equations, from which some physically important relations can be deduced. Together, they form an extended, over-determined system of equations which is normally structurally unstable. Structure-preserving approximation thus ensues, which are known numerically as structure-preserving algorithms/schemes. In this presentation, I will discuss some structure-preserving numerical strategies for developing numerical algorithms for thermodynamically consistent multiphase materials models, which are derived from thermodynamical principles.

[03012] Energy stability analysis and error estimate of a maximum bound principle preserving scheme for the dynamic Ginzburg--Landau equations under the temporal gauge

Author(s) : Zhonghua Qiao (The Hong Kong Polytechnic University)
Abstract : This paper proposes a decoupled numerical scheme of the time-dependent Ginzburg--Landau equations under the temporal gauge. For the magnetic potential and the order parameter, the discrete scheme adopts the second type Nedélec element and the linear element for spatial discretization, respectively; and a linearized backward Euler method and the first order exponential time differencing method for time discretization, respectively. The maximum bound principle (MBP) of the order parameter and the energy dissipation law in the discrete sense are proved. The discrete energy stability and MBP-preservation can guarantee the stability and validity of the numerical simulations, and further facilitate the adoption of adaptive time-stepping strategy, which often plays an important role in long-time simulations of vortex dynamics, especially when the applied magnetic field is strong. An optimal error estimate of the proposed scheme is also given. Numerical examples verify the theoretical results of the proposed scheme and demonstrate the vortex motions of superconductors in an external magnetic field.

[04941] Phase-field modelling of three-phase solidification with density variation

Author(s) : Pengtao Yue (Virginia Tech)Jiaqi Zhang (Beijing Normal University-Hong Kong Baptist University United International College)Yichen Li (Virginia Tech)
Abstract : We present a non-isothermal quasi-incompressible phase-field model for three-phase solidification that involves water, ice, and air. Water-ice phase transition and water-air interface are handled by the Allen-Cahn and Cahn-Hilliard equations, respectively. Constitutive relations are derived based on non-negative entropy production. Our model automatically captures curvature and pressure effects as dictated by the Gibbs-Thomson and Clausius-Clapeyron equations, as well as volume expansion during solidification. Numerical results on tip formation of a freezing droplet will be presented.

[02938] Multiscale topology optimization method for lattice materials

Author(s) : Yibao Li (Xi'an Jiaotong University)Qing Xia (Xi'an Jiaotong University)Xin Song (Xi'an Jiaotong University)Qian Yu (Xi'an Jiaotong University)Binhu Xia (Xijing University)
Abstract : In this talk, we will introduce an efficient multiscale topology optimization method for lattice materials. In macro-scale, we present a second-order unconditionally energy stable schemes for the topology optimization problem. Using porous media approach, our objective functional composes of five terms including mechanical property, Ginzburg-Landau energy, two penalized terms for solid and the volume constraint. A Crank-Nicolson method is proposed to discrete the coupling system. We prove that our proposed scheme is unconditionally energy stable. In macro-scale, we propose a simple volume merging method for triply periodic minimal structure. A modified Allen–Cahn type equation with a correction term is proposed. The mean curvature on the surface will be constant everywhere at the equilibrium state. Computational experiments are presented to demonstrate the efficiency of the proposed method.

00262 (2/3) : 3D @E705 [Chair: Xiaoming He]

[04079] New unconditionally stable higher-order consistent splitting schemes for the Navier-Stokes equations

Author(s) : JIE SHEN (Purdue University)Fukeng Huang (National University of Singapore)
Abstract : The consistent splitting schemes for the Navier-Stokes equations decouple the computation of pressure and velocity, and do not suffer from the splitting error. However, only the first-order version of the consistent splitting schemes is proven to be unconditionally stable for the time dependent Stokes equations.

We construct a new class of consistent splitting schemes of orders two to four for Navier-Stokes equations based on Taylor expansions at time t_{n+k} where $k \geq 1$ is a tunable parameter. We show that, for some suitable choices of k, they are unconditionally stable for the time dependent Stokes equations, and by combining them with the generalized scalar auxiliary variable (GSAV) approach, we construct, for the very first time, unconditionally stable (in H^1 norm) and totally decoupled schemes of orders two to four for the velocity and pressure, and provide rigorous optimal error estimates. We shall also present some numerical results to show the computational advantages of these schemes.

[04302] Multi-phase-field modeling of grain growth and multiphase flow in additive manufacturing

Author(s) : Tomohiro Takaki (Kyoto Institute of Technology)
Abstract : A multi-phase-field model for predicting material microstructures formed during the powder bed fusion additive manufacturing of a metallic alloy is developed. Here, multi-phase-field models for solidification and multiphase flow problems are coupled to express polycrystalline solidification with melt flow in the melt pool.

[04437] An efficient nonsmooth global optimization-based bound-preserving approach for the Cahn-Hilliard equation

Author(s) : Xiangxiong Zhang (Purdue University)
Abstract : It is quite difficult to construct bound-preserving schemes for many high order time-dependent PDEs. For instance, it is difficult to prove that the Cahn-Hilliard equation with polynomial potential admits a bound-preserving solution, yet a bound-preserving numerical solution is often preferred. Instead of directly constructing a bound-preserving scheme, we consider a global optimization based post processing in each time. Due to the nonsmooth terms in the cost function, such an optimization based approach has often been regarded as inefficient. However, it is possible to obtain an efficient solver by using optimal parameters obtained from asymptotic convergence rate formula. We demonstrate that the selection of optimization algorithm parameters from combing such an asymptotic convergence rate formula with time continuation in a time-dependent problem can give an efficient high order accurate bound-preserving post-processing solver, which costs O(n) per time step.

[05375] Efficient decoupling energy stable approach for coupled type gradient flow systems with anisotropy for alloys

Author(s) : Xiaofeng Yang (University of South Carolina)
Abstract : The multi-component alloy phase-field model is a highly complex coupled gradient-like flow model that involves the coupling of multiple Allen-Cahn/Cahn-Hilliard equations with different types of flow field equations. Our ultimate goal is to develop efficient numerical algorithms of the decoupling type for this model. In our initial attempt, we focus on designing a second-order linear unconditional energy stable scheme for the solidification of pure metal, which is further coupled with free flow incorporating Darcy's force. The numerical method is primarily based on the derivative class of the IEQ (Invariant Energy Quadratization) method, which has gained prominence in recent years. Specifically, we combine the so-called EIEQ method with the modified projection method and employ the novel ZEC (Zero-Energy-Contribution) decoupling method to obtain the desired numerical scheme. This approach is versatile and can be applied to a wide range of models involving flow, magnetic, and electric field coupling. To validate the effectiveness of the scheme, we conduct extensive 2D and 3D numerical simulations as well.

00262 (3/3) : 3E @E705 [Chair: Jia Zhao]

[03552] High-order exponential integrators for semilinear parabolic equations with nonsmooth data

Author(s) : Shu MA (City University of Hong Kong)Buyang Li (The Hong Kong Polytechnic University)
Abstract : A multistep exponential integrator is proposed for the semilinear parabolic equation with nonsmooth initial data, using variable stepsizes and contour integral approximations to address the initial singularity. The approach is extended to the semilinear subdiffusion equation with nonsmooth initial data. We propose an exponential convolution quadrature that combines contour integral representation of the solution, quadrature approximation of contour integrals, multistep exponential integrators for ordinary differential equations, and locally refined stepsizes to resolve the initial singularity. The proposed k-step exponential integrator and exponential convolution quadrature can have kth-order convergence for bounded measurable solutions of the semilinear parabolic and subdiffusion equations, respectively, based on the natural regularity of the solutions corresponding to the bounded measurable initial data.

[04765] Mathematical modeling and numerical approximation of bulk-surface model

Author(s) : Xueping Zhao (University of Nottingham Ningbo China)
Abstract : In biological systems, many molecules, such as proteins and RNAs can phase separate and form liquid condensates in living cells. Many of those biological molecules can bind to the biological surfaces with some domains. How the kinetic processes are affected by surface binding is still unknown. Here, we derive the governing equations of the bulk-membrane coupled system with membrane-binding using irreversible thermodynamic theory. A three-dimensional numerical solver for kinetic equations is developed to study the effects of membrane binding on the various kinetic process. Our results suggest that membrane binding play crucial roles in the underlying physical principles(e.g. time scales) of kinetic processes of the bulk-membrane system.

[02279] Discovery of Governing Equations with Recursive Deep Neural Networks

Author(s) : Jia Zhao (Utah State University)
Abstract : In this talk, I will focus on the model discovery problem when the data is not efficiently sampled. This is common due to limited experimental accessibility and labor/resource constraints. Specifically, we introduce a recursive deep neural network (RDNN) for data-driven model discovery. By embedding the known physics knowledge, this recursive approach can retrieve the governing equation in a simple and efficient manner, and it can significantly improve the approximation accuracy by increasing the recursive stages.

[00263] Problems in incompressible fluid flows: Stability, Singularity, and Extreme Behavior

Session Time & Room :

00263 (1/3) : 1C (Aug.21, 13:20-15:00) @D401

00263 (2/3) : 1D (Aug.21, 15:30-17:10) @D401

00263 (3/3) : 1E (Aug.21, 17:40-19:20) @D401

Type : Proposal of Minisymposium
Abstract : The objective of the mini-symposium is to survey recent progress regarding a number of problems in theoretical fluid mechanics and to foster an exchange of new ideas in this field. It will cover a range of topics related to the existence of equilibrium solutions and their stability, extreme behaviors realizable in fluid flows, regularity of solutions versus singularity formation, transport, and turbulence. Both vicious and inviscid flows will be considered as well as some other simplified models of fluid flow. The mini-symposium will emphasize insights obtained by exploiting connections between rigorous mathematical analysis, physics, and numerical computations.

[00695] Enforcing conservation laws in truncated fluid models: the effect on heavy-tailed statistics

Format : Online Talk on Zoom
Author(s) : Mohammad Farazmand (North Carolina State University)Zack Hilliard (North Carolina State University)
Abstract : A significant class of partial differential equations (PDEs) have conserved quantities, arising from conservation of mass, energy, momentum, etc. These conserved quantities are not necessarily preserved when the PDE is discretized for numerical simulations. A recent method called reduced-order nonlinear solutions (RONS) allows us to ensure these conserved quantities are preserved after a Galerkin-type truncation of the PDE. We apply RONS to the Euler equation for ideal fluids, Navier--Stokes equations for incompressible flow, and shallow water equation modeling tsunamis. In each case, we discuss the effect of conserved quantities on the extreme events and energy fluxes and compare the results to conventional Galerkin truncations.

[00308] Verifying global stability of fluid flows despite transient growth of energy

Format : Online Talk on Zoom
Author(s) : David Goluskin (University of Victoria)Federico Fuentes (Pontificia Universidad Católica de Chile)Sergei Chernyshenko (Imperial College London)
Abstract : To verify nonlinear stability of a laminar fluid flow against all perturbations, all past results rely on monotonic decrease of perturbation energy or a similar quadratic generalized energy. This "energy method" cannot show stability if perturbation energy can grow transiently, as in parallel shear flows at moderate Reynolds numbers. I will describe a more general approach that uses sum-of-squares polynomials to computationally construct non-quadratic Lyapunov functions that verify stability. Computational implementation for the example of 2D plane Couette flow verifies global stability at Reynolds numbers above the energy stability threshold found by Orr in 1907.

[01836] Invariant solutions representing extreme behaviour in turbulence

Format : Talk at Waseda University
Author(s) : Genta Kawahara (Osaka University)
Abstract : Invariant solutions to the incompressible Navier-Stokes equations are reviewed to theoretically interpret extreme behaviour observed in turbulent flows. Turbulent bursting in near-wall turbulence is characterised in terms of homoclinic orbits to the periodic edge state at low Reynolds numbers, while it is discussed using another vigorous turbulent saddle at high Reynolds numbers. The ultimate state, i.e. anomaly of energy and scalar dissipation, of turbulent thermal convection is represented by steady solutions.

[03543] Numerical simulation of the convex integration for the dissipative Euler flow

Format : Talk at Waseda University
Author(s) : Takeshi Matsumoto (Department of physics, Kyoto university)
Abstract : Weak solutions to the three-dimensional, incompressible Euler equations, which can dissipate the energy, were constructed with the convex integration by De Lellis, Szekelyhidi and collaborators. We develop a numerical simulation of the physically appealing construction by Buckmaster et al. Specifically, we study the solutions with the standard tools in physics of analyzing turbulent flows, such as the structure functions. We discuss insights obtained from them and also limitations of the simulation.

00263 (2/3) : 1D @D401 [Chair: Takeshi Matsumoto]

[00597] Systematic search for singularities in 3D Euler flows

Format : Talk at Waseda University
Author(s) : Bartosz Protas (McMaster University)Xinyu Zhao (McMaster University)
Abstract : We consider the question about formation of singularities in incompressible Euler flows. Based on the local well-posedness result guaranteeing existence of smooth solutions in the Sobolev space H^m, $m > 5/2$, we search for potentially singular flows systematically by solving a PDE optimization problem where the H^3 norm is maximized at time T. Solutions of this problem obtained using an adjoint-based gradient descent method indicate the possibility of singularity formation if the time T is sufficiently long.

[00371] Mathematical reformulation of the Kolmogorov-Richardson energy cascade in terms of vortex stretching and related topics

Format : Talk at Waseda University
Author(s) : Tsuyoshi Yoneda (Hitotsubashi University)Susumu Goto (Osaka University)Tomonori Tsuruhashi (University of Tokyo)
Abstract : With the aid of direct numerical simulations of forced turbulence in a periodic domain, we mathematically reformulate the Kolmogorov-Richardson energy cascade in terms of vortex stretching. More precisely, under the assumptions of the scale-locally of the vortex stretching/compressing process and the statistical independence between vortices that are not directly stretched or compressed, we can derive the -5/3 power law of the energy spectrum of statistically stationary turbulence without directly using the Kolmogorov hypotheses.

[03746] Structure and scaling of extremely large velocity gradients in hydrdynamic turbulence.

Format : Talk at Waseda University
Author(s) : Alain Pumir (CNRS and Ecole Normale Supérieure de Lyon)Dhawal Buaria (New York University)
Abstract : I will discuss extreme events in the velocity gradient tensor of turbulent flows, using data from Direct Numerical Simulations (DNS) of turbulent flows up to a Taylor-scale Reynolds number of 1300. I will review some essential properties of the velocity gradient tensor, and in particular, the dependence of the strain, conditioned on vorticity, and the dependence on the Reynolds number of the probability density functions of the vorticity and strain. These properties lead to the proposition of a simple framework to quantify the extreme events and the smallest scales of turbulence. This work accentuates the importance of the relation between strain and vorticity in developing an accurate understanding of intermittency in turbulence.
In exploring further this relation, I will discuss the unexpected role of strain for very intense vortices, and discuss the self-attenuation of intense vortices in DNS of turbulent flows.

[00303] A model of turbulent flows based on a random Constantin-Lax-Majda-DeGregorio equation

Format : Talk at Waseda University
Author(s) : Takashi Sakajo (Kyoto University)Yuta Tsuji (Kyoto University)
Abstract : The generalized Constantin-Lax-Majda-DeGregorio (gCLMG) equation with the viscous dissipation under a large-scale forcing is utilized as a one-dimensional model of turbulent flows generating the cascade of the conserved quantity. In this talk, we show the global existence of a unique solution of the gCLMG equation subject to random forcing functions that are chosen from a given distribution. Moreover, we numerically investigate the solutions' statistical properties by Galerkin approximation of random variables with generalized Polynomial Chaos.

00263 (3/3) : 1E @D401 [Chair: Takashi Sakajo]

[00786] Extending the Gibbon-Fokas-Doering stagnation-point-type ansatz to finite-energy initial conditions: A solution to the Navier-Stokes Millennium Prize Problem?

Format : Talk at Waseda University
Author(s) : Miguel David Bustamante (University College Dublin)
Abstract : The stagnation-point-type solution to the 3D incompressible Navier-Stokes equations found in {Gibbon, Fokas and Doering, (Physica \, D) **132**, 497 {1999}} produced an infinite family of solutions to the 3D incompressible Euler equations that blow up in a finite time. There is an exact formula for the singularity time as a functional of the initial conditions {Constantin, (Int. \, Math.\, Res.\, Not.) **2000**, 455 {2000}; Mulungye, Lucas and Bustamante, (J.\, Fluid\, Mech.) **771**, 468 {2015}; ___ , (J.\, Fluid\, Mech.) **788**, R3 {2016}}, and the solutions to this and related models are best understood in terms of infinitesimal Lie symmetries {Bustamante, (Phil.\, Trans.\, R.\, Soc.\, A) **380**, 20210050 {2022}}. The main drawback of these solutions, *from the viewpoint of the Clay Millennium Prize*, is that the velocity field depends linearly on the out-of-plane spatial coordinate, and thus the initial condition has infinite energy. In this talk, I will present a way to extend these solutions in order to have an arbitrary dependence on the out-of-plane coordinate, allowing in principle for finite-energy solutions. This extension seems to break the infinitesimal Lie symmetry structure inherent to the previous infinite-energy solutions, so a statement regarding finite-time blowup is not yet available analytically in the finite-energy case. However, the extension allows for a novel numerical attempt at the finite-energy solution, via a hierarchy of systems of coupled 2D partial differential equations, which are much easier to handle than a full 3D problem. I will present results and prospects, and discuss potential applications to real-life experiments.

[04968] Singularity detection via regularization: Blow-up criteria for 3D Euler and related equations

Format : Talk at Waseda University
Author(s) : Adam Larios (University of Nebraska-Lincoln)Edriss Titi (Texas A&M University)Isabel Safarik (University of Nebraska-Lincoln)
Abstract : The 3D Euler-Voigt equations can be thought of as a regularization of the 3D Euler equations in the sense that they are globally well-posed, and the solutions approximate the solutions to the 3D Euler equations. We describe a blow-up criterion for the 3D incompressible Euler equations based on inviscid Voigt regularization. Therefore, the blow-up criterion allows one to gain information about possible singularity formation in the 3D Euler equations indirectly; namely, by simulating the "better-behaved" 3D Euler-Voigt equations. Analytical and computational results will be discussed. We will also discuss a applications to Navier-Stokes and a recent Voigt-type regularization and blow-up criterion based on the Velocity-Vorticity formulation of the 3D Navier-Stokes equations.

[02897] Thermalisation in finite-dimensional, inviscid equations of hydrodynamics

Format : Talk at Waseda University
Author(s) : Samriddhi Sankar Ray (International Centre for Theoretical Sciences, Tata Institute of Fundamental Research (ICTS-TIFR))Sugan D. Murugan (International Centre for Theoretical Sciences, Tata Institute of Fundamental Research (ICTS-TIFR))
Abstract : The question of thermalisation of classical systems with many degrees of
freedom is a fundamentally important one in statistical physics. There are
several examples of such systems, with explicitly broken integrability, which
thermalise. A slightly different class of such systems which are even less
understood are the finite-dimensional (Galerkin-truncated) equations of ideal
hydrodynamics. The long time solutions of these equations
thermalise---characterised by a Gibbs distribution of the velocity field and
kinetic energy equipartition amongst its (finite) Fourier modes---by virtue of
a phase-space and energy conservation and a simple application of Liouville's
theorem. While this property has been long known, the precise mechanisms which
trigger such states have only been discovered recently. In
this talk we discuss this mechanism and show how there could be ways to prevent
the onset of thermalisation and provide a way to tackle the important questions
of finite-time blow-up and weak solutions numerically.

[00758] How advection delays singularity formation in the Navier-Stokes equations

Format : Online Talk on Zoom
Author(s) : Koji Ohkitani (RIMS, Kyoto University)
Abstract : We numerically study the Navier-Stokes equations modified by depleting advection.
In the inviscid case some solutions blow up in finite time when advection is discarded,
Constantin 1986. We use a pair of orthogonally offset vortex tubes as initial data.
We show that: 1) blowup persists even with viscosity when advection is discarded,
and 2) the time of breakdown increases logarithmically as we reinstate advection,
consistent with the regularity of the Navier-Stokes equations.

[00264] Card-based Protocols and PEZ Protocols

Session Time & Room : 5D (Aug.25, 15:30-17:10) @A206

Type : Proposal of Minisymposium
Abstract : Secure computation protocols enable distrustful parties, each holding secret input, to compute a function of their inputs without revealing their inputs beyond the function value. Zero-knowledge protocols allow a prover to convince a verifier that there exists a solution to the puzzle without revealing the solution itself. While these cryptographic protocols are usually implemented on electronic computers, there is another line of research on cryptography using everyday physical objects instead of electronic devices. This mini-symposium will be devoted to so-called card-based protocols and PEZ protocols, which establish cryptographic tasks using a deck of physical cards and a PEZ dispenser, respectively.
Organizer(s) : Kazumasa Shinagawa, Kengo Miyamoto, Takaaki Mizuki
Classification : 94A60
Minisymposium Program :

00264 (1/1) : 5D @A206

[04248] Physical ZKPs for Logic Puzzles Using a Standard Deck of Cards

Author(s) : Suthee Ruangwises (The University of Electro-Communications)
Abstract : Recently, many researchers have been focusing on constructing physical zero-knowledge proof (ZKP) protocols for logic puzzles using a deck of cards. However, all of the developed protocols so far require several identical copies of some cards, making them impractical. In this talk, we introduce more practical ZKP protocols for two of the most famous logic puzzles: Sudoku and Makaro, that can be implemented using a standard deck (a deck consisting of all different cards).

[05000] Open Problems in Card-Based Cryptography

Author(s) : Alexander Koch (CNRS, IRIF)
Abstract : Card-based cryptographic protocols for secure multiparty computation allow to jointly compute a function, without giving anything away about someone's input that is not obvious from the output, using only a deck of cards. Since the five-card AND protocol of den Boer (EUROCRYPT 1989), this topic has developed into a full-blown research area. The talks identifies some open problems in card-based cryptography, with a focus on lower bounds on protocol parameters for different functions and models.

[05052] Recent Progress in Card-Based Cryptography

Author(s) : Daiki Miyahara (The University of Electro-Communications / AIST)
Abstract : Research on card-based cryptography began with the five-card trick, invented in 1989, which computes the two-input logical AND function using a deck of five cards without revealing any information other than necessary. In this talk, I will first introduce it and provide an overview of the major trends in this line of research. Subsequently, I present recent work published in 2021 that deals with the three-input majority function employing the five-card trick.

[05471] Introduction to Private PEZ Protocol

Author(s) : Yoshiki Abe (The University of Electro-Communications)
Abstract : A PEZ dispenser is a stack-like physical device. We explain the model and construction of the multiparty computation using a PEZ dispenser called private PEZ protocols. First, we will discuss the security requirements for private PEZ protocols by comparing secure and insecure protocols for computing the logical AND function. Then, we show the recursive structure in private PEZ protocols through an example of a three-input majority voting protocol.

[00268] Neumann—Poincaré Operator, Layer Potential Theory, Plasmonics and Related Topics

Session Time & Room :

00268 (1/4) : 1E (Aug.21, 17:40-19:20) @G701

00268 (2/4) : 2C (Aug.22, 13:20-15:00) @G701

00268 (3/4) : 2D (Aug.22, 15:30-17:10) @G701

00268 (4/4) : 2E (Aug.22, 17:40-19:20) @G701

Type : Proposal of Minisymposium
Abstract : The Neumann—Poincaré operator （abbreviated by NP） is a boundary integral linear operator known as one of the important tools associated with boundary value problems in the field of partial differential equations. The detailed properties of NP operators can be comprehended as governing dynamics of many physical systems. Especially, the NP spectrum controls some physical systems （Electro dynamics, elastic systems and etc.）.
Our purpose here is to discuss the spectral structure of NP operators and their applications to physical systems.

N.B. We would like to hold 4 sessions at this minisymposium.
Organizer(s) : Kazunori Ando, Yoshihisa Miyanishi
Classification : 35P05, 31-06, Neumann--Poincaré operator, Spectrum
Minisymposium Program :

00268 (1/4) : 1E @G701 [Chair: Yoshihisa Miyanishi]

[03110] Homogenization and the spectrum of the Neumann Poincaré operator

Format : Talk at Waseda University
Author(s) : Eric Bonnetier (Institut Fourier, Université Grenoble Alpes)
Abstract : Resonances of metallic nano-particles has been an active topic of investigation in the last decade, as this phenomenon allows localization of strong electro-magnetic fields in very small regions of space, an interesting feature for many applications. Asymptotically as the size of the particles tends to 0, the resonant frequencies are related to the spectral properties of the Neumann-Poincaré operator (NP).

In this talk, we discuss the spectrum of that integral operator, when one considers a periodic distribution of inclusions made of metamaterials in a dielectric background medium. The underlying question, is what can happen when many resonant particles interact ?

We show that under the assumptions that the inclusions are fully embedded in the periodicity cells, the spectra σ_ε of the NP operators for a collection of period ε converge to a limiting set composed of 2 parts : the union of the Bloch spectra of NP operators defined over periodicity cells with quasi-periodic boundary conditions and a boundary spectrum associated with eigenfunctions which spend a not too small part of their energy near
the boundary.

This is joint work with Charles Dapogny and Faouzi Triki.

[00406] From condensed matter theory to sub-wavelength physics

Format : Talk at Waseda University
Author(s) : Habib Ammari (ETH Zurich)
Abstract : The ability to manipulate and control waves at scales much smaller than their wavelengths is revolutionizing nanotechnology. The speaker will present a mathematical framework for this emerging field of physics and elucidate its duality with condensed matter theory.

[00777] Eigenvalues of zero order pseudodifferential operators and applications to Neumann-Poincare

Format : Online Talk on Zoom
Author(s) : Grigori Rozenblioum (Chalmers University of Technology)
Abstract : The NP operator for 3D elasticity is a zero order pseudodifferential operator, polynomially compact for a homogeneous material . For such operators we study behavior of eigenvalues converging to the points of essential spectrum and find their relation with the geometry of the body. For a nonhomogeneous material the essential spectrum fills intervals, we study eigenvalues converging to the tips of the essential spectrum.

00268 (2/4) : 2C @G701 [Chair: Kazunori Ando]

[00564] On a uniqueness property of harmonic functions

Format : Online Talk on Zoom
Author(s) : Dmitry Khavinson (University of South Florida)
Abstract : This is not a new result, yet the paper was dedicated to Walter Hayman and the main question , raised there is still unanswered. The paper was the joint work with late Harold S. Shapiro. We shall discuss the problem of uniqueness for functions u harmonic in a domain G in R^n and vanishing on some parts of the intersection V {not necessarily connected} of G with a line m. The question originated more than two decades ago with N. Nadirashvili {private communication}. For example, let G be a spherical shell, i.e., the region between two concentric spheres, and m is a line through the origin. Does u vanish on both segments along which m intersects G if it does so on one of them? To illustrate the cunning depth of the question note that if you let G to be the annulus with a sector cut out, the function u= arg z in the plane does vanish on the positive part of the real axis, but not on the whole intersection. What happens if G is a spherical shell but m does NOT pass through the center? What if we replace harmonic functions by polyharmonic functions, or, more generally, solutions of analytic elliptic equations, or even worse, by linear combinations of Riesz potentials that satisfy no PDE altogether? The answers are by no means obvious and, in many cases, may be judged as surprising.

[00367] Factorization of Neumann-Poincare operator

Format : Talk at Waseda University
Author(s) : Mihai Putinar (University of California)
Abstract : It is well known that the Neumann-Poincare operator (double layer potential) is symmetrizable.
We will discuss a factorization of this singular integral operator which explains this essential spectral feature.

[00452] The quasi-static plasmonic problem for polyhedra

Format : Talk at Waseda University
Author(s) : Karl-Mikael Perfekt (NTNU)
Abstract : I will present a characterization of the essential spectrum of the plasmonic problem for polyhedra in $\mathbb{R}^3$. The description is particularly simple for convex polyhedra and relative permittivities $\varepsilon < -1$. The results are obtained through detailed analysis of the double layer potential for polyhedral cones and polyhedra.

Based on joint work with Marta de León-Contreras.

00268 (3/4) : 2D @G701 [Chair: Yoshihisa Miyanishi]

[00364] Surface localized resonances and applications

Format : Talk at Waseda University
Author(s) : Hongyu Liu (City University of Hong Kong)
Abstract : In this talk, I shall discuss our recent discoveries on certain novel surface localized resonances which were inspired by the surface plasmon resonance. These localized resonances generate a variety of interesting applications.

[01244] Spectral structure of the Neumann-Operator on thin domains

Format : Talk at Waseda University
Author(s) : Hyeonbae Kang (Inha University)
Abstract : The Neumann-Poincare operator on thin domains, such as thin rectangles, thin prolate spheroids, flat oblate ellipsoids, exhibits interesting spectral structure. In this talk we review recent development on this topic.

[00730] A unified approach to the field concentration problem

Format : Talk at Waseda University
Author(s) : Sanghyeon Yu (Korea University)
Abstract : Composite materials shows the high field concentration when the inclusions have geometric singularities in their boundaries. This phenomenon has many practical applications in imaging, spectroscopy, and meta-materials. In this talk, we discuss a new way of tackling the field concentration problem via the spectral analysis of the Neumann-Poincare operator. We focus on two kinds of important singularities: nearly touching surfaces and high curvature points.

00268 (4/4) : 2E @G701 [Chair: Yoshihisa Miyanishi]

[00354] Spectral properties of the Neumann–Poincaré operator on rotationally symmetric domains

Format : Talk at Waseda University
Author(s) : Yong-Gwan Ji (Korea Institute for Advanced Study)Hyeonbae Kang (Inha University)
Abstract : In this talk, we will discuss the spectral properties of the Neumann-Poincaré operator when domains have rotational symmetry. We prove that if a domain Ω, in two dimensions, has rotational symmetry then NP spectrum on Ω contains NP spectrum on D which generates rotationally symmetric domain Ω by m-th root transformation.

[01245] Vector field decomposition and eigenvalues of elastic Neumann-Poincaré operators

Format : Talk at Waseda University
Author(s) : Shota Fukushima (Inha University)Yong-Gwan Ji (Korea Institute for Advanced Study)Hyeonbae Kang (Inha University)
Abstract : We show that all vector fields restricted to a surface is decomposed into three components and each component is characterized by the divergence-free or rotation-free harmonic extension to inside or outside of the domain. These three components correspond to three accumulation points of the eigenvalues of the elastic Neumann-Poincaré operator, which is a singular integral operator on the boundary.

[01265] Essential spectrum of elastic Neumann-Poincar'e operators with a corner

Format : Talk at Waseda University
Author(s) : Daisuke Kawagoe (Kyoto University)
Abstract : The elastic Neumann--Poincar'e operator is a boundary integral operator naturally appearing when we solve the Lam\'e system in a bounded domain. For the two-dimensional case, if the boundary is smooth, then its spectrum consists of two sequences of eigenvalues with two accumulation points. In this talk, we consider the situation where the planar domain is smooth except at a corner and show that the essential spectrum appears around the above accumulation points.

[00662] Fundamental solutions in Colombeau algebra

Format : Talk at Waseda University
Author(s) : Nobuto Yoneyama (Shinshu university)Yoshihisa Miyanishi (Shinshu University)
Abstract : The notion of fundamental solutions {abbreviated by FS} is introduced in Colombeau algebra. Then we can construct a little more generalized FS even for Lewy-type equation whereas there are no FS in the sense of distributions.

[00276] Interplay of Numerical and Analytical Methods in Nonlinear PDEs

Session Time & Room :

00276 (1/2) : 1C (Aug.21, 13:20-15:00) @G502

00276 (2/2) : 1D (Aug.21, 15:30-17:10) @G502

Type : Proposal of Minisymposium
Abstract : Devising reliable numerical schemes and analytically understanding fine properties of solutions of nonlinear partial differential equations are challenging mathematical tasks. Theoretically and practically relevant examples are geometrically constrained PDEs such as harmonic maps and isometric bending problems. Modern applications arise in the development of new storage technologies and micro tools. Numerical simulations provide valuable experimental insight that can motivate analytical results, e.g. about singularities. Conversely, stability results for solutions lead to convergence theories for numerical schemes. The minisymposium aims at bringing together scientists from analysis and numerics working on nonlinear PDEs in order to inspire new mathematical developments.
Organizer(s) : Sören Bartels, Diane Guignard, Christof Melcher
Classification : 35Bxx, 65Nxx, 49Jxx
Minisymposium Program :

00276 (1/2) : 1C @G502 [Chair: Christof Melcher]

[05323] Hartree-Fock theory with a self-generated magnetic field

Format : Talk at Waseda University
Author(s) : Carlos J. Garcia Cervera (UCSB)Rafael Lainez Reyes (UCSB)
Abstract : The study of a quantum system of N electrons interacting with K nuclei through the Coulomb potential has a long history in the mathematics community. In the first part of my talk, I will go over some of the quantum mechanical models developed to describe these systems, focusing on their mathematical structure and properties.

Following that, I will describe how these theories change when a magnetic field is present. In particular, I will define the Hartree-Fock ground state problem for a system of N electrons and K nuclei in the presence of self-generated magnetic fields and direct coupling and we will study the existence of the ground state and excited states, as well as some numerical approaches for its computation. The work I present is in collaboration with Rafael Lainez Reyes.

[02913] Uniform flow in axisymmetric devices through permeability optimization

Format : Online Talk on Zoom
Author(s) : Harbir Antil (George Mason University)Drew P Kouri (Sandia National Labs)Denis Ridzal (Sandia National Labs)David Robinson (Sandia National Labs)Maher Salloum (Sandia National Labs)
Abstract : Porous media enable the intimate contact between a fluid and a functional solid that can accomplish tasks valuable to chemical engineers, such as catalytic reaction, chemical separations, chemical species detection, and filtration. New additive manufacturing technologies enable the creation of porous media with precise control of the geometry of each pore, which could enable improved performance and more flexible design of chemical engineering devices. However, new design tools are needed to accomplish this. In this talk, we analyze an optimization problem, constrained by Darcy's law, to design porous media columns that achieve uniform fluid flow properties despite having nonuniform geometries. We prove existence of solutions to our problem, as well as differentiability, which enables the use of rapidly converging, derivative-based optimization methods. We demonstrate our approach on two

axisymmetric columns where we achieve a desired velocity field with uniform
transit times despite varying device cross sections.

[03496] Regularised stochastic Landau-Lifshitz equations and their application in numerical analysis

Format : Talk at Waseda University
Author(s) : Chunxi Jiao (RWTH Aachen University)
Abstract : We revisit a regularised stochastic Landau-Lifshitz equation (sLLE) with bi-Laplacian in the effective field and study a similarly regularised stochastic Landau-Lifshitz-Bloch equation (sLLBE) in a two-dimensional domain. We derive the rate of convergence (in probability) of numerical solutions of a finite-element scheme for the regularised sLLBE to the solution of sLLBE, and outline the difficulty of applying this approach to sLLE. This talk is based on a joint work with Beniamin Goldys and Ngan Le.

[03482] A least squares Hessian/Gradient recovery method for fully nonlinear PDEs in Hamilton--Jacobi--Bellman form

Format : Talk at Waseda University
Author(s) : Omar Lakkis (University of Sussex)Amireh Mousavi (Jena Universität)
Abstract : Least squares recovery methods provide a simple and practical way to approximate linear elliptic PDEs in nondivergence form where standard variational approach either fails or requires technically complex modifications. This idea allows the creation of relatively efficient solvers for fully nonlinear elliptic equations, the linearization of which leaves us with an equation in nondivergence form. An important class of fully nonlinear elliptic PDEs is that of Hamilton--Jacobi--Bellman form.

Suitable functional spaces and penalties in the cost functional must be carefully crafted in order to ensure stability and convergence of the scheme with a good approximation of the gradient and Hessian which is useful, for example, for Newton--Raphson, semismooth Newton, or a policy iteration (Howard) approximation of a Hamilton--Jacobi--Bellman equation. We prove convergence and provide convergence rates under a Cordes condition.

00276 (2/2) : 1D @G502 [Chair: Diane Guignard]

[01636] Convergent finite element approximation of liquid crystal polymer networks

Format : Talk at Waseda University
Author(s) : Shuo Yang (Yanqi Lake Beijing Institute of Mathematical Sciences and Applications)Ricardo Nochetto (University of Maryland)Lucas Bouck (University of Maryland)
Abstract : Liquid crystals polymer networks (LCN) deform spontaneously upon temperature or optical actuation. In this talk, we discuss a $2D$ membrane model of LCN and its properties. We design a finite element discretization for this model, propose a novel iterative scheme to solve the non-convex discrete minimization problem, and prove stability of the scheme and a convergence of discrete minimizers. We present a wide range of numerical simulations.

[01583] Evolving FEMs with artificial tangential velocities for curvature flows

Format : Talk at Waseda University
Author(s) : Jiashun Hu (Hongkong Polytechnic University)Buyang Li (Hongkong Polytechnic University)
Abstract : By considering a limiting situation in the method proposed by Barrett, Garcke and Nurnberg, a new artificial tangential velocity is introduced into the evolving finite element methods for mean curvature flow and Willmore flow to improve the mesh quality of the numerically computed surfaces. Stability and optimal-order convergence of the evolving finite element methods are established.

[03481] Finite element approximation of implicitly constituted non-Newtonian fluids

Format : Online Talk on Zoom
Author(s) : Endre Suli (University of Oxford)
Abstract : The framework of classical continuum mechanics, built upon an explicit constitutive equation for the stress tensor, is too narrow to describe inelastic behaviour of solid-like materials or viscoelastic properties of materials. We

present a survey of recent results concerning the mathematical analysis of finite element approximations of implicit power-law-like models for viscous incompressible fluids, where the stress tensor and the symmetric part of the velocity gradient are related by a, possibly multi-valued, maximal monotone graph.

[01330] Error analysis for a local discontinuous Galerkin approximation for systems of p-Navier–Stokes type

Format : Talk at Waseda University
Author(s) : Alex Kaltenbach (University of Freiburg)
Abstract : In this talk, we propose a Local Discontinuous Galerkin (LDG) approximation for systems of p-Navier–Stokes type involving a new numerical flux in the stabilization term and a new discretization of the convective term. A priori error estimates are derived for the velocity, which are optimal for all $p > 2$ and $\delta \geq 0$. A new criterion is presented that yields a priori error estimates for the pressure, which are optimal for all $p > 2$ and $\delta \geq 0$.

[00278] Nonlocal Modeling, Analysis, and Computation

Session Time & Room :

00278 (1/4) : 2C (Aug.22, 13:20-15:00) @G406

00278 (2/4) : 2D (Aug.22, 15:30-17:10) @G406

00278 (3/4) : 2E (Aug.22, 17:40-19:20) @G406

00278 (4/4) : 3C (Aug.23, 13:20-15:00) @G406

Type : Proposal of Minisymposium
Abstract : The past decade has seen a rapid growth in the development of nonlocal mathematical models. Nonlocal modeling is now being used in applications including continuum mechanics and fracture mechanics, anomalous diffusion and advection diffusion, and other fields. This minisymposium seeks to bring together mathematicians and domain scientists from different disciplines working on nonlocal modeling and is intended to serve as an international forum for the state of the art in the modeling, analysis, and numerical aspects of nonlocal models.
Organizer(s) : Patrick Diehl, Pablo Seleson, Robert Lipton, Qiang Du

Minisymposium Program :

00278 (1/4) : 2C @G406 [Chair: Patrick Diehl]

[02501] Coarse-Graining and Nonlocality

Format : Online Talk on Zoom
Author(s) : Stewart A Silling (Sandia National Laboratories)
Abstract : The most intuitive applications of nonlocal modeling arise when long-range interactions, such as electrostatic fields, are present in a physical system. However, nonlocal descriptions are also produced by the homogenization or coarse-graining of heterogeneous, small-scale systems. In this talk, it is shown that the coarse-graining of molecular systems or of local, elastic, heterogeneous systems leads to the peridynamic nonlocal linear momentum balance. Examples demonstrate the discovery of nonlocal material models applicable to a coarse-grained description.

[00366] Wellposedness, regularity, and convergence of nonlocal solutions to classical counterparts

Format : Talk at Waseda University
Author(s) : Petronela Radu (University of Nebraska-Lincoln)
Abstract : The successful employment of nonlocal models in a variety of applications relies on a deep understanding of mathematical properties and analysis of the underlying integral operators and associated systems of equations. In this talk I will present some recent results on nonlocal frameworks systems based on some existing, as well as newly introduced, nonlocal operators. The studies include a series of results on nonlocal versions of integration by parts

theorems, boundary conditions (both, Dirichlet and Neumann), Helmholtz-Hodge type decompositions, as well as convergence of operators to their classical equivalents as the interaction horizon vanishes.

[00370] Coupling of an atomistic model and peridynamic model using an extended Arlequin framework

Author(s) : Jieqiong Zhang (Northwest University)Fei Han (Dalian University of Technology)
Abstract : A general nonlocal coupling technique between an atomistic (AM) model and the bond-based peridynamic (PD) model is proposed, based on the Arlequin framework. This technique applies the complementary weight function and constraint conditions to transmit energies through the overlapping region between the AM and PD regions. We extend the original Arlequin framework to discrete cases by redefining constraint conditions by the peridynamic differential operator, which enables the interpolation and corresponding derivative of scattered data. Besides, the preconditioning of calibration for the PD effective micromodulus is implemented to guarantee the equilibrium of energy. One-dimensional benchmark tests investigate the coupling effects influenced by several key factors, including the coupling length, weight function, grid size and horizon in the PD model, and constraint conditions. Two- and three-dimensional numerical examples are provided to verify the applicability and effectiveness of this coupling model. Results illustrate this AM–PD coupling model takes the mutual advantages of the computational efficiency of PD model and the accuracy of AM model, which provides a flexible extension of the Arlequin framework to couple particle methods.

[00445] Local and nonlocal energy-based coupling models

Format : Talk at Waseda University
Author(s) : Julio D. Rossi (Buenos Aires Univ.)
Abstract : In this talk we will present two different ways of coupling a local operator with a nonlocal one in such a way that the resulting equation is related to an energy functional.
In the first strategy the coupling is given via source terms in the equation and in the
second one a flux condition in the local part appears.
For both models we prove existence and uniqueness of a solution that is obtained
via direct minimization of the related energy functional.
In the second part of this talk we extend these ideas to deal with local/nonlocal elasticity models in which we couple classical local elasticity with nonlocal peridynamics.

joint work with G. Acosta and F. Bersetche.

00278 (2/4) : 2D @G406 [Chair: Patrick Diehl]

[01086] Machine-learning based coupling of local and nonlocal models

Format : Talk at Waseda University
Author(s) : Patrick Diehl (LSU)Noujoude Nader (LSU)Serge Prudhomme (PolyMTL)
Abstract : This talk will present a machine-learning coupling approach for local and nonlocal models. We will identify when to switch two the coupled system and where to place the nonlocal region within the local region. We will present some one-dimensional and two-dimensional examples to showcase the applicability of the approach.

[01235] Nonlocal Neural Operators for Learning Complex Physical Systems with Momentum Conservation

Format : Online Talk on Zoom
Author(s) : Yue Yu (Lehigh University)
Abstract : Neural operators have recently become popular tools for learning responses of complex physical systems. Nevertheless, their applications neglects the intrinsic preservation of fundamental physical laws. Herein, we introduce a novel integral neural operator architecture, to learn physical models with conservation laws of linear and angular momentums automatically guaranteed. As applications, we demonstrate our model in learning complex material behaviors from both synthetic and experimental datasets, and show that our models achieves state-of-the-art accuracy and efficiency.

[03023] A Numerical Study of the Peridynamic Differential Operator Discretization of Incompressible Navier-Stokes Problems

Format : Online Talk on Zoom
Author(s) : Burak Aksoylu (Texas A&M University-San Antonio)Fatih Celiker (Wayne State University)
Abstract : We study the incompressible Navier-Stokes equations using the Projection Method. The applications of interest are the classical channel flow problems such as Couette, shear, and Poiseuille. In addition, we consider the Taylor-Green vortex and lid-driven cavity applications. For discretization, we use the Peridynamic Differential Operator (PDDO). The main emphasis of the paper is the performance of the PDDO as a discretization method under these flow problems. We present a careful numerical study with quantifications and report convergence tables with convergence rates. We also study the approximation properties of the PDDO and prove that the N-th order PDDO approximates polynomials of degree at most N exactly. As a result, we prove that the PDDO discretization guarantees the zero row sum property of the arising system matrix.

[03546] An efficient peridynamics-based coupling method for composite fracture

Format : Talk at Waseda University
Author(s) : Zihao Yang (Northwestern Polytechnical University)
Abstract : In this talk, we will introduce a peridynamics-based statistical multiscale framework and related numerical algorithms to predict the fracture of composite structure with randomly distributed particles. The heterogeneities of composites, including the shape, spatial distribution and volume fraction of particles, are characterized within the representative volume elements, and their impact on structure failure are extracted as two types of peridynamic parameters, namely, statistical critical stretch and equivalent micromodulus. Two- and three-dimensional numerical examples illustrate the validity, accuracy and efficiency of the proposed method.

00278 (3/4) : 2E @G406

[03632] Nonlocal Boundary Value Problems with Local Boundary Conditions

Author(s) : James Scott (Columbia University)
Abstract : We state and analyze classical boundary value problems for nonlocal operators. The model takes its horizon parameter to be spatially dependent, vanishing near the boundary of the domain. We show the variational convergence of solutions to the nonlocal problem with mollified Poisson data to the solution of the localized classical Poisson problem with H^{-1} data as the horizon uniformly converges to zero. Several classes of boundary conditions are considered.

[03718] On the optimal control of a linear peridynamic model

Format : Talk at Waseda University
Author(s) : Tadele Mengesha (University of Tennessee Knoxville)Abner Salgado (University of Tennessee Knoxville)Joshua Siktar (University of Tennessee Knoxville)
Abstract : We present a result on a non-local optimal control problem involving a linear, bond-based peridynamics model.
In addition to proving existence and uniqueness of solutions to our problem, we investigate their behavior as the horizon parameter, which controls the degree of nonlocality, approaches zero. We then study a finite element-based discretization of this problem, its convergence, and the so-called asymptotic compatibility as the discretization parameter and the horizon parameter vanish simultaneously.

[03800] Nonlocal half-ball vector operators and their applications to nonlocal variational problems

Author(s) : Xiaochuan Tian (UC San Diego)Zhaolong Han (UC San Diego)
Abstract : Motivated by the growing interests in nonlocal models, and particularly peridynamics, we present a nonlocal vector calculus framework defined using the half-ball gradient, divergence, and curl operators. Theoretical developments of the nonlocal half-ball vector operators include nonlocal vector identities, nonlocal Poincare inequality on bounded domains, and Bourgain-Brezis-Mironescu type compactness results. As a result, well-posedness of nonlocal variational problems can be obtained, and the applications include nonlocal convection-diffusion problems and the peridynamics correspondence model. In particular, we illustrate that the new peridynamics correspondence model defined by the half-ball vector operator is energy stable which removes the known zero-energy mode instability issue of peridynamics correspondence models.

[05210] CabanaPD: A meshfree GPU-enabled peridynamics code for exascale fracture simulations

Format : Online Talk on Zoom
Author(s) : Pablo Seleson (Oak Ridge National Laboratory)Sam Reeve (Oak Ridge National Laboratory)
Abstract : Peridynamics is a nonlocal reformulation of classical continuum mechanics suitable for material failure and damage simulation, which has been successfully demonstrated as an effective tool for the simulation of complex fracture phenomena in many applications. However, the nonlocal nature of peridynamics makes it highly computationally expensive, compared to classical continuum mechanics, which often hinders large-scale fracture simulations. In this talk, we will present ongoing efforts to develop CabanaPD, a meshfree GPU-enabled peridynamics code for large-scale fracture simulations. CabanaPD is built on top of two main libraries: Kokkos and Cabana, both developed throughout the Exascale Computing Project (ECP). CabanaPD is performance-portable and exascale-capable, and it is designed to run on U.S. Department of Energy's supercomputers, including the newly deployed Frontier, which is the first exascale machine and today's top supercomputer worldwide.

[00280] Canonical Scattering Theory and Application

Session Time & Room :

00280 (1/2) : 3D (Aug.23, 15:30-17:10) @D403

00280 (2/2) : 3E (Aug.23, 17:40-19:20) @D403

Type : Proposal of Minisymposium
Abstract : A resurging interest in metamaterials, in particular acoustic metamaterials, comprising multi-scale rigid, porous, and/or elastic materials with subwavelength resonators renews the need for a mathematical theory capable of dealing with wave interactions with such objects. This session will comprise advances across a range of canonical scattering and diffraction problems applicable to acoustic metamaterials. This lays the foundation for understanding and exploiting these materials across a range of industrial applications such as sound absorbent linings, acoustic cloaking devices, and acoustic lensing
Organizer(s) : Lorna Ayton

00280 (1/2) : 3D @D403 [Chair: Lorna Ayton]

[02735] Diffraction of acoustic waves by multiple independent semi-infinite arrays.

Format : Talk at Waseda University
Author(s) : Matthew Allan Nethercote (University of Manchester)Raphael Assier (University of Manchester)Anastasia Kisil (University of Manchester)
Abstract : We consider multiple wave scattering problems with several semi-infinite periodic arrays of point scatterers. For each array, a coupled system of equations must be satisfied by the scattering coefficients. All of these systems are solved using the discrete Wiener--Hopf technique and the result leads to a invertible matrix equation. In particular, we look at two arrays forming a wedge interface and will make comparisons with numerical methods that do not rely on the array periodicity.

[05383] Extending the Unified Transform Method for Periodic Scattering Problems

Format : Talk at Waseda University
Author(s) : Shiza Batool Naqvi (University of Cambridge)Lorna Ayton (University of Cambridge)
Abstract : The Unified Transform method (also known as Fokas method) is employed in unbounded convex domains to model wave scattering governed by the Helmholtz equation. The method is extended to consider periodic boundary conditions allowing for computation of infinite scattering patterns which have been previously studied using periodic

Green's functions and large-dimension Wiener--Hopf matrices. The method is amenable to impedance and elastic surfaces. Furthermore, complex arrangements of scatterers, such as non-parallel cascading plates, are considered.

[01576] A Mathematical Method to Solve Diffraction Problems with Generalised Linear Boundary Conditions

Format : Talk at Waseda University
Author(s) : Alistair Hales (University of Cambridge)
Abstract : The Wiener—Hopf Technique is a popular method used in the analysis of diffraction problems and elsewhere. We present a novel methodology that can solve the gust diffraction problem for a surface with a general linear boundary condition, with the view of applying said solutions to leading or trailing edge noise problems for general (possibly non-rigid) materials.
We discuss how solving such a problem is primarily difficult due to the factorization procedure required for the Wiener—Hopf technique to work. However, such boundary conditions may be simplified using a transformation of variables to a trigonometric polynomial, whose roots give the information required to split the scalar kernel into individual factors. This methodology provides insight into the underlying structure of the kernel while also allowing numerical methods to be easily applied thanks to the Maliuzhinets function that originates from wedge diffraction problems.
As an initial demonstration of the theory, we compare different canonical choices for impedance boundaries and demonstrate not only how changing the impedance of the surface can affect the solution, but how choosing a correct boundary condition initially may prove cruci

[03068] Acoustic emission of a vortex ring near a porous edge

Format : Talk at Waseda University
Author(s) : Huansheng Chen (Lehigh University)Zachary Yoas (General Dynamics Electric Boat)Mitchell Swann (Applied Research Laboratory, Pennsylvania State University)Justin Jaworski (Lehigh University)Michael Krane (Applied Research Laboratory, Pennsylvania State University)
Abstract : The sound of a vortex ring in a quiescent fluid passing near a semi-infinite porous edge is investigated analytically to determine its time-dependent pressure signal and directivity in the acoustic far field as a function of a single dimensionless parameter. Results for this configuration furnish an analogue to scaling results from standard trailing-edge noise analyses and permit a direct comparison to companion experiments that circumvent measurement contamination by background noise sources of a mean flow.

00280 (2/2) : 3E @D403 [Chair: Lorna Ayton]

[03187] Spectral computations for defect scattering in disordered topological insulators

Format : Talk at Waseda University
Author(s) : Andrew Horning (Massachusetts Institute of Technology)Matthew Colbrook (University of Cambridge)Kyle Thicke (Texas A&M University)Alex Watson (University of Minnesota)
Abstract : Topological insulators (TIs) support remarkable electronic wave phenomena that persist even in the presence of material defects and disorder. However, these phenomena are governed by an infinite-dimensional Hamiltonian with exotic spectral properties, which has frustrated the development of rigorous computational methods for disordered TIs. We use recent advances in computational spectral theory to rigorously and efficiently calculate conductivities and the generalized eigenstates that mediate interfacial electronic transport in two-dimensional TIs.

[02368] Analysis of oversampled collocation methods for wave scattering problems

Format : Talk at Waseda University
Author(s) : Georg Maierhofer (Sorbonne Université)
Abstract : In this talk, we will explore the extent to which the convergence properties of collocation methods for Fredholm integral equations can be improved by least-squares oversampling. We provide rigorous analysis to show that superlinear oversampling can enhance the convergence rates of the collocation method and reduce its sensitivity to the distribution of collocation points. We support our analysis with several numerical examples for the two-dimensional Helmholtz equation. This is joint work with Daan Huybrechs.

[03067] Revisiting the frozen-gust assumption for edge scattering using spatially-varying wavepackets

Format : Talk at Waseda University
Author(s) : Sonya Tiomkin (Lehigh University)Justin Jaworski (Lehigh University)
Abstract : An analytic solution for the noise generated by a wavepacket traveling near the edge of a rigid semi-infinite flat plate is determined in closed form in the time domain. The spatially-varying wavepacket constitutes a surrogate model for turbulent flow distortions engendered by the edge geometry. This approach permits a relaxation of the common frozen gust assumption for trailing-edge noise prediction, whereby the local vorticity is assumed to be unaffected by the edge.

[03239] Green's function for wave scattering by a semi-inifinite flat plate with a serrated edge

Format : Talk at Waseda University
Author(s) : Benshuai Lyu (Peking University)
Abstract : An analytical Green’s function is developed to study the wave scattering by a semi-infinite flat plate with a serrated edge. The scattered pressure is solved using the Wiener-Hopf technique in conjunction with the adjoint technique. The kernel decomposition can be performed analytically in the high-frequency regime, which yields closed-form analytical Green's functions for any arbitrary piecewise linear serrations. The Green's function is shown to agree well with Finite Element Method (FEM) computations at high frequencies.

[00283] Recent developments in mathematical imaging and modeling in magnetic particle imaging

Session Time & Room :

00283 (1/3) : 4D (Aug.24, 15:30-17:10) @G301

00283 (2/3) : 4E (Aug.24, 17:40-19:20) @G301

00283 (3/3) : 5B (Aug.25, 10:40-12:20) @G301

Type : Proposal of Minisymposium
Abstract : Mathematical imaging and modeling are two key challenges in the imaging modality magnetic particle imaging (MPI). MPI provides reconstructions of the concentration of magnetic nanoparticles in 4D. To address this inverse problem properly, various dynamics need to be taken into account, e.g., the particles’ magnetization behavior and the dynamics in the fluid tracer. MPI provides challenging problems in imaging, modeling, and parameter identification. In this mini-symposium, we aim at bringing together researchers working on MPI and related mathematical fields. We cover theoretical and practical topics focusing on mathematical and physical as well as algorithmic and computational issues.

[03274] The image reconstruction problem in magnetic particle imaging and an application of the deep image prior

Format : Talk at Waseda University
Author(s) : Tobias Kluth (University of Bremen)
Abstract : Magnetic particle imaging (MPI) is a tracer-based imaging modality detecting the concentration of superparamagnetic iron oxide nanoparticles. The imaging problem is a linear inverse problem given by a Fredholm integral equation of the first kind describing the concentration-to-voltage mapping. The talk provides a general introduction to MPI and the imaging problem. We further investigate general deep image prior concepts for inverse problems and their application to image reconstruction in MPI.

[05253] A hybrid model for image reconstruction in MPI using a FFL

Format : Online Talk on Zoom

Author(s) : Jürgen Frikel (OTH Regensburg)

Abstract : In Magnetic Particle Imaging (MPI), most model-based reconstruction methods rely on idealized assumptions, such as an ideal field-free line (FFL) topology. However, real MPI scanners generate magnetic fields with distortions that often lead to inaccurate reconstructions and artifacts. To improve the reconstruction quality in MPI, it is essential to develop more realistic models. In this talk, we present a hybrid MPI model that can integrate real measurements of the applied magnetic fields into a physical model. Based on this model, we introduce a novel calibration procedure that allows the acquisition of the required magnetic field measurements, independent of the resolution, and with significantly less time consumption than a measurement-based model. In addition, we present a discretization strategy for the model that can be used in algebraic reconstructions.

[04125] MPI using an FFL-scanner: Radon-based image reconstruction for realistic setup assumptions

Format : Talk at Waseda University

Author(s) : Stephanie Blanke (Universität Hamburg)Christina Brandt (Universität Hamburg)

Abstract : Magnetic particle imaging is a tracer-based imaging modality exploiting the nonlinear magnetization response of magnetic particles to changing magnetic fields. We adapt forward model and reconstruction methods towards more realistic setup assumptions for the specific choice of using a field-free line scanner. In this case, the scanning geometry resembles those of computerized tomography and we are able to jointly reconstruct particle concentration and corresponding Radon data by means of total variation regularization.

[04651] Parameter estimation for modeling of nanoparticle dynamics

Format : Online Talk on Zoom

Author(s) : Hannes Albers (Universität Bremen)Tobias Kluth (University of Bremen)

Abstract : In order to overcome the limitations of needing full delta probe calibrations for MPI, accurate and fast model-based image reconstruction with as few as possible calibration measurements are highly desirable. We discuss methods for estimating particle parameters from calibration measurements and subsequently applying them to dynamic particle models, such as the Néel relaxation model, to obtain modeled system matrices of high quality for reconstruction.

00283 (2/3) : 4E @G301 [Chair: Tobias Kluth]

[05030] Implicit neural representations for super-resolution in magnetic particle imaging

Format : Talk at Waseda University

Author(s) : Franziska Schrank (RWTH Aachen University)Volkmar Schulz (RWTH Aachen University)

Abstract : Magnetic particle imaging is a medical imaging technology based on the non-linear magnetization of magnetic nanoparticles. For image reconstruction, the received signal from the excitation of the nanoparticles is converted into the particles’ concentration distribution via the system matrix, which is commonly measured in a calibration scan. We propose to parametrize this system matrix using implicit neural representations, enabling to super-resolve it or to reduce the matrix’ acquisition time by processing an undersampled matrix.

[05026] Reducing displacement artifacts in multi-patch magnetic particle imaging

Format : Online Talk on Zoom

Author(s) : Marija Boberg (University Medical Center Hamburg-Eppendorf)Tobias Knopp (University Medical Center Hamburg-Eppendorf)Martin Möddel (University Medical Center Hamburg-Eppendorf)

Abstract : Magnetic particle imaging determines the spatial distribution of superparamagnetic nanoparticles within a small field-of-view. Multi-patch approaches can expand the field-of-view at the cost of artifacts caused by field imperfections. Time-consuming calibration scans can reduce these displacement artifacts by measuring system matrices for each patch. In this contribution, only one central system matrix is used, which is warped according to the underlying magnetic fields, resulting in low calibration times and higher image quality.

[05158] Deconvolution of direct Chebyshev reconstructions in MPI with neural networks

Format : Online Talk on Zoom
Author(s) : Mathias Eulers (Universität zu Lübeck)Marco Maass (Universität zu Lübeck)Christine Droigk (Universität zu Lübeck)Alfred Mertins (Universität zu Lübeck)
Abstract : Recently, a direct reconstruction method using Chebyshev polynomials for multi-dimensional MPI has been proposed. The reconstruction method weights and sums the frequency components of the voltage signals with tensor products Chebyshev polynomials, followed by a deconvolution step to perform a very fast image reconstruction. Unfortunately, the method is degraded by image artifacts. In this presentation, the method itself will be explained and a data-driven deconvolution model is presented which improves the image quality.

00283 (3/3) : 5B @G301 [Chair: Tobias Kluth]

[04792] A Flexible Approach to Model-Based Reconstruction in Magnetic Particle Imaging

Format : Talk at Waseda University
Author(s) : Thomas März (Hochschule Darmstadt)
Abstract : In Magnetic Particle Imaging (MPI) images are usually reconstructed using a system matrix obtained via
a time-consuming calibration procedure.
Our approach employs a mathematical model based on the MPI signal encoding and its analytical properties.
We present our two-stage algorithm:
First stage: we estimate components of the MPI Core Operator by using a variational formulation.
Second stage: the image is reconstructed by regularized deconvolution while fitting
the results of the first stage.
We demonstrate the performance of our algorithm with simulated data.

[04806] Reconstruction of Dynamic Concentrations with Sequential Subspace Optimization

Format : Talk at Waseda University
Author(s) : Marius Nitzsche (University of Stuttgart)
Abstract : Magnetic particle imaging faces challenges in dealing with dynamics, which often results in motion artifacts and lower quality reconstructions due to limited averaging. Standard algorithms cannot produce high-quality images under these circumstances. To address these issues, we utilize the Regularized Sequential Subspace Optimization (Resesop) algorithm, which can account for model imperfections caused by motion without requiring strong prior information. We demonstrate the effectiveness of Resesop on both simulated and real dynamic MPI data.

[04730] Joint motion estimation and image reconstruction for dynamic MPI

Format : Talk at Waseda University
Author(s) : Christina Brandt (Universität Hamburg)Lena Zdun (Universität Hamburg)
Abstract : Potential applications of MPI include highly dynamic tasks as blood flow imaging and instrument tracking during
inteventions. In this talk, we propose to tackle the additional challenges caused by the dynamics by a joint image
reconstruction and motion estimation approach. We combine a multi-scale motion estimation algorithm with a
stochastic primal-dual algorithm for image reconstruction. Convincing numerical results are achieved on in-vitro and
in-vivo data using motion models matching the specific application.

[00286] Low-Reynolds-number swimming: modelling, analysis and applications

Session Time & Room :

00286 (1/2) : 2D (Aug.22, 15:30-17:10) @A510

00286 (2/2) : 2E (Aug.22, 17:40-19:20) @A510

Type : Proposal of Minisymposium
Abstract : Swimming in a fluid at microscopic scale is at the heart of many questions pertaining to biology, soft matter physics and micro-robotics.
It usually involves a complex balance of hydrodynamics, elasticity and internal activity, yielding a wide range of issues requiring various mathematical viewpoints, from modelling the fluid-structure interaction to optimal propulsion and efficient control of the swimmer's trajectory, with perspectives on future applications to biomedical micro-robots. This minisymposium brings together a group of young and experienced researchers to share their contributions to some of the latest developments in the theoretical and numerical analysis of micro-swimmers.
Organizer(s) : Jessie Levillain, Clément Moreau

Minisymposium Program :

00286 (1/2) : 2D @A510 [Chair: Clément Moreau]

[03028] Results on Classical Elastohydrodynamics for a Swimming Filament

Format : Talk at Waseda University
Author(s) : Laurel A Ohm (University of Wisconsin--Madison)
Abstract : We consider two models of an immersed inextensible filament undergoing planar motion: (1) the classical elastohydrodynamic model using resistive force theory and Euler-Bernoulli beam theory, and (2) a novel curve evolution incorporating effects of linear viscoelasticity. We mention our recent PDE results on these models and highlight how this analysis can help to understand undulatory swimming at low Reynolds number. This includes the development of a novel numerical method to simulate inextensible swimmers.

[04238] A limiting model for a low Reynolds number swimmer with N passive elastic arms

Format : Talk at Waseda University
Author(s) : Jessie Levillain (CMAP, Ecole Polytechnique)François Alouges (Centre Borelli, École Normale Supérieure Paris-Saclay)Aline Lefebvre-Lepot (CMAP, École polytechnique)
Abstract : We study a simple model of artificial microswimmer, consisting of a rigid extensible arm followed by an N-mass-spring system.
We further study the limit as the number of springs tends to infinity and the parameters are scaled conveniently, and provide a rigorous proof of the convergence of the discrete model to the continuous one.
Numerical experiments show performances of the displacement in terms of frequency or amplitude of the oscillation of the active arm.

[05406] Activation processes of flagellated micro-swimmers

Format : Online Talk on Zoom
Author(s) : Irene Anello (SISSA)Jessie Levillain (CMAP, Ecole Polytechnique)François Alouges (Centre Borelli, Ecole Normale Supérieure Paris-Saclay)Aline Lefebvre-Lepot (CMAP, Ecole Polytechnique)Antonio De Simone (SISSA)
Abstract : We study the activation processes of flagellated micro-swimmers investigating microscopic details inside the flagellum.
The flagellum is composed of a structure called axoneme, composed of nine filament pairs along which are disposed force-generating elements called molecular motors.
After describing the biology behind it, we first model these motors individually before introducing a mathematical representation of the whole system.
The aim is to couple this microscopic description with a macroscopic beam equation for flagellated swimmers.

[02171] Emergent rheotaxis of shape-changing swimmers in Poiseuille flow

Format : Talk at Waseda University
Author(s) : Benjamin Benjamin Walker (University of Bath)Kenta Ishimoto (Kyoto University)Clement Moreau (RIMS, Kyoto University)Eamonn Gaffney (University of Oxford)Mohit Dalwadi (University College London)
Abstract : The complexity of microscale swimming has driven the development of simple, representative models. In this talk, we'll examine an apparently simple model of a swimming cell in a channel and reveal a surprisingly complex dynamics that evolves on three distinct timescales. Through an asymptotic analysis, we'll show how the long-time behaviours of this system can be reduced to the study of a single ordinary differential equation, whose evolution turns out to be remarkably simple.

00286 (2/2) : 2E @A510 [Chair: Jessie Levillain]

[03303] Nonlinear dynamics, bifurcations and stability transitions in motion of periodically-actuated micro-swimmers

Format : Online Talk on Zoom
Author(s) : Yizhar Or (Mechanical Engineering, Technion)
Abstract : We study simple models of robotic-like microswimmers with periodic actuation. We start from the well-known Purcell’s three-link swimmer model, and modify it in order to add realistic effects of passive elasticity and/or mechanical actuation, rather than kinematic control. We also focus on minimal models of magnetically-actuated microswimmers. We show that the nonlinear dynamics of such models include bifurcations and stability transitions of periodic solutions, which can be analyzed both numerically and analytically using asymptotic methods.

[05278] Low-Reynolds-number swimming via reinforcement learning

Format : Online Talk on Zoom
Author(s) : Alan C. H. Tsang (University of Hong Kong)Yangzhe Liu (University of Hong Kong)Zonghao Zou (Cornell University)Ali Gurbuz (Santa Clara University)On Shun Pak (Santa Clara University)
Abstract : The application of machine learning methods in the development of microswimmers has garnered significant interest recently. In particular, reinforcement learning has proven to be valuable in empowering microswimmers to learn effective propulsion strategies through their interactions with the environment. In this talk, we will discuss our latest progress in integrating reinforcement learning techniques into the design of smart microswimmers capable of performing complex tasks relevant to their biomedical applications.

[03505] Controllability of microswimming systems with and without drift

Format : Talk at Waseda University
Author(s) : Clement Moreau (RIMS, Kyoto University)
Abstract : In this talk, I will discuss the controllability properties of microswimmer models, i.e. their capacity to reach a given target, depending on important assumptions such as the way the swimmer's deformation is controlled and its environment. I will focus on the example of a magneto-elastic swimmer to present a result on the local controllability of control-affine systems with a drift.

[03844] Recent trends in micro-swimming

Format : Talk at Waseda University
Author(s) : Marta Zoppello (Politecnico di Torino)Marco Morandotti (Politecnico di Torino - P. IVA 00518460019)
Abstract : Inertialess hydrodynamics is notorious for its time-reversibility constraint, which leads to the well known "Scallop Theorem”. One way to overcome it is to couple two or more micro-swimmer units. In this talk we will show some recent results about the controllability of more than one micro-swimmer immersed in a viscous fluid, highlighting the crucial role of hydrodynamic interaction in achieving it.

[00289] Nonconvex nonlinear programming: Theory and algorithms

Session Time & Room :

00289 (1/2) : 1C (Aug.21, 13:20-15:00) @D501

00289 (2/2) : 1D (Aug.21, 15:30-17:10) @D501

Type : Proposal of Minisymposium
Abstract : Nonconvex nonlinear programming problems arise extensively in many important applications including machine learning, image processing, etc. This minisymposium intends to present the latest advances on nonconvex nonlinear programming both in theory and in algorithms. The talks will be particularly focused on large scale problems, Lagrangian methods, gradient methods, and stochastic methods.

00289 (1/2) : 1C @D501 [Chair: Yakui Huang]

[02633] A Stochastic Conjugate Gradient Algorithm with Variance Reduction

Format : Talk at Waseda University
Author(s) : Caixia Kou (Beijing University of Posts and Telecommunications)
Abstract : Stochastic gradient descent methods are popular for large scale optimization but has slow convergence asymptotically due to the inherent variance. To remedy this problem, we firstly propose a new stochastic conjugate gradient algorithm, called SCGA. Besides, developing a new stochastic gradient estimate of unbiasedness with minimized variance, we also present another two stochastic conjugate gradient algorithms. The convergence theory can be established and experiments show the new algorithms have satisfactory numerical performance.

[01352] Golden ratio Bregman proximal gradient algorithm for nonconvex optimization problems

Format : Talk at Waseda University
Author(s) : Xue Gao (Hebei University of Technology)Kai Wang (Nanjing University of Science and Technology)
Abstract : We focus on solving the nonconvex nonsmooth minimization problem over abstract constraint set, whose objective function is the sum of a proper lower semicontinuous
convex function and a smooth nonconvex function, where the differentiable part is freed from the restrictive assumption of global Lipschitz gradient continuity. We design, analyze and test a golden ratio Bregman proximal gradient algorithm (GBPG). The globally convergence of GBPG is proved and numerical simulations demonstrate its feasibility and effectiveness.

[02076] On the quadratic termination property of the gradient method

Format : Talk at Waseda University
Author(s) : Yakui Huang (Hebei University of Technology)
Abstract : The gradient method is one of the most popular algorithms in solving large scale unconstrained optimization problems. However, most of existing gradient methods do not enjoy the quadratic termination property. In this talk, we will provide a summary account of recent and new results on how to equip gradient methods with the two-dimensional quadratic termination property. Moreover, a new mechanism for the gradient method to achieve three- and higer-dimensional quadratic termination will be presented.

[03083] A novel augmented Lagrangian and its application in linear programming

Format : Talk at Waseda University
Author(s) : Xinwei Liu (Hebei University of Technology)
Abstract : We introduce a twice differentiable augmented Lagrangian for optimization with general inequality constraints. Our function is a combination of the augmented Lagrangian and the logarithmic-barrier technique, and is a generalization of the Hestenes-Powell augmented Lagrangian. The associated augmented Lagrangian method is proved to have strong global convergence, the capability of rapidly detecting the possible infeasibility, and linear convergence to the KKT point. The preliminary numerical experiments on some small benchmark test problems demonstrate our theoretical results. The application in linear programming shows its superiority.

00289 (2/2) : 1D @D501 [Chair: Mengwei Xu]

[01520] Sensitivity analysis for value functions with application to bilevel programs

Format : Talk at Waseda University
Author(s) : Kuang Bai (The Hong Kong Polytechnic University)
Abstract : In this talk, we will study sensitivity analysis of value functions and optimality conditions of bilevel programs. First, for the sensitivity analysis, based on a recent work of the speaker on parametric nonlinear programs, we will further study the directional sensitivity analysis of value functions for parametric set-constrained problems, which include many classical problems as special cases and can be nonsmooth and nonconvex. In particular, we will derive sufficient conditions for the directional Lipschitz continuity, formulae of the directional derivative and upper estimates for the directional limiting\Clarke subdifferential of value functions. Finally, based on the recent development on directional constraint qualifications and directional optimality conditions, using the directional differential properties of value functions, we will derive sharp optimality conditions for general bilevel programs.

[03119] Extrapolated Bregman proximal difference-of-convex(DC) algorithm for structured DC optimization problems

Format : Talk at Waseda University
Author(s) : Bo Wen (Hebei University of Technology)
Abstract : In this talk, we mainly consider a Bregman proximal DC method with extrapolation for solving structured DC optimization problems. We first show different extrapolation strategies to possibly accelerate Bregman proximal DC algorithm, and then we discuss the convergence behavior and convergence rates of the Bregman extrapolated proximal DC algorithms. Finally, some numerical experiments have been conducted to illustrate the theoretical results.

[03077] Relaxed constant positive linear dependence constraint qualification for disjunctive programs

Format : Talk at Waseda University
Author(s) : Mengwei Xu (Hebei University of Technology)Jane Ye (University of Victoria)
Abstract : The disjunctive program is a class of optimization problems in which the constraint involves a disjunctive set which is the union of finitely many polyhedral convex sets. In this paper, we introduce a notion of the relaxed constant positive linear dependence constraint qualification (RCPLD) for the disjunctive program. Our notion is weaker than the one we introduced for a nonsmooth system which includes an abstract set constraint recently (J. Glob. Optim. 2020) and is still a constraint qualification for a Mordukhovich stationarity condition for the disjunctive program. To obtain the error bound property for the disjunctive program, we introduce the piecewise RCPLD under which the error bound property holds if all inequality constraint functions are subdifferentially regular and the rest of the constraint functions are smooth. We then specialize our results to the ortho-disjunctive program, which includes the mathematical program with equilibrium constraints (MPEC), the mathematical program with vanishing constraints (MPVC) and the mathematical program with switching constraints (MPSC) as special cases. For MPEC, we recover MPEC-RCPLD, a MPEC variant of RCPLD and propose the MPEC piecewise RCPLD to obtain the error bound property. For MPVC, we introduce MPVC-RCPLD as a constraint qualification and the piecewise RCPLD as a sufficient condition for the error bound property. For MPSC, we show that both RCPLD and the piecewise RCPLD coincide and hence it is not only a constraint qualification, but also a sufficient condition for the error bound property.

[03103] An Oracle Gradient Regularized Newton Method for Quadratic Measurements Regression

Author(s) : Jun Fan (Hebei University of Technology)
Abstract : Recently, recovering an unknown signal from quadratic measurements has gained popularity because it includes as special cases many interesting applications such as phase retrieval, fusion frame phase retrieval and positive operator-valued measure. In this paper, by employing the least squares approach to reconstruct the signal, we establish the non-asymptotic statistical property showing that the gap between the estimator and the true signal is vanished in the noiseless case and is bounded in the noisy case by an error rate of $O(\sqrt{p\log(1+2n)/n})$, where n and p are the number of measurements and the dimension of the signal, respectively. We develop a gradient regularized Newton method (GRNM) to solve the least squares problem and prove that it converges to a unique local minimum at a superlinear rate under certain mild conditions. In addition to the deterministic results, GRNM can reconstruct the true signal exactly for the noiseless case and achieve the above error rate with a high probability for the noisy case. Numerical experiments demonstrate the GRNM performs nicely in terms of high order of recovery accuracy, faster computational speed, and strong recovery capability.

[00294] Machine Learning and Differential Equations

Session Time & Room :

00294 (1/2) : 4C (Aug.24, 13:20-15:00) @G401

00294 (2/2) : 4D (Aug.24, 15:30-17:10) @G401

Type : Proposal of Minisymposium
Abstract : This Minisymposium aims at exploring the multiple relations between Machine Learning and Differential Equations. For one, it is possible to use Machine Learning to learn the solutions of challenging, high-dimensional or parameterized Differential Equations. On the other hand, some network architectures, like ResNet or Fractional-DNN, can be understood as time discretizations of Differential Equations. This interplay of different research directions leads to exciting problem formulations and the opportunity to benefit from the respective expertise.

[01809] Certified machine learning: Rigorous a posteriori error bounds for physics-informed neural networks

Author(s) : Birgit Hillebrecht (SimTech, University of Stuttgart)Benjamin Unger (SimTech, University of Stuttgart)
Abstract : Prediction error quantification has been left out of most methodological investigations of neural networks for both purely data-driven and physics-informed approaches. Beyond statistical investigations and generic a-priori results on the approximation capabilities of neural networks, we present a rigorous upper bound on the prediction error of physics-informed neural networks applied to linear PDEs. Our bound can be calculated without knowing the true solution and using only the characteristic properties of the underlying dynamical system.

[04004] Control of kinetic collective dynamics by deep neural feedback laws

Author(s) : Sara Bicego (Imperial College London)Giacomo Albi (Università degli Studi di Verona)Dante Kalise (Imperial College London)
Abstract : We address how to successfully condition high dimensional multi agent systems towards designed cooperative goals via dynamic optimization. The problem reads as the minimization of a cost functional subject to individual-based dynamics; thus, its solution becomes unfeasible as the number of agents grows. We propose a NN-accelerated Boltzmann scheme for approaching the solution from suboptimality. Under the quasi-invariant limit of binary interactions we approximate the mean field PDE governing the dynamics of the agents' distribution.

[04705] An Operator-Learning Approach for Computational Fluid Dynamics

Author(s) : Viktor Hermann Grimm (University of Cologne)Axel Klawonn (University of Cologne)Alexander Heinlein (Delft University of Technology (TU Delft))
Abstract : We present an operator-learning approach for Computational Fluid Dynamics using Convolutional Neural Networks (CNNs). We aim to approximate the solution operator for the incompressible Navier-Stokes equations in varying geometries using CNNs trained only on the underlying physics. No reference simulations are required for training. We show that our method is able to predict the flow field in various geometries sufficiently accurate and compare its performance to traditional numerical methods.

[04777] Dynamic Control in Machine Learning: Geometric Interpretation of deep neural networks for Multi-Classification and Universal Approximation.

Author(s) : Martin Sebastian Hernandez Salinas (Friedrich-Alexander-Universität Erlangen-Nürnberg)Enrique Zuazua (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : In this talk, we will present recent results on the interplay between control and Machine Learning. We analyze the Residual Neural Networks architecture and the Multilayer Perceptron with minimal width. Adopting a dynamic control and geometric interpretation of the neural networks, we train them in a constructive manner to solve multi-classification problems and achieve simultaneous controllability. We also derive the so-called universal approximation theorems in L^p spaces for both architectures.

00294 (2/2) : 4D @G401

[05167] Fourier Neural Poisson Reconstruction

Author(s) : Aras Bacho (Ludwig-Maximilians-Universität München)Héctor Andrade Loarca (Ludwig-Maximilians-Universität München)Julius Hege (Ludwig-Maximilians-Universität München)Gitta Kutyniok (Ludwig-Maximilians-Universität München)
Abstract : 3D Shape Poisson reconstruction is a method for recovering a 3D mesh from an oriented point cloud by solving the Poisson equation. It is widely used in industrial and academic 3D reconstruction applications, but typically requires a large number of points for a reasonable reconstruction. In this talk, I will present a new approach that utilizes Fourier Neural Operators to improve Poisson reconstruction in the low and middle-sampling regime. This method outperforms existing methods in terms of reconstructing fine details and is also resolution-agnostic. This allows for training the network at lower resolutions with less memory usage and evaluating it at higher resolutions with similar performance with much less data points. Furthermore, we demonstrate that the Poisson reconstruction problem is well-posed on a theoretical level by providing a universal approximation theorem for the Poisson problem with distributional data utilizing the Fourier Neuronal Operator which underpins our practical findings.

[05373] Adaptive Time Stepping in Deep Neural Networks

Author(s) : Harbir Antil (George Mason University)Hugo Diaz (University of Delaware)Evelyn Herberg (University Heidelberg)
Abstract : We highlight the common features of optimal control problems with partial differential equations and deep learning problems. Furthermore, we introduce a new variable in the neural network architecture, which can be interpreted as a time step-size. The proposed framework can be applied to any of the existing networks such as ResNet or Fractional-DNN. This framework is shown to help overcome the vanishing and exploding gradient issues. The proposed approach is applied to an ill-posed 3D-Maxwell's equation.

[00295] Estimation problems over groups

Session Time & Room :

00295 (1/3) : 5B (Aug.25, 10:40-12:20) @E604

00295 (2/3) : 5C (Aug.25, 13:20-15:00) @E604

00295 (3/3) : 5D (Aug.25, 15:30-17:10) @E604

Type : Proposal of Minisymposium
Abstract : We discuss a class of estimation problems that aim for unknown group elements or a signal affected by group actions. Three prominent examples of such problems are synchronization over groups, multireference alignment, and the recovery problem in single-particle cryo-EM. The talks will cover computational and theoretical aspects, including the sample complexity of the problems, constructing group invariant operators, sparsity, recovery strategies, machine learning-based methods, group-robust metrics, data modeling, autocorrelation analysis, and its acceleration techniques, manifold optimization in cryo-EM, synchronization analysis, and more. This mini-symposium is divided into three sections and will host senior and junior researchers as its speakers.

[05122] Vector bundles for alignment and dimensionality reduction

Author(s) : Jose Perea (Northeastern University)Luis Scoccola (Northeastern University)
Abstract : Vector bundles have rich structure and arise naturally when trying to solve dimensionality reduction and synchronization problems in data science. I will show in this talk how the classical machinery (e.g., classifying maps, characteristic classes, etc) can be adapted to the world of algorithms and noisy data, as well as the insights one can gain.

[04867] Group-robust metrics

Format : Online Talk on Zoom
Author(s) : William Leeb (University of Minnesota, Twin Cities)
Abstract : This talk will describe a family of metrics between functions. These metrics are provably robust to a large class of perturbations of the inputs, including the group of integral-preserving reparameterizations; they are also robust to additive noise, and can be evaluated rapidly. Their theoretical properties will be illustrated by numerical experiments.

00295 (2/3) : 5C @E604 [Chair: Nir Sharon]

[04814] The sample complexity of multireference alignment and cryo-EM

Format : Talk at Waseda University
Author(s) : Tamir Bendory (Tel Aviv University)
Abstract : The problem of multi-reference alignment (MRA) involves retrieving a signal from multiple copies that have been corrupted by noise and transformed by a random group element. MRA is of particular interest in the context of single-particle cryo-electron microscopy (cryo-EM), a prominent technique used to reconstruct biological molecular structures. During this talk, I will examine the sample complexity of both the MRA and cryo-EM models using tools from representation theory, sparse coding, and generative models.

[04753] Autocorrelation analysis for cryo-EM with sparsity constraints

Format : Talk at Waseda University
Author(s) : Tamir Bendory (Tel Aviv University)Yuehaw Khoo (The University of Chicago)Joe Kileel (UT Austin)Oscar Mickelin (Princeton University)Amit Singer (Princeton University)
Abstract : This work presents new results for the method of moments applied to cryo-electron microscopy. We prove that autocorrelations of noisy tomographic projection images can reconstruct molecular structures that are modeled as sparse sums of Gaussians. This significantly reduces the sample complexity of the problem, compared to previous results. Additionally, we detail a practical ab initio reconstruction algorithm using tools adapted from crystallographic phase retrieval.

00295 (3/3) : 5D @E604 [Chair: Yuehaw Khoo]

[03118] Optimal Spectral Methods for Synchronization Problems

Format : Talk at Waseda University
Author(s) : Anderson Ye Zhang (University of Pennsylvania)
Abstract : We study the performance of spectral methods for synchronization problems with additive Gaussian noises and incomplete data. Spectral methods refer to algorithms that use the leading eigenvectors of the data matrix followed by a normalization step. (1) For phase synchronization and orthogonal group synchronization, we prove that they achieve the minimax lower bound of the problem with a matching leading constant under a squared ℓ_2 loss. This shows that the spectral method has the same performance as more sophisticated procedures including MLE, generalized power method, and SDP when consistent parameter estimation is possible. (2) For permutation synchronization, we propose a novel spectral method that overcomes a crucial limitation of existing ones and has improved numerical performance. We further show the proposed method is statistically optimal with an exponentially small error that matches the minimax rate.

[05181] Orthogonal Matrix Retrieval with Spatial Consensus for 3D Unknown-View Tomography

Format : Talk at Waseda University
Author(s) : Shuai Huang (Emory University)Mona Zehni (University of Illinois at Urbana-Champaign)Ivan Dokmanic (University of Basel)Zhizhen Zhao (University of Illinois at Urbana Champaign)
Abstract : A line of work starting with Kam (1980) employs the method of moments (MoM) with rotation-invariant features to reconstruct a 3D density map from its 2D tomographic projections at unknown, random orientations, assuming that the orientations are uniformly distributed. This line of work includes the recent orthogonal matrix retrieval approaches. In this talk, we extend the previous approaches and propose to jointly recover the density map and the orthogonal matrices by imposing spatial nonnegativity constraint.

[00296] Recent advances on two-phase flows, fluid-structure interactions, and interface problems

Session Time & Room :

00296 (1/3) : 1C (Aug.21, 13:20-15:00) @E701

00296 (2/3) : 1D (Aug.21, 15:30-17:10) @E701

00296 (3/3) : 1E (Aug.21, 17:40-19:20) @E701

Type : Proposal of Minisymposium
Abstract : This mini-symposium for ICIAM2023 concerns different important topics such as mathematical modeling, theoretical analysis, and numerical methods. An important goal of this workshop is to foster collaboration between mathematicians, computational scientists, and engineers.

Applications include classic interface problems, Newtonian and non-Newtonian fluids, fluid and porous media, or viscoelastic, or poroelastic media couplings, finite element, finite volume, and finite differences or other numerical methods. Wellposedness of mathematical models and so on. The nature of this workshop will be mathematics centered with multi-disciplinary and multi-physics applications.

[02815] High Order Compact Finite Difference Schemes for Helmholtz Interface Problem

Format : Talk at Waseda University
Author(s) : Bin Han (University of Alberta)Qiwei Feng (University of Alberta)Michelle Michelle (Purdue University)Yau Shu Wong (University of Alberta)
Abstract : The Helmholtz equation is numerically challenging to solve, due to highly oscillating solutions and ill-conditioned huge matrices. Introducing Dirac-Assisted-Tree DAT method and high-order compact FDMs, we can handle 1D-heterogeneous and special 2D-Helmholtz interface problem with large wavenumbers by only solving small linear systems. We present 5th-order compact FDMs for 2D-Helmholtz interface problem with discontinuous wavenumbers and reduced pollution effect. Numerical experiments demonstrate effectiveness and superior performance of our proposed methods for Helmholtz interface problem.

[03418] Cubic Hermite splines plus correction terms: a way of adaption to the presence of singularities

Format : Talk at Waseda University
Author(s) : Juan Ruiz-Alvarez (Universidad Politecnica de Cartagena)Zhilin Li (North Carolina State University)Sergio Amat (Universidad Politécnica de Cartagena)Juan Carlos Trillo (Universidad Politécnica de Cartagena)Concepción Solano (Universidad Politécnica de Cartagena)
Abstract : Hermite interpolation is classically used to reconstruct smooth data when the function and its derivatives are available at certain nodes. If derivatives are not available, it is easy to set a system of equations imposing some regularity conditions at the data nodes in order to obtain them. This process leads to the construction of a Hermite spline. The problem of the described Hermite splines is that the accuracy is lost if the data contains singularities. The consequence is the appearance of oscillations, if there is a jump discontinuity in the function, that globally affects the accuracy of the spline, or the smearing of singularities, if the discontinuities are in the derivatives of the function. This work is devoted to the construction and analysis of a new technique that allows for the computation of accurate derivatives of a function close to singularities using a Hermite spline. The idea is inspired in the immersed interface method (IIM) and aims to correct the system of equations of the spline in order to attain the desired accuracy even close to the singularities. Once we have computed the derivatives with enough accuracy, a correction term is added to the Hermite spline in the intervals that contain a singularity. The aim is to reconstruct piecewise smooth functions with $O(h^4)$ accuracy even close to the singularities. The process of adaption requires some knowledge about the position of the singularity and the values of the function and its derivatives at the singularity. The whole process can be used as a post-processing, where a correction term is added to the classical cubic Hermite spline. Proofs for the accuracy and regularity of the corrected spline and its derivatives are given. We also analyse the mechanism that eliminates the Gibbs phenomenon close to jump discontinuities in the function. The numerical experiments presented confirm the theoretical results obtained.

[02836] Difference Finite Element Method for 3D Steady Navier-Stokes Equations

Format : Talk at Waseda University
Author(s) : Xinlong Feng (Xinjiang University)
Abstract : In this work, a difference finite element (DFE) method for the 3D steady Navier–Stokes (N–S) equations is presented. This new method consists of transmitting the FE solution of 3D steady N–S equations into a series of the FE solutions of 2D steady Oseen iterative equations, which are solved by using the finite element pair (P1b,P1b,P1)×P1 satisfying the discrete inf-sup condition in a 2D domain ω . In addition, we use finite element pair ((P1b,P1b,P1)×P1)×(P1×P0) to solve 3D steady Oseen iterative equations, where the pair satisfies the discrete inf-sup condition in a 3D domain Ω under the quasi-uniform mesh condition. To overcome the difficulty of nonlinearity, we apply the Oseen iterative method and present the weak formulation of the DFE method for solving 3D steady Oseen iterative equations. Moreover, we provide the existence and uniqueness of the DFE solutions of 3D steady Oseen iterative equations and deduce the first order convergence with respect to the discrete step parameter of the DFE solutions to the exact solution of 3D steady N–S equations. Finally, numerical tests are presented to show the accuracy and effectiveness of the proposed method.

[03698] Finite difference method on staggered grids for Stokes-Biot problems

Format : Online Talk on Zoom
Author(s) : Hongxing Rui (Shandong University)
Abstract : In this talk, we will present a looking-free finite difference method based on staggered grids for coupled Stokes-Biot problems. The model problems are used to describe Stokes fluid coupled with a poroelastic flow with a interfece. The construction of the finite difference schemes, analysis for the existence and uniqueness of the approximation solutions, superconvergence will be presented. Numerical experiments are presented to confirm the theoretical results. Then we will present a semi-decoupled scheme for the Stokes-Biot system, where the displacement of structure is split from the whole system using the time-lagging scheme. We will also present some ongoing works on coupled problem briefly.

00296 (2/3) : 1D @E701 [Chair: Juan Ruiz-Alvarez]

[05336] Value function approximation of PDEs

Format : Talk at Waseda University
Author(s) : Kazufumi Ito (North Carolina State University)
Abstract : \title{\bf Value function approximation of PDEs}
\author{Kazufumi Ito\thanks{Department of Mathematics, North Carolina State University, USA}

\noindent {\bf Abstract} In this paper we discuss a value function approximation of a general class
of nonlinear system of parabolic equations. Our approach is based on the backward stochastic
differential equations of nonlinear expectation. The approach uses the discrete time dynamic programing
formulation of the value function update. It results in an operator splitting of
the diffusion term and a semi-implicit method for the nonlinear hyperbolic term.
It is very easy to implemented and provides an accurate value function approximation.
We apply the method several applications including elliptic interface problems,
conservation laws and Navier-Stokes equations.
We analyze the stability and convergence of the proposed method.
Numerical results are presented to demonstrate the applicability

[03699] A hybrid asymptotic and augmented compact FVM for degenerate interface problem with extreme conditions

Format : Talk at Waseda University
Author(s) : Zhiyue Zhang (Nanjing Normal University)
Abstract : An accurate and efficient numerical method has been proposed for degenerate interface problem with extreme conditions such as very big jump ratio, coefficient blow-up and geometric singularity interface . The scheme combines Puiseux series asymptotic technique with augmented fourth order compact finite volume method for the problem. Error estimates are obtained. Numerical examples confirm the theoretical analysis and efficiency of the method. We also apply this method for solving time dependent problems and 2D problems.

[03531] A fast front-tracking approach for a temporal multiscale blood flow problem

Format : Talk at Waseda University
Author(s) : Ping Lin (University of Dundee)Zhenlin Guo (Beijing Computational Science Research Center)
Abstract : We consider a blood flow problem (fast system) coupled with a slow plaque growth with memory effect (slow system) at the artery wall. We construct an auxiliary temporal periodic problem and an effective time-average equation to approximate the original problem and analyze the approximation error of the corresponding PDE system, where the front-tracking technique is used to update the moving boundary. An effective multiscale method is then designed and its approximation error is analysed.

[03479] An Energy Stable Immersed Boundary Method for Deformable Membrane Problem with Non-uniform Density and Viscosity

Format : Online Talk on Zoom
Author(s) : Dongdong He (The Chinese University of Hong Kong, Shenzhen)Qinghe Wang (The Chinese University of Hong Kong, Shenzhen)Mingyang Pan (Hebei University of Technology)Yu-Hau Tseng (Kaohsiung University)
Abstract : Membrane problems commonly encountered in engineering and biological applications involve large deformations and complex configurations. Immersed boundary method, formulated by the fluid equations in which the fluid-structure interaction is described in terms of the Dirac function, is one of the most powerful tools to simulate such problems. However, the IB method suffers from severe time step restrictions to maintain stability if the discretization

lacks conservation of energy, especially for two-phase flows. In this paper, we develop an energy stable IB method for solving deformable membrane problems with non-uniform density and viscosity. Unlike the classic IB formulation, the evolution of membrane, including elastic tension and bending force, is controlled by its tangent angle and arc length. After minor modifications, it is shown that the model satisfies the continuous energy law. Thus, for the reformulated model, we proposed an implicit unconditionally energy stable scheme, where the energy of the scheme is proved to be dissipative. The resultant system is solved iteratively and the numerical results show that the proposed scheme is energy stable and capable of predicting the dynamics of extensible and inextensible interface problems with non-uniform density and viscosity.

00296 (3/3) : 1E @E701

[00297] Wave scattering problems: numerical methods with applications

Session Time & Room :

00297 (1/3) : 1E (Aug.21, 17:40-19:20) @F310

00297 (2/3) : 2C (Aug.22, 13:20-15:00) @F310

00297 (3/3) : 2D (Aug.22, 15:30-17:10) @F310

Type : Proposal of Minisymposium
Abstract : Wave scattering problems in acoustics, elastodynamics and electromagnetics are important in a large number of applications wherein challenging mathematical and numerical issues require sophisticated methods and techniques to resolve. The study of numerical methods for solving wave scattering problems has been heavily focused by researchers in both mathematical and engineering committees. This symposium devotes to combining experts from different countries and discussing some latest advances in computational modelling and simulation of complex wave phenomena with their application to real-world problems.

[02173] Fast butterfly compressed Hadamard-Babich integrators for Helmholtz equations

Format : Talk at Waseda University
Author(s) : Jianliang Qian (Michigan State University)Yang Liu (Lawrence Berkeley National Laboratory)
Abstract : We present a butterfly-compressed representation of the Hadamard-Babich (HB) ansatz for the Green's function of the high-frequency Helmholtz equation in smooth inhomogeneous media. The proposed scheme can accurately model wave propagation in 2D domains with 640 wavelengths per direction and in 3D domains with 54 wavelengths per direction {on a state-the-art supercomputer at Lawrence Berkeley National Laboratory}.

[03005] Inverse wave-number dependent source problems

Format : Talk at Waseda University
Author(s) : Guanghui Hu (Nankai University, Tianjin, China)
Abstract : We consider an inverse problem for imaging the support of a wave-number-dependent source function. The source function is given by the Fourier transform of some time-dependent source with a priori given radiating period. Using the multi-frequency far-field data at a fixed observation direction, we provide a necessary and sufficient criterion for characterizing the smallest strip containing the support and perpendicular to the observation direction.

[04115] The PML-method for a scattering problem for a local perturbation of an open periodic waveguide

Format : Talk at Waseda University
Author(s) : Andreas Kirsch (Karlsruher Institut für Technologie)Ruming Zhang (Technische Universität Berlin)
Abstract : In this talk, we study the convergence of the PML method to approximate wave propagating in an open periodic waveguide. Different from the scattering problem with periodic surfaces, the existence of propagating modes

makes things challenging. We apply a complex contour integral method to deal with the difficulty. Finally an exponential convergence of the PML method is proved.

[03704] A PML method for signal-propagation problems in axon

Format : Talk at Waseda University
Author(s) : Xue Jiang (Beijing University of Technology)maohui lyu (Chinese Academy of Sciences)Tao Yin (Chinese Academy of Sciences)Weiying Zheng (Chinese Academy of Sciences)
Abstract : This talk concerns the modelling of signal propagations in myelinated axons to characterize the functions of the myelin sheath in the neural structure. We derive a two-dimensional neural-signaling model in cylindrical coordinates from the time-harmonic Maxwell's equations. The well-posedness of model is established. Using the PML method, we propose an approximate problem. The well-posedness of the PML problem and the exponential convergence of the approximate solution to the exact solution are established.

00297 (2/3) : 2C @F310 [Chair: Tao Yin]

[01969] Frequency-time Green function acceleration for simulation, optimization and design

Format : Talk at Waseda University
Author(s) : Oscar P Bruno (Caltech)
Abstract : We present a novel "Interpolated Factored Green Function" method (IFGF), including a massively parallel implementation, for the accelerated evaluation of the integral operators in scattering theory and other areas. The IFGF algorithm runs on a small memory footprint, and it is better suited than other methods for efficient distributed-memory parallelization. A variety of applications will be mentioned, including frequency- and time-domain scattering in interior and exterior domains, atmospheric propagation and metamaterial design.

[03041] Analysis of scattering matrix algorithm

Format : Talk at Waseda University
Author(s) : Andreas Rathsfeld (Weierstrass Institute for Applied Analysis and Stochastics, Berlin)
Abstract : The scattering matrix algorithm is a popular numerical method for the diffraction of optical waves by periodic surfaces. The computational domain is divided into horizontal slices and, by a clever recursion, an approximated operator, mapping incoming into outgoing waves, is obtained. Combining this with numerical schemes inside the slices, methods like RCWA and FMM have been designed. The key for the analysis is the scattering problem with special radiation conditions for inhomogeneous cover materials.

[04576] On the coupling schemes of finite element and boundary integral equation methods solving the acoustic/elastic scattering problems

Format : Talk at Waseda University
Author(s) : Liwei Xu (University of Electronic Science and Technology of China)
Abstract : In this talk, we introduce two coupling schemes of finite element and boundary integral equation methods solving the acoustic/elastic scattering problems. The first one is the coupling of finite element and Fourier series based boundary integral solving the exterior time-harmonic elastic scattering problem. The second is the coupling of discontinuous Galerkin finite element and boundary integral equations solving the fluid-structure interaction problem. Well-posedness of the approximate problems, analysis on the accuracy and stability of numerical schemes, and numerical results will be presented.

[03004] Fast multipole method in layered media: from Helmholtz to Maxwell's equations

Format : Talk at Waseda University
Author(s) : Bo Wang (LCSM(MOE), School of Mathematics and Statistics, Hunan Normal University, Changsha, Hunan, 410081, P. R. China.)
Abstract : In this talk, a fast multipole method (FMM) for the dyadic Green's function of Maxwell's equations in layered isotropic media is presented. As in the homogeneous media, layered dyadic Green's function (LDGF) of Maxwell's equation is shown closely related to the Green's function of Helmholtz equation in layered media. Actually, there are only two essential components in the LDGF.By following the theory developed for the Green's function of Helmholtz equation, we derive multipole expansions (MEs) and local expansions (LEs) as well as the multipole-to-local translation

(M2L) operators for all the reaction field components of the LDGF. Then, the FMMs for the LDGF is implemented with the target particles and equivalent polarization sources associated with the reaction field components. Numerical results validate the fast convergence of the MEs and the O(N) complexity of the FMM for N particle problem in 3-D layered media.

00297 (3/3) : 2D @F310 [Chair: Liwei Xu]

[03722] Dirac points for the honeycomb lattice with impenetrable obstacles

Format : Online Talk on Zoom
Author(s) : Junshan Lin (Auburn University)
Abstract : Dirac points are special vertices in the band structure when two bands of the spectrum for the operator touch in a linear conical fashion, and their investigations play an important role in the design of novel topological materials. In this talk, I will discuss Dirac points for the honeycomb lattice with impenetrable obstacles arranged periodically in a homogeneous medium. I will discuss both the Dirichlet and Neumann eigenvalue problems and prove the existence of Dirac points for both eigenvalue problems at crossing of the lower band surfaces as well as higher band surfaces. In addition, quantitative analysis for the eigenvalues and the slopes of two conical dispersion surfaces near each Dirac point will be presented by a combination of the layer potential technique and asymptotic analysis.

[03675] Electronic Structure of Incommensurate 2D Heterostructures with Mechanical Relaxation

Format : Online Talk on Zoom
Author(s) : Daniel Massatt (Louisiana State University)
Abstract : Momentum space transformations for incommensurate 2D electronic structure calculations are fundamental for reducing computational cost and for representing electronic structure data in a more physically motivating format, as exemplified in the Bistritzer-MacDonald model. However, these transformations can be difficult to implement in more complex systems such as when mechanical relaxation patterns are present. In this work, we aim for two objectives. Firstly, we strive to simplify the understanding and implementation of this transformation by rigorously writing the transformations between the four relevant spaces, which we denote real space, configuration space, momentum space, and reciprocal space. This provides a straight-forward algorithm for writing the complex momentum space model from the original real space model. Secondly, we implement this for twisted bilayer graphene with mechanical relaxation affects included. We also analyze the convergence rates of the approximations, and show the tight-binding coupling range increases for smaller relative twists between layers, demonstrating that the 3-nearest neighbor coupling of the Bistritzer-MacDonald model is insufficient when mechanical relaxation is included for very small angles. We quantify this and verify with numerical simulation.

[03832] Structural Symmetry and Fabry-Perot Bound States in the Continuum: A Numerical Study

Format : Talk at Waseda University
Author(s) : Zitao MAI (City University of Hong Kong)Ya Yan LU (City University of Hong Kong)
Abstract : Fabry-Perot BIC is a special type of BIC occurs in systems with two parallel identical structures acting as ideal mirrors. Similar phenomena may arise in two-layer periodic dielectric structures by tuning different parameters such as the spacing between two layers. In our study, structures with different symmetry properties are used to verify the existence of Fabry-Perot BIC, and the minimum number of tuning parameters required is also examined.

[00304] Phase transition and control of PDE models in applied sciences

Session Time & Room : 4D (Aug.24, 15:30-17:10) @G801

Type : Proposal of Minisymposium
Abstract : The minisymposium aims to discuss recent developments and applications on phase transition and control for partial differential equations, abbreviated as PDEs, in applied sciences, such as biology, material sciences, engineering and so on.
Partial differential equations are important tools to model and study the various phenomena in applied sciences. The models with phase transition and control issues give rise to a great deal of challenging problems both in theoretical and numerical studies. The sessions focus on the seminal and extensive works in phase transition, boundary stabilization, optimal control of PDE models, such as Keller-Segel model, multi species BGK models, and aggregation models.

[01375] Crowd pressure and turbulence in crowd disasters

Format : Talk at Waseda University
Author(s) : Liangze Yang (Yanqi Lake Beijing Institute of Mathematical Sciences and Applications)
Abstract : In this study, a mixed-type continuum model for multidirectional pedestrian flow was developed that explicitly
considers the different movement characteristics of pedestrians under different situations: laminar flow in a low-density system and turbulent flow in a high-density system. In addition to the phase transition, the proposed
model can reveal the effects of both force chains and panic sentiment, which are commonly observed phenomena during crowd disasters, by estimating the aggregated pushing pressure.

[01721] Traceability of Water Pollution governed by an Inverse Source Problem

Format : Talk at Waseda University
Author(s) : Shenwen Yu (Yau Mathematical Sciences Center, Tsinghua University)Lingyun Qiu (Yau Mathematical Sciences Center, Tsinghua University)Zhongjing Wang (Department of Hydraulic Engineering, Tsinghua University)Hui Yu (Yau Mathematical Sciences Center, Tsinghua University)
Abstract : We aim to find the time-dependent source term in the diffusion equation from the boundary measurement. Based on the idea of dynamic complex geometrical optics (CGO) solutions, we analyze a variational formulation of the inverse source problem and prove the uniqueness and stability result. A two-step reconstruction algorithm is proposed, which first recovers the locations of the point sources, and then the emission concentration functions. Some numerical experiments on simulated data are conducted.

[03877] A Cucker-Smale inspired deterministic Mean Field Game with velocity interactions

Format : Talk at Waseda University
Author(s) : Woojoo Shim (Kyungpook National University)Filippo Santambrogio (Université Claude Bernard - Lyon 1)
Abstract : In this talk, I would like to introduce a mean field game model for pedestrians moving in a given domain and choosing their trajectories so as to minimize a cost including a penalization on the difference between their own velocity and that of the other agents they meet. During the talk, we will study the existence of an equilibrium in a Lagrangian setting using its variational structure and then study its properties and regularity.

[05554] Provable convergence of blow-up time of numerical approximations for a class of convection-diffusion equations

Format : Online Talk on Zoom
Author(s) : Yang Yang (Michigan Technological University)
Abstract : In this talk, we investigate the numerical algorithms to capture the blow-up time for a class of convection-diffusion equations with blow-up solutions, such as the chemotaxis model. The blow-up time is difficult to capture since we cannot distinguish whether the blow-up is physical or is due to the instability. We propose two ways to define the numerical blow-up time and prove the convergence to the exact one.

[00305] Computational Modeling on Biomedical Diseases

Session Time & Room :

00305 (1/2) : 4E (Aug.24, 17:40-19:20) @A511

00305 (2/2) : 5B (Aug.25, 10:40-12:20) @A511

Type : Proposal of Minisymposium
Abstract : Several studies have demonstrated that mathematical and computational data analysis models are required to obtain a systematic understanding of the diseases and find effective treatments. As a result, many mathematical models using both stochastic and deterministic methods have been developed to study the evolutionary processes of the diseases' initiation and progression. Some of the results of these computational models were used to predict the outcome of various drugs to obtain optimal treatment strategies. This mini-symposium will bring together scientists who are interested in the mathematical modeling of different biomedical diseases, including COVID-19, AIDs, TB, cancer, etc.
Organizer(s) : Wenrui Hao, Wing-Cheong Lo, Leli Shahriyari

Minisymposium Program :

00305 (1/2) : 4E @A511 [Chair: Wing-Cheong Lo]

[00317] Role of senescent tumor cells and macrophages in building a cytokine shield in the tumor microenvironment: mathematical modeling

Format : Talk at Waseda University
Author(s) : Yangjin Kim (Konkuk University)Junho Lee (B)Chaeyoung Lee (Korea University)Sean Lawler (Brown University)
Abstract : Cellular senescence can induce dual effects (promotion or inhibition) on cancer progression. While immune cells naturally respond and migrate toward various chemotactic sources from the tumor mass, various factors including senescent tumor cells (STCs) in the tumor microenvironment (TME) may affect this chemotactic movement. In this work, we investigate the mutual interactions between the tumor cells and the immune cells (T cells and macrophages) that either inhibit or facilitate tumor growth by developing a mathematical model that consists of taxis-reaction-diffusion equations and receptor kinetics for the key players in the interaction network. We first apply a mathematical model to a transwell Boyden chamber invasion assay used in the experiments to illustrate that STCs can play a pivotal role in negating immune attack through tight regulation of intra- and extra-cellular signaling molecules. In particular, we show that senescent tumor cells in cell cycle arrest can block intratumoral infiltration of CD8+ T cells by secreting a high level of CXCL12, which leads to significant reduction its receptors, CXCR4, on T cells, and thus impaired chemotaxis. Macrophages also play an important role in mediating or inhibiting given signaling pathways between different cells in TME. The predictions of nonlinear responses to CXCL12 were in good agreement with experimental data. We tested several hypotheses on immune-tumor interactions under various biophysical- and biochemical- conditions in the tumor microenvironment and developed new concepts for anti-tumor strategies targeting senescence induced immune impairment.

[00373] Patch formation driven by stochastic effects of interaction between viruses and defective interfering particles

Format : Talk at Waseda University
Author(s) : Qiantong Liang (City University of Hong Kong)Wing-Cheong Lo (City University of Hong Kong)
Abstract : We develop a model with a new hybrid method to study the spatial-temporal dynamics of viruses and DIPs co-infections within hosts. We present two scenarios of virus production and compare the results from deterministic and stochastic models to demonstrate how the stochastic effect is involved in the spatial dynamics of virus transmission. Our simulations demonstrate that DIPs can slow down the growth of virus particles and make the spread of virus more patchy.

[01228] Modeling about prediction and improvement of therapeutic efficacy of immune checkpoint inhibitors

Format : Talk at Waseda University
Author(s) : Xiulan Lai (Renmin University of China)
Abstract : Immune checkpoint inhibitors have been shown to be highly successful against some solid metastatic malignancies, but the overall patient response rate is limited due to the interpatient heterogeneity. In this project, we explored the effect of favorable and unfavorable gut bacteria on the therapeutic efficacy of anti-PD-1 against cancer by modeling the tumor-immune-gut microbiome interactions, and further examined the predictive markers of responders and non-responders to anti-PD-1. The dynamics alteration of PD-L1 expression status during cancer evolution and treatment are also obstacles for PD-1/PD-L1 inhibitors. We established a comprehensive modeling and computational framework for estimating the dynamic alternation of PD-L1 heterogeneity during cancer progression and treatment, and predicting the overall survival of patients.

[01252] Travelling waves of a new glioma invasion model.

Format : Talk at Waseda University
Author(s) : Ryan Thiessen (University of Alberta)
Abstract : Recently a detailed study of in-vivo glioma invasion patterns in the healthy brain tissue of living mice shows that specialized cancer cells build a network similar to a healthy brain neuronal network. We develop a model for this new phenomenon via a kinetic formulation. After making some simplifying assumptions, we arrive at a reaction-diffusion model. In this talk, I will explore travelling waves for the simplified new glioblastoma model.

00305 (2/2) : 5B @A511 [Chair: Wenrui Hao]

[01194] The role of the autoregulation mechanism in hypertension and hypotension in humans

Format : Talk at Waseda University
Author(s) : Radu C Cascaval (University of Colorado Colorado Springs)
Abstract : We present a nonlinear model for the propagation of the pressure and flow velocity waves in the human cardiovascular system, including deep learning tools with available physiological data. This model is used for understanding the system-level dynamics of the pressure and flow rates. This time-domain analysis is best to describe time-dependent controls, collectively known as the autoregulation mechanism. We discuss an application of our model to the study of the hypertension and hypotension.

[01215] Collaborative research toward data driven mathematical modeling of cancer to arrive at effective treatments

Format : Talk at Waseda University
Author(s) : Leili Shahriyari (University of Massachusetts Amherst)
Abstract : Cancer is a complex disease with many unknown features. The evolution of tumors greatly depends on the interaction network among different cell types, including immune cells and cancer cells in the tumor. To overcome some of the outstanding challenges of mathematical modeling of cancer, we have utilized and integrated several computational techniques. Importantly, in collaboration with scientists with diverse backgrounds, we have used patients' data and rich spatio-temporal mouse data to develop data-driven mathematical models for tumors' progression. We believe a collaborative model for conducting research and sharing resources, including codes, data, and results would improve our chances to arrive at more effective treatments and ultimately eliminate cancer as a major health problem for this and future generations. In this talk, I will provide an overview of some of our recent collaborative works and outline several outstanding challenges and possible next steps to address them.

[01334] Phase-field model of mechanical stability of blood clot

Format : Online Talk on Zoom
Author(s) : Zhiliang Xu (University of Notre Dame)
Abstract : Deformation and detachment of blood clot (thrombus) under different flow conditions are studied. The fibrin and activated platelets are assumed to concentrate in the core of a thrombus and less-activated platelets are assumed to concentrate in the shell region near the boundary of a thrombus. Interactions among different components are simulated by using Cahn-Hilliard type systems of equations. The macroscopic motion of fluid is described by incompressible Navier-Stokes equations with terms representing viscos, elastic and phase interaction forces as well as porous media drag force. Model simulations predict that the permeability and porosity o of the shell region are shown to effect the stalbility of the blood clot. The stablity of the red blood cell cavity at different position in the blood clot are also illustrated.

[00306] Mathematical approaches to nonlinear phenomena with singularities

Session Time & Room :

00306 (1/3) : 4C (Aug.24, 13:20-15:00) @G601

00306 (2/3) : 4D (Aug.24, 15:30-17:10) @G601

00306 (3/3) : 4E (Aug.24, 17:40-19:20) @G601

Type : Proposal of Minisymposium

Abstract : In the advanced sciences and technologies, singularity has been one of characteristic keywords of complex and dynamic nonlinear phenomena, such as phase transitions, crystallization processes, image denoising processes, and so on. Also, in recent years, the theoretical/numerical methods to deal with such singularity have been developed by a lot of researchers, from various viewpoints. The objective of this mini-symposium is to let wide range of experts of this field meet together, and to exchange the latest hot topics on the mathematical models of nonlinear phenomena, such as solvability, regularities, stability, optimizations, and so on.

Organizer(s) : Ken Shirakawa, Salvador Moll, Hiroshi Watanabe

Classification : 35J75, 35K67, 35L81, 49S05, 35R35

Minisymposium Program :

00306 (1/3) : 4C @G601 [Chair: Ken Shirakawa]

[04427] Crystalline inverse mean curvature flow

Format : Talk at Waseda University

Author(s) : Marcos Solera Diana (Universidad Autónoma de Madrid/Universitat de València)

Abstract : We obtain existence of minimizers for the p-capacity functional defined with a symmetric anisotropy for $1 < p < \infty$ and the associated Euler-Lagrange equation. After a change of variables and letting $p \downarrow 1$ we are led to the existence of solutions to the elliptic PDE associated with the level set formulation of the crystalline inverse mean curvature flow.

[04365] Pseudo-parabolic model of grain boundary motion coupled with solidification effect

Format : Talk at Waseda University

Author(s) : Daiki Mizuno (Chiba University)Ken Shirakawa (Chiba University)

Abstract : In this talk, we consider a coupled nonlinear system, which consists of an Allen-Cahn type equation and a pseudo-parabolic KWC type system. The system is based on the ϕ-η-θ model of grain boundary motion with solidification (cf. RIMS Kokyuroku, 1210, 2001). Under suitable assumptions, the mathematical results concerned with the well-posedness, including open question of uniqueness, and fine-regularity of the solution will be discussed in the Main Theorems of this talk.

[04655] Elliptic problems involving a Hardy potential

Format : Talk at Waseda University

Author(s) : Alexis Molino (University of Almeria)

Abstract : In this talk we consider different elliptic differential equations with a potential Hardy type singularity in a domain and Dirichlet conditions on the boundary. Specifically, the regularizing effect of lower order terms is revealed, as well as the existence of solutions beyond the well-known Hardy constant.

[04200] Solvability of a phase-field model of 3D-grain boundary motion

Format : Talk at Waseda University

Author(s) : Salvador Moll (Universitat de Valencia)Ken Shirakawa (Chiba University)Hiroshi Watanabe (Oita University)

Abstract : We consider a phase-field model of 3D-grain boundary motion. The model is based on the three dimensional Kobayashi--Warren model for the dynamics of polycrystals. To formulate our 3D-model, we use a quaternion formulation for the orientation variable.

In this talk, we obtain existence of solutions to the L^2-gradient descent flow of the constrained energy functional via several approximating problems. Moreover, we also obtain an invariance principle for the orientation variable.

00306 (2/3) : 4D @G601 [Chair: Hiroshi Watanabe]

[03754] Variational models for segmentation in non-euclidian settings

Format : Talk at Waseda University

Author(s) : Salvador Moll (Universitat de Valencia)

Abstract : I will present some new results on image segmentation in the general framework of perimeter measure spaces; including the anisotropic case and non-euclidian settings such as random walk spaces or metric graphs.

I will show the linkage between the ROF model for denoising and the two phases piecewise constant segmentation and I will show different applications of the results to nonlocal image segmentation, via discrete weighted graphs, and to multiclass classification on high dimensional spaces.

[04356] Periodic solution to KWC-type system under dynamic boundary condition

Format : Talk at Waseda University
Author(s) : Ryota Nakayashiki (Salesian Polytechnic)Ken Shirakawa (Chiba University)
Abstract : The aim of this study is to observe the periodic stability for KWC-type system of grain boundary motion under dynamic boundary condition. The KWC-type system is a collective term of PDE model of grain boundary motion (cf. Kobayashi et al, Physica D 140, 2000), which is governed by variable-dependent singular diffusion equation. As one of key-results of the study, we will prove the main theorem concerned with the existence of periodic solution.

[03968] Cahn-Hilliard equations with forward-backward dynamic boundary condition and non-smooth potentials

Format : Talk at Waseda University
Author(s) : Pierluigi Colli (Università degli Studi di Pavia)Takeshi Fukao (Ryukoku University)Luca Scarpa (Politecnico di Milano)
Abstract : The asymptotic behavior as the coefficient of the surface diffusion acting on the boundary phase variable goes to 0 is investigated. By this analysis we obtain a forward-backward dynamic boundary condition at the limit. We can deal with a general class of potentials having a double-well structure, including the non-smooth double-obstacle potential. We illustrate that the limit problem is well-posed by also proving a continuous dependence estimate

[04411] Optimal control for shape memory alloys of the simplipied Fr′emond model in the one-dimensional case

Format : Talk at Waseda University
Author(s) : Noriaki Yamazaki (Kanagawa University)Ken Shirakawa (Chiba University)Pierluigi Colli (Universita a degli Studi di Pavia)M. Hassan Farshbaf-Shaker (Weierstrass Institute for Applied Analysis and Stochastics)
Abstract : In this talk, we consider optimal control problems for the one-dimensional Fremond model for shape memory alloys.
Then, we prove the existence of an optimal control that minimizes the cost functional for a nonlinear and nonsmooth state problem. Moreover, we show the necessary condition of the optimal pair by using optimal control problems for approximating systems.

00306 (3/3) : 4E @G601 [Chair: Salvador Moll]

[03661] Geometric convergence in regularization of inverse problems

Format : Talk at Waseda University
Author(s) : Jose A. Iglesias (University of Twente)Gwenael Mercier (University of Vienna)Kristian Bredies (University of Graz)Otmar Scherzer (University of Vienna)
Abstract : We present some results bridging classical regularization theory of ill-posed inverse problems and regularity properties of almost-minimizers of the corresponding regularization energies. In the regime of vanishing noise and regularization parameter, we obtain results of convergence in Hausdorff distance of level sets of minimizers (which can be interpreted as objects to be recovered in an imaging context) and uniform L^∞ bounds. These hold both for the classical total variation, and for some fractional energies.

[04617] Numerical algorithms for optimization problems of grain boundary motions

Format : Talk at Waseda University
Author(s) : Shodai Kubota (National Institute of Technology, Miyakonojo College)Ken Shirakawa (Chiba University)Makoto Okumura (Konan University)
Abstract : We consider a class of optimal control problems for state problems of one-dimensional systems. Each state problem is associated with the phase-field model of grain boundary motion, proposed by Ryo Kobayashi et al. In this regard, each optimal control problem is prescribed as a minimization problem of a cost. Under suitable assumptions, the convergence of numerical algorithms for optimization problems governed by state systems will be reported as the main theorem of this talk.

[04370] Temperature optimization problems governed by pseudo-parabolic model of grain boundary motion

Format : Talk at Waseda University
Author(s) : Ken Shirakawa (Chiba University)Daiki Mizuno (Chiba University)
Abstract : In this talk, we consider a class of optimal temperature control problems governed by pseudo-parabolic PDE systems. The PDE systems are based on the KWC-model of grain boundary motion (cf. Kobayashi et al, Physica D, 140, 2000). Under suitable assumptions, we will focus on the Main Theorems, concerned with: the mathematical solvability and parameter dependence of pseudo-parabolic PDE systems and optimal controls; and the first-order necessary optimality conditions for the optimal control problems.

[04841] On well-posedness of 1-harmonic map flows

Format : Online Talk on Zoom
Author(s) : Lorenzo Giacomelli (Sapienza University of Rome)Michal Lasica (Institute of Mathematics of the Polish Academy of Sciences)Salvador Moll (Universitat de ValenciaUniversity of Valencia)
Abstract : We look at the formal gradient flow of the total variation of a manifold-valued unknown function. After introducing the problem and the state-of-the-art, I will discuss recent results with M. Lasica and S. Moll concerning local/global-in-time well-posedness of Lipschitz solutions and global existence of BV-solutions for one-dimensional domains. Uniqueness, gradient flow structures, and open questions will also be discussed.

[00307] Advanced Solver for Computational Poromechanics

Session Time & Room : 2C (Aug.22, 13:20-15:00) @D404

Type : Proposal of Minisymposium
Abstract : The numerical simulation of coupled flow and mechanical deformation in porous media is desired in several branches of technology and natural sciences for analyzing experimental data and designing quantitative theories based on mathematical concepts. The fluid-structure interaction is subject to various complexities and multiscale mechanisms. This is due to the mixed or mixed dimensional type of the model equations, nonlinearities in constitutive relations or boundary conditions, functionals used in variational formulations of error control or optimization problems. Recent progress in the design, analysis and application to large-scale problems of robust and efficient solvers for poromechanics is presented by leading experts.
Organizer(s) : Markus Bause, Florin A. Radu
Classification : 76S05, 65M60, 35M33, 65N55, Poromechanics
Minisymposium Program :

00307 (1/1) : 2C @D404 [Chair: Markus Bause]

[01387] A coupled multi-field model of dynamic poro-elasticity in anisotropic porous media

Format : Talk at Waseda University
Author(s) : Massimiliano Ferronato (University of Padova)Nico De Marchi (University of Padova)Giovanna Xotta (University of Padova)Valentina Salomoni (University of Padova)
Abstract : A fully coupled multi–field model for the dynamic simulation of anisotropic porous materials is presented. The multi-field formulation of the dynamic poro-elastic PDEs is addressed by using inf-sup stable Finite Element spaces and solved in a fully-implicit way. The GMRES convergence of the discrete non-symmetric linearized systems is accelerated by an ad-hoc Multi-Physics Reduction preconditioning technique. A set of dynamic test problems verify the potential and computational efficiency of the proposed numerical model.

[01468] Space-time finite element multigrid solver for fully dynamic poroelasticity

Format : Talk at Waseda University
Author(s) : Markus Bause (Helmut Schmidt University Hamburg)Mathias Anselmann (Helmut Schmidt University Hamburg)
Abstract : Space-time finite element methods ((STFEMs)) allow the natural construction of higher order discretizations and to achieve accurate results on computationally feasible grids. We present and analyze higher order STFEMs for two-

and multi-field modelling of poroelastic wave propagation studied, for instance, in computational seismology or biomedicine. To solve the arising complex algebraic systems, geometric multigrid preconditioning with local Vanka-type smoother of GMRES iterations is suggested. The STFEMs performance is investigated for three-dimensional test problems.

[01676] Multiscale Dynamics in Glioblastoma Growth and Spread within the Fibrous Brain Environment

Format : Talk at Waseda University
Author(s) : Dumitru Trucu (University of Dundee, Division of Mathematics)
Abstract : Despite significant recent advancements, the 3D glioblastoma invasion patterns in the brain are still poorly understood. A particular role in the collective migration of the glioblastoma cells is played by the distribution of both major brain fibres and collagen fibres present at the tumour site. To address this aspect, in this talk we present our recent advances in this direction, focusing on our recent 3D multiscale moving-boundary modelling and computational framework development for glioblastoma invasion.

[01820] Efficient splitting schemes for poromechanics

Format : Online Talk on Zoom
Author(s) : Florin Adrian Radu (University of Bergen)
Abstract : In this work we will present robust and efficient numerical schemes for poromechanics. Monolithic or splitting solvers will be discusssed. A special focus will be on non-linear poromechanics models, including soft material poromechanics. Splitting ideas will be combined with L-scheme and Anderson acceleratin to design robust and effective numerical schemes. Convergence aspects will be discussed both theoretically and numerically.

[00309] Population Dynamics in Biology and Medicine

Session Time & Room :

00309 (1/4) : 1C (Aug.21, 13:20-15:00) @A601

00309 (2/4) : 1D (Aug.21, 15:30-17:10) @A601

00309 (3/4) : 1E (Aug.21, 17:40-19:20) @A601

00309 (4/4) : 2C (Aug.22, 13:20-15:00) @A601

Type : Proposal of Minisymposium
Abstract : The mini-symposium covers diverse topics in population dynamics, from the control of insect populations, which are important disease vectors or agricultural pests, to disease spreading and their relationship with the individual immunological status in an ecological ambiance. Different approaches will be discussed in this context, combining techniques from control theory, asymptotic analysis, bifurcation theory, sensitivity analysis, and networks. The group committed to this mini-symposium is heterogeneous, coming from different institutions in North and South America, Europe, and Asia, and well-balanced between women and men researchers.

00309 (1/4) : 1C @A601 [Chair: Olga Vasilieva]

[01291] Exploring the effects of the latent eggs on the efficacy of Wolbachia-carrying release technique

Format : Talk at Waseda University
Author(s) : Claudia Pio Ferreira (Unesp)
Abstract : I will present an ordinary differential system that takes into account the interaction of two populations of mosquito, infected and uninfected with wolbachia. Each population will be split in egg, latent egg, larva and adult stage, but for the infected population no transition to larvae coming through latent egg is possible. Therefore, we will explore the contribution of uninfected eggs coming from the latent stage to the efficacy of wolbachia-aedes release.

[01943] Mathematical models for practical application of the Sterile Insect Technique

Format : Talk at Waseda University
Author(s) : Yves Dumont (CIRAD - University of Pretoria)
Abstract : Sterile Insect Technique-SIT is an autocidal control method used against Pests and Vectors. While conceptually very simple, it can be difficult to set up in the field. That is why, it is sometimes successful, and sometimes not. We show that modeling, analysis and simulations can be helpful to limit the risk of failure in SIT feasability programs. We present some results obtained against Aedes albopictus and Bactrocera dorsalis in Réunion island, a French overseas department.

[01092] A generalized next generation method for the effective reproduction number

Format : Talk at Waseda University
Author(s) : Suani Tavares Rubim de Pinho (Universidade Federal da Bahia)Daniel Cardoso Pereira Jorge (Universidade Estadual Paulista)Juliane Fonseca Oliveira (CIDACS - Fundação Oswaldo Cruz)José Garcia Vivas Miranda (Universidade Federal da Bahia)Roberto Fernandes Silva Andrade (Universidade Federal da Bahia)
Abstract : The effective reproduction number $R(t)$ plays a key role in the study of infectious diseases, indicating the current average number of new infections caused by an infected individual. In this work, we present a generalization of next generation method, leading to expressions of $R(t)$ and generation interval distributions, within and between model sub-compartments, provided by an arbitrary compartmental model and by incidence data. Ref: Jorge, DCP et al. (2022). R. Soc. Open Sci. 9, 220005.

[03871] Modelling human behavioural change during the outbreak of emerging infectious disease

Format : Talk at Waseda University
Author(s) : Ryosuke Omori (Hokkaido University)
Abstract : Disease dynamics like SARS-CoV-2 is difficult to describe by mathematical modelling. One of reasons is lack of knowledge of behavioral change due to the difficulty of measuring individual decision. To solve this problem, we defined index for the mobility avoidance in response to epidemic measured using accommodation reservation data and decision timing for behavioral change can be quantified. Using this index, we revealed general patterns in host behavioral change dynamics in response to SARS-CoV-2 outbreaks.

00309 (2/4) : 1D @A601 [Chair: Claudia P. Ferreira]

[01440] Mathematical insights of chemical and Wolbachia-based mosquito control

Format : Talk at Waseda University
Author(s) : OLGA VASILIEVA (Universidad del Valle)Daiver Cardona-Salgado (Universidad Autonoma de Occidente)Lilian Sofia Sepulveda-Salcedo (niversidad Autonoma de Occidente)
Abstract : Wolbachia is a symbiotic bacterium that can block virus replication in Aedes aegypti mosquitoes, the primary transmitters of different vector-borne diseases. This thwarts the virus transmission from mosquitoes to humans. In recent years, Wolbachia-based biocontrol of Ae. aegypti mosquitoes have been gradually replacing the traditional control interventions based on insecticide spraying. In this presentation, we assess the pros and cons of Wolbachia-based biocontrol through the mathematical modeling of the mosquito population dynamics.

[02743] ON THE ORIGIN OF COMPLEX DYNAMICS IN MULTI-STRAIN DENGUE MODELS

Format : Talk at Waseda University
Author(s) : Maira Aguiar (Basque Center for Applied Mathematics)
Abstract : Dengue fever epidemiological dynamics shows large fluctuations in disease incidence. Multi-strain models show complex dynamics and qualitatively a very good result when comparing empirical data and model simulations, however, the extent of biological mechanisms generating complex behavior in simple epidemiological models is still unexplored. In this talk, I will present a set of models motivated by dengue fever epidemiology and compare different dynamical behaviors originated when increasing complexity into the model framework.

[04155] Covid-19: Vaccination impact after lockdown lifting and its large fluctuations

Format : Talk at Waseda University
Author(s) : Nico Stollenwerk (BCAM, Bilbao, Pais Vasco)
Abstract : The initial phase of the COVID-19 pandemic in beginning 2020 with exponential growth of infected and hospitalizations led to severe lockdown measures in many countries. The subsequent lifting of the lockdowns prohibited new exponential growth, but lead to large subcritical fluctuations, with power law characteristics close to endemic thresholds, analysed for Basque Country data on a daily base for actual management purposed. We extended the modelling framework sucessfully into the vaccine introduction period.

[03501] Optimization of Vaccination strategies on a metropolitan area

Format : Talk at Waseda University
Author(s) : Lucas Machado Moschen (School of Applied Mathematics - FGV EMAp)Maria Soledad Aronna (School of Applied Mathematics - FGV EMAp)
Abstract : We propose a model for vaccination in a network that models a typical metropolitan area. By employing tools of mathematical epidemiology and optimal control, we analyze the effectiveness of different allocation policies for distribution of vaccines and we search for optimal strategies.

00309 (3/4) : 1E @A601 [Chair: NONE - no section; talk 04326 is the same as 04328]

[04326] Population Dynamics in Biology and Medicine

Format : Talk at Waseda University
Author(s) : Sunmi Lee (Kyung Hee University)
Abstract : The rapid spread of COVID-19 worldwide has highlighted the importance of non-pharmaceutical interventions. Policies that limit gatherings and enforce social distancing help to mitigate the spread of the disease, but also negatively impact the economy. Consequently, policymakers face the dilemma of whether to slow the outbreak by imposing strict rules or reduce the economic burden. This paper presents a novel framework for designing intervention policies based on deep reinforcement learning. The social distancing policies used by the South Korean government and their effects on the national economy are surveyed and integrated into a newly designed multi-patch epidemic model. The mobility between each pair of 17 patches (South Korean regions) is reconstructed using official data. The proximity policy optimization algorithm is adopted to optimize the policy model. The reward function incorporates the outbreak and economic loss, with an additional control variable that helps policymakers to determine the desired equilibrium between disease outbreak and economic recession. Our results highlight region-specific social distancing interventions compromising the dilemma between epidemic costs and economic costs.

00309 (4/4) : 2C @A601 [Chair: Maria Soledad Aronna]

[04328] Population Dynamics in Biology and Medicine

Format : Talk at Waseda University

[01337] A mathematical model to melanoma growth with macrophages and immunotherapy

Format : Talk at Waseda University
Author(s) : Paulo F. A. Mancera (UNESP)Jairo G Silva (IFMT)Mostafa Adimy (Inria and UCBL 1, Lyon France)Guilherme Rodrigues (UNESP)
Abstract : We present a new mathematical model based on ODE to describe the dynamics of melanoma under an immunotherapeutic treatment. The novelty of the proposed model is the inclusion of the tumor-associated macrophage (TAM) population, enabling the in silico analysis of its influence on the failure of this immunotherapy.

[02941] A Mathematical Perspective on Resilience and Sustainability in Climate and Biodiversity

Format : Talk at Waseda University
Author(s) : Michel DE LARA (CERMICS - Ecole des Ponts ParisTech)
Abstract : In this talk, I will

- scan through the IPCC (climate) and IPBES (biodiversity) international bodies reports,
- address theoretical aspects: how can we formalize sustainability and resilience with tools from control theory (including viability) and decision under uncertainty?
- present methods: how can we tackle problem solving, once mathematically formalized?
- outline examples: biodiversity (fisheries, epidemiology), energy and climate,
- raise open questions and challenges, especially for the stochastic optimization community.

[01827] Potential Impacts of Mass Nutritional Supplementation on Measles Dynamics

Format : Online Talk on Zoom
Author(s) : Navideh Noori (Institute for Disease Modeling, Bill & Melinda Gates Foundation)Laura A Skrip (School of Public Health, University of Liberia)Assaf P Oron (Institute for Health Metrics and Evaluation, University of Washington)Kevin A McCarthy (Institute for Disease Modeling, Bill & Melinda Gates Foundation)Joshuna L Proctor (Institute for Disease Modeling, Bill & Melinda Gates Foundation)Guillaume Chabot-Couture (Institute for Disease Modeling, Bill & Melinda Gates Foundation)Benjamin M Althouse (Information School, University of Washington)Kevin P.Q. Phelan (The Alliance for International Medical Action (ALIMA))Indi Trehan (Department of Pediatrics, Global Health, and Epidemiology, University of Washington)
Abstract : The bidirectional interaction between undernutrition and infection can be devastating to child health. Treatment of acute malnutrition can reverse some of its deleterious effects and reduce susceptibility to infection. To understand how integrating nutrition interventions and vaccination affects a vaccine-preventable disease dynamics, we developed a measles transmission model. We show leveraging mass nutritional supplementation as a contact point with the health system to increase measles vaccination coverage has a synergistic benefit beyond either intervention alone.

[00316] Dynamics of patterns and traveling waves arising from reaction-diffusion systems

Session Time & Room :

00316 (1/2) : 5B (Aug.25, 10:40-12:20) @G501

00316 (2/2) : 5C (Aug.25, 13:20-15:00) @G501

Type : Proposal of Minisymposium
Abstract : Reaction-diffusion systems reveal rich phenomena related to mathematical biology and evolutionary dynamics, like pattern formation, propagation of traveling waves. These results are also related to the free boundary problems coming from the fast reaction limits. In order for the communication with other researchers, we organize a minisymposium consisting of the topics on patterns, traveling waves and entire solutions for reaction-diffusion systems. The speakers introduce their works from the approach by center manifold reduction, comparison principles and variational methods. We expect to have new and positive contributions to these fields.
Organizer(s) : Chueh-Hsin Chang, Chih-Chiang Huang
Classification : 35C07, 35K57, 35A15, 35R35, 35B08
Minisymposium Program :

00316 (1/2) : 5B @G501 [Chair: Chang-Hong Wu]

[03601] Cross-diffusion derived from predator-prey models with two behavioral states in predators

Format : Talk at Waseda University
Author(s) : Hirofumi Izuhara (University of Miyazaki)Masato Iida (University of Miyazaki)Ryusuke Kon (University of Miyazaki)
Abstract : Cross-diffusion may be an important driving force of pattern formation in population models. Recently, a relation between cross-diffusion and reaction-diffusion systems has been revealed from the mathematical modeling point of view. In this talk, we derive a predator-prey model with cross-diffusion from a simple reaction-diffusion system with two behavioral states in the predator population and examine whether cross-diffusion can induce spatial patterns in predator-prey models.

[00453] Weak entire solutions of reaction–interface systems

Format : Talk at Waseda University
Author(s) : YANYU CHEN (National Taiwan University)
Abstract : In this talk, the singular limit problems arising from FitzHugh–Nagumo–type reaction–diffusion systems are studied, which are called reaction–interface systems. All weak entire solutions originating from finitely many excited intervals are completely characterized. For weak entire solutions originating from infinitely many excited intervals, periodic wave trains and time periodic solutions are discussed.

[03042] Pulse bifurcations in a three-component FitzHugh-Nagumo system

Format : Talk at Waseda University
Author(s) : Kei Nishi (Kyoto Sangyo University)
Abstract : Pulse dynamics in a three-component FitzHugh-Nagumo system in one dimensional space is considered. The system admits a pulse solution of bistable type, which exhibits a variety of interface dynamics, not observed for the two-component FitzHugh-Nagumo system. In order to analytically investigate the mechanism for the pulse behavior, we apply the multiple scales method to the original reaction-diffusion system, and derive finite-dimensional ordinary differential equations which describe the motions of the pulse interfaces. The reduced ODEs enable us to reveal the global bifurcation structures of the pulse solutions, and to clarify the mechanism behind the variety of the pulse dynamics from a view point of bifurcation theory.

[05009] The Motion of Weakly Interacting Waves for Reaction-Diffusion Equations in a Cylinder

Format : Talk at Waseda University
Author(s) : Chih-Chiang Huang (National Chung Cheng University)Shin-Ichiro Ei (Hokkaido University)
Abstract : In the talk, I am going to introduce the well-known results of the weakly interaction of two waves in a real line, for the Allen-Cahn equation, the FitzHugh-Nagumo system and competition-diffusion systems. Next, I would like to discuss such an interaction for reaction-diffusion equations with a triple-well potential in a cylinder. In this case, we can construct a stable traveling wave which is made up by two repulsive fronts. Based on a perturbation theory, the wave profile and wave speed can be characterized by a small parameter. This work is joint with Prof. Shin-Ichiro Ei.

00316 (2/2) : 5C @G501 [Chair: Hirofumi Izuhara]

[02140] Some Progress on the spreading properties of two-species Lotka-Volterra competition-diffusion systems

Format : Talk at Waseda University
Author(s) : Chang-Hong Wu (National Yang Ming Chiao Tung University)
Abstract : The Lotka-Volterra competition-diffusion system is a well-established model for understanding the interactions between competing species. In particular, the two-species case has been extensively studied, revealing the existence of traveling waves that can provide insight into the spreading behaviors of the species. In this presentation, we will present some recent progress on the spreading properties of this system.

[02366] Weak interaction between traveling wave solutions in the three-species competition-diffusion systems

Format : Talk at Waseda University
Author(s) : Chueh-Hsin Chang (National Chung Cheng University, Department of Mathematics)
Abstract : In this talk we consider the weak interaction between two trivial three-species traveling wave solutions (one component is trivial) of the threes-species Lotka-Volterra competition-diffusion systems. By the asymptotic behavior of the trivial threes-species waves and the existence results of the three-species waves from gluing bifurcation approaches in our previous results, we can observe the dynamics of the distance between the trivial three-species waves. The interaction between the two trivial three-species waves are attractive or repulsive due to different conditions of parameters. We let the growth rate of the third species as the bifurcation parameter.

[04983] Defects in the segmented pattern for oscillated reaction-diffusion systems

Format : Talk at Waseda University
Author(s) : Ayuki Sekisaka (Meiji university)
Abstract : In this talk, the existence and stability of the modulated waves of a certain three-component reaction-diffusion system will be discussed. The modulated waves appearing in this equation are called defects, and their formulation and basic properties have been investigated by Sandstede and Scheel. In this talk, we will discuss the basic properties of the deffects appearing in the equations and their stability using the infinite dimensional Evans function.

[04560] Linearized eigenvalue problems in a mass-conserved reaction-diffusion compartment model

Format : Talk at Waseda University
Author(s) : Tsubasa Sukekawa (Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University Institute for Advanced Study, Kyoto University)
Abstract : In a mass-conserved reaction-diffusion system, we can observe by numerical simulations that a transient pattern
such as a stripe one converges to a spatially monotone pattern.
To understand the dynamics theoretically, we introduce a reaction-diffusion compartment model. This model equation is defined on multiple regions (compartments), and each compartment is connected by diffusive coupling.
In this talk, we analyze linearized eigenvalue problems of spatially non-monotone stationary solutions
in mass-conserved reaction-diffusion compartment model.

[00319] Robust formulations for coupled multiphysics problems – Theory and applications

Session Time & Room :

00319 (1/5) : 1C (Aug.21, 13:20-15:00) @E710

00319 (2/5) : 1D (Aug.21, 15:30-17:10) @E710

00319 (3/5) : 1E (Aug.21, 17:40-19:20) @E710

00319 (4/5) : 2C (Aug.22, 13:20-15:00) @E710

00319 (5/5) : 2D (Aug.22, 15:30-17:10) @E710

Type : Proposal of Minisymposium
Abstract : The proposed minisymposium aims to bring together experts in the construction and analysis of novel discretization techniques for multiphysics models that maintain robustness with respect to model constants of interest. Particular emphasis will be placed on rigorous analysis of stability using saddle-point and perturbed saddle-point theory, a priori and a posteriori error estimation, as well on the design of robust solvers based on tailored domain decomposition techniques or on operator preconditioning. The session will also focus on the application of these new methodologies in the solution of coupled models arising in mechanobiology and similar multiphysics systems. For instance, our minisymposium features submissions involving brain tissue dynamics, cardiac electromechanics, and respiratory system

modeling; but it also welcomes talks related to geophysical flows or other types of fluid-structure interaction multiphysics problems.

Organizer(s) : Wietse Boon, Martin Hornkjøl, Miroslav Kuchta, Ricardo Ruiz Baier
Classification : 65N30, 65M30, 65F08
Minisymposium Program :

00319 (1/5) : 1C @E710 [Chair: Ricardo Ruiz Baier]

[01558] A diffuse interface method for fluid-poroelastic structure interaction

Format : Talk at Waseda University
Author(s) : Martina Bukač (University of Notre Dame)Boris Muha (University of Zagreb)Sunčica Čanić (University of California, Berkeley)
Abstract : The interaction between a free flowing fluid and a poroelastic structure, commonly formulated as a Navier-Stokes/Biot coupled system, has been used to describe problems arising in many applications, including environmental sciences, hydrology, geomechanics and biomedical engineering. Many existing numerical for this problem are based on a sharp interface approach, in the sense that the interface between the two regions is parametrized using an exact specification of its geometry and location, and the nodes in the computational mesh align with the interface. However, the exact location is sometimes not known, or the geometry is complicated, making a proper approximation of the integrals error-prone and difficult to automate. Hence, in this talk, we present a diffuse interface method for the coupled fluid-poroelastic structure interaction. The method uses a phase-field function which transitions from 1 in one region to 0 in the other region. We will first present the analysis of convergence of the discrete diffuse interface solution to the continuous sharp interface solution for the Stokes-Darcy problem. Then, we will discuss the extensions to Navier-Stokes/Biot system, and apply the method to study the optimal design of a bioartificial pancreas.

[01781] Parameter-robust methods for the Biot-Stokes interfacial coupling

Format : Talk at Waseda University
Author(s) : Martin Hornkjøl (University of Oslo)Wietse Boon (KTH Royal Institute of Technology)Miroslav Kuchta (Simula Research Laboratory)Kent-Andre Mardal (University of Oslo)Ricardo Ruiz Baier (Monash University)
Abstract : In this talk I will discuss a fluid-structure interaction model of the monolithic coupling between the free flow of
a viscous Newtonian fluid and a deformable porous medium separated by an interface. I will present a five-field
mixed-primal finite element scheme, with a preconditioner, for solving the Stokes velocity-pressure and Biot displacement-total pressure-fluid pressure. With adequate inf-sup conditions the stability of the formulation is established robustly in all material parameters.

[02817] Robust parallel solvers in cardiac modeling

Format : Talk at Waseda University
Author(s) : Nicolás Alejandro Barnafi Wittwer (University of Chile)
Abstract : We will see the physics involved in cardiac modeling, and focus on their efficient solution in an HPC infrastructure measured in both CPU time and scalability. As we will see, one of the main tools for improving performance is quasi-Newton methods, which do not sacrifice on scalability when initialized adequately. In some contexts, it will be possible to circumvent the solution of a linear system, which drastically reduces the complexity of the proposed solvers.

[02934] Stochastic Galerkin mixed finite element approximation for poroelasticity with uncertain inputs

Format : Talk at Waseda University
Author(s) : Arbaz Khan (IIT Roorkee)Catherine E Powell (University of Manchester, UK)
Abstract : Linear poroelasticity models have important applications in biology and geophysics. In particular, the well-known Biot consolidation model describes the coupled interaction between the linear response of a porous elastic medium {saturated with fluid} and a diffusive fluid flow within it, assuming small deformations. This is the starting point for modeling human organs in computational medicine and for modeling the mechanics of permeable rock in geophysics. Finite element methods for Biot's consolidation model have been widely studied over the past four decades. In the first part of talk, we discuss a novel locking-free stochastic Galerkin mixed finite element method for the Biot consolidation model with uncertain Young's modulus and hydraulic conductivity field. After introducing a five-field mixed variational formulation of the standard Biot consolidation model, we discuss stochastic Galerkin mixed finite element approximation, focusing on the issue of well-posedness and efficient linear algebra for the discretized system. We introduce a new preconditioner for use with MINRES and establish eigenvalue bounds. Finally, we present specific numerical examples to illustrate the efficiency of our numerical solution approach. In the second part of the talk, we discuss a posteriori error estimators for SGFEM of Biot's consolidation model with uncertain inputs.

00319 (2/5) : 1D @E710 [Chair: Rekha Khot]

[03195] Finite element analysis for semilinear problems in liquid crystals

Format : Talk at Waseda University
Author(s) : Neela Nataraj (Professor)Ruma Maity (Postdoc Fellow)Apala Majumdar (Strathclyde University)
Abstract : A unified framework for the error control of different lowest-order finite element methods for approximating the regular solutions of systems of partial differential equations is established under a set of hypotheses.

The systems involve cubic nonlinearities in lower order terms, non-homogeneous Dirichlet boundary conditions, and the results are established under minimal regularity assumptions on the exact solution. The results for existence and local uniqueness of the discrete solutions using Newton-Kantorovich theorem and error control are presented.

The results are applied to conforming, Nitsche, discontinuous Galerkin, and weakly over penalized symmetric interior penalty schemes for variational models of ferronematics liquid crystals.

[01845] Twofold Saddle-Point Formulation of Biot Poroelasticity with Stress-Dependent Diffusion

Format : Talk at Waseda University
Author(s) : Ricardo Ruiz Baier (Monash University)Martin Hornkjøl (University of Oslo)Alberto Martin (Australian National University)Santiago Badia (Monash University)Kent-Andre Mardal (University of Oslo)Arbaz Khan (IIT Roorkee)
Abstract : We present a new stress/total-pressure formulation for poroelasticity that incorporates the coupling with steady nonlinear diffusion modified by stress. This nonlinear problem is written in mixed-primal form, which combines a perturbed twofold saddle-point system with an elliptic problem. We analyze the continuous formulation within the framework of abstract fixed-point theory and Fredholm alternative for compact operators. A mixed finite element method is proposed, and its stability and convergence are analyzed. The resulting model can be used to study the steady case of waste removal in the brain, providing insight into the transport of solutes in poroelastic structures under the influence of stress.

[03220] Finite element analysis for the Navier-Lamé eigenvalue problem

Format : Talk at Waseda University
Author(s) : Jesus Vellojin (Universidad del Bío-Bío)Felipe Lepe (Universidad del Bío Bío)Gonzalo Rivera (Universidad de Los Lagos)
Abstract : In this talk, the author presents the eigenvalue problem for the Navier-Lamé system. The analysis of the spectral problem is based in the compact operators theory. A finite element method based in polynomials of degree $k \geq 1$ is considered. An a posteriori error analysis is performed, where the reliability and efficiency of the proposed estimator is proved. A series of numerical tests are reported in order to assess the performance of the proposed numerical method.

[04279] Isogeometric solvers for derived cardiac stem cell reaction-diffusion models

Format : Talk at Waseda University
Author(s) : Sofia Botti (Università della Svizzera Italiana and University of Pavia)Michele Torre (University of Pavia)
Abstract : Regenerative cardiology is recently employing human induced pluripotent stem cells derived cardiomyocytes to advance in patient-specific medicine. A multiphysics approach to the problem allows to couple the cardiac Monodomain reaction diffusion model with stem cell ionic models to simulate the action potential propagation in the engineered ventricle. The coupled model is then discretized using Isogeometric Analysis in space and finite differences in time to obtain a virtual representation of a derived cardiomyocytes ventricle.

00319 (3/5) : 1E @E710 [Chair: Wietse Boon]

[03598] Virtual element methods for Biot--Kirchhoff poroelasticity

Format : Talk at Waseda University
Author(s) : Rekha Mallappa Khot (Monash University)David Mora (Universidad del B'io-B'io)Ricardo Ruiz Baier (Monash University)
Abstract : We propose and analyse conforming and nonconforming virtual element formulations for the coupling of solid and fluid phases in deformable porous plates. The governing equations consist of one fourth-order equation for the transverse displacement of the middle surface coupled with a second-order equation for the pressure head relative to the solid. The discretisation supports arbitrary polynomial degrees on general polygonal meshes and we design companion

operators with orthogonal properties and best-approximation estimate. We derive both a priori and a posteriori error estimates in appropriate norms, and these error bounds are robust with respect to the main model parameters. A few computational examples illustrate the properties of the numerical methods.

[04832] Analyzing Multi-Dimensional Time-Dependent Solute Transport Models

Format : Talk at Waseda University
Author(s) : Marius Zeinhofer (Simula Research Laboratory)Rami Masri (Simula Research Laboratory)Miroslav Kuchta (Simula Research Laboratory)Marie Elisabeth Rognes (Simula Research Laboratory)
Abstract : We derive and analyze 3D-1D time dependent solute transport models for convection, diffusion, and exchange in and around pulsating vascular and perivascular networks from their 3D-3D counterpart. These models are applicable e.g.
for transport in vascularized tissue and brain perivascular spaces. We discuss existence and uniqueness questions, quantify the modelling error, discuss finite element discretizations and present numerical results. Technical key challenges are controlling constants in classical numerical analysis tools, such as Poincaré's inequality.

[03951] Unfitted finite element methods for PDEs with dynamic interfaces and boundaries

Format : Talk at Waseda University
Author(s) : Santiago Badia (Monash University)Hridya Dilip (Monash University)Francesc Verdugo (Vrije Universiteit Amsterdam)Pere Antoni Martorell (Universitat Politecnica de Catalunya)
Abstract : In this presentation, we will present recent advances in the numerical approximation of PDEs with moving interfaces/boundaries using unfitted finite element methods. We will describe the numerical discretisation of transient problems using unfitted finite elements that are robust with respect to the small cut cell problems. We will design these algorithms for transient problems, e.g., by defining space-time discrete extension operators.

We will propose two different ways to design space-time unfitted methods. One approach is a pure space-time formulation, in which our geometries are considered in 4D (for a 3D problem in space). This approach is suitable, e.g., for problems in which the geometry is described via level sets. For complex geometrical representations in terms of oriented surface meshes, we propose a geometrical discretisation framework (for 3D in space) that provides all the quadrature rules needed to integrate our numerical methods on unfitted meshes. The extension of this 3D algorithm to 4D is a challenge.

We propose another space-time approach that solves the problem in the time-varying domain by using an extrusion of the 3D problem and a geometrical map. This way, one does not require 4D geometrical algorithms. In time, we consider discontinuous Galerkin spaces. The integration of inter-slab jump terms involves two functions on each side of the interface that are defined on different meshes (the background mesh and the mapped background mesh). In order to exactly compute these integrals, we propose to use intersection algorithms.

[05346] A two-way coupled Stokes-Biot-transport model

Format : Talk at Waseda University
Author(s) : Sergio Caucao (Catolica University Concepcion)Xing Wang (University of Pittsburgh)Ivan Yotov (University of Pittsburgh)
Abstract : We study mathematical and computational modeling for coupled fluid-poroelastic structure interaction with transport. The model is two-way coupled and nonlinear, with the velocity driving the transport and the concentration affecting the fluid viscosity. We use a Galerkin method, energy estimates, compactness arguments, and fixed point theory to establish well-posedness of the model. We study the finite element approximation of the model and obtain solvability, stability, and error estimates. Computational experiments are conducted to illustrate the theoretical convergence rates and the performance of the method for modeling physical flow and transport phenomena.

00319 (4/5) : 2C @E710 [Chair: Martin Hornkjøl]

[04578] Conservative and robust methods for the Biot-Brinkman equations in vorticity form

Format : Talk at Waseda University
Author(s) : Alberto Francisco Martin Huertas (Australian National University)Ruben Caraballo-Diaz (Universidad del Bio-Bio)Chansophea Wathanak In (Monash University)Ricardo Ruiz-Baier (Monash University)
Abstract : In this talk we present a new formulation, a suitable finite element method, along with robust/mesh-independent preconditioners, for the steady coupling of viscous flow in deformable porous media using divergence-conforming filtration fluxes. Apart from the well-posedness of the different formulations, and optimal error estimates,

our mathematical analysis confirms robustness of the different methods presented in the case of large Lam'e parameters and small permeability and storativity coefficients. A few representative numerical examples are presented to back up the analysis.

[04697] A five-field mixed formulation for stationary magnetohydrodynamic flows in porous media

Format : Talk at Waseda University

Author(s) : Jessika Camaño (Universidad Católica de la Santísima Concepción)

Abstract : We introduce a new mixed variational formulation for a stationary magnetohydrodynamic flows in porous media problem, whose governing equations are given by the steady Brinkman-Forchheimer equations coupled with the Maxwell equations. Unique solvability of the continuous and discrete systems has been proven.
Stability, convergence, and optimal a priori error estimates for the associated Galerkin scheme are obtained. Numerical tests illustrate the theoretical results.

[04964] Domain decomposition solvers for problems with strong interface perturbations

Format : Online Talk on Zoom

Author(s) : Miroslav Kuchta (Simula Research Laboratory)

Abstract : Operators formed by an elliptic part in the bulk domain and a parameter weighted interface perturbation arise in
coupled multiphysics systems as solution operators or as part of their preconditioners. Such systems are often not amenable to off-the-shelf methods if robustness with respect to the coupling is to be retained. In this talk we develop robust and scalable solvers for interface-perturbed operators based on domain/subspace decomposition. We demonstrate performance of the algorithms for single and multiphysics problems such as the EMI and Darcy-Stokes equations.

[04995] Numerical solution of the Biot/elasticity interface problem using virtual element methods

Format : Online Talk on Zoom

Author(s) : Nitesh Verma (Indian Institute of Technology Bombay)Ricardo Ruiz Baier (Monash University)David Mora (Universidad del Bio-Bio)Sarvesh Kumar (Indian Institute of Space Science and Technology)

Abstract : We propose, analyse and implement a virtual element discretisation for an interfacial poroelasticity/elasticity consolidation problem. The formulation of the time-dependent poroelasticity equations uses displacement, fluid pressure and total pressure, and the elasticity equations are written in the displacement-pressure formulation. The construction of the virtual element scheme does not require Lagrange multipliers to impose the transmission conditions (continuity of displacement and total traction, and no flux for the fluid) on the interface. We show the stability and convergence of the virtual element method for different polynomial degrees, and the error bounds are robust with respect to delicate model parameters (such as Lame constants, permeability, and storativity coefficient). Finally, we provide numerical examples that illustrate the properties of the scheme.

00319 (5/5) : 2D @E710 [Chair: Alberto F. Martin]

[04946] A conforming finite element method for a nonisothermal fluid-membrane interaction

Format : Talk at Waseda University

Author(s) : Ricardo Oyarzúa (Universidad del Bio-Bio)

Abstract : We propose a conforming finite element method for a nonisothermal fluid-membrane interaction problem. The governing equations are given by a Navier-Stokes/Darcy system for the fluid variables and a convection-diffusion model for the temperature. Both systems are coupled through buoyancy terms and a set of transmission conditions on the fluid-membrane interface given by mass conservation, balance of normal forces, the Beavers-Joseph-Saffman law, and the continuity of the heat flux and the fluid temperature.

[05072] Multipoint mixed finite elements for Biot poroelasticity using a rotation-based formulation

Format : Talk at Waseda University
Author(s) : Wietse Boon (Politecnico di Milano)Alessio Fumagalli (Politecnico di Milano)Anna Scotti (Politecnico di Milano)
Abstract : We propose a discretization method for Biot poroelasticity that employs the lowest-order Raviart-Thomas finite element space for the solid displacement and piecewise constants for the fluid pressure. The solid rotation and fluid flux are introduced as auxiliary variables and subsequently removed from the system using a local quadrature rule, leading to a multipoint rotation-flux mixed finite element method. By analyzing the method in terms of weighted norms, we additionally obtain parameter-robust preconditioners.

[05593] Application of CutFEM to the modeling of coastal processes through vegetation

Author(s) : Chris Kees (Louisiana State University)Wen-Huai Tsao (Louisiana State University)
Abstract : We consider viscous and depth-averaged models of non-hydrostatic coastal wave propagation through vegetation. Our aim is to model wave height attenuation and momentum dissipation through marsh vegetation. Each model requires a significantly different set of numerical methods to achieve higher-order accuracy in a robust manner, and we will discuss several of these, including CutFEM and multiscale methods. Finally we present results on experimental data obtained from physical models of wave/structure interaction.

[00322] Methodological advancement in rough paths and data science

Session Time & Room :

00322 (1/3) : 4C (Aug.24, 13:20-15:00) @E502

00322 (2/3) : 4D (Aug.24, 15:30-17:10) @E502

00322 (3/3) : 4E (Aug.24, 17:40-19:20) @E502

Type : Proposal of Minisymposium
Abstract : Rough path theory is an emerging mathematical technology that captures macroscopically interactions of highly oscillatory streamed data. Formally, it extends the domain of definition for the calculus of deterministic controlled differential equations, allowing them to be driven by complex signals, potentially rougher than Brownian motion. This area has built bidirectional connections with data science and machine learning, enabling the development of novel, mathematics-informed methods for efficiently analyzing time series data, e.g. PDE-based Signature kernel, path development layer with Lie group representation. This minisymposia series facilitates the discussion of new methodological innovations on this interface between rough paths and data science.

[01385] A real analytic view on signatures

Format : Talk at Waseda University
Author(s) : Josef Teichmann (ETH Zurich)Valentin Tissot-Daguette (Princeton U)
Abstract : We introduce classical (convenient) concepts of real analytic functions on path spaces and apply them to the approximation of path space functionals. We also provide an invariance theory perspective on the Hambly-Lyons theorem that signatures characterize paths up to tree like equivalences.

[01366] PCF-GAN: generating sequential data via the characteristic function of measures on the path space

Format : Talk at Waseda University
Author(s) : Hao Ni (UCL)Hang Lou (UCL)Siran Li (Shanghai Jiao Tong University)
Abstract : Implicit Generative Models(IGMs) are powerful tools for generating high-fidelity synthetic data. However, they struggle to capture the temporal dependence of time-series data. To tackle this issue, we directly compare the path distributions via the characteristic function of measures on the path space(PCF) from rough path theory, which uniquely characterises the law of stochastic processes. We then develop a novel PCF-GAN model by incorporating PCF with IGM for time series generation, leading to significant performance boost.

[01336] Nyström approximation and convex kernel quadrature

Format : Talk at Waseda University
Author(s) : Satoshi Hayakawa (University of Oxford)
Abstract : We will discuss a refined analysis of Nyström approximation for an integral operator based on statistical learning theory, and demonstrate how we can use these results to obtain an improved estimate of the performance of convex kernel quadrature rules that are given by the low-rank kernel of Nyström approximation.

[01374] Taylor remainder estimate for rough differential equations

Format : Online Talk on Zoom
Author(s) : Danyu Yang (Chongqing University)
Abstract : We consider a remainder estimate for truncated Taylor expansion for differential equations driven by inhomogeneous geometric rough paths. The estimate can be applied to differential equations driven by general stochastic processes with a regular drift term. It can also be useful when dealing with differential equations driven by branched rough paths and quasi-geometric rough paths which are isomorphic to inhomogeneous geometric rough paths.

00322 (2/3) : 4D @E502 [Chair: Hao Ni]

[01331] Optimal stopping with signatures

Format : Talk at Waseda University
Author(s) : Christian Bayer (Weierstrass Institute)John Schoenmakers (Weierstrass Institute)Paul Hager (Humboldt-Universität zu Berlin)Sebastian Riedel (University of Hagen)
Abstract : We propose a new method for solving optimal stopping problems under minimal assumptions on the underlying stochastic process X. We consider stopping times represented by functionals of the rough path signature $\mathbb{X}^{<\infty}$, and prove that maximizing over these classes of signature stopping times solves the original optimal stopping problem. Using the algebraic properties of the signature, we can then recast the problem as a deterministic optimization problem on the expected signature.

[01439] Analysis on unparameterised path space: towards a coherent mathematical theory

Format : Talk at Waseda University
Author(s) : Thomas Cass (Imperial College London)William Turner (Imperial College London)
Abstract : The signature is a non-commutative exponential that appeared in the foundational work of K-T Chen in the 1950s. It is also a fundamental object in the theory of rough paths (Lyons, 1998). More recently, it has been proposed, and used, as part of a practical methodology to give a way of summarising multimodal, possibly irregularly sampled, time-ordered data in a way that is insensitive to its parameterisation. A key property underpinning this approach is the ability of linear functionals of the signature to approximate arbitrarily any compactly supported and continuous function on (unparameterised) path space. We present some new results on the properties of a selection of topologies on the space of unparameterised paths. We discuss various applications in this context. Based on joint work with Will Turner.

[01370] On some stability results in mathematical finance via rough path theory

Format : Talk at Waseda University
Author(s) : CHONG LIU (ShanghaiTech University)
Abstract : In this talk I will present some recent progress on establishing some stability results in mathematical finance, e.g., in portfolio theory and utility maximization problems, via an approach of rough path theory.

[01438] Kernels Methods for Stochastic Processes

Format : Talk at Waseda University
Author(s) : Harald Oberhauser (University of Oxford)
Abstract : Kernels provide a powerful approach to learning from structured data. An important case of structured data arises when there is a natural sequential order in a data point; classic examples are time series or text. I will talk about the signature kernel that allows the computation of inner products of the signature of paths after they've been lifted to paths evolving in an infinite-dimensional Hilbert space.

00322 (3/3) : 4E @E502 [Chair: Yue Wu]

[01994] Optimal approximation with path signatures

Format : Talk at Waseda University
Author(s) : Emilio Ferrucci (University of Oxford)
Abstract : Path signatures have been used extensively as a way of representing the information encoded in multimodal data streams. This choice of a feature set is motivated by the famous universality result of Hambly & Lyons, 2010 and the fact that a broad class of parametrisation-invariant functions of a stream can be arbitrarily well approximated as linear functions of its signature. However, not much is known on the quantitative aspects of such approximations, and, just like Taylor approximations of smooth functions, they can converge slowly. Moreover, just like monomials in a real variable, the signature may fail to be a basis, meaning a function on paths does not have a canonical coefficient corresponding to each coordinate iterated integral. In this talk we explore ways of addressing these issues.

[01279] Using AI to Accelerate (S)PDE Solving

Format : Online Talk on Zoom
Author(s) : Qi Meng (Microsoft Research)
Abstract : Partial differential equations play an important role in science and engineering. Recently, AI emerged as a disruptive technique on scientific computing and could break the computational bottleneck on solving complex PDE systems via training deep neural network models. In this talk, I will introduce our recent work on AI accelerated PDE solving including DeepVortexNet and DLR-Net, which uses probabilistic representation and regularity features to achieve robust supervision signal and well-generalized neural network architecture, respectively.

[00769] Markov Chain Cubature for Bayesian Inference

Format : Online Talk on Zoom
Author(s) : James Foster (University of Bath)
Abstract : Markov Chain Monte Carlo is widely regarded as the "go-to" approach for Bayesian inference and, due to the theory of stochastic differential equations, many physics-inspired MCMC algorithms can scale to high dimensions.

In this talk, we consider an alternative to Monte Carlo for SDE simulation known as "Cubature on Wiener Space". In particular, by applying SDE cubature and resampling particles in a spatially balanced manner, we introduce a novel interacting particle algorithm for Bayesian inference.

[01377] Iterated integrals of Gaussian fields and ill-posedness of heat equations

Author(s) : Ilya Chevyrev (University of Edinburgh)
Abstract : In this talk, I will present a probabilistic method to show norm inflation, and thus local ill-posedness, for non-linear heat equations above scaling criticality. One of the motivations is a proof that the DeTurck-Yang-Mills heat flow is ill-posed on any Banach space that carries the 3D Gaussian free field, which complements recent well-posedness results. The method is inspired by work of Lyons, 1991, on iterated integrals of Brownian paths. Based on arXiv:2205.14350.

[00323] Integrating rough paths into domain applications

Session Time & Room :

00323 (1/3) : 5B (Aug.25, 10:40-12:20) @E501

00323 (2/3) : 5C (Aug.25, 13:20-15:00) @E501

00323 (3/3) : 5D (Aug.25, 15:30-17:10) @E501

Type : Proposal of Minisymposium
Abstract : Streamed data are ubiquitous. In this context, a key challenge is to quantify our understanding and account for the interaction between channels. Rough path theory provides new insights for producing actionable inference for multimodal path-like data. The path signature is a mathematical object with desirable approximation properties and geometric interpretation which leads to more effective features and analysis. Further, the expected signature provides a powerful way to describe empirical measures on streams. Applications include award-winning machine learning methods in healthcare and finance, as well as commercial-quality Chinese handwriting software. We expose new challenges and work on applications in this area.
Organizer(s) : Terry Lyons, Lingyi Yang

Minisymposium Program :

00323 (1/3) : 5B @E501 [Chair: Lingyi Yang]

[01350] Signatures and Functional Expansions

Format : Online Talk on Zoom
Author(s) : Bruno Dupire (Bloomberg)Valentin Tissot-Daguette (Princeton University)
Abstract : Path dependent options can be generated by combinations of signatures. We focus on the case of one asset augmented with time. We construct an incremental basis of signature elements which allows us to write a smooth path dependent payoff as a converging series of signature elements. By recalling the main concepts of Functional Itô Calculus, a natural framework for path-dependence, we draw links between two approximation results, the Taylor expansion and the Wiener chaos decomposition. We also establish the pathwise Intrinsic Expansion and link it to Functional Taylor Expansion.

[01349] Neural Stochastic PDEs: Resolution-Invariant Learning of Continuous Spatiotemporal Dynamics

Format : Talk at Waseda University
Author(s) : Maud Lemercier (University of Oxford)Cristopher Salvi (Imperial College London)Andris Gerasimovics (University of Bath)
Abstract : Neural SDEs are a class of physics-inspired neural networks that are particularly well-suited for modelling temporal dynamics. However, they may not be the most appropriate tool to model systems that vary both in space and in time. In this talk, I will present a way to address this issue, leveraging the notion of a mild solution of an SPDE. I will introduce the Neural SPDE model and demonstrate its ability to learn solution operators of PDEs with stochastic forcing from partially observed data.

[01332] Neural Controlled Differential Equations: The Log-ODE Method

Format : Talk at Waseda University
Author(s) : Benjamin Walker (University of Oxford)
Abstract : Neural controlled differential equations (NCDEs) are a powerful approach to time-series modelling. Their output is a linear map of a CDE's solution, where the vector field is learnt and the control is a continuous interpolation of the input data. This work demonstrates that NCDEs can achieve start-of-the-art performance on long time-series given two modifications: ensuring the vector field is smooth by bounding its Lip(2)-norm, and applying the Log-ODE method to the learnt vector field.

[01297] Nowcasting with signatures

Format : Talk at Waseda University
Author(s) : Lingyi Yang (Alan Turing Institute)Samuel Cohen (University of Oxford)
Abstract : Nowcasting refers to inference of the recent past, present, or near future. This is common in economics as key indicators, like GDP, are published with significant delays due to data collection/cleansing. The signature, a mathematical object arising from rough analysis, captures geometric properties and handles missing data from complex sampling patterns. We look at nowcasting with regression on signatures and show that this simple model subsumes the popular Kalman filter in theory and performs well in practice.

00323 (2/3) : 5C @E501 [Chair: Lingyi Yang]

[00458] Path-Dependent Neural Jump ODEs

Format : Talk at Waseda University
Author(s) : Florian Krach (ETH Zurich)Marc Nübel (ETH Zurich)Josef Teichmann (ETH Zurich)
Abstract : In this talk we discuss the problem of forecasting general stochastic processes using a path-dependent extension of the Neural Jump ODE (NJ-ODE) framework.
While NJ-ODE was the first framework to establish convergence guarantees for the prediction of irregularly observed time-series, these results were limited to data stemming from It\^o-diffusions with complete observations, in particular Markov processes where all coordinates are observed simultaneously.
Here, we first revisit the NJ-ODE and its results and then generalise them to generic, possibly non-Markovian or discontinuous, stochastic processes with incomplete observations, by utilising the reconstruction properties of the signature transform.
These theoretical results are supported by empirical studies, where it is shown that the path-dependent NJ-ODE outperforms the original NJ-ODE framework in the case of non-Markovian data.

[00499] Signature Methods for Outlier Detection

Format : Talk at Waseda University
Author(s) : Paola Arrubarrena (Imperial College London and DataSig)Terry Lyons (University of Oxford)Thomas Cass (Imperial College University)Maud Lemercier (University of Oxford and DataSIg)
Abstract : An anomaly detection methodology is presented that identifies if a given observation is unusual by deviating from a corpus of non-contaminated observations. The signature transform is applied to the streamed data as a vectorization to obtain a faithful representation in a fixed-dimensional feature space. This talk is applied to radio astronomy data to identify very faint radio frequency interference (RFI) contaminating the rest of the data.

[01312] Path Development Network with Finite-dimensional Lie Group

Format : Online Talk on Zoom
Author(s) : Hang Lou (University College London)Hao Ni (University College London)Siran Li (Shanghai Jiao Tong University)
Abstract : We propose a novel, trainable path development layer that exploits representations of sequential data through finite-dimensional Lie groups. The path development, which originates from rough path theory, inherits useful analytical properties from path signatures while also offering much richer group structures. Empirical results show the superiority of the development layer over signature features in terms of accuracy and dimensionality. The compact hybrid model, which stacks a one-layer LSTM with the development layer, achieves state-of-the-art performance against various RNN and continuous time series models on various datasets.

[01355] From CCTV video streams to inferring NO2 emissions at city-scale

Format : Online Talk on Zoom
Author(s) : Mohamed Ibrahim (University of Leeds)Terry Lyons (Oxford university)
Abstract : In this talk, we show how we can infer NO2 emissions from CCTV video streams at city-scale through rough path theory. we introduce a framework for mapping objects in CCTV video streams as a stream of paths highlighting the order in which events take place. This temporal representation gives a descriptive summary for video contents which we can maximise: 1) data anonymity, and 2) systematic readability of large-scale video streams.

00323 (3/3) : 5D @E501 [Chair: Terry Lyons]

[01359] Addressing bias adversarially in online learning.

Format : Online Talk on Zoom
Author(s) : Elena Gal (University of Oxford)
Abstract : We consider a class of online problems where the true label is only observed when a data point is assigned a positive label by a learner, eg for bank loans. In this setting the labelled training set suffers from accumulating bias since it is created by learners past decisions.
We propose to address the bias in the training set using adversarial domain adaptation. Our approach significantly exceeds SOTA on a set of challenging benchmark problems.

[01353] Improving Training of Neural CDEs

Format : Online Talk on Zoom
Author(s) : Jason Michael Rader (University of Oxford)
Abstract : Neural CDEs are continuous-time analogues of recurrent neural networks which are effective at handling irregular time steps, densely sampled data, and long time series. We present recent advances in training neural CDEs in a

memory efficient manner for large-scale problems.

[03470] From MMD-Regime detection to MMD-Generative Models with Applications

Format : Online Talk on Zoom
Author(s) : Blanka Horvath (Universiry of Oxford)Zacharia Issa (King's College London)
Abstract : Time series data derived from asset returns are known to exhibit certain properties, termed stylised facts, that are consistently prevalent across asset classes and markets. For example, to name a few, asset price returns are widely accepted to be non-stationary, non-auto correlative, and to exhibit volatility clustering. We refer the reader to \cite{cont2001empirical} for a thorough discussion of such properties. In this article we will turn our attention to one property in particular, the heteroscedastic nature of financial time series, since it is of imminent practical relevance to financial analysts and quants for a multitude of practical applications. In this context, one may be interested in whether a given asset returns series---or a set of series, in case of multiple assets---can be divided into periods in which the (random) asset price dynamics can be attributed to the same underlying distribution (up to, perhaps, a small estimation error). Such periods are often referred to as market regimes, and we call the task of finding an effective way of grouping these regimes the market regime clustering problem (MRCP). This article is devoted to the online detection of such regimes, i.e. to developing tools that help us recognise in real time (as data comes in) if a shift in the underlying regime is happening.

[01236] Capturing Graphs with Hypo-Elliptic Diffusions

Format : Online Talk on Zoom
Author(s) : Csaba Toth (University of Oxford)Darrick Lee (University of Oxford)Celia Hacker (MPI for Mathematics in the Sciences)Harald Oberhauser (University of Oxford)
Abstract : Convolutional layers within graph neural networks operate by aggregating information about local neighbourhood structures; one common way to encode such substructures is through random walks. The distribution of these random walks evolves according to a diffusion equation defined using the graph Laplacian. We extend this approach by leveraging classic mathematical results about hypo-elliptic diffusions. This results in a novel tensor-valued graph operator, which we call the hypo-elliptic graph Laplacian. We provide theoretical guarantees and efficient low-rank approximation algorithms.

[00324] Minisymposium on Combinatorial Reconfiguration

Session Time & Room : 2E (Aug.22, 17:40-19:20) @G302

Type : Proposal of Minisymposium
Abstract : Combinatorial reconfiguration is an emerging branch of discrete mathematics that deals with gradual changes of combinatorial objects. While several related concepts have been studied over the years from different perspectives, the theory is growing up by combining its mathematical, computational and practical aspects.

This minisymposium aims at communicating recent research trends on combinatorial reconfiguration and discussing possible future directions.
Organizer(s) : Takehiro Ito, Yusuke Kobayashi, Yoshio Okamoto
Classification : 05Axx, 05Cxx, 52Cxx, 52Bxx
Minisymposium Program :

00324 (1/1) : 2E @G302 [Chair: Yoshio Okamoto]

[04748] Invitation to Combinatorial Reconfiguration

Format : Talk at Waseda University
Author(s) : Takehiro Ito (Tohoku University)
Abstract : Combinatorial Reconfiguration studies reachability and related questions over combinatorial structures. A typical example asks if the solution space of a Boolean formula is connected with respect to the Boolean cube topology, formed by flipping one bit at the time. Reconfiguration problems have been studied intensively in this decade from the algorithmic viewpoints. In this talk, we will give a broad introduction of combinatorial reconfiguration, and show some recent progress on the topic.

[04759] Geometric algorithms for reconfiguring modular robots

Format : Online Talk on Zoom
Author(s) : Irene Parada (BarcelonaTech (UPC))
Abstract : Modular self-reconfigurable robots consist of units that can move and connect to form larger shapes. A central problem is how to efficiently reconfigure between shapes while maintaining connectivity. We explore the computational complexity of this reconfiguration problem for the most fundamental lattice-based models of modular robots. Some lattices and moves allow for efficient reconfiguration algorithms, while in other models the problem is PSPACE-complete. For those cases, we identify simple conditions that guarantee universal reconfigurability.

[05218] Toric Promotion and Permutoric Promotion

Format : Online Talk on Zoom
Author(s) : Colin Defant (Massachusetts Institute of Technology)
Abstract : We introduce toric promotion and, more generally, permutoric promotion operators. These operators, which are variants of Schutzenberger's famous promotion operator, act on labelings of a graph. We highlight cases where these operators have surprisingly nice orbit structures. Our investigation of permutoric promotion is surprisingly involved and relies on the analysis of gliding globs, sliding stones, and colliding coins. This work on permutoric promotion is joint with Rachana Madhukara and Hugh Thomas.

[04747] Triangulations of cyclic polytopes through the lens of reconfiguration

Format : Talk at Waseda University
Author(s) : Nicholas James Williams (Lancaster University)
Abstract : We discuss the reconfiguration problem given by taking the set of triangulations of a cyclic polytope as the state space, with the reconfiguration moves given by bistellar flips (the higher-dimensional analogue of flipping a diagonal within a quadrilateral). The state space is connected, and we will outline how this is proven using a certain partial order on the states called the higher Stasheff-Tamari order. We will further consider as many different other aspects of the reconfiguration as time permits, including the significance of triangulations of higher-dimensional cyclic polytopes for reconfigurations of lower-dimensional cyclic polytopes, efficient combinatorial descriptions of triangulations of cyclic polytopes, and the diameter of the state space.

[00336] Recent advances in Optimization methods with applications

Session Time & Room : 1E (Aug.21, 17:40-19:20) @F312

Type : Proposal of Minisymposium
Abstract : The aim of this session is to present recent advances in optimization (e.g. calculus of variations, control theory, decision theory, etc). We are interested in its different approaches: theoretical, numerical analysis or applications to real life. Potential topics include, but are not limited to: Optimization, Numerical Mathematics, Optimal Control, Calculus of Variations, consensus theory, Mathematical Modeling, Dynamical Systems, Applications to Physics, Biology, Medicine and Robotics, and fractional calculus.
Organizer(s) : Ricardo Almeida, Natália Martins
Classification : 47N10, 65K10, 34B60, 26A33
Minisymposium Program :

00336 (1/1) : 1E @F312 [Chair: Ricardo Almeida]

[02720] HABITAT LOSS AND COOPERATIVE HUNTING ON A THREE-SPECIES TROPHIC SYSTEM

Format : Talk at Waseda University
Author(s) : Jorge Duarte (Instituto Superior de Engenharia de Lisboa)Cristina Januário (Instituto Superior de Engenharia de Lisboa)Nuno Martins (Instituto Superior Tecnico)
Abstract : Changes in ecosystems progress at a rapid pace mainly due to the climate crisis and human-induced perturbations. Researchers have used mathematical models to understand how species respond to these changes in habitat in order to ultimately forecast species extinctions and develop efficient conservation strategies. Our work highlights the fragility of predators hunting cooperatively under the loss of habitat.

[02816] Modeling of impulsive perturbations by generalized fractional differential equations

Format : Talk at Waseda University
Author(s) : Snehana Hristova (Plovdiv University)
Abstract : The main aim is to emphasize on the statement of the impulsive perturbations in fractional differential equations. It will be considered two types of impulses- instantaneous impulses and non-instantaneous ones. To be more general we will consider the generalized proportional fractional derivatives of both Caputo type and Riemann-Liouville type in differential equations. Some existence results as well as stability properties of the solutions will be presented.

[02710] Necessary conditions to optimize functionals involving a generalized fractional derivative

Format : Talk at Waseda University
Author(s) : Ricardo Almeida (University of Aveiro)
Abstract : In this work we combine two ideas: fractional derivatives of variable order and fractional derivatives depending on another function. With such operators, we develop a variational problem theory by presenting necessary conditions of optimization. The fundamental problem will be addressed, proving an Euler-Lagrange equation, and then other versions will be considered such as the isoperimetric problem or the Herglotz problem. An integration by parts formula is also proven. To end, we provide a numerical tool to solve fractional problems dealing with such fractional derivatives. The main idea is to approach the fractional derivative by an expansion formula in terms of integer order derivatives and then rewrite the fractional problema as a classical one.

[02725] Herglotz's Variational Problem involving distributed-order fractional derivatives with arbitrary kernels

Format : Talk at Waseda University
Author(s) : Natália Martins (University of Aveiro)
Abstract : In this talk we extend the study of fractional variational problems of Herglotz type for the case where the Lagrangian
function depends on distributed-order fractional derivatives with arbitrary smooth kernels, the endpoints conditions,
and a real parameter. The fact that the Lagrangian depends on the boundary conditions and
an arbitrary parameter is not an artificial generalization, as this formulation is important in many problems, such as in physics and economics.

[00340] New trends in phase fields: theory & applications

Session Time & Room :

00340 (1/5) : 2D (Aug.22, 15:30-17:10) @E701

00340 (2/5) : 2E (Aug.22, 17:40-19:20) @E701

00340 (3/5) : 3C (Aug.23, 13:20-15:00) @E701

00340 (4/5) : 3D (Aug.23, 15:30-17:10) @E701

00340 (5/5) : 3E (Aug.23, 17:40-19:20) @E701

Type : Proposal of Minisymposium
Abstract : The phase field method is a powerful numerical method to solve moving boundary problems appearing in Materials Science and Engineering. Phase field theories are parameterized by a set of physically motivated variables and their governing equations. This mini-symposium will bring together numerical analysts and computational scientists working on phase field methods to present their recent advances in algorithm designs and applications of phase field methods. The main purposes of this mini-symposium are to review the current status, identify problems and future directions, and to promote phase field methods to a wider scientific and engineering community.

00340 (1/5) : 2D @E701

[04343] Energy stability of variable step higher order ETD-MS scheme for gradient flows

Author(s) : Xiaoming Wang (Missouri University of Science and Technology)
Abstract : We present a family of ETD-MS based variable-step higher order numerical schemes for a family of gradient flows. We demonstrate the energy stability of this family of numerical algorithms. Numerical examples will be provided to show the effectiveness of the schemes.

[04034] Energy Dissipation of Time-Fractional Phase-Field Equations: Analysis and Numerical methods

Author(s) : Jiang Yang (Southern University of Science and Technology)
Abstract : There exists a well defined energy dissipation law for classical phase-field equations, i.e., the energy is non-increasing with respect to time. However, it is not clear how to extend the energy definition to time-fractional phase-field equations so that the corresponding dissipation law is still satisfied. In this work, we will try to settle this problem for phase-field equations with Caputo time-fractional derivative, by defining a nonlocal energy as an averaging of the classical energy with a time-dependent weight function. To deal with this, we propose a new technique on judging the positive definiteness of a symmetric function, that is derived from a special Cholesky decomposition. Then, the nonlocal energy is proved to be dissipative under a simple restriction of the weight function. Within the same framework, the time fractional derivative of classical energy for time-fractional phase-field models can be proved to be always nonpositive. At the discrete level, a fast L2-1_σ method on general nonuniform meshes is employed. The global-in-time H^1-stability is established via the same framework.

[02973] A Spectral Element in Time Method for Nonlinear Gradient Systems

Author(s) : Shiqin Liu (University of Chinese Academy of Sciences)Haijun Yu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : We present a spectral element in time method for large scale nonlinear gradient systems, with the phase-field Allen-Cahn equation as an example. Different to commonly-used spectral in time methods that employ Petrov-Galerkin or weighted Galerkin approximations, the present method employs a natural variation Galerkin form that maintains volume conservation and energy dissipation property of the continuous dynamical systems. Explicit extrapolation is applied to handle the nonlinear term, which makes the method efficient. The explicit method can be improved by a few Picard iterations to obtain superconvergence. Numerical experiments confirm that the method outperforms the popular BDF4 scheme and the ETD-RK4 method.

[02987] Energy stability and error analysis of high-precision algorithms for two-phase incompressible flows

Author(s) : Xiaoli Li (Shandong University)
Abstract : In this talk, we will first present several efficient and high-precision schemes for the two-phase incompressible flows. These schemes are linear, decoupled and only require solving a sequence of Poisson type equations at each time step. We carry out a rigorous error analysis for the first-order scheme, establishing optimal convergence rate for all relevant functions in different norms. Next we shall discuss the consistent splitting GSAV approach for the Navier-Stokes equations and carry out theoretical analysis.

00340 (2/5) : 2E @E701

[03070] NONLOCAL CAHN-HILLIARD TYPE MODEL FOR IMAGE INPAINTING

Author(s) : Majdi AZAIEZ (Bordeaux INP & I2M UMR 5295)Dandan JIANG (Xiamen University)Chuanju Xu (Xiamen University)Alain Miranville (Poitier University)
Abstract : In this talk, we propose a Cahn-Hilliard type nonlocal model for image inpainting
which is equipped with a nonlocal diffusion operator for image inpainting. For its approximation we use the modified convex splitting method for the temporal discretization with the non-local diffusion term treated implicitly, and the fidelity term treated explicitly. Spatial discretization is performed by the Fourier collocation method. We will provide several numerical experiments to assess the efficiency of our method.

[03100] A Variety of Gradient Flows: Modeling and Numerical Methods

Author(s) : Chuanju Xu (Xiamen University)
Abstract : In this talk I will discuss a variety of gradient flow models for multi-phase problems,
derived from an energy variational formulation. The models includes fractional differential equations, equations describing the interfacial dynamics of immiscible and incompressible two-phase fluids,
dendritic crystal growth model, thermal phase change problems etc.
The talk starts with a review of the models and numerical methods for these models.
Then a new class of time-stepping schemes will be discussed.

00340 (3/5) : 3C @E701

00340 (4/5) : 3D @E701

00340 (5/5) : 3E @E701

[00341] Graph Coloring

Session Time & Room : 4E (Aug.24, 17:40-19:20) @A617

Type : Proposal of Minisymposium
Abstract : Graph coloring are fundamental objects of study in graph theory and have many applications including thetheoritical computer scinence, scheduling problems, and mobile phone network problems.

Beginning with the four color theorem, many conjectures and extensions of graph coloring have been proposed.
In addition, relationships with other subjects of graph theory have also been discovered.
However, despite the efforts of many mathematicians, there are still many unsolved problems in graph coloring.
In this mini-symposium, we will explore the latest topics and results concerning coloring conjectures, extensions, and relationships with other subjects.

[02669] Flows and coloring of triangle-free graphs on surfaces

Format : Talk at Waseda University
Author(s) : Zdeněk Dvořák (Charles University)
Abstract : The near-quadrangulations of surfaces, i.e., graphs where almost all faces have length four, play an important role in the theory of 3-colorability of triangle-free graphs on surfaces. We present a powerful approach to coloring near-quadrangulations using nowhere-zero flows and explore its applications. In particular, we show a connection between the maximum edgewidth of triangle-free non-3-colorable graphs on a given surface and a long-standing conjecture concerning the maximum width of polytopes containing no integer points.

[02782] Alon-Tarsi number of planar graphs

Format : Online Talk on Zoom
Author(s) : Xuding Zhu (Zhejiang Normal University)Yangyan Gu (Zhejiang Normal University)
Abstract : This talk presents a simple proof of the result that planar graphs have Alon-Tarsi number at most 5, and that each planar graph G has a matching M such that $G-M$ has Alon-Tarsi number at most 4. The former result is a strengthening of Thomassen's result that planar graphs are 5-choosable, and the latter result implies that every planar graph G has a matching M such that $G-M$ is online 4-choosable, which is a generalization of Cushing-Kierstead's result that planar graphs are 1-defective 4-choosable.

[02488] Edge-colourings, hamiltonian cycles, and a problem of Kotzig

Format : Online Talk on Zoom
Author(s) : Carol T. Zamfirescu (Ghent University)
Abstract : This talk concerns proper edge-colourings of regular graphs in which certain colour pairs form hamiltonian cycles -- such a pair is called perfect. We present a theorem solving Kotzig's problem asking whether planar 5-regular

graphs exist admitting an edge-colouring in which all ten pairs are perfect. If time permits, we shall also discuss certain edge-colouring enumeration problems. This talk is based on joint work with Nico Van Cleemput.

[03108] Coloring Graphs with Forbidden Minors

Format : Online Talk on Zoom
Author(s) : Zi-Xia Song (University of Central Florida)Michael Lafferty (University of Central Florida)
Abstract : Hadwiger's Conjecture from 1943 states that every graph with no K_t minor is $(t-1)$-colorable; it remains open for all $t \geq 7$. Jakobsen in 1971 proved that every graph with no $\mathcal{K}_7^{-2}$ minor is 6-colorable. In this talk, we present our recent work that every graph with no $\mathcal{K}_8^{-4}$ minor is 7-colorable, and every graph with no $\mathcal{K}_9^{-6}$ minor is 8-colorable, where $\mathcal{K}_t^{-s}$ denote the family of graphs obtained from K_t by removing s edges.

[00342] Localized waves in nonlinear discrete systems

Session Time & Room :

00342 (1/2) : 4D (Aug.24, 15:30-17:10) @F308

00342 (2/2) : 4E (Aug.24, 17:40-19:20) @F308

Type : Proposal of Minisymposium
Abstract : There are various spatially discrete nonlinear media in nature and engineering systems as diverse as solid crystal, metamaterial, and optical waveguide array, etc. Such media are mathematically modeled by nonlinear lattice dynamical systems. In both of experimental and mathematical systems, nonlinear localized waves such as solitons and discrete breathers are widely observed. The nonlinear localized waves have attracted much interest from the point of view of applied mathematics and that of physics problems such as thermalization and charge transport. So, mathematical and/or numerical analyses have been actively made. This MS aims at sharing and discussing recent results on the topic.

[00658] Existence of multi-pulse discrete breathers in Fermi-Pasta-Ulam-Tsingou lattices

Format : Talk at Waseda University
Author(s) : Kazuyuki Yoshimura (Tottori University)
Abstract : Discrete breathers are spatially localized periodic solutions in nonlinear lattices. We prove the existence of odd symmetric, even symmetric, and multi-pulse discrete breathers in strong localization regime in one-dimensional infinite Fermi-Pasta-Ulam-Tsingou (FPUT) lattices with even interaction potentials. The multi-pulse discrete breather consists of an arbitrary number of the odd-like and/or even-like primary discrete breathers located separately on the lattice. The proof applies to both cases of pure attractive and repulsive-attractive interaction potentials.

[01557] Spectral properties of nonlinear excitations in semiclassical systems with charge transport

Format : Online Talk on Zoom
Author(s) : Juan FR Archilla (Universidad de Sevilla)Janis Bajars (University of Latvia)Yusuke Doi (Osaka University)Masayuki Kimura (Setsunan University)
Abstract : We study the spectral properties of polarobreathers, that is, breathers carrying charge in a semi-classical model. Lattice particles are described mathematically, while the charged particle is described as a quantum one within the tight-binding approximation. Three different spectra are considered: the spectra of the atom positions, the spectra of the charge carrier probability and the spectra of charge carrier probability amplitude. The observed spectrum properties are related with the physical properties of the semiclassical system.

[01269] Nonlinear waves in multistable mechanical metamaterials

Format : Talk at Waseda University
Author(s) : Hiromi Yasuda (Japan Aerospace Exploration Agency)Hang Shu (University of Pennsylvania)Weijian Jiao (University of Pennsylvania)Vincent Tournat (Institut d'Acoustique - Graduate School (IA-GS), CNRS, Le Mans Université)Jordan R. Raney (University of Pennsylvania)
Abstract : We explore collision behaviors of nonlinear waves in a multistable mechanical system with coupling between translational and rotational degrees of freedom. We show that the system can support two different types of nonlinear waves, specifically elastic vector solitons and topological solitons. Moreover, we experimentally and numerically demonstrate the nucleation of topological solitons via collisions of vector solitons. Our findings show a new potential way of generating and controlling nonlinear waves in a mechanical structure.

[01230] Soliton billiards

Format : Online Talk on Zoom
Author(s) : Jesus Cuevas-Maraver (University of Seville)
Abstract : A point particle elastically reflected within an enclosed 2D domain is known as a billiard. Depending on the features of this domain, the trajectory of the particle can be closed or ergodic. In this talk, we show the similarities and differences when, instead of a classical particle, a soliton is scattered from closed 2D potentials. To this aim, we have considered a 2D NLS equation with saturable nonlinearity and square barriers (among other potentials).

00342 (2/2) : 4E @F308 [Chair: Kazuyuki Yoshimura]

[00812] Universality Classes for Nonlinear Wave Thermalization

Format : Talk at Waseda University
Author(s) : Sergej Flach (Institute for Basic Science)
Abstract : We study the slowing down of thermalization of many-body dynamical systems upon approaching integrable limits. We identify two fundamentally distinct long-range and short-range classes. The long-range class results in a single parameter scaling of the Lyapunov spectrum, with the rescaled spectrum approaching an analytical function. The short-range class results in a rescaled Lyapunov spectrum approaching a non-analytic function through an exponential suppression of all Lyapunov exponents relative to the largest one.

[01278] Numerical experiment on nonlinear localized oscillation propagating in a mass-spring chain

Format : Talk at Waseda University
Author(s) : Yosuke Watanabe (Setsunan University)Yusuke Doi (Osaka University)
Abstract : Nonlinear localized oscillations excited and propagated in a mass-spring chain are studied. Letting the mass at one end of the chain driven sinusoidally at high frequency and large amplitude, localized oscillations can be excited intermittently near the end and propagated down the chain one after another at a constant speed. This phenomenon is known as supratransmission. We have experimentally observed the supratransmission by a mechanical mass-spring chain which emulates the Fermi-Pasta-Ulam one of beta type. The experimental results are compared with the numerical ones.

[01274] Moving Intrinsic Localized Modes Created by Transforming Wavenumber-frequency Spectrum of a Static Intrinsic Localized Mode in FPUT-NKG Mixed Lattices

Format : Talk at Waseda University
Author(s) : Masayuki Kimura (Setsunan University)Kosuke Kawasaki (Kyoto University)Shinji Doi (Kyoto University)
Abstract : Intrinsic localized mode (ILM), also known as discrete breather (DB), is a spatially localized vibration in nonlinear lattices. It is well known that ILM can travel the lattices without decay of energy localization for a long period of time. In this study, initial values of moving ILMs with arbitrary speed are created by transforming the wavenumber-frequency spectrum of a static ILM. We will discuss the characteristics of the created moving ILMs.

[00992] Structure of pairwise interaction symmetric lattice for moving discrete breather

Format : Talk at Waseda University
Author(s) : Yusuke Doi (Osaka University)Kazuyuki Yoshimura (Tottori University)
Abstract : The mobility of discrete breathers is an essential issue from the viewpoint of energy transport in microstructure and nanostructures. In this presentation, we construct a nonlinear lattice with long-range interaction, which supports the smooth mobility of the discrete breather by considering the invariance of the interaction potential to a certain mapping corresponding to the translational manipulation of the waveform. Numerical results on the dynamics of the discrete breather in the constructed lattice are also presented.

[00345] Recent Developments for High-frequency Waves and Tomography

Session Time & Room :

00345 (1/2) : 3C (Aug.23, 13:20-15:00) @G808

00345 (2/2) : 3D (Aug.23, 15:30-17:10) @G808

Type : Proposal of Minisymposium
Abstract : Wave propagation is ubiquitous in our daily life, yet computing wave motion efficiently and accurately is still challenging in the high-frequency regime in many practical applications, such as nano-optics, material sciences, and geosciences. This mini-symposium gathers researchers in the field and provides a forum to exchange new ideas on recent theoretical and computational developments in high-frequency wave propagation and optics, as well as significant applications in medical and seismic tomography.
Organizer(s) : Jianliang Qian, Shingyu Leung
Classification : 35R30, 86A22, 35L05
Minisymposium Program :

00345 (1/2) : 3C @G808 [Chair: Jianliang Qian]

[03696] Learning based on data and numerical solutions for differential equations

Format : Talk at Waseda University
Author(s) : Jin Cheng (Professor)Yu Chen (Dr.)
Abstract : Numerical methods for partial differential equations are the important and powerful tols for the engineering problems. The study of numerical methods for PDE is one of the hottest research topics in the applied mathematics and computational mathematics. Based on ideas from data learning, we propose a new method for finding numerical solutions of differential equations effectively, especially for the Helmholtz equations with the high wave numbers. The main idea of this method is to construct the approximation solutions by utilizing the relevant information from the solution we already have, which include the explicit solutions, the measured data from the experiments, the expression of the basic solution and the numerical solution obtained from the numerical experiments, etc. This is also a fast and high-precision numerical algorithm. It is shown that, especially for high-frequency problems, this method provides feasible solutions.

[01633] Butterfly-compressed Hadamard-Babich Integrator for High-Frequency Helmholtz and Maxwell Equations in Inhomogeneous Media

Format : Talk at Waseda University
Author(s) : Yang Liu (Lawrence Berkeley National Laboratory)Jian Song (Michigan State University)Robert Burridge (University of New Mexico)Jianliang Qian (Michigan State University)
Abstract : We present a butterfly-compressed representation of the Hadamard-Babich (HB) ansatz for the Green's function of the high-frequency Helmholtz and Maxwell equations in smooth inhomogeneous media with arbitrary excitation sources. The proposed algorithm first solves the phase and HB coefficients via eikonal and transport equations using a coarse mesh, and then compresses the resulting HB interactions using several newly developed butterfly algorithms, leading to an optimal CPU complexity for any bounded 3D domains.

[02074] Development and Analysis a higher-order numerical method for Helmholtz equation with high wave number

Format : Talk at Waseda University
Author(s) : Wenyuan Liao (University of Calgary)
Abstract : Numerical solution of the Helmholtz equation with high wave numbers is a challenging task due to several reasons, such as the large size and indefiniteness of the discrete linear system. In this talk, we introduce a new iterative method which is motivated by the idea of the normal equation method. We then solve the equivalent positive definite normal equation. Combined with acceleration techniques, the new method is efficient and accurate for solving the Helmholtz equation.

[02172] Fixed Angle Inverse Scattering For Velocity

Format : Talk at Waseda University
Author(s) : Rakesh Rakesh (University of Delaware)
Abstract : An inhomogeneous acoustic medium is probed by a plane wave and the resultant time dependent wave is measured on the boundary of a ball enclosing the inhomogeneous part of the medium. We describe our partial results about the recovery of the velocity of the medium from the boundary measurement. This is a formally determined inverse problem for the wave equation, consisting of the recovery of a non-constant coefficient of the principal part of the operator from the boundary measurement.

00345 (2/2) : 3D @G808 [Chair: Shingyu Leung]

[02057] Eulerian PDE methods for complex-valued eikonals in attenuating media

Format : Online Talk on Zoom
Author(s) : Jiangtao Hu (Chengdu University of Technology)Jianliang Qian (Michigan State University)Shingyu Leung (The Hong Kong University of Science and Technology)
Abstract : Seismic waves in earth media usually undergo attenuation. In the regime of high-frequency asymptotics, a complex-valued eikonal is essential for describing wave propagation in attenuating media. Conventionally, it is computed by ray-tracing methods defined by ODEs, but those irregularly distributed results hinder their applications. This talk proposes a unified eulerian PDE for several popular real ray-tracing methods. We also develop a highly accurate numerical scheme using factorization and LxF-WENO scheme.

[01878] Uniformly convex neural networks and iterated network Tikhonov (iNETT) method

Format : Online Talk on Zoom
Author(s) : Davide Bianchi (Harbin Institute of Technology, Shenzhen)Guanghao Lai (Harbin Institute of Technology, Shenzhen)Wenbin Li (Harbin Institute of Technology, Shenzhen)
Abstract : We propose a non-stationary iterated network Tikhonov (iNETT) method for the solution of ill-posed inverse problems. The iNETT employs deep neural networks to build a data-driven regularizer, and it avoids the difficult task of estimating the optimal regularization parameter. To achieve the theoretical convergence of iNETT, we introduce uniformly convex neural networks to build the data-driven regularizer. Rigorous theories and detailed algorithms are proposed for the construction of convex and uniformly convex neural networks. In particular, given a general neural network architecture, we prescribe sufficient conditions to achieve a trained neural network which is component-wise convex or uniformly convex; moreover, we provide concrete examples of realizing convexity and uniform convexity in the modern U-net architecture. With the tools of convex and uniformly convex neural networks, the iNETT algorithm is developed and a rigorous convergence analysis is provided. Lastly, we show applications of the iNETT algorithm in 2D computerized tomography, where numerical examples illustrate the efficacy of the proposed algorithm.

[03580] Linearized Inverse Potential Problems at a High Frequency

Format : Talk at Waseda University
Author(s) : Boxi XU (Shanghai University of Finance and Economics)
Abstract : We investigate the recovery of the potential function from many boundary measurements at a high frequency for linear or nonlinear equations. By considering such a linearized form, we obtain Hölder type stability which is a big improvement over logarithmic stability in low frequencies. Increasing stability bounds for these coefficients contain a Lipschitz term with a factor growing polynomially in terms of the frequency, a Hölder term, and a logarithmic term that decays with respect to the frequency as a power. Based on the linearized problem, a reconstruction algorithm is proposed aiming at the recovery of sufficiently many Fourier modes of the potential function. By choosing the high frequency appropriately, the numerical evidence sheds light on the influence of the growing frequency and confirms the improved

resolution.
This is the joint work with Prof. Victor Isakov, Prof. Shuai Lu, Prof. Mikko Salo, and Mr. Sen Zou.

[03600] An Embedding Method for Hyperbolic Conservation Laws on Implicit Surfaces

Format : Talk at Waseda University
Author(s) : Chun Kit Hung (The Hong Kong University of Science and Technology)Shingyu Leung (The Hong Kong University of Science and Technology)
Abstract : In this talk, we will present a novel embedding method for solving scalar hyperbolic conservation laws on surfaces. The proposed method represents the interface implicitly through the zero-level set of its signed distance function and introduces a pushforward operator to extend the surface flux function to neighboring level surfaces. By solving an extended conservation law in a tubular neighborhood of the interface, it has been proven that the solution is the constant-normal extension of the surface conservation law. Numerical examples will be presented to demonstrate the accuracy and performance of the proposed method.

[00353] Interpretable constrained tensor decompositions: models, algorithms, efficient implementations and applications

Session Time & Room :

00353 (1/3) : 3C (Aug.23, 13:20-15:00) @G306

00353 (2/3) : 3D (Aug.23, 15:30-17:10) @G306

00353 (3/3) : 5B (Aug.25, 10:40-12:20) @E803

Type : Proposal of Minisymposium
Abstract : Tensor decompositions are a fundamental tool in the data sciences for extracting interpretable patterns, removing or reducing noise, and providing reduced-dimension or low-complexity models for tensor data. In recent years, significant progress has been made to propose and understand new constrained tensor models to aid in interpretability or to satisfy known constraints on the data. In this minisymposium, we present some of the state-of-the-art approaches to interpretable constrained tensor decompositions, including efficient inference algorithms with convergence guarantees, efficient implementations of these algorithms compatible with modern hardware, and application of these models to challenging data analysis problems across several domains.
Organizer(s) : Axel Marmoret, Daniel M. Dunlavy, Jeremy E. Cohen
Classification : 15Axx, 65Kxx, 68-XX, Tensor decompositions
Minisymposium Program :

00353 (1/3) : 3C @G306 [Chair: Daniel Dunlavy]

[03825] Implicit balancing in penalized low-rank approximations

Format : Talk at Waseda University
Author(s) : Jeremy E. Cohen (CREATIS, CNRS)
Abstract : Tensor decompositions are an important tool in machine learning, particularly due to their interpretability which makes them well-adapted to solving inverse problems for a wide range of applications. Additional constraints and penalizations are often imposed to enhance the interpretability of these models. Because of scale-invariance in tensor decompositions, one may show that adding regularization terms, which are scale-dependent, induces an implicit balancing of the factor matrices. By explicitly imposing balancing during an optimization algorithm, I show that it is possible to improve the precision and speed of that algorithm for both nonnegative PARAFAC and Tucker decompositions.

[02791] Hierarchical and neural nonnegative tensor factorizations

Format : Online Talk on Zoom
Author(s) : Jamie Haddock (Harvey Mudd College)Joshua Vendrow (Massachusetts Institute of Technology)Deanna Needell (University of California, Los Angeles)
Abstract : Nonnegative matrix factorization (NMF) has found many applications including topic modeling and document analysis. Hierarchical NMF (HNMF) variants are able to learn topics at various levels of granularity and

illustrate their hierarchical relationship. Recently, nonnegative tensor factorization (NTF) methods have been applied in a similar fashion in order to handle data sets with complex, multi-modal structure. Hierarchical NTF (HNTF) methods have been proposed, however these methods do not naturally generalize their matrix-based counterparts. Here, we propose a new HNTF model which directly generalizes a HNMF model special case, and provide a supervised extension. Our experimental results show that this model more naturally illuminates the topic hierarchy than previous HNMF and HNTF methods. We also describe training methods for hNTF models built upon a neural network structure.

[03781] Nonnegative canonical tensor decomposition with linear constraints: nnCANDELINC

Format : Talk at Waseda University

Author(s) : Derek DeSantis (Los Alamos National Labs)Boian Alexandrov (Los Alamos National Labs)Gianmarco Manzini (Los Alamos National Labs)Erik Skau (Los Alamos National Labs)

Abstract : Nonnegative tensor factorization produces sparse and easily understandable latent features. However, the Canonical Polyadic Decomposition (CPD) struggles with tensors that have rank deficient factors. The PARALIND algorithm addresses this for real-valued tensors by first computing a Tucker decomposition (TD) and then performing a CPD on the TD core to extract latent features. This work explores the theory behind the nonnegative version of PARALIND. We demonstrate nnPARALIND on several real and synthetic examples, highlighting its sensitivity and discussing when it can be applied.

[04213] Joint Data Fusion and Blind Unmixing using Nonnegative Tensor Decomposition

Format : Online Talk on Zoom

Author(s) : Clémence Prévost (University of Lille, CNRS Centrale Lille, UMR 9189 CRIStAL F-59000 Lille, France)Valentin Leplat (Skoltech Center for Artificial Intelligence Technology (CAIT) Moscow, Russia)

Abstract : We present a new method for solving hyperspectral super-resolution and spectral unmixing of the
unknown super-resolution image. Our method relies on (1) the nonnegative block-term decomposition, (2) joint tensor factorization with multiplicative updates, and (3) the formulation of optimization problems with the beta-divergence. We propose a family of algorithms, adaptable to various noise statistics. Experiments show that our approach competes favorably with state-of-the-art for solving both problems for various noise statistics.

, blockterm
decomposition, -divergence, blind spectral unmixing,
hyperspectral super-resolution.

00353 (2/3) : 3D @G306 [Chair: Jeremy E. Cohen]

[04776] A quadratically convergent proximal algorithm for nonnegative tensor decomposition

Format : Talk at Waseda University

Author(s) : Nico Vervliet (KU Leuven)Andreas Themelis (Kyushu University)Panagiotis Patrinos (KU Leuven)Lieven De Lathauwer (KU Leuven)

Abstract : The canonical polyadic decomposition is key in a variety of applications in signal processing and data analysis. While this decomposition is unique under mild conditions, including prior knowledge such as nonnegativity often helps to interpret the components. We derive a proximal Gauss-Newton-type algorithm for nonnegative tensor factorization. We show global convergence to local minima, as well as a Q-quadratic convergence rate to global optima in the exact case.

[03079] PARAFAC2-based coupled matrix and tensor factorizations with constraints

Format : Online Talk on Zoom

Author(s) : Carla Schenker Xiulin Wang (Dalian University of Technology)Evrim Acar (Simula Metropolitan Center for Digital Engineering)

Abstract : There is an emerging need to jointly analyze time-evolving data sets together with static data in many areas such as social networks and omics data analysis. PARAFAC2-based coupled matrix and tensor factorizations are a promising approach in that direction, since PARAFAC2 is capable of capturing time-evolving patterns. We present a flexible algorithmic framework for such factorizations which facilitates linear couplings and various constraints on all modes, including the evolving mode in the PARAFAC2 model.

[03791] Constrained Tucker Decompositions and Conservation Principles for Direct Numerical Simulation Data Compression

Format : Talk at Waseda University
Author(s) : Daniel Dunlavy (Sandia National Laboratories)
Abstract : Low-rank tensor decompositions applied to numerical simulation data for compression and reduced-order modeling often focus only on minimizing global error norms between data and the low-rank model. We present an approach for computing goal-oriented low-rank tensor decompositions that incorporates problem-specific quantities of interest (QoIs) through general nonlinear constraints added to the tensor model loss function. Results for compression of direct numerical simulation data from multiple applications are presented to demonstrate the utility of this approach.

[03819] Incremental Nonnegative Tucker Decomposition with Block-coordinate Descent and Recursive Approaches

Format : Online Talk on Zoom
Author(s) : Rafal Zdunek (Wroclaw University of Science and Technology)Krzysztof Fonal (Wroclaw University of Science and Technology)
Abstract : We extend the standard model of Nonnegative Tucker decomposition (NTD) to an incremental or online version, assuming volatility of observed multi-way data along one mode. Two computational approaches are proposed: one is based on the recursive update model, and the other uses the concept of the block-Kaczmarz method. The experimental results performed on various datasets and streaming data demonstrate high efficiently of both algorithmic approaches with respect to the baseline NTD methods.

00353 (3/3) : 5B @E803 [Chair: Daniel Dunlavy]

[05162] Speeding up Nonnegative Low-rank Approximations with Parallelism and Randomization.

Format : Online Talk on Zoom
Author(s) : Koby Hayashi (Georgia Institute of Technology)
Abstract : Many algorithms for constrained matrix and tensor factorization follow an alternating updating scheme. In such a scheme, the factor matrices are updated one at a time using some update rule. Computationally many update rules require the same bulk computations. That is the most expensive parts of the computations needed to perform an update are shared between update rules. Using this observation, we design a Framework for Alternating Updating NMF and NTF (FAUN). FAUN defines the bulk computations needed throughout an AU type algorithm allowing us to focus on optimizing these computations for multiple methods. Based on this we implement a distributed, highly parallel code called PLANC which optimizes computation and communication and allows for the use of various updating rules such as Hierarchical Least Squares, Nonnegative Least Squares, ADMM, Nesterov updates, ect... More recently we have explored the use of randomization in FAUN. As in the parallel case we can largely decouple the randomized aspects of the algorithms from the update rules.

[03142] A probabilistic nonnegative tensor factorization method for tumor microenvironment analysis

Format : Online Talk on Zoom
Author(s) : Neriman Tokcan (University of Massachusetts Boston)
Abstract :
The tumor microenvironment (TME) comprises the intricate environment surrounding cancer cells, such as stromal, immune, and extracellular elements. We have devised a probabilistic non-negative tensor factorization approach to model the TME of Hodgkin Lymphoma. We have also incorporated a statistical pipeline to produce robust and biologically relevant factors. Our methodology will enhance our understanding of the TME by identifying cellular heterogeneity and intrinsic pathways driving tumor growth and immune evasion.

[03182] Scalable symmetric Tucker tensor decomposition

Format : Online Talk on Zoom
Author(s) : Ruhui Jin (UW-Madison)Joe Kileel (UT-Austin)Tamara Kolda (MathSci.ai)Rachel Ward (UT-Austin)
Abstract : We study the best low-rank Tucker decomposition of symmetric tensors. The motivating application is in decomposing higher-order multivariate moments, which has special structure and is important to various data science problems. We advocate for a straightforward projected gradient descent (PGD) method and the higher-order eigenvalue

decomposition (HOEVD) approximation as computation schemes. Most importantly, we develop scalable adaptations of the basic PGD and HOEVD methods to decompose sample moment tensors. With the help of implicit and streaming technique, we evade the overhead cost of building and storing the moment tensor. Such reductions make computing the Tucker decomposition realizable for large data instances in high dimensions. Numerical experiments demonstrate the efficiency of the algorithms and the applicability of moment tensor decompositions to real-world datasets. Finally we study the convergence on the Grassmannian manifold and prove that the update sequence derived by the PGD solver achieves first and second-order
criticality

[02021] A tensor factorization model of mulitlayer network interdependence

Format : Online Talk on Zoom
Author(s) : Izabel Aguiar (Stanford University)Dane Taylor (University at Buffalo the State University of New York)Johan Ugander (Stanford University)
Abstract : We use the nonnegative Tucker decomposition (NNTuck) with KL-divergence as an expressive factor model for multilayer networks that naturally generalizes existing methods for stochastic block models of multilayer networks. The NNTuck provides a factor-based perspective on layer dependence, enabling linear-algebraic techniques for analyzing dependence in specific layers. We propose a definition of layer dependence based on a likelihood ratio test and evaluate the NNTuck in synthetic and real-world data.

[00356] Recent progress in variational problems with nonlocality

Session Time & Room :

00356 (1/2) : 3C (Aug.23, 13:20-15:00) @F401

00356 (2/2) : 3D (Aug.23, 15:30-17:10) @F401

Type : Proposal of Minisymposium
Abstract : This minisymposium will discuss some recent developments in the analysis of variational problems from science and engineering in which nonlocal interactions have a pronounced effect. Examples will include geometric variational problems with long-range repulsion, topologically non-trivial spin configurations in magnetic materials, long-range interactions in phase transitions, capillary theory and theory of dislocations.
Organizer(s) : Cyrill Muratov, Matteo Novaga, Valeriy Slastikov
Classification : 49J99, 35R11, 35B65, 53E99
Minisymposium Program :

00356 (1/2) : 3C @F401 [Chair: Matteo Novaga]

[03768] Nonlocal capillarity theory

Format : Online Talk on Zoom
Author(s) : Enrico Valdinoci (University of Western Australia)
Abstract : We describe some recent results motivated by a nonlocal theory of capillarity, as related to the formation of droplets due to long-range interaction potentials. We will discuss the notion of contact angle in this setting, considering a nonlocal version of the classical Young's Law, together with some regularity and asymptotic properties.

[03751] Skyrmion theory in magnetic thin films: the role of non-local magnetic dipolar interaction

Format : Talk at Waseda University
Author(s) : Anne Bernand-Mantel Cyrill Muratov (University of Pisa)Theresa Simon (Muenster University)Valeriy Slastikov (Bristol University)
Abstract : Compact magnetic skyrmion are potential bit-encoding states for spintronic memory and logic applications that have been the subject of a rapidly growing number of studies in recent years. We will present our recent work where we used rigorous mathematical analysis to develop a skyrmion theory that takes into account the full dipolar energy in the thin film regime and provides analytical formulas for compact skyrmion radius, rotation angle and energy.

[05516] Long-range phase transition equations

Format : Talk at Waseda University
Author(s) : Serena Dipierro (University of Western Australia)
Abstract : In this talk, we will review recent results on long-range phase transitions.

[04003] A distributional approach to nonlocal curvature motions

Format : Online Talk on Zoom
Author(s) : Massimiliano Morini (University of Parma)
Abstract : After reviewing the new distributional approach recently developed to provide a well-posed formulation of the crystalline mean curvature flow, we show how to extend it to some nonlocal motions. Applications include the fractional mean curvature flow and the Minkowski flow; i.e., the geometric flow generated by the (n-1)-dimensional Minkowski pre-content. This is a work in collaboration with F. Cagnettti (University of Sussex) and D. Reggiani (Scuola Superiore Meridionale).

00356 (2/2) : 3D @F401 [Chair: Cyrill Muratov]

[03830] The elastica functional as the critical Gamma-limit of the screened Gamow model

Format : Talk at Waseda University
Author(s) : Theresa Simon (University of Münster)Cyrill Muratov (University of Pisa)Matteo Novaga (University of Pisa)
Abstract : I will consider the large mass limit of a nonlocal isoperimetric problem in two dimensions with screened Coulomb repulsion. In this regime, the nonlocal interaction localizes on the boundary of the sets. It turns out that in the case of exactly cancelled surface area, the problem changes from length to curvature minimization: The next-order Gamma limit is given by the elastica functional, i.e., the integral over the squared curvature over the boundary.

[04447] Minimisers of anisotropic Coulomb energies in 3d

Format : Talk at Waseda University
Author(s) : Lucia Scardia (Heriot-Watt University)
Abstract : Nonlocal energies are continuum models for large systems of particles with long-range interactions.
Under the assumption that the interaction potential is radially symmetric, several authors have investigated qualitative properties of energy minimisers.
But what can be said in the case of anisotropic kernels?

I will present some results and partial answers in this direction obtained in a long-standing collaboration with
Maria Giovanna Mora and Luca Rondi, and with Jose' Antonio Carrillo, Joan Mateu and Joan Verdera.

[03755] Minimal partitions for local and nonlocal energies

Format : Talk at Waseda University
Author(s) : Annalisa Cesaroni (University of Padova)
Abstract : The Kelvin problem, posed by Lord Kelvin in 1887, is the problem of finding a partition of $\mathbb{R}^3$ into cells
of equal volume, so that the total area of the surfaces separating them is as small as possible.
I will discuss some related problems in $\mathbb{R}^n$, in particular the problem of finding the foam whose
cell minimizes a general perimeter functional among all periodic partitions given by lattice tilings.
Moreover I will present some qualitative results in low dimension.

[03839] Asymptotics of phase field models for crystal defects

Format : Talk at Waseda University
Author(s) : Adriana Garroni (Sapienza, University of Rome)Sergio Conti (University of Bonn)Stefan Mueller (University of Bonn)
Abstract : We consider Nabarro Peierls type model for line defects in crystals. We study the asymptotics in scaling regime which allows for the number of dislocations to diverge and results, in the limit as the lattice spacing tends to zero, in a macroscopic model for plasticity where the relevant variable is a diffuse quantity that represents the dislocation density.

[00357] Topics at the Interface between Applied mathematics and Microeconomics

Session Time & Room : 2E (Aug.22, 17:40-19:20) @D501

Type : Proposal of Minisymposium
Abstract : Traditionally, economic models were easier to understand in the context of economics. Still, recent advances in mathematical methods, particularly in applied mathematics and computer science, enable a more realistic and intuitive approach to economic phenomena. This session will present recent research on how economic theory relates to applied mathematics.
Organizer(s) : Yujiro Kawasaki, Kuninori Nakagawa

Minisymposium Program :

00357 (1/1) : 2E @D501 [Chair: Kuninori Nakagawa]

[01659] Commitment games with mutual interferences

Format : Talk at Waseda University
Author(s) : Ryosuke Ishii (Shimonoseki City University)
Abstract : As a stabilization device of an efficient outcome that is not an equilibrium as it now stands outcome, commitments have been assembled in game theory literature. Earlier studies suggest that efficient outcomes are subgame perfect if a game is expressed by an extensive form with a perfect information. However, an outcome of a game with simultaneous moves is not always efficient, most often happen when players face a prisoners' dilemma like situation. This research considers a game in which players can determine success or failure of other players' commitment one another. The result is similar to a Folk Theorem. That is, players can achieve efficiency in prisoners' dilemma games. In contrast, the worst mixed equilibrium outcome is subgame perfect in coordination games.

[01666] Equilibria in a spatial competition with uninformed consumers

Format : Talk at Waseda University
Author(s) : Kuninori Nakagawa (University of Hyogo)Shinnosuke Kawai (Shizuoka University)
Abstract : We extend a model that analyses explicit product differentiation in Varian's model of sales using a one-dimensional spatial competition framework. We study the price equilibrium in the case of a uniform distribution of informed consumers. We give examples of price game equilibria given pairs of locations and discuss the difficulties associated with computing equilibria.

[01655] Gradient flows in travelers' visitation network: comparison with centrality indices

Format : Online Talk on Zoom
Author(s) : Yujiro Kawasaki (Nagoya Institute of Technology)Kenta Kojima (Kansai University)Jun'ichi Miki (Tohoku University of Community Service and Science)
Abstract : The Hodge decomposition defined on discrete graphs has been applied to analyzing network structures related to various economic activities. We use the travel data of tourists visiting a regional city in Japan to examine the effectiveness of the Hodge decomposition on the network of tourist movements between sightseeing spots. By employing centrality indices together, we provide robust trends of tourist visits and, thus, the function of each sightseeing spot.

[01678] Information Design and Pre-trade Investment

Format : Online Talk on Zoom
Author(s) : Keiichi Kawai (Keio University)
Abstract : We analyze a bilateral trade model where, after the buyer makes a take-it-or-leave-it offer, the seller can make a costly investment which stochastically increases the value of the good to both players. The seller partially learns about the investment outcome before deciding whether to trade. The efficiency of the outcome is undermined by both the adverse selection problem in trade, and the seller's moral hazard in investment. We identify all second-best outcomes.

[00372] Recent advances on computational wave propagation

Session Time & Room :

00372 (1/3) : 3D (Aug.23, 15:30-17:10) @D404

00372 (2/3) : 3E (Aug.23, 17:40-19:20) @D404

00372 (3/3) : 4C (Aug.24, 13:20-15:00) @D404

Type : Proposal of Minisymposium
Abstract : This mini-symposium is organized to provide a forum for fellow researchers working on numerical methods for wave propagation problems to present and discuss their recent advances and achievements. Topics to be covered include but not limited to: FDTD methods, finite element methods, spectral methods, multiscale methods, novel techniques for metamaterials and graphene.
Organizer(s) : Jichun Li, Nathan Gibson
Classification : 78-10, 65Nxx, 35Mxx, 35Qxx, Computational Electromagnetics; Maxwell's Equations; Wave Propagation
Minisymposium Program :

00372 (1/3) : 3D @D404 [Chair: Jichun Li]

[01429] Analysis and simulation of carpet cloak model with metamaterials

Format : Talk at Waseda University
Author(s) : Jichun Li (University of Nevada Las Vegas)
Abstract : This talk is concerned about a time-domain carpet invisibility cloak model. Here we consider two new finite element schemes to solve it. Stability and optimal error estimates are proved for both schemes. Numerical results are presented to support our analysis and demonstrate the cloaking phenomenon.

[01639] Edge elements on nonaffine quadrilateral and hexahedral grids for Maxwell eigenproblem

Format : Talk at Waseda University
Author(s) : HUOYUAN DUAN (Wuhan University, School of Mathematics and Statistics)
Abstract : Most of the edge elements on nonaffine quadrilateral and hexhaedral grids do not satisfy the so-called discrete compactness property. Consequently, they generate spurious eigenmodes and are not spectral correct. We propose some new finite element methods for Maxwell eigenproblems so that all the edge elements on nonaffine quadrilateal and hexhaedral grids are spurious-free and spectral correct. The new methods have been confirmed by theory and numerics.

[01856] Deriving consistent surface fields for compatible FETD discretizations of Maxwell's equations

Format : Talk at Waseda University
Author(s) : Duncan McGregor (Sandia National Laboratories)
Abstract : The coupling of electromagnetic energy to a cable is a critical quantity of interest in some engineering applications. These cables can be modelled as internal boundaries with a perfect electric conductor condition. An intuitive method is a loop integral of the magnetic field around the cable. This leads to physical and mathematical concerns. As such, we use Dirichlet-to-Neumann map to compute surface currents. We will describe our method and present numerical results.

[01860] FDTD Method With Explicit Non-Iterative and Second Order Treatment for Kerr Nonlinearities

Format : Talk at Waseda University
Author(s) : Jinjie Liu (Delaware State University)
Abstract : In this talk, we introduce a new explicit non-iterative FDTD algorithm for solving Maxwell's equations in nonlinear Kerr media. The FDTD method is a widely used numerical technique for solving Maxwell's equations in complex media. Our method balances accuracy and computational cost, offering similar accuracy to Newton's iterative method but at a lower computational expense. The effectiveness of our method is demonstrated by its quadratic

convergence rate, as well as several numerical examples such as simulations of four-wave mixing and soliton propagation.

00372 (2/3) : 3E @D404 [Chair: Nathan Gibson]

[02077] Harnessing the Power of Exascale Computing for Microelectronics Modeling

Format : Talk at Waseda University

Author(s) : Zhi Jackie Yao (Lawrence Berkeley National Lab)Revathi Jambunathan (Lawrence Berkeley National Lab)Andy Nonaka (Lawrence Berkeley National Lab)Prabhat Kumar (Lawrence Berkeley National Lab)Saurabh Sawant (Lawrence Berkeley National Lab)

Abstract : As the era of Moore's law comes to a close, there has been a surge in the development of microdevices that involve more complex physical interactions than conventional electromagnetic waves and single-phase materials. However, gaining a deeper understanding of these interactions has been hindered by the significant disparity in time and length scales and a lack of effective modeling techniques.

To address these challenges, we have developed ARTEMIS, a scalable simulation tool that harnesses the power of GPU-based supercomputing systems to model next-generation microelectronic devices, including electronic, spintronic, superconducting, and ferroelectric systems. ARTEMIS leverages the developments of two Exascale Computing Projects and supports dispersive material properties, user-defined excitations and boundary conditions, and heterogeneous physical coupling. Specifically, with its micromagnetics module, ARTEMIS is suitable for nonlinear spintronic applications and can be used as a device-level design and optimization tool.

This new approach also provides a path to understanding and developing fully integrated electronic systems that go beyond the capabilities of traditional semiconductor technologies. ARTEMIS will enable a broader exploitation of new materials and provide new mechanisms for everything from low-power computing to high-efficiency microwave components, contributing to the development of next-generation architectures.

[02080] Simulating Time Domain Electromagnetic Waves on a Differentiable Programming Platform

Format : Talk at Waseda University

Author(s) : Yanyan Hu (University of Houston)Yuchen Jin (University of Houston)Xuqing Wu (University of Houston)Jiefu Chen (University of Houston)

Abstract : A trainable theory-guided recurrent neural network (RNN) equivalent to finite-difference-time-domain (FDTD) method is designed to formulate electromagnetic propagation, solve Maxwell's equations, and the inverse problem on differentiable programming platform PyTorch. For forward modeling, the computation efficiency is substantially improved. The inverse problem can be solved by setting the trainable weights of RNN as the material-related parameters and network training. Numerical results demonstrate the effectiveness and efficiency of the method for forward and inverse electromagnetic modeling.

[02117] Iterative two-level algorithm for nonsymmetric or indefinite problems

Format : Talk at Waseda University

Author(s) : Ming Tang (South China Normal University)Xiaoqing Xing (South China Normal University)Ying Yang (Guilin University of Electronic Technology)Liuqiang Zhong (South China Normal University)

Abstract : In this talk, some new iterative two-level algorithms are designed and analyzed for solving the finite element discretization for nonsymmetric or indefinite elliptic/Maxwell problems. The two-level methods use only the same coarse spaces as the traditional two- grid algorithm, but its "fine spaces" use the higher order finite element space under the coarse grid. Therefore, the iterative two-level algorithm only need one grid and achieve the same convergence order of the traditional two-grid algorithms. At last. Numerical experiments are implemented to support the theoretical results, especially, the computational cost of two-level algorithms are lower to achieve the same convergence order for traditional two-grid algorithms.

[01863] Analysis and application of FEMs for Ziolkowski's PML model

Format : Talk at Waseda University

Author(s) : Li Zhu (Portland State University)Jichun Li (University of Nevada Las Vegas)

Abstract : Perfectly Matched Layer PML technique is an effective tool proposed by Berenger to solve a wave

propagation problem in unbounded domain without reflections. Here we are interested in the Ziolkowski PML reformulated in an integro-differential form, We introduce two novel FEMs for solving this equivalent PML model. Stability and convergence analysis are established for both schemes. Numerical results are presented to support our analysis and demonstrate the wave absorption effectiveness of this PML.

00372 (3/3) : 4C @D404 [Chair: Jichun Li]

[02737] Highly Efficient Iterative Method with High Order ABC for Acoustic Scattering

Format : Talk at Waseda University
Author(s) : Vianey Roman Villamizar (Brigham Young University)Tahsin Khajah (University of Texas at Tyler)Jonathan Hale (University of Wisconsin)
Abstract : In this paper, we have developed a highly efficient numerical method for acoustic multiple scattering. This novel method consists of a high order local absorbing boundary condition combined with an isogeometric finite element and finite differences methods. By employing high order NURB basis, a globally high order method results. In our numerical experiments, we obtain errors close to machine precision by appropriate implementation of p- and h-refinement. We include numerical results which demonstrate the improved accuracy and efficiency of this new formulation compared with similar methods.

[02916] The effect normal electric fields on the flow structure beneath waves

Format : Talk at Waseda University
Author(s) : Roberto Ribeiro Santos Junior (Universidade Federal do Parana)Marcelo V. Flamarion (Rural Federal University of Pernambuco)Tao Gao (University of Essex)Alex Doak (University of Bath)
Abstract : Waves with constant vorticity and electrohydrodynamics flows are two topics in fluid dynamics that have attracted much attention from scientists for both the mathematical challenge and their industrial applications. The coupling of electric fields and vorticity is of significant research interest. In this talk, we present numerical results on the effect of normal electric fields on the flow structure beneath periodic and solitary rotational waves. By using a combination of conformal mapping techniques and pseudo-spectral numerical methods, we show how variations in voltage potential can affect particle trajectories and the pressure within the bulk of the fluid

[00378] Mathematical Methods in System Reliability

Session Time & Room :

00378 (1/2) : 2C (Aug.22, 13:20-15:00) @D408

00378 (2/2) : 2D (Aug.22, 15:30-17:10) @D408

Type : Proposal of Minisymposium
Abstract : System reliability is a measure of the performance of an engineering system. High-tech industrial processes increase in complexity and at the same time, system failures are having more significant impacts on society than ever before. Hence, the importance of reliability in modern engineering processes, can hardly be overstated.
The reliable performance of complex systems depends on the performance of their components and the system's structure. In recent years, advanced statistical, probabilistic and algebraic methods and techniques have been applied to system reliabilty. This minisymposium brings together recent developments of mathematical methods applied to industrial system reliability.
Organizer(s) : Fatemeh Mohammadi, Eduardo Sáenz-de-Cabezón, Henry Wynn
Classification : 90B25, 62N05, 68M15, Reliability Theory
Minisymposium Program :

00378 (1/2) : 2C @D408 [Chair: Christian Tanguy]

[01347] Domination and multistate systems

Format : Talk at Waseda University
Author(s) : Arne Bang Huseby (University of Oslo)
Abstract : Domination functions has been studied extensively in the context of binary systems, where the structure function is a sum of products of the component states, and with coefficients given by the domination function. Using matroid theory, properties of the domination function can be derived. We generalise these results to multistate systems. The domination is determined by the poset generated by the minimal paths, and two systems with isomorphic posets also have the same domination function.

[01419] Mathematical analysis of the reliability of stable systems

Format : Talk at Waseda University
Author(s) : Eduardo Sáenz-de-Cabezón (University of La Rioja)
Abstract : One of the main characteristics of coherent systems is redundancy. In this talk we define stability as a way to encode redundancy in a way that generalizes well known systems like k-out-of-n and variants. We furthermore provide a complete algebraic analysis of the reliability of these systems and design based on stability.

[01422] Algebraic probability: the case of system reliability

Format : Online Talk on Zoom
Author(s) : Henry Wynn (London School of Economics)
Abstract : Algebra arises in probability because of additivity over set disjointness and multiplication with independence. With
systems such as those in causal analysis, data analysis and reliability we can have rich algebraic structures. In reliability, under coherence, failure patterns give rise to monomial ideals and from there Betti numbers and Hilbert series lead to efficient identities and bounds for failure probabilities. Structures such as mixed series-parallel systems and multi state systems have special features.

[01425] Algebraic analysis of importance measures of coherent systems

Format : Online Talk on Zoom
Author(s) : Patricia Pascual-Ortigosa (University of La Rioja)Eduardo Sáenz-de-Cabezón (University of La rioja)Rodrigo Iglesias (University of La Rioja)
Abstract : The aim of this talk is to do an analysis of importance measures of coherent systems using an algebraic approach.
First of all, we introduce what importance measures are, providing a classification of them and some background for all of them. Then, we will show how Algebra can help us to study structural measures of importance of coherent systems. Finally, we present some examples explaining the advantages and disadvantages of this approach.

00378 (2/2) : 2D @D408 [Chair: Eduardo Sáenz-de-Cabezón]

[01455] New exactly solvable architecture for system reliability and safety

Format : Talk at Waseda University
Author(s) : Christian Tanguy (Orange)
Abstract : Network reliability is a crucial performance index for telecommunication operators. In the general case, the calculation of the two-terminal reliability is known to be #P-complete, even for identical links and perfect nodes of the network's underlying graph. Exact solutions have nonetheless been found for a few recursive architectures. We present a new example of such an architecture, which could be of interest to reliability practitioners and graph theorists.

[01469] Application of Logic Differential Calculus in Reliability Analysis

Format : Online Talk on Zoom
Author(s) : Michal Mrena (University of Zilina)
Abstract : Logic differential calculus – specifically logic derivatives – provides an efficient way to investigate the reliability of systems described by a structure function. The structure function captures the topology of the system and the derivatives describe the behavior of the system when the state of a component changes. Consequently, they allow us to calculate importance measures for individual components. In this contribution, we present a comprehensive framework for the evaluation of various system reliability characteristics.

[03092] Stochastic comparisons of coherent systems with active redundancy at component level and system level

Format : Talk at Waseda University
Author(s) : Pradip Kundu (XIM University, Bhubaneswar)Arindam Panja (Indian Statistical Institute)Biswabrata Pradhan (Indian Statistical Institute)
Abstract : An effective way to increase system reliability is to use redundancies (spares) into the systems. In this paper, we derive sufficient conditions under which a coherent system with a set of active redundancy at the component level or the system level provides better system reliability than that of the system with another set of redundancy, with respect to some stochastic orders. We have derived the results for the component lifetimes following accelerated life (AL) model.

[00379] Numerical techniques for coarse-graining, model reducing and simulation of complex physical systems

Session Time & Room :

00379 (1/4) : 1C (Aug.21, 13:20-15:00) @E505

00379 (2/4) : 1D (Aug.21, 15:30-17:10) @E505

00379 (3/4) : 1E (Aug.21, 17:40-19:20) @E505

00379 (4/4) : 2C (Aug.22, 13:20-15:00) @E505

Type : Proposal of Minisymposium
Abstract : The simulation of complex physical systems for prediction and control requires robust, efficient mathematical modeling and numerical algorithms, as the problem size and time scales of interest in many applications are typically beyond which can be simulated directly. In recent years, a wealth of new techniques and algorithms have been developed to help reduce problem size/dimension and accelerate the accurate simulation of various classes of physical observables while quantifying the uncertainty of the resulting predictions made. Examples of such techniques include Coarse-Grained Molecular Dynamics, Nonlocal Theories of Mechanics, Time Accelerated Dynamics, Hyperdynamics, Space-Time Homogenization, and so on. These techniques and numerical algorithms have made successful applications in a diverse range of models.

In view of the wide range of applicability of these algorithms and the ideas which lie behind them, this minisymposium seeks to bring together both theoreticians and practitioners who study and use numerical simulations for a range of practical scientific problems, aiming to facilitate discussion and two-way dissemination of ideas across disciplinary and topical boundaries.

[02156] Ahyper-reduced MAC scheme for the parametric Stokes and Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Lijie Ji (Shanghai Jiao Tong University)
Abstract : The classical reduced basis method is popular due to an offline-online decomposition and a mathematically rigorous a posteriorerror estimator which guides a greedy algorithm offline. For nonlinear and nonaffine problems, hyper reduction techniques have been introduced to make this decomposition efficient. However, they may be tricky to implement and often degrade the offline and online computational efficiency. In this talk, I will introduce an adaptive enrichment strategy for R2-ROC rendering it capable of handling parametric fluid flow problems. Tests on lid-driven cavity and flow past a backward-facing step problems demonstrate its high efficiency, stability and accuracy.

[02166] Hybrid Projection Methods for Solution Decomposition in Large-scale Bayesian Inverse Problems

Format : Talk at Waseda University
Author(s) : Jiahua Jiang (University of Birmingham)Julianne Chung (Emory University)Arvind Krishna Saibaba (North Carolina State University)Scot Miller (John Hopkins)
Abstract : We develop hybrid projection methods for computing solutions to large-scale inverse problems, where the solution represents a sum of different stochastic components. Such scenarios arise in many imaging applications (e.g., anomaly detection in atmospheric emissions tomography) where the reconstructed solution can be represented as a combination of two or more components and each component contains different smoothness or stochastic properties. In a deterministic inversion or inverse modeling framework, these assumptions correspond to different regularization terms for each solution in the sum. Although various prior assumptions can be included in our framework, we focus on the scenario where the solution is a sum of a sparse solution and a smooth solution. For computing solution estimates, we develop hybrid projection methods for solution decomposition that are based on a combined flexible and generalized Golub-Kahan processes. This approach integrates techniques from the generalized Golub-Kahan bidiagonalization and the flexible Krylov methods. The benefits of the proposed methods are that the decomposition of the solution can be

done iteratively, and the regularization terms and regularization parameters are adaptively chosen at each iteration. Numerical results from photoacoustic tomography and atmospheric inverse modeling demonstrate the potential for these methods to be used for anomaly detection.

[02484] A reduced basis method for the parametrized Monge-Ampere equation

Format : Talk at Waseda University
Author(s) : Shijin Hou (University of Science and Technology of China)
Abstract : In this talk, we first introduce a highly efficient solver for the parameterized optimal mass transport problem by adapting the reduced residual reduced over-collocation approach to the parameterized Monge-Ampère equation. This new reduced basis technique allows us to handle the strong and unique nonlinearity pertaining to the Monge-Ampère equation achieving online efficiency. After that, several numerical tests will be presented to demonstrate the accuracy and high efficiency of our reduced solver.

[04068] Novel Reduced Basis Method for Radiative Transfer Equation

Format : Talk at Waseda University
Author(s) : ZHICHAO PENG (Michigan State University)Yanlai Chen (University of Massachusetts Dartmout)Yingda Cheng (Michigan State University)Fengyan Li (Rensselaer Polytechnic Institute)
Abstract : One prominent computational challenge to simulate radiative transfer (RTE), a fundamental kinetic description of energy or particle transport through mediums affected by scattering and absorption processes, comes from the high dimensionality of the phase space. Leveraging the existence of a low-rank structure in the solution manifold induced by the angular variable in the scattering dominating regime, reduced order models are designed and tested here for the linear RTE model based on reduced basis methods.

00379 (2/4) : 1D @E505 [Chair: Xingjie Helen Li]

[03752] Large Deviations for Model Coarse Graining

Format : Talk at Waseda University
Author(s) : Tobias Grafke (Warwick Mathematics Institute)
Abstract : Systems with time-scale separation allow effective model reduction via averaging and homogenization, where average effects of fluctuating degrees of freedom are as reduced dynamics. In the language of probability theory, this averaging corresponds to a law-of-large numbers, making it natural to ask about expected fluctuations and large deviations. In this talk, I will introduce developments regarding large deviations in the presence of time-scale separation for the computation of rare event probabilities in reduced models.

[03592] Mean curvature flow as the limit of a spin system

Format : Talk at Waseda University
Author(s) : Patrick van Meurs (Kanazawa University)
Abstract : I will present the derivation of a continuum mean-curvature flow as a certain hydrodynamic scaling limit of a stochastic particle system (Glauber-Kawasaki) on the discrete torus in d dimensions. The particles can jump to neighboring vacant sites and there is a creation and annihilation mechanism. Our work combines techniques from probability theory (in particular the relative entropy method), numerical analysis and PDE theory.

Collaborators: T. Funaki, S. Sethuraman, K. Tsunoda.

[04679] Model reduction methods for non-reversible multiscale dynamics: a comparison

Format : Talk at Waseda University
Author(s) : Lara Neureither (BTU Cottbus)
Abstract : In this talk we will compare existing coarse graining methods such as averaging, effective dynamics as well as the normal form approach among others for multiscale dynamics given by a non-reversible Ornstein-Uhlenbeck process driven by degenerate noise. We will address the following questions: which of the methods yields the best approximation to the original dynamics? What causes the differences in the approaches, if there are any?

[04002] Model Reduction using the Koopman Operator

Format : Talk at Waseda University
Author(s) : Xiu Yang (Lehigh University)Bian Li (Lehigh University)Yi-An Ma (University of California at San Diego)J. Nathan Kutz (University of Washington)
Abstract : We propose the adaptive spectral Koopman (ASK) method to solve nonlinear autonomous dynamical systems. ASK leverages the spectral method and the Koopman operator to obtain the solution. Specifically, this solution is represented by Koopman operator's eigenfunctions, eigenvalues, and Koopman modes. Numerical experiments demonstrate high accuracy of ASK for solving both ordinary and partial differential equations. Using ASK as a surrogate model, we can design novel efficient uncertainty quantification methods.

00379 (3/4) : 1E @E505 [Chair: Xiaochuan Tian]

[04693] Machine-learning-based spectral methods for partial differential equations

Format : Talk at Waseda University
Author(s) : Panos Stinis (Pacific Northwest National Laboratory)Saad Qadeer (Pacific Northwest National Laboratory)Brek Meuris (University of Washington)
Abstract : We use deep neural operators to identify custom-made basis functions for constructing spectral methods for partial differential equations. The custom-made basis functions are studied both for their approximation capability and used to expand the solution of linear and nonlinear time-dependent PDEs. The proposed approach advances the state of the art and versatility of spectral methods and, more generally, promotes the synergy between traditional scientific computing and machine learning.

[03852] Optimal control for fractional order equations

Format : Talk at Waseda University
Author(s) : Christian Glusa (Sandia National Laboratories)
Abstract : We consider adjoint-based optimization for control problems involving fractional-order state equations, applied to the inference of kernel parameters. We will discuss optimality conditions, error estimates and techniques to efficiently explore the parameter space and approximate gradients.

[04163] Multi-Resolution and FVM inspired Neural Network (MuRFiV-Net) for PDE prediction

Format : Talk at Waseda University
Author(s) : Xin-Yang Liu (University of Notre Dame)Jian-Xun Wang (University of Notre Dame)
Abstract : Predicting physical processes requires modeling complex spatiotemporal dynamics. Traditional numerical methods are expensive in many-query tasks, while data-driven neural networks face issues of high training costs and poor generalizability. Physics-informed deep learning (PiDL) combines numerical methods and deep learning, offering a promising approach to overcome these limitations. This work proposes MuRFiV-Net, a novel PiDL architecture based on a multi-resolution mesh and finite volume method. The merit of MuRFiV-Net is demonstrated on several PDE-governed dynamic systems.

00379 (4/4) : 2C @E505

[00382] Stochastic control and stochastic analysis in finance and insurance

Session Time & Room :

00382 (1/3) : 2C (Aug.22, 13:20-15:00) @D514

00382 (2/3) : 2D (Aug.22, 15:30-17:10) @D514

00382 (3/3) : 2E (Aug.22, 17:40-19:20) @D514

Type : Proposal of Minisymposium

Abstract : Stochastic control and stochastic analysis have played core roles in quantitative finance and insurance. Newly emerging financial and risk models, trading constraints, behavioral decision making and time inconsistency issues have brought many new mathematical challenges. Some novel PDE techniques, mean field game formulation, optimal transport, deep learning and reinforcement learning have been rapidly developed in addressing these problems. The goal of this minisymposium is to provide a forum for some experts to exchange ideas and explore possible collaborations in modelling and methodologies in financial and insurance applications.

Organizer(s) : Xiaolu Tan, Kazutoshi Yamazaki, Xiang Yu

Classification : 91Gxx, 93Exx, 60-XX, 90Bxx

Minisymposium Program :

00382 (1/3) : 2C @D514 [Chair: Xiang Yu]

[02210] Lévy bandits under Poissonian decision times

Format : Talk at Waseda University

Author(s) : Kazutoshi Yamazaki (University of Queensland)Jose Luis Perez (CIMAT)

Abstract : We consider a version of the continuous-time multi-armed bandit problem where decision opportunities arrive at Poisson arrival times, and study its Gittins index policy. When driven by spectrally one-sided Lévy processes, the Gittins index can be written explicitly in terms of the scale function, and is shown to converge to that in the classical Lévy bandit of Kaspi and Mandelbaum (1995).

[02144] Optimal Consumption with Loss Aversion and Reference to Past Spending Maximum

Format : Talk at Waseda University

Author(s) : Xun LI (The Hong Kong Polytechnic University)Xiang Yu (The Hong Kong Polytechnic University)Zhang Qinyi (The Hong Kong Polytechnic University)

Abstract : This talk studies an optimal consumption problem for a loss-averse agent with reference to past consumption maximum. To account for loss aversion on relative consumption, an S-shaped utility is adopted that measures the difference between the non-negative consumption rate and a fraction of the historical spending peak. We consider the concave envelope of the realization utility with respect to consumption, allowing us to focus on an auxiliary HJB variational in- equality on the strength of concavification principle and dynamic programming arguments. By applying the dual transform and smooth-fit conditions, the auxiliary HJB variational inequality is solved in closed-form piecewisely and some thresholds of the wealth variable are obtained. The optimal consumption and investment control of the original problem can be derived analytically in the piecewise feedback form. The rigorous verification proofs on optimality and concavification principle are provided. Some numerical sensitivity analysis and financial implications are also presented.

[02873] On the Entropy martingale optimal transport

Format : Talk at Waseda University

Author(s) : Shuoqing Deng (The Hong Kong University of Science and Technology)Erhan Bayraktar (University of Michigan)Dominykas Norgilas (University of Michigan)

Abstract : We study the Entropy Martingale Optimal Transport of Doldi and Frittelli (Finance&Stochastics, 2023). Compared with classical MOT, marginal constraints and linear pricing rules are respectively replaced by penalisation on deviations from the reference measures and utility-induced nonlinear rules. Inspired by techniques from classical MOT, we prove the duality with different arguments and weaker conditions. In particular, combining minimax arguments and the optional decomposition theorem, we generalise their duality without continuity requirement for the dynamic strategy.

[02785] Functional convex order for the McKean-Vlasov equation

Format : Talk at Waseda University

Author(s) : Yating Liu (Paris Dauphine University)Gilles Pagès (Sorbonne University)

Abstract : We introduce the functional convex order for two McKean-Vlasov processes X and Y with respective marginal distributions $(\mu_t)_{t\in

[0, T]}and(\nu_t)_{t\in

[0, T]}$. For a convex functional$G $defined on the product space involving the path space and its marginal distribution space, we obta$ \mathbb{E}\,G(X, (\mu_t)_{t\in

[0, T]}) \leq \mathbb{E}\,G(Y, (\nu_t)_{t\in

[0, T]})$ under appropriate conditions. This presentation also includes two applications of the convex order result to mean-field control and mean-field games.

00382 (2/3) : 2D @D514 [Chair: Xiaolu Tan]

[03167] Incentive to shape equilibria in double auction markets

Format : Talk at Waseda University
Author(s) : Thibaut Mastrolia (UC Berkeley)Mathieu Rosenbaum (Ecole Polytechnique)Joffrey Derchu (Ecole Polytechnique)
Abstract : We study a toy two-player game for periodic double auction markets with imperfect information between the players. It allows us to link market spreads with signal strength. We first derive some market statistics related to the model studied. Then, we characterize Nash equilibria in cases with or without incentives from the exchange. This enables us to derive new insights about price formation and incentives design.

[04566] On time-consistent equilibrium stopping under aggregation of diverse discount rates

Format : Talk at Waseda University
Author(s) : Jiacheng Zhang (UC Berkeley)Shuoqing Deng (The Hong Kong University of Science and Technology)Xiang Yu (The Hong Kong Polytechnic University)
Abstract : This paper studies the central planner's decision making on behalf of a group of members with diverse discount rates. In the context of optimal stopping, we work with a smooth aggregation preference to incorporate all heterogeneous discount rates with an attitude function that reflects the aggregation rule in the same spirit of ambiguity aversion in the smooth ambiguity preference proposed in Klibanoff et al.(2005). The optimal stopping problem renders to be time inconsistent, for which we develop an iterative approach using consistent planning and characterize all time-consistent equilibria as fixed points of an operator in the setting of one-dimensional diffusion processes. We provide some sufficient conditions on both the underlying models and the attitude function such that the smallest equilibrium attains the optimal equilibrium in which the attitude function becomes equivalent to the linear aggregation rule as of diversity neutral. When the sufficient condition of the attitude function is violated, we can illustrate by various examples that the characterization of the optimal equilibrium may differ significantly from some existing results for an individual agent, which now sensitively depends on the attitude function and the diversity distribution of discount rates.

[02775] CONVERGENCE OF POLICY IMPROVEMENT FOR ENTROPY-REGULARIZED STOCHASTIC CONTROL PROBLEMS

Format : Talk at Waseda University
Author(s) : Yu-Jui Huang (University of Colorado, Boulder)Zhenhua Wang (University of Michigan)Zhou Zhou (University of Sydney)
Abstract : For a general entropy-regularized stochastic control problem on an infinite horizon, we prove that a policy improvement algorithm (PIA) converges to an optimal relaxed control. Contrary to the standard stochastic control literature, classical Hölder estimates of value functions do not ensure the convergence of the PIA, due to the added entropy-regularizing term. To circumvent this, we carry out a delicate estimation by moving back and forth between appropriate Hölder and Sobolev spaces. This requires new Sobolev estimates designed specifically for the purpose of policy improvement and a nontrivial technique to contain the entropy growth. Ultimately, we obtain a uniform Hölder bound for the sequence of value functions generated by the PIA, thereby achieving the desired convergence result. Characterization of the optimal value function as the unique solution to an exploratory Hamilton– Jacobi–Bellman equation comes as a by-product.

[03347] Continuous time q-learning for McKean-Vlasov control problems

Format : Talk at Waseda University
Author(s) : Xiaoli Wei (Tsinghua Shenzhen International Graduate School)Xiang Yu (The Hong Kong Polytechnic University)
Abstract : For continuous time McKean-Vlasov control problems, we study the continuous time version of Q-learning for reinforcement learning under entropy regularization. Due to the complexity of distribution dependence, the counterpart of the martingale characterization of q-function in the single-agent control problem fails in our framework. To resolve the challenge, we introduce two distinct q-functions, which share the same integral under all test stochastic policies. The first q-function is associated to the optimal policy and policy improvement, and the second q-function can be used to develop the weak martingale characterization of some related processes under all test stochastic policies. Based on the weak martingale characterization and the relationship between two q-functions, we can design some q-learning algorithms for the learning McKean-Vlasov control problems and present several financial applications.

00382 (3/3) : 2E @D514 [Chair: Kazutoshi Yamazaki]

[02892] Skew Brownian Motion with Two-Valued Drift

Format : Talk at Waseda University
Author(s) : Xiaowen Zhou (Concordia University)
Abstract :
We consider a skew Brownian motion with two-valued drift as the unique solution to the following SDE
dX_t=\big(\mu- *1*{{X_ta}}\big)dt +dB_t+\beta dL^a_t(X),
where μ_- and μ_+ are constants, $-1 < \beta < 1$, B is a Brownian motion and $L_t^a(X)$ denotes the symmetric local time for X at level a. Such a process can be identified as a regime switching model depending on whether the process X takes values above or below level a. In this talk we present some properties for such processes and discuss an optimization problem that is motivated by the optimal dividend problem for risk processes.

This talk is based on joint work with Zhongqin Gao.

[02928] Pathwise uniqueness of SDEs driven by stable processes

Format : Talk at Waseda University
Author(s) : Hiroshi Tsukada (Kagoshima University)
Abstract : We consider one-dimensional stochastic differential equations (SDEs) driven by strictly stable processes. In this talk, we give some non-Lipschitz conditions on diffusion and drift coefficients under which the pathwise uniqueness of solutions to the SDEs is established. Moreover, we provide sufficient conditions for the non-contact property of strong solutions to the SDEs with different initial values.

[05583] Mean field portfolio games

Format : Talk at Waseda University
Author(s) : Guanxing Fu (The Hong Kong Polytechnic University)
Abstract : We study mean field portfolio games, which is proved to be equivalent to an (F)BSDE, by martingale optimality principle and dynamic programming principle. A key implication is the uniqueness result of the game. Closed form solution is possible under stronger assumptions. If time permits, I will introduce possible extensions.

[03375] A mean-field version of Bank--El Karoui's representation of stochastic processes

Format : Talk at Waseda University
Author(s) : Xiaolu Tan (The Chinese University of Hong Kong)
Abstract : We investigate a mean-field version of Bank--El Karoui's representation theorem of stochastic processes. Under different technical conditions, we established some existence and uniqueness results. As motivation and first applications, the results of mean-field representation provide a unified approach for studying various mean-field games (MFGs) in the setting with common noise and multiple populations, including the MFG of timing and the MFG with singular control, etc. As a crucial technical step, a stability result was provided on the classical Bank--El Karoui's representation theorem. It has its own interests and other applications, such as deriving the stability results of optimizers (in the strong sense) for a class of optimal stopping and singular control problems.

[00384] Origami Engineering (1/2)

Session Time & Room :

00384 (1/3) : 2D (Aug.22, 15:30-17:10) @F411

00384 (2/3) : 2E (Aug.22, 17:40-19:20) @F411

00384 (3/3) : 3C (Aug.23, 13:20-15:00) @F411

Type : Proposal of Minisymposium
Abstract : Discussions on topics related to origami engineering will take place at this mini-symposium. Presenters will present their research aimed at applying the technology of origami, the folding of flat materials to create shapes, to engineering, and exploring the geometric properties of origami from a mathematical perspective to explore its range of applications.
Organizer(s) : Jun Mitani, Sachiko Ishida, Kazuya Saito
Classification : 51-08, 74A05, 70B10, 74K25, 74S05, Origami
Minisymposium Program :

00384 (1/3) : 2D @F411 [Chair: Jun Mitani]

[01360] Farthest point map on the double cover of a parallelotope

Format : Talk at Waseda University
Author(s) : Yoshikazu Yamagishi (Ryukoku University)Sayaka Ueda (Ryukoku University)
Abstract : We describe the source unfolding on the double cover of a parallel polytope of dimension n. Suppose two persons p,q play the squash in a parallelotope. Where is the farthest point q from a given point p? What happens if they keep playing the squash by choosing the farthest points? It is shown that the limit set is a union of quadratic curves.

[01518] Deployable earwig fan dome with the algorithmic design tool

Format : Talk at Waseda University
Author(s) : Chisaki KITAJIMA (Kyushu University)Kazuya Saito (Kyushu University)
Abstract : Earwigs can fold their wing most compactly of all insects, therefore the characteristics have potential for engineering applications. In previous studies, we have already revealed how to design the crease pattern of the earwigs fan. Here we show a method to create three-dimensional forms from the folding simulation of the earwig fan with an algorithmic design tool. Furthermore, we propose to design compactly foldable dome-shape structures based on crease pattern of earwig fan.

[01519] Geometry and mechanics of molting in snakes and caterpillars

Format : Talk at Waseda University
Author(s) : Taiju Yoneda (Kyushu University)Kazuya Saito (Kyushu University)
Abstract : Snakes and caterpillars have longer bodies and grow by molting, but the molting process is different.
Snakes molt by reversing the front and back of their skin. In the molting of caterpillars, their skin is folded with buckling.
Which mode is expected to be determined by geometric factors such as thickness and mechanical factors such as friction. We quantify these boundary conditions using a combination of buckling experiments and finite element method with cylindrical shell models.

[01523] Linear transformation of crease pattern boundaries preserving internal graph isomorphisms

Format : Talk at Waseda University
Author(s) : Yohei Yamamoto (University of Tsukuba)
Jun Mitani (University of Tsukuba)
Abstract : A crease pattern whose boundaries are similar before and after flat-folding can be tiled to create larger origami works. In order to increase the variation, linearly transforming the boundary shape is a useful approach, but if the entire crease pattern is transformed, the flat-foldability is not maintained. We propose a method for linear transformation of the boundaries while preserving internal graph isomorphisms. The characteristics of generated crease patterns and the folded states are discussed.

00384 (2/3) : 2E @F411 [Chair: Yoshikazu Yamagishi]

[01571] Laboratory-scale Workshop for Enhancing Designability of Origami Cores

Format : Talk at Waseda University
Author(s) : Sachiko Ishida (Meiji University)
Abstract : The objective of this study is to develop a laboratory-scale fabrication method to prototype origami-like foldable cores with our own designs. As the first attempt, we formed honeycomb cores in such a way that thermoplastic sheets were pressed between heated molds with corrugated configuration and glued together. This method worked well to enhance designability of honeycomb cores, because the press forming was applicable even for complex designs and could improve shape accuracy.

[01618] Strip folding as Boolean matrix algebra and its Categorical Meanings

Format : Talk at Waseda University
Author(s) : Yiyang Jia (Seikei University)Jun Mitani (University of Tsukuba)
Abstract : Strip folding, known as map folding in the one-dimensional case, derives from a classical flat-foldability decision problem in the field of computational origami. In this manuscript, different from the existing computational and algorithmic methodology, we investigate strip folding using abstract algebraic language and then characterize it from a categorical viewpoint. We first present a boolean matrix description of strip folding, based on which we then build the category of strip folding. This category gives rise to a natural meet semi-lattice structure. Furthermore, in this category, every product exists. We use the right adjoint functor of the diagonal functor to define these products. Furthermore, the definition of products can be used to build a Grothendieck topology in the space of flatly folded states. Our result shows that the analysis of strip folding can be associated with contemporary mathematical methodologies such as category theory and algebraic geometry.

[02328] Application of the proposed method to a transport origami box

Format : Online Talk on Zoom
Author(s) : Toshie Sasaki (Meiji University)Yang Yang (Meiji University)Ichiro Hagiwara (Meiji University)
Abstract : Fruits and vegetables are damaged during transportation because there is a mortal frequency band for each transport. We propose a new method named “Energy Density Topology Changing Method” based on the fact that the eigen frequency is determined by equivalent stiffness and equivalent mass. We demonstrate the effectiveness of this method by showing that it can be successfully applied to a transport origami box which cannot be applied by conventional topology optimization method.

00384 (3/3) : 3C @F411 [Chair: Tomohiro Tachi]

[01536] Refoldability between polyhedra

Format : Talk at Waseda University
Author(s) : Tonan Kamata (Japan Advanced Institute of Science and Technology)
Abstract : Refolding is an operation of reshaping a polyhedron into a polyhedron by cutting open the surface of the original one and folding the resulting unfolding to make the other one. Refolding is a natural subject with applications in space engineering, design engineering, and bioinformatics, but the known result is not so much. In this talk, we will present design methods of refolding for some specific classes of polyhedra and the possibility of reconfiguration by refoldings.

[05407] Optimal Simple Fold-and-Cut of a Polygonal Line

Format : Talk at Waseda University
Author(s) : Ryuhei Uehara (Japan Advanced Institute of Science and Technology)
Abstract : We investigate a natural variant of the fold-and-cut problem. We are given a long paper strip P and a polygonal line, which consists of a sequence of line segments, drawn on P. We cut all the line segments by one complete straight cut after overlapping all of them by a sequence of simple foldings. Our goal is to minimize the number of simple foldings to do that. When the polygonal line satisfies some certain geometric conditions, we can find a shortest sequence of simple foldings for the given polygonal line that consists of n line segments in O(n^3) time and O(n^2) space.

[02335] Geometrical Comparison of Two kinds of Pairing Origami Polyhedron and Their Application to Beverage Containers

Format : Online Talk on Zoom
Author(s) : Aya Abe (Meiji University)Yang Yang (Meiji University)Chie Nara (Meiji University)Ichiro Hagiwara (Meiji University)
Abstract : Tachi-Miura Polyhedron is gaining attention as a 3-dimensional version of Miura-Ori. Meanwhile, Nojima Polyhedron is similar as TMP in that it can be folded both in the axial and radial direction. In this study, whether both are rigid folding or not is geometrically confirmed, and quantitatively considered how it affects the energy absorption properties. As a result, it effects the deformation modes but does not affect the purpose of investigating the feasibility of industrialization.

[00385] Origami Engineering (2/2)

[01402] Solitons in Origami / Kirigami Tessellations and Their Underlying Dynamical Systems

Format : Talk at Waseda University
Author(s) : Rinki Imada (The University of Tokyo)Tomohiro Tachi (The University of Tokyo)
Abstract : The non-uniform folding of origami/kirigami tessellation, the folding where the configuration of their unit cell isn't identical, is potentially a great source of nonlinear phenomena. We can mathematically understand these phenomena by the nature of the dynamical systems induced by their geometry.
In this presentation, we report the "soliton-like" phenomenon with the propagation of localized deformation in origami/kirigami tessellations which comes from different mechanisms, i.e., the homoclinic/heteroclinic solutions of their dynamical systems.

[01403] Macroscopic Behavior of Kirigami Tessellations with Contact Surfaces

Format : Talk at Waseda University
Author(s) : Akito Adachi (The University of Tokyo)Tomohiro Tachi (The University of Tokyo)
Abstract : Origami and kirigami tessellations with contact surfaces have potential applications including flexible electronics and wearable devices. However, the manufacturing process requires a simultaneous folding of all creases, which makes the pattern difficult to be manufactured. In this study, we reveal the macroscopic behavior of kirigami variations with contact surfaces through singular value decomposition of the kinematic deformation of each module; through this study, we explore the possibility of manufacturing such tessellations by tension-induced buckling.

[01432] Miura fold bending in two directions and their combination

Format : Talk at Waseda University
Author(s) : Sora Moriyama (The University of Tokyo)Tomohiro Tachi (The University of Tokyo)Kuo-chih Chuang (Zhejiang University)
Abstract : For Miura folds, where the unit cell is usually composed of parallelograms, it is known that folds that are not parallel to the row's direction can be deformed in-plane after folding. If the unit cell is constructed so that it has different angles in the column's direction, it is deformable out-of-plane after folding. By understanding and combining these mathematically, we will present the Miura fold, which can be deformed in any direction.

[01526] Development study of foldable and portable comfortable acoustic space

Format : Online Talk on Zoom

Author(s) : Keiko Yamazaki (Meiji University)Masanori Hashiguchi (KEISOKU ENGINEERING SYSTEM CO., LTD.)Dahai Mi (KEISOKU ENGINEERING SYSTEM CO., LTD.)Ichiro Hagiwara (Meiji University)

Abstract : The purpose of our research is to develop a simple sound-reducing shade to enjoy playing music at home. The requirements for the shade are relatively inexpensive, foldable, suitable size and acoustic environment for playing, and most importantly sound dampening ability. Normally, the development of such a product requires many prototypes and verifications, but in this research, by utilizing finite element analysis to find the optimum material and shape without producing a large number of prototypes.

00385 (2/2) : 3E @F411 [Chair: Akito Adachi]

[01562] A remark on the foldability of non-simply connected paper

Format : Talk at Waseda University

Author(s) : Hiroko Murai (Nara Women's University)Akari Iwamura (Nara Women's University)

Abstract : It is known that for any simply connected piece of paper P,
any flat folded state (f, λ) of P is realized by a motion from the unfolded state.
In this talk, we show that the above result does not hold if the paper is not simply connected
and give some examples.

[05414] Origami Structures and Materials: Energy Absorption and Impact Mechanics

Format : Talk at Waseda University

Author(s) : Guoxing Lu (Swinburne University of Technology)

Abstract : This presentation introduces energy absorption and impact response of origami inspired structures and metamaterial, which we have recently studied. Several examples of incorporating the concepts of origami will be presented. They include thin-walled structures under axial loading, Miura metamaterials and its variations under quasi-static and dynamic compression and origami sandwich panels under quasi-static loading and ballistic impact.

Responses of such materials and structures involve large plastic deformation as well as dynamic effects. For metamaterials, analytical models have been developed to describe the strength and energy absorption capacity. It is assumed that the base material is ductile and can be approximated as a perfectly-plastic material. The analytical model is verified by the numerical simulations as well as quasi-static compression test of a four-sheet origami specimen. Response of such material under impact loading is also investigated and a shock model is proposed for high velocity impact.

[02536] Platonic solids-based optimization for kirigami honeycomb fabrication of complex structures

Author(s) : Junichi Shinoda (Interlocus CO.LTD)Keiko Yamazaki (Meiji University)Ichiro Hagiwara (Meiji University)Luis Diago (Meiji University)

Abstract : The aerospace, automotive, and marine industries are heavily reliant on sandwich panels with cellular material cores. In this work, a platonic solids-based optimization algorithm has been developed to select the direction of the cells of the kirigami-honeycomb panel with the smallest waste of materials by rotating the 3D solid model of any shape according to the normal vectors in the platonic solids.

[02542] Development of beautifully foldable PET bottles

Author(s) : Yang Yang (Meiji University)Chie Nara (Meiji University)Ichiro Hagiwara (Meiji University)

Abstract : Although many have attempted to develop a PET bottle that is foldable in the axial direction without bending, such bottles are not yet on the market. This is because that although the model with several foldable layers can be folded rather easily without bending, it springs back to almost its original height after compression. Thus, we develop new types of PET bottle with two or three spiral layers to resolve this spring back issue.

[00389] Randomized methods for solving linear systems and eigenvalue problems

Session Time & Room :

00389 (1/3) : 2C (Aug.22, 13:20-15:00) @E811

00389 (2/3) : 2D (Aug.22, 15:30-17:10) @E811

00389 (3/3) : 2E (Aug.22, 17:40-19:20) @E811

Type : Proposal of Minisymposium
Abstract : Although the field of randomized numerical linear algebra has grown significantly, developments on accurate randomized solvers only start to emerge in recent years. This minisymposium intends to bring together researchers to exchange ideas on producing fast and accurate randomized solvers, studying their performance, and exploring new applications. We will specifically focus on randomized methods for solving linear systems and eigenvalue problems and on randomized strategies that can produce reliable high-quality solutions or approximations. Some topics include randomized iterative solvers, preconditioning, matrix approximations, low-rank compression, and eigenvalue detection. Applications to PDE solutions, machine learning, and data analysis will also be discussed.

[03670] Making the Nystrom method highly accurate for low-rank approximations

Format : Online Talk on Zoom
Author(s) : Jianlin Xia (Purdue University)
Abstract : The Nystrom method is a convenient method to quickly obtain a low-rank approximation to a kernel matrix with low or modest accuracies. In this work, we propose a type of Nystrom methods that can reach high accuracies. The methods (called high-accuracy Nystrom methods) treat the Nystrom method and a skinny rank-revealing factorization as a fast pivoting strategy in a progressive alternating direction refinement process. A rank expansion strategy based on fast subset updates is further proposed and can quickly advance the sizes of the basis matrices. A fast randomized accuracy control strategy is also given. Different versions of high-accuracy Nystrom methods are derived and can produce low-rank approximations with prespecified accuracies, sometimes with near SVD quality.

[04016] Superfast iterative refinement of Low Rank Approximation of a Matrix

Format : Online Talk on Zoom
Author(s) : Victor Pan (CUNY)
Abstract : Every superfast (aka sublinear cost) Low Rank Matrix Approximation (LRA) algorithm -- involving much fewer flops and memory cells than matrix has entries -- cannot work on ANY input, failing even with randomization, but our LRA algorithms are efficient or nearly optimal for MANY (large class of) inputs. Moreover, we propose, analyze, and test novel superfast algorithms for iterative refinement of any crude but sufficiently close LRA, according to both formal study and numerical tests.

[00881] Relaxation in low-rank updates of Schur complement preconditioners in fluid flow problems

Format : Talk at Waseda University
Author(s) : Sabine Le Borne (Hamburg University of TechnologyHamburg University of Technology)
Abstract : In the simulation of fluid dynamic problems we often have to solve large-scale saddle-point systems. Low-rank updates can adapt standard preconditioners and accelerate convergence. We consider a low-rank correction for pressure Schur complement preconditioners and introduce a relaxation of the initial preconditioner which can improve the update scheme. Numerical results for the linearized Navier-Stokes equations illustrate the action of the update scheme.

[00530] Randomized low-rank approximations beyond Gaussian random matrices

Format : Online Talk on Zoom
Author(s) : Arvind Krishna Saibaba (North Carolina State University)Agnieszka Miedlar (Virginia Tech)
Abstract : Randomized algorithms have been a revolutionary force in the field of low-rank approximations. A key step in these randomized algorithms is the randomized range finder which involves products with random matrices. The prevalent approach is to take the random matrix to be standard Gaussian which has favorable theoretical properties and is easy to implement in practice. Although several non-Gaussian random matrices have been used and analyzed, there are many open questions on what classes of random matrices are suitable for the randomized range finder. We analyze three different classes of random matrices: independent subgaussian entries, independent subgaussian columns, and independent bounded columns. These bounds provide a unified approach to studying various classes of random matrices and are supported by numerical experiments on test and real-world matrices.

00389 (2/3) : 2D @E811 [Chair: Jianlin Xia]

[04523] Are randomized NLA algorithms numerically stable?

Format : Talk at Waseda University
Author(s) : Yuji Nakatsukasa (University of Oxford)Joel A. Tropp (Caltech)
Abstract : We develop algorithms for linear systems and eigenvalue problems that apply fast randomized sketching to accelerate standard subspace projection methods, such as GMRES and Rayleigh-Ritz. This modification allows for incorporating nontraditional bases for the approximation subspace. When the basis is numerically full rank, these algorithms have accuracy similar to classic methods but run faster. We illustrate a 70x speedup over gmres. Time (and progress) permitting, I will discuss recent developments in related topics.

[05547] Randomized orthogonalization process

Format : Online Talk on Zoom
Author(s) : Laura Grigori (EPFL and PSI)
Abstract : In this talk we will review recent progress on deriving algorithms for orthogonalizing a set of vectors. We will discuss then how this algorithms could be used to solve linear systems of equations and eigenvalue problems. We will conclude with numerical experiments that show the numerical stability of the proposed algorithms.

[04952] A robust randomized indicator method for accurate symmetric eigenvalue detection

Format : Online Talk on Zoom
Author(s) : Zhongyuan Chen (Medical College of Wisconsin)Jiguang Sun (Michigan Technological University)Jianlin Xia (Purdue University)
Abstract : We propose a robust randomized indicator method for accurate eigenvalue detection for symmetric matrices A, which gives a novel way to use randomization to design eigensolvers for finding interior eigenvalues. An indicator detects the existence of eigenvalues inside an interval based on some statistical norm estimators for a spectral projector. Previous work on eigenvalue indicators relies on a threshold which is only heuristically chosen, thus often resulting in spurious or missed eigenvalues. In this work, we use rigorous statistical analysis to guide the design of a robust indicator. Multiple randomized estimators for a contour integral operator in terms of A are analyzed. In particular, when A has eigenvalues inside a given interval, we show that the failure probability (for the estimators to return very small estimates) is extremely low. This enables to design a robust rejection indicator based on the control of the failure probability. We then illustrate how the indicator method may potentially be used to develop new randomized symmetric eigensolvers, where fast indicator evaluation via shifted linear system solution is employed in a bisection scheme. Unlike previous indicator methods that only produce eigenvalues, our method can conveniently reuse computations from indicator evaluations to find eigenvectors with little extra cost.

[05321] The Adversarially Robust Generalized Eigenvalue Problem

Format : Online Talk on Zoom
Author(s) : Ming Gu (UC Berkeley)Jiaming Wang (UC Berkeley)
Abstract : In this talk, we will introduce novel algorithms for solving the adversarially robust generalized eigenvalue problem, a highly non-convex optimization problem that has long eluded traditional optimization solvers. We will first discuss the rank-one case and then move on to the general-rank case. We will also show the potential applications of our algorithms in robust adaptive beamforming.

00389 (3/3) : 2E @E811 [Chair: Jianlin Xia]

[03799] Stochastic Gradient Descent with Conjugate Gradient-style Momentum

Format : Online Talk on Zoom
Author(s) : Bao Wang (University of Utah)Qiang Ye (University of Kentucky)
Abstract : Momentum may be crucial in stochastic gradient-based optimization algorithms for convergence acceleration. The classical conjugate gradient algorithm may be considered as gradient descent with momentum. In this talk, we introduce a stochastic gradient descent algorithm with a conjugate gradient-style momentum. We will discuss its convergence properties and present some numerical examples to demonstrate its effectiveness.

[01342] Robust randomized preconditioning for kernel ridge regression

Format : Talk at Waseda University
Author(s) : Mateo Diaz Diaz (Johns Hopkins University)Ethan Epperly (Caltech)Zachary Frangella (Stanford)Joel Tropp (Caltech)Robert Webber (California Institute of Technology)
Abstract : We advocate two randomized preconditioning approaches for applying kernel ridge regression (KRR) to a moderate or large number of data points ($N \geq 10^4$). RPCholesky preconditioning is guaranteed to solve the exact KRR equations involving the $N \times N$ kernel matrix in just $\mathcal{O}(N^2)$ operations, assuming eigenvalue decay. KRILL preconditioning is guaranteed to solve the restricted KRR equations involving a $N \times k$ kernel submatrix in just $\mathcal{O}((N + k^2) k \log k)$ operations, with no assumptions on the kernel matrix or the regularization parameter. Experiments with dozens of data sets validate the effectiveness of RPCholesky and KRILL. Additionally, our theoretical analysis shows that RPCholesky and KRILL have stronger robustness properties compared to other commonly used preconditioners.

[01305] Structured matrix recovery using randomized matrix-vector products

Format : Talk at Waseda University
Author(s) : Diana Halikias (Cornell University)Alex Townsend (Cornell University)
Abstract : Can one recover a matrix efficiently from only matrix-vector products? If so, how many are needed? We describe randomized algorithms of this type for various structured matrices. In particular, we recover an $N \times N$ hierarchical matrix with rank-k off-diagonal blocks using $\mathcal{O}(k \log(N))$ matrix-vector products. While existing algorithms employ a recursive “peeling" procedure of elimination, we use recursive projection, which may be preferable when matrix-vector products are noisy, or for recovering the nearest hierarchical matrix.

[00390] Recent Advances in Machine Learning Theory and Applications

Session Time & Room :

00390 (1/2) : 1C (Aug.21, 13:20-15:00) @E804

00390 (2/2) : 1D (Aug.21, 15:30-17:10) @E804

Type : Proposal of Minisymposium
Abstract : Successful applications of machine learning algorithms usually motivate theoretical studies of their computational and consistent properties. These theoretical studies help researchers and practitioners better understand the algorithms, identify appropriate application domains, and set up hyperparameters to achieve the best performance. On the other side, theoretical studies can also in turn motivate new algorithms by addressing the limitations of existing algorithms. This usually improves the performance in some specific scenarios or broaden the application domains of the existing algorithms. This minisymposium will collect talks on recent advances that address the interplay of mathematical foundations of machine learning and their applications.
Organizer(s) : Andreas Christmann, Han Feng, Qiang Wu
Classification : 68Q32, 68T09

[03668] Learning through empirical gain maximization

Format : Online Talk on Zoom
Author(s) : Yunlong Feng (State University of New York at Albany)Qiang Wu (Middle Tennessee State University)
Abstract : In this presentation, we introduce a novel empirical gain maximization (EGM) framework for addressing robust regression problems with heavy-tailed noise or outliers in the response variable. EGM focuses on approximating the noise distribution's density function rather than directly approximating the truth function. This approach, stemming from minimum distance estimation, allows for the exclusion of abnormal observations, unlike traditional maximum likelihood estimation. We demonstrate that well-known robust nonconvex regression techniques, such as Tukey regression and truncated least square regression, can be reformulated within this new framework. By developing a learning theory for EGM, we provide a unified analysis for these established, yet not fully-understood, regression methods. This framework offers fresh insights into existing bounded nonconvex loss functions and reveals close connections between seemingly unrelated terminologies, such as Tukey's biweight loss and the triweight kernel. We also show that other prevalent bounded nonconvex loss functions in machine learning can be reinterpreted from specific smoothing kernels in statistics. Lastly, our framework facilitates the creation of new bounded nonconvex loss functions for robust learning.

[01357] SKELETAL BASED IMAGE PROCESSING FOR CNN BASED IMAGE CLASSIFICATION

Format : Online Talk on Zoom
Author(s) : Cen Li (Middle Tenn State University)Tsega Tsahai (Middle Tenn State University)
Abstract : This work studies image processing techniques as a preprocessing step in image classification. Deep Learning based Human Pose Estimation was used to preprocess raw image to extract key posture information, and CNN was applied to learn the classification models for human postures. Two applications have been developed: (1) teaching a humanoid robot to play an interactive game of Simon Says, (2) a fall detection system for elderly residents in an assisted living facility.

[01023] Total stability of kernel methods and localized learning

Format : Online Talk on Zoom
Author(s) : Andreas Christmann (University of Bayreuth)Hannes Koehler (University of Bayreuth)
Abstract : Regularized kernel-based methods typically depend on the underlying probability measure P and very few hyperparameters.
We investigate the influence of simultaneous slight pertubations of P, the hyperparameters, and the kernel on the resulting predictor.
Furthermore, kernel methods suffer from their super-linear computational requirements for big data.
Hence we extend our results to the context of localized learning.
The talk is based on Koehler and Christmann, JMLR, 23, 1-41, 2022.

00390 (2/2) : 1D @E804 [Chair: Qiang Wu]

[01397] Learning Ability of Interpolating Convolutional Neural Networks

Format : Talk at Waseda University
Author(s) : Tian-Yi Zhou (Georgia Institute of Technology)Xiaoming Huo (Georgia Institute of Technology)
Abstract : It is frequently observed that overparameterized neural networks generalize well. Regarding such phenomena, existing theoretical work mainly devotes to linear settings or fully connected neural networks.
This paper studies the learning ability of an important family of deep neural networks, deep convolutional neural networks (DCNNs), under underparameterized and overparameterized settings. We establish the best learning rates of underparameterized DCNNs without parameter restrictions presented in the literature. We also show that, by adding well-defined layers to an underparameterized DCNN, we can obtain some interpolating DCNNs that maintain the good learning rates of the underparameterized DCNN. This result is achieved by a novel network deepening scheme designed for DCNNs. Our work provides theoretical verification of how overfitted DCNNs generalize well.

[03542] Classification with Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Lei Shi (Fudan University)Zihan Zhang (Fudan University & City University of Hong Kong)Dingxuan Zhou (University of Sydney)
Abstract : Classification with deep neural networks (DNNs) has made impressive advancements in various learning tasks. Due to the unboundedness of the target function, generalization analysis for DNN classifiers with logistic loss remains scarce. This talk will report our recent progress in establishing a unified framework of generalization analysis

for both bounded and unbounded target functions. Our analysis is based on a novel oracle-type inequality, which enables us to deal with the boundedness restriction of the target function. In particular, for logistic classifiers trained by deep fully connected neural networks, we obtain the optimal convergence rates only by requiring the H"{o}lder smoothness of the conditional probability. Under certain circumstances, such as when decision boundaries are smooth and the two classes are separable, the derived convergence rates can be independent of the input dimension. This talk is based on joint work with Zihan Zhang and Prof. Ding-Xuan Zhou.

[03729] Robust Deep Learning with Applications

Format : Talk at Waseda University
Author(s) : Qiang Wu (Middle Tennessee State University)Shu Liu (Middle Tennessee State University)
Abstract : Deep neural networks are playing increasing roles in machine learning and artificial intelligence. Their performance highly depends on the network architecture and the loss function. The classical square loss is widely known to be sensitive to outliers. We propose the use of robust loss and two stage algorithms for deep neural networks, which are able to extract robust features and deal with outliers effectively. Applications in regression analysis and adversarial machine learning will be discussed.

[00391] Recent Advances in Multiscale Transforms for Image Analysis

Session Time & Room : 4D (Aug.24, 15:30-17:10) @A502

Type : Proposal of Minisymposium
Abstract : This minisymposium will bring together researchers working on multiscale image transforms beyond wavelets and discuss deeper connections between harmonic analysis and image analysis. We plan to discuss various methods to decompose an image into "predictable" local segments and their residuals that allow efficient and sparse image approximation and associated tools based on new types of directional wavelets and monogenic signal representations. The key idea here is how to predict main features, e.g., dominant orientation information in texture images, in each local segment in such a way that the unpredictable portion in that segment is easily compressible or remains as noise.

Organizer(s) : Naoki Saito, Katsu Yamatani

[01735] Multiscale monogenic image representations using Poisson kernels

Format : Talk at Waseda University
Author(s) : Brian Knight (University of California, Davis)Naoki Saito (University of California, Davis)
Abstract : By viewing a 1D signal as the boundary value of a harmonic function in the unit disc in $\mathbb{C}$, one can obtain a multiscale analytic signal representation by supplementing its conjugate counterpart. This is done by the Poisson/Cauchy integral formula. We generalize this for a 2D image by sandwiching it by quaternionic Poisson/Cauchy kernels. This leads to a natural multiscale monogenic image representation. We also plan to discuss its application in oriented texture image analysis.

[02090] Image Interpolation Technique by the PCA of the Gradient Distribution

Format : Talk at Waseda University
Author(s) : Masaki Morita (Meijo University)Yuto Kimura (Meijo University)Katsu Yamatani (Meijo University)Masayoshi Nakagawa (Meijo University)
Abstract : We propose a method to reconstruct local image patches with gradient data and boundary information. In this talk, we present an image interpolation technique based on the principal component analysis of the gradient distribution of image intensities. Our numerical experiments show superiority of our proposed method over previous method based on the interpolation using harmonic functions.

[02079] Improvement of coding procedures for Haar transform-based lossy image compression

Format : Talk at Waseda University
Author(s) : Keita Ashizawa (Shizuoka Institute of Science and Technology)Katsu Yamatani (Meijo University)
Abstract : We discuss an improved version of our Multi−neighbor Predictors and Residual Orthogonal Transformations, MPROT, which was a Haar transform-based lossy image compression method without generating mosquito noise. Due to the slow decay of the Haar coefficients, however, the PSNR values of certain test images compressed by the MPROT were not entirely satisfactory. Our new coding scheme takes advantage of redundancy of the MPROT coefficients and improves high-resolution image compression quality.

[02086] Edge enhancement with directional wavelet transform

Format : Talk at Waseda University
Author(s) : Kensuke Fujinoki (Kanagawa University)Keita Ashizawa (National Institute of Technology, Maizuru College)
Abstract : We introduce a two-dimensional directional discrete wavelet transform that can decompose an image into twelve multiscale nearly isotropic directional edge components. The transform is designed in fully discrete setting and therefore is easy to implement in the spatial domain. Experimental results for image edge detection and enhancement show that both global and local edge structures of images are successfully represented.

[00400] Bilevel optimization in machine learning and imaging sciences

Session Time & Room :

00400 (1/2) : 2C (Aug.22, 13:20-15:00) @A618

00400 (2/2) : 2D (Aug.22, 15:30-17:10) @A618

Type : Proposal of Minisymposium
Abstract : In the framework of functional minimisation approaches, the task of customising the functional expression of both the prior and the likelihood terms to the data at hand by means of a further optimisation problem has been recently popularised under the name of bilevel optimisation. In this minisymposium, we gather experts working in such field both from theoretical and algorithmic perspectives with the intent of providing an overview of how bilevel learning can be effectively employed to estimate data-adaptive regularisation and data models for both imaging and machine learning applications.

[03653] Fixed-Point Automatic Differentiation of Forward--Backward Splitting Algorithms for Partly Smooth Functions

Format : Talk at Waseda University
Author(s) : Sheheryar Mehmood (University of Tuebingen)Peter Ochs (Saarland University)
Abstract : A large class of non-smooth practical optimization problems can be written as minimization of a sum of smooth and partly smooth functions. We consider such structured problems which also depend on a parameter vector and study the problem of differentiating its solution mapping with respect to the parameter which has far reaching applications in sensitivity analysis and parameter learning optmization problems. We show that under partial smoothness and other mild assumptions, Automatic Differentiation (AD) of the sequence generated by proximal splitting algorithms converges to the derivative of the solution mapping. For a variant of automatic differentiation, which we call Fixed-Point Automatic Differentiation (FPAD), we remedy the memory overhead problem of the Reverse Mode AD and moreover provide faster convergence theoretically. We numerically illustrate the convergence and convergence rates of AD and FPAD on Lasso and Group Lasso problems and demonstrate the working of FPAD on prototypical practical image denoising problem by learning the regularization term.

[05289] A framework for bilevel optimization that enables stochastic and global variance reduction algorithms

Format : Talk at Waseda University
Author(s) : Thomas Moreau (Inria - MIND)
Abstract : Bilevel optimization, the problem of minimizing a value function that involves the arg-minimum of another function, appears in many areas of machine learning. In a large-scale empirical risk minimization setting where the number of samples is huge, it is crucial to develop stochastic methods, which only use a few samples at a time to progress. However, computing the gradient of the value function involves solving a linear system, which makes it difficult to derive unbiased stochastic estimates. To overcome this problem we introduce a novel framework, in which the solution of the inner problem, the solution of the linear system, and the main variable evolve at the same time. These directions are written as a sum, making it straightforward to derive unbiased estimates. The simplicity of our approach allows us to develop global variance reduction algorithms, where the dynamics of all variables are subject to variance reduction. This allows to design near-optimal algorithms to solve the bi-level problem.

[03309] Bilevel Optimization with a Lower-level Contraction: Optimal Sample Complexity without Warm-Start

Format : Talk at Waseda University
Author(s) : Saverio Salzo (Sapienza Università di Roma)Riccardo Grazzi (Istituto Italiano di Tecnologia)Massimiliano Pontil (Istituto Italiano di Tecnologia)
Abstract : We present a stochastic algorithm for a general class of bilevel problems consisting of a minimization problem at the upper-level and a fixed-point equation at the lower-level. This setting includes instances of meta-learning, equilibrium models, and hyperparameter optimization. The main feature of our solution is to avoid using the warm-start procedure at the lower-level, which is not always well-suited in applications, and yet to achieves order-wise optimal or near-optimal sample complexity.

[02768] Bilevel subspace optimisation in heterogeneous clustering for cryo-EM

Format : Talk at Waseda University
Author(s) : Willem Diepeveen (University of Cambridge)Carlos Esteve-Yagüe (University of Cambridge)Jan Lellmann (University of Lübeck)Ozan Öktem (KTH Royal Institute of Technology)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : In heterogeneous Cryo-EM we are concerned with retrieving protein conformations from noisy 2D projection images. Attempting to solve this directly is challenging in the absence of a good prior. In recent work, it has been observed that MD simulations live on low-dimensional manifold of conformation space. Although this subspace might not be a perfect reflection of reality, it potentially yields a good prior. In this work we attempt to use this information in Cryo-EM conformation retrieval. In particular, we aim to retrieve conformations and the actual manifold from Cryo-EM data, but we want the manifold to match the MD data. We propose a bilevel optimisation approach to this problem.

00400 (2/2) : 2D @A618 [Chair: Luca Calatroni/Samuel Vaiter]

[05645] Test like you train in implicit deep learning

Author(s) : Pierre Ablin (Apple)
Abstract : Implicit deep learning relies on expressing some components of deep learning pipelines implicitly via a root equation. The training of such a model is thus a bi-level optimization. In practice, the root equation is solved using a fixed number of iterations of a solver. We discuss the effect of having a different number of iterations at test time than at train time, challenging a popular assumption that more iterations at test time improve performance.

[00404] Large-Scale Eigenvalue Computations and Optimization

Session Time & Room :

00404 (1/2) : 1C (Aug.21, 13:20-15:00) @E603

00404 (2/2) : 1D (Aug.21, 15:30-17:10) @E603

Type : Proposal of Minisymposium

Abstract : The minisymposium aims at presenting a few recent developments in large-scale eigenvalue computations and optimization, as well as investigating the intimate connection between them. Of particular interest are not only standard and generalized eigenvalue problems but also nonlinear eigenvalue problems, multiparameter eigenvalue problems, singular value decompositions, and their applications such as those in data science and control theory. Orthogonal transformations and projections to proper subspaces play vital roles for computing and optimizing eigenvalues numerically in the large-scale setting. The minisymposium focuses on the use of such tools in modern algorithms for large-scale eigenvalue computations, optimization, and applications.

[03074] Consistent Estimation Using SVD for a Linear Regression Model

Format : Talk at Waseda University

Author(s) : Kensuke Aishima (Hosei University)

Abstract : In this talk, we consider parameter estimation of an errors-in-variables linear regression model. The standard approach to such parameter estimation is to formulate an optimization problem and solve it numerically using the singular value decomposition (SVD). Using the property that the SVD identifies the image and null spaces of a matrix, with orthogonal projections to the subspaces, we derive a consistent estimator for a linear regression model with the errors in a subset of variables.

[04078] Fast optimization of eigenvalues for frequency-based damping of second-order systems

Format : Online Talk on Zoom

Author(s) : Nevena Jakovčević Stor (University of Split)Tim Mitchell (Queens College / CUNY)Zoran Tomljanović (University of Osijek)Matea Ugrica (Max Planck Institute for Dynamics of Complex Technical Systems)

Abstract : We consider optimizing eigenvalues of certain parametric second-order systems that model vibrating mechanical systems, where the goal is to achieve frequency-weighted damping by moving eigenvalues away from undesirable areas on the imaginary axis. We present two new complementary approaches for this task. First, we propose determining damper viscosities via solving new nonsmooth constrained optimization problems. Second, we also propose a fast new eigensolver for the structured quadratic eigenvalue problems that appear in such vibrating systems.

[02304] Rectangular multiparameter eigenvalue problems

Format : Talk at Waseda University

Author(s) : Bor Plestenjak (University of Ljubljana)Michiel E Hochstenbach (TU Eindhoven)Tomaž Košir (University of Ljubljana)

Abstract : In a rectangular multiparameter eigenvalue problem we have a k-variate, $k \geq 2$, polynomial pencil of rectangular matrices $W(\lambda) \in \mathbb{C}^{(n+k-1)\times n}$ and $\lambda_0 \in \mathbb{C}^k$ is an eigenvalue if ${\rm rank}(W(\lambda_0))

[04501] Simultaneous diagonalization and new bounds on shared invariant subspaces

Format : Talk at Waseda University

Author(s) : Brian Sutton (Randolph-Macon College)

Abstract : Commuting Hermitian matrices may be simultaneously diagonalized by a common eigenvector matrix. However, the numerical aspects are delicate, and existing Jacobi-like algorithms have a prohibitively large operation count on large matrices. We derive new error bounds on shared invariant subspaces and use them to develop a new simultaneous diagonalization algorithm with a running time that is a small multiple of a single eigenvalue-eigenvector computation.

00404 (2/2) : 1D @E603 [Chair: Emre Mengi]

[03188] Estimation of the dominant poles of a large-scale descriptor system

Format : Talk at Waseda University

Author(s) : Emre Mengi (Koc University)

Abstract : The dominant poles of the transfer function of a descriptor system are those poles that can cause large frequency response. They can be used to form reduced-order approximations to the system. We describe a subspace

framework to estimate the dominant poles of a large-scale descriptor system based on Petrov-Galerkin projections. The projection subspaces are expanded gradually by means of the dominant poles of the projected systems. We argue formally that the framework converges quadratically.

[03212] Subspace Methods for Nonlinear Eigenvalue Problems

Format : Talk at Waseda University
Author(s) : Rifqi Aziz (Koc University)Emre Mengi (Koc University)Matthias Voigt (UniDistance Suisse)
Abstract : We will discuss numerical methods for nonlinear eigenvalue problems that are described by matrices of large dimension. We project the large matrices within an interpolatory framework in order to obtain a reduced nonlinear eigenvalue problem that can be solved more efficiently. Based on the eigenpair residuals, new interpolation points and corresponding projection matrices can be computed in order to obtain a few eigenvalues close to a desired target point.

[05296] Optimizing orthogonality in large-scale tensor networks

Format : Talk at Waseda University
Author(s) : Roel Van Beeumen (Lawrence Berkeley National Laboratory)
Abstract : Orthogonality plays a key role in eigenvalue computations. In 1D tensor networks such as tensor trains, the orthogonality is maintained by using QR or truncated SVD factorizations. However, this technique does not extend to 2D tensor networks such as projected entangled pair states (PEPS). Moreover, orthogonality inside a PEPS keeps the computational complexity of eigenvalue evaluations bounded. We will discuss and compare several approximate orthogonalization techniques and strategies for orthogonalizing PEPS columns and rows.

[05462] Linearizability of eigenvector nonlinearities

Format : Online Talk on Zoom
Author(s) : Elias Jarlebring (KTH Royal Institute of Technology)
Abstract : We present a method to linearize, without approximation, a specific class of eigenvalue problems with eigenvector nonlinearities (NEPv), where the nonlinearities are expressed by scalar functions that are defined by a quotient of linear functions of the eigenvector. The exact linearization relies on an equivalent multiparameter problem (MEP) that contains the exact solutions of the NEPv. Based on the linearization we propose numerical schemes that exploit the structure of the linearization.

[00410] Recent advances in Bayesian optimal experimental design

Session Time & Room : 2D (Aug.22, 15:30-17:10) @G304

Type : Proposal of Minisymposium
Abstract : Computational measurement models may involve several uncertain parameters in addition to the unknown quantities of primary interest. In Bayesian optimal experimental design, the goal is to design a measurement configuration, e.g. optimal placement of sensors to collect observational data, which maximizes the expected utility---such as the expected information gain---for obtaining information on the unknown quantities subject to uncertainties in the measurement model. This is especially important when there is a limited budget for collecting actual measurement data. This minisymposium showcases recent theoretical and computational developments to overcome the major challenges encountered in problems arising within this field.

[04376] A transport map approach for Bayesian optimal experimental design

Format : Talk at Waseda University
Author(s) : Karina Koval (Heidelberg University)Roland Herzog (Heidelberg University)Robert Scheichl (Heidelberg University)
Abstract : Solving the Bayesian optimal experimental design (BOED) problem requires optimizing an expectation of a utility function or optimality criterion that assesses the quality of each design. For Bayesian inverse problems with non-Gaussian posteriors, a closed-form expression for the criterion is typically unavailable. Thus, access to a computationally efficient approximation is crucial for numerical solution of the optimal design problem. We propose a flexible approach

for approximating the expected utility function and solving the BOED problem that is based on transportation of measures. The key to our method is the approximation of the joint density on the design, observation and inference parameter random variables via the pushforward of a simple reference density under an inverse Knothe-Rosenblatt (KR) rearrangement. This KR map exposes certain conditional densities which enables approximation of the optimality criterion for any design choice. We present our approach and assess the effectiveness of the resulting optimal designs with some numerical examples.

[04957] Accelerating A-Optimal Design of Experiments Using Neural Networks

Format : Talk at Waseda University
Author(s) : Jinwoo 4702324183 Go (Georgia Institute of Technology)Peng Chen (Georgia Institute of Technology)
Abstract : Designing experiments for large-scale problems demands significant computational resources, and Partial Differential Equation (PDE) surrogates have emerged as a widely-adopted approach to address this challenge. This study enhances this methodology by independently training PDE surrogates and their Jacobians. Leveraging the trained Jacobian of PDEs, we approximate the posterior covariance matrix. Subsequently, we compute the trace of this matrix and evaluate the reduction in uncertainty resulting from executing the experimental setup.

[05059] Stability of Bayesian optimal experimental design in inverse problem

Format : Talk at Waseda University
Author(s) : Tapio Helin (LUT University)Jose Rodrigo Rojo Garcia (LUT University)Duc-Lam Duong (LUT University)
Abstract : In this talk, I will explore the stability properties of Bayesian optimal experimental design towards misspecification of distributions or numerical approximations. Specifically, I will present a framework for addressing this problem in a non-parametric setting, and demonstrate a stability result for the expected utility with respect to likelihood perturbations. To provide a more concrete illustration, I will then consider non-linear Bayesian inverse problems with Gaussian likelihood, where the forward mapping is replaced by an approximation.

[05080] Quasi-Monte Carlo methods for Design of Experiment

Format : Talk at Waseda University
Author(s) : Claudia Schillings (FU Berlin)Vesa Kaarnioja (Free University of BerlinFU Berlin)
Abstract : Bayesian experimental design aims to optimize the placement of measurements in an experiment such that information about unknown quantities is maximized (w.r. to a suitable criterion). The optimization problem requires the evaluation of the information gain, which corresponds to the evaluation of an integral w.r. to the posterior distribution. We will explore the use of quasi-Monte Carlo methods for Bayesian design problems in this talk and present convergence results.

[00413] Numerical Methods for Dispersive PDEs and Applications

Session Time & Room :

00413 (1/2) : 4D (Aug.24, 15:30-17:10) @G605

00413 (2/2) : 4E (Aug.24, 17:40-19:20) @G605

Type : Proposal of Minisymposium
Abstract : Dispersive partial differential equations (PDEs) play a fundamental role in many fields such as the nonlinear optics, water wave theory, quantum mechanics, etc. From the perspective of computational mathematics, it is significant to design efficient numerical methods to solve dispersive PDEs with in-depth numerical analysis and provide an intuitive view for physical phenomena. The proposed minisymposium invites experts in this field to review recent advances in numerical methods for dispersive PDEs and applications.

[05510] Numerical studies of two regularized versions of the cubic NLS

Format : Online Talk on Zoom
Author(s) : Christof Sparber (University of Illinois Chicago)
Abstract : We consider two types of regularization for the focusing, cubic nonlinear Schrödinger equation (NLS) posed in two and/or three spatial dimensions. One type of regularization is given by a defocusing quintic nonlinearity, while the other is given by a second order elliptic differential operator, describing off-axis variations of the NLS in the context of laser physics. While the non-regularized NLS is know to exhibit finite-time blow-up, these augmented equations are proved to be globally well-posed. In both cases we numerically investigate the long time behavior of solutions using a time-splitting method. In particular, we are interested in the orbital (in-)stability of least action ground states in the radially symmetric case. This is joint work with Christian Klein, Remi Carles, and Jack Arbunich.

[05557] Dirac equations for the modeling of electron dynamics on strained graphene surfaces

Format : Talk at Waseda University
Author(s) : Emmanuel Lorin de la Grandmaison (Carleton University)
Abstract : This talk is devoted to the modelling of the dynamics of electrons on strained graphene surfaces. A hierarchy of mathematical models will be derived, and some numerical experiments illustrating the scattering of wave packets on locally deformed graphene will be proposed

[02732] Low regularity exponential-type integrators for the "good" Boussinesq equation

Format : Talk at Waseda University
Author(s) : Chunmei Su (Tsinghua University)Hang Li (Tsinghua University)
Abstract : We introduce a series of semi-discrete low regularity exponential-type time integrators for the “good” Boussinesq equation. Compared to the existing numerical methods, the temporal convergence of ours can be achieved under weaker regularity assumptions on the exact solutions. The methods are constructed based on twisted variables and some harmonic analysis techniques in approximating the exponential integral. The methods are explicit and easy to be implemented efficiently when combined with pseudospectral method for spatial discretization.

[04017] Computational methods for stationary states of nonlinear Schrödinger/Gross-Pitaevskii equations

Format : Talk at Waseda University
Author(s) : Wei Liu (National University of Singapore)
Abstract : I will present some recent advances in the computation of stationary-state solutions to the nonlinear Schrödinger/Gross-Pitaevskii equations, primarily in the context of Bose-Einstein condensation. The (normalized) energy ground/excited states and action ground states will be mainly considered. Based on the analysis of variational characterizations and stabilities/instabilities for these stationary-state solutions, efficient and accurate numerical methods utilizing novel artificial dynamical flows and/or optimization techniques will be developed, with further extensions to challenging high-spin or fast-rotating models.

00413 (2/2) : 4E @G605 [Chair: Yue Feng]

[05499] Scattering and uniform in time error estimates for splitting method in NLS

Format : Online Talk on Zoom
Author(s) : Rémi Carles (CNRS & Univ Rennes)Chunmei Su (Tsinghua University)
Abstract : We consider the nonlinear Schrödinger equation with a defocusing nonlinearity which is mass-(super)critical and energy-subcritical. We prove uniform in time error estimates for the Lie–Trotter time splitting discretization. This uniformity in time is obtained thanks to a vectorfield which provides time decay estimates for the exact and numerical solutions. This vectorfield is classical in scattering theory and requires several technical modifications compared to previous error estimates for splitting methods.

[05587] Resonances as a computational tool

Format : Online Talk on Zoom
Author(s) : Katharina Schratz (Sorbonne University)
Abstract : A large toolbox of numerical schemes for dispersive equations has been established, based on different discretization techniques such as discretizing the variation-of-constants formula (e.g., exponential integrators) or splitting the full equation into a series of simpler subproblems (e.g., splitting methods). In many situations these classical schemes allow a precise and efficient approximation. This, however, drastically changes whenever non-smooth phenomena enter the scene such as for problems at low regularity and high oscillations. Classical schemes fail to capture the oscillatory nature of the solution, and this may lead to severe instabilities and loss of convergence. In this talk I present a new class of resonance based schemes. The key idea in the construction of the new schemes is to tackle and deeply embed the underlying nonlinear structure of resonances into the numerical discretization. As in the continuous case, these terms are central to structure preservation and offer the new schemes strong geometric properties at low regularity.

[01752] Error estimates of numerical methods for the nonlinear Schr" {o}dinger equation with low regularity potential and nonlinearity

Format : Talk at Waseda University
Author(s) : Weizhu Bao (National University of Singapore)Chushan Wang (National University of Singapore)
Abstract : We prove optimal error bounds of time-splitting methods and the exponential wave integrator for the nonlinear Schr"{o}dinger equation (\text{(NLSE)}) with low regularity potential and nonlinearity, including purely bounded potential and locally Lipschitz nonlinearity. Arising from different physical applications, low regularity potential and nonlinearity are introduced into the NLSE such as the discontinuous potential or non-integer power nonlinearity, which make the error estimates of classical numerical methods very subtle and challenging.

[00418] Nonlinear PDE: beyond the well-posedness theory

Session Time & Room : 2C (Aug.22, 13:20-15:00) @F402

Type : Proposal of Minisymposium
Abstract : The theory of nonlinear partial differential equations (PDEs) is of fundamental importance in mathematical analysis, and through recent developments, it has reached a stage where some difficult and important questions beyond the well-posedness theory can be fruitfully addressed. The aim of this session focuses on a large class of nonlinear PDEs particularly related to Hamilton-Jacobi equations, level-set mean curvature flow equations, mean field games, and reaction diffusion equations, and brings experts to give a constructive and inspiring reflection on the state of the literature surrounding such equations, which will boost some further research in related areas.

[01572] Hessian Riemannian flows in mean-field games

Format : Talk at Waseda University
Author(s) : Diogo Gomes (KAUST)
Abstract : Hessian Riemannian flows are a powerful tool for the construction of numerical schemes for monotone mean-field games that have their origin in constrained optimization problems. In this talk, we discuss the general construction of these flows for monotone mean-field games, their existence and regularity properties, and their asymptotic convergence.

[02413] Homogenization of Reactions in Random Media

Format : Talk at Waseda University
Author(s) : Yuming Paul Zhang (Auburn University)Andrej Zlatos (University of California, San Diego)
Abstract : Homogenization is a general phenomenon when physical processes in periodic or random environments exhibit homogeneous long time dynamic due to large space averaging of the variations in the environment. While this area of Mathematics saw a slew of remarkable developments in the last 20 years, the progress in the case of reaction-diffusion equations has been somewhat limited due to the homogenized dynamic involving discontinuous solutions to

different (first-order) equations. In this talk I will discuss stochastic homogenization for reaction-diffusion equations in several spatial dimensions. These include the cases of both time-independent and time-dependent reactions, with the later proof employing a new subadditive ergodic theorem for time-dependent environments. This talk is based on joint works with Andrej Zlatoš.

[02535] Continuum limit of dislocations with annihilation in one dimension

Format : Talk at Waseda University
Author(s) : Norbert Pozar (Kanazawa University)
Abstract : In this talk I discuss the many-particle limit for a system of particles in one dimension. The particles carry a signed charge, interact via a Newtonian potential and when two particles with opposite charges meet, they annihilate and are removed from the system. This serves as a simplified model of dislocation dynamics in a crystalline lattice. This talk is based on joint work with Mark Peletier and Patrick van Meurs.

[04586] Quantitative periodic homogenization of a front propagation model in dynamic environments

Format : Talk at Waseda University
Author(s) : Wenjia Jing (Tsinghua University)
Abstract : In this talk we review the developments of homogenization theory for a front propagation model. It is described by a first order Hamilton-Jacobi equation with a Hamiltonian that grows linearly with respect to the absolute value of the momentum variable. We focus on the case of dynamic environment where the Hamiltonian has highly oscillations in time as well as in space. We present some key steps in the proof of the qualitative homogenization theory and in the quantification of the convergence rate in the periodic setting. The talk is based on several joint works with Souganidis, Tran and Yu.

[00420] Painlevé equations, Applications, and Related Topics

Session Time & Room :

00420 (1/4) : 2D (Aug.22, 15:30-17:10) @A617

00420 (2/4) : 2E (Aug.22, 17:40-19:20) @A617

00420 (3/4) : 3C (Aug.23, 13:20-15:00) @A617

00420 (4/4) : 3D (Aug.23, 15:30-17:10) @A617

Type : Proposal of Minisymposium
Abstract : Recently, problems arising in statistical and probabilistic models with an underlying integrable structure have been found to possess deep links to continuous and discrete Painlevé equations.
The theory of Painlevé equations has therefore come to play an increasingly important role in the study of such problems. The way in which Painlevé equations appear, and the types of equations that appear in these problems pose deep questions on the side of the theory of Painlevé equations.
This mini-symposium aims to bring together experts both in Painlevé equations and the broad range of problems in which they appear, and illustrate this interplay.

[04296] The Identification Problem for Discrete Painlevé Equations

Format : Talk at Waseda University
Author(s) : Anton Dzhamay (University of Northern Colorado and BIMSA)
Abstract : We describe a refined version of the discrete Painlevé equations identification problem. We emphasize that, in addition to determining the surface type of the equation, it is important to determine the actual translation element, up to conjugation, and to keep in mind possible special point configurations that can affect the symmetry group of the

equation. We illustrate this by a variety of examples that appear in applications, especially in the theory of orthogonal polynomials.

[04597] Orthogonal polynomials and discrete Painlevé equations on the $D_5^{(1)}$ Sakai surface

Format : Talk at Waseda University
Author(s) : Alexander Stokes (The University of Tokyo)Anton Dzhamay (University of Northern Colorado)Galina Filipuk (University of Warsaw)
Abstract : We show that two recurrences coming from the theory of orthogonal polynomials are transformable to discrete Painlevé equations, which share the same surface type $D_5^{(1)}$ in the Sakai classification scheme but are non-equivalent.
The surfaces associated with these recurrences do not have the full parameter freedom for their type, and we find the symmetry groups of these examples as subgroups of the extended affine Weyl group of type $A_3^{(1)}$ from the generic case.

[03019] Orthogonal polynomials, Schur flow and Painlevé equations

Format : Talk at Waseda University
Author(s) : Walter Van Assche (KU Leuven)
Abstract : We give a brief introduction to orthogonal polynomials on the unit circle and show how an exponential modification of the weight function leads to the Ablowitz-Ladik lattice equations for the recurrence coefficients (Verblunsky coefficients) of these polynomials. As shown by Periwal and Shevitz (1990) these orthogonal polynomials appear in unitary matrix models. The Verblunsky coefficients satisfy the discrete Painlevé II equation and the ratio of these coefficients satisfy Painlevé III. The Lax pair can be written in terms of the CMV matrix, which is a pentadiagonal infinite matrix similar to the Jacobi matrix for orthogonal polynomials on the real line.

[04527] Symmetries of discrete Nahm systems and Normalizers in Coxeter groups

Format : Online Talk on Zoom
Author(s) : yang shi (Flinders university)Giorgio Gubbiotti (Universita degli Studi di Milano)
Abstract : It is known that discrete Nahm systems arise as autonomous versions of
Sakai's classification of discrete Painlev\e equations. Here we study the groups of symmetries of these systems using the theory of normalizers of Coxeter groups developed by Brink and Howlett (Invent. Math, 1999).

00420 (2/4) : 2E @A617 [Chair: Tomoyuki Takenawa]

[04366] On the bilinear equations of the Painlev'e transcendents

Format : Talk at Waseda University
Author(s) : Hidetaka Sakai (University of Tokyo)Tatsuya Hosoi (University of Tokyo)
Abstract : The sixth Painlev'e equation is a basic equation with three fixed singular points, corresponding to Gauss's hypergeometric differential equation among linear equations. Similar to hypergeometric equation, for nonlinear equations, we would like to determine the equation from the local behavior around the three singularities. In this talk, the sixth Painlev'e equation is derived by imposing the condition that it is of type (H) at each three singular points for quadratic 4th-order differential equation.

[04932] Large-degree asymptotics of Generalized Hastings-McLeod functions

Format : Talk at Waseda University
Author(s) : Robert Buckingham (University of Cincinnati)
Abstract : The Generalized Hastings-McLeod functions form an infinite sequence of solutions to the inhomogeneous Painleve-II equation. The functions have recently arisen in a variety of random matrix and interacting particle system problems. Using Riemann-Hilbert analysis and the nonlinear steepest-descent method, we establish the leading-order asymptotic behavior inside and outside the pole region as the inhomogeneous term tends to infinity. This is joint work with Kurt Schmidt.

[04515] Spaces of initial values for equations with the quasi-Painleve property

Format : Online Talk on Zoom
Author(s) : Thomas Kecker (University of Portsmouth)
Abstract : Considering differential equations and Hamiltonian systems with the property that all movable singularities of all their solutions in the complex plane are algebraic poles (quasi-Painlevé property), we generalise the concept of the

Okamoto's space of initial values for these types of equations. Starting from a general equation with analytic coefficient functions, the construction of this space yields certain differential conditions on these functions that are equivalent to the resonances found e.g. by the (quasi-)Painlevé test.

[02754] On the (quasi-)Painleve equations

Format : Online Talk on Zoom
Author(s) : Galina Filipuk (University of Warsaw)
Abstract : Painleve equations are second order nonlinear differential equations solutions of which have no movable critical points. They appear in many applications. For solutions of quasi-Painleve equations algebraic singularities are allowed. The so-called geometric approach may help in many cases to understand the nature of singularities. In this talk I shall present some recent results on the geometric approach for the Painleve and quasi-Painleve equations. This is a joint work with A. Stokes.

00420 (3/4) : 3C @A617 [Chair: Anton Dzhamay]

[03574] A dynamical systems approach to map enumeration

Format : Online Talk on Zoom
Author(s) : Joceline Lega (University of Arizona)
Abstract : Freud orbits are trajectories of discrete Painlevé equations that describe the evolution of recurrence coefficients for orthogonal polynomials. We will introduce a nonlinear transformation, which converts a Freud orbit into a solution that converges towards a fixed point along a center manifold. Subsequent analysis will lead to an asymptotic expansion whose terms are generating functions for map enumeration. Examples of map counts will be provided. This is joint work with Nick Ercolani and Brandon Tippings.

[03010] An affine Weyl group action on the basic hypergeometric series

Format : Talk at Waseda University
Author(s) : Takao Suzuki (Kindai University)
Abstract : Recently, we formulated a higher order generalization of the q-difference Painlevé equations called the q-Garnier system in a framework of an extended affine Weyl group of type $A^{(1)}_{2n+1} \times A^{(1)}_1 \times A^{(1)}_1$.
On the other hand, the q-Garnier system admits a particular solution in terms of the basic hypergeometric series ${}_{n+1}\phi_n$.
In this talk, we investigate an action of the extended affine Weyl group on ${}_{n+1}\phi_n$.

[03311] On the growth properties of some families of birational maps

Format : Online Talk on Zoom
Author(s) : Giorgio Gubbiotti (Universita degli Studi di Milano)Michele Graffeo (Politecnico di Milano)
Abstract : We characterise the growth and integrability properties of a family of elements in the Cremona group of a complex projective space in dimension three using techniques from algebraic geometry. This collection consists of maps obtained by composing the standard Cremona transformation $\mathrm{c}_3 \in \mathrm{Bir}(\mathbb{P}^3)$ with projectivities permuting the fixed points of c_3 and the points over which c_3 performs a divisorial contraction. Time permitting, we discuss the possible extensions of this construction to higher dimensions.

[05042] Laguerre (q-Laguerre) Weight Recurrence and Geometric Theory of Painlevé equations

Format : Online Talk on Zoom
Author(s) : Jie Hu (Jinzhong University（晋中学院）)
Abstract : The Sakai geometric theory of Painlevé equations is useful for identify difference or differential equations as corresponding Painlevé equations. In this talk we consider two examples of recurrence relations appearing in study of recurrence coefficients of semi-classical orthogonal polynomials, namely, polynomials with Laguerre weight and with the deformed q-Laguerre weight. Using the geometry, we give explicit change of variables matching these equations with some standard discrete Painlevé equations.

00420 (4/4) : 3D @A617 [Chair: Alexander Stokes]

[04054] Folding transformations for q-Painleve equations

Format : Online Talk on Zoom
Author(s) : Mikhail Bershtein (Kavli IPMU, Landau Institute and Skoltech)
Abstract : Folding transformation of the Painleve equations is an algebraic (of degree greater than 1) transformation between solutions of different equations. In 2005 Tsuda, Okamoto and Sakai classified folding transformations of differential Painleve equations. These transformations are in correspondence with automorphisms of affine Dynkin diagrams. We give a complete classification of folding transformations of the q-difference Painleve equations, these transformations are in correspondence with certain subdiagrams of the affine Dynkin diagrams (possibly with automorphism). The method is based on Sakai's approach to Painleve equations through rational surfaces.
Based on joint work with A. Shchechkin [arXiv:2110.15320]

[04739] Laguerre (q-Laguerre) Weight Recurrence and Geometric Theory of Painlevé equations

Format : Online Talk on Zoom
Author(s) : Jie HU (Jinzhong University)
Abstract : Sakai's geometric theory of Painlevé equations is used to identify difference or differential equations with corresponding Painlevé equations. In this talk we will consider two classes of examples of recurrence coefficients of semi-classical orthogonal polynomials: Laguerre weight and the deformed q-Laguerre weight. We will gives the identification procedure on how to deduce related solutions of canonical discrete Painlevé equations from coefficients. Meanwhile, we also give the explicit birational function of variables achieving that reduction.

[00421] When random comes to the rescue of numerical computation

Session Time & Room : 4D (Aug.24, 15:30-17:10) @E506

Type : Proposal of Minisymposium
Abstract : The need of efficient IA and deep learning applications has impulse a new way of performing floating-point computations based on low precision representation formats and their corresponding hardware support.
Among the peculiarity raised is the need of operators, analyses, methodologies, and tools to estimate accuracy needs, overcome unwanted behaviors such as stagnation (numerical loss during sequences of tiny updates) and optimize performance.
In this minisymposium, we will focus on a few aspects of randomization in numerical computation, covering its advantages for IA applications, probabilistic error analysis, variant of stochastic rounding mode and the detection of numerical abnormalities and precision analysis.
Organizer(s) : David DEFOUR
Classification : 65CXX, 65Yxx
Minisymposium Program :

00421 (1/1) : 4D @E506 [Chair: David DEFOUR]

[02748] The computer arithmetic new deal: AI is pushing the frontier

Format : Talk at Waseda University
Author(s) : Eric Petit (Intel)
Abstract : Recent years have seen a tremendous number of new research contributions to computer arithmetic, challenging lower precision arithmetic and rounding mode, leaving the IEEE754 standard far behind. This all comes from the rise of AI workloads as one of the main driver in the data center software and architecture design. Keeping on par with the incredibly fast changing usage of computer arithmetic has push our algorithms, tools, and capacity to their limit.
This is an opportunity to rethink and redesign our approach about floating point hardware and software, promoting new tools and methodologies, and allowing ground breaking solution to be promoted to main stream software and hardware implementation.
In this talk I will provide some more context about this change and discuss some of the exciting work I am sharing with collaborators inside and outside intel.

[01590] New stochastic rounding modes for numerical verification

Format : Talk at Waseda University
Author(s) : Bruno LATHUILIERE (EDF R&D)Nestor Demeure (Data and analytics services group, National Energy Research Scientific Computing Center, Berkeley)
Abstract : In the context of industrial code verification, the use of stochastic rounding modes allows to estimate the numerical quality of the results through multiple independent executions of the software. But in some rare cases, the introduction of stochastic rounding can lead to a runtime error because the software implicitly relies on the determinism of IEEE floating-point operations.
To overcome this problem, we propose new deterministic stochastic rounding modes: these maintain the stochastic properties between different executions of the software while guaranteeing the determinism of the floating operations having the same parameters within one execution. Results based on an implementation of the method in the Verrou tool will be presented.

[04711] Stochastic rounding as a model of round-to-nearest

Format : Talk at Waseda University
Author(s) : Devan Sohier (LI-PaRAD, UVSQ)
Abstract : Round-to-nearest (RN), the default rounding mode in the omnipresent IEEE754 standard, is difficult to analyze. Deterministic bounds, as well as their refinements like interval arithmetic, generally prove overly pessimistic, compared to the day-to-day observations of numerical scientists. Stochastic rounding (SR) may be used as a model of RN, the results of which are easier to analyze, and closer to these observations. In this talk, I will present a methodology to analyze results of a SR simulation of RN. The widely used formula for the number of significant bits $-\log\frac{\sigma}{\mu}$ can be refined and given a precise statistical ground in the case when the error has a normal distribution; when no normality assumption is substantiated, other tools based on Bernoulli estimations need to be used. Using SR as a model for RN also has some limits: SR does not present stagnation phenomena typical of RN, and SR also does not give the same results when the program recomputes twice the same operation. Finally, I will discuss flaws of various severeness of some software implementations of SR, and present some remarks regarding possible future implementations of SR, both in software and hardware.

[03452] VPREC to analyze the precision appetites and numerical abnormalities of several proxy applications

Format : Talk at Waseda University
Author(s) : Roman Iakymchuk (Umeå University)Pablo de Oliveira Castro (Université Paris-Saclay)
Abstract : The energy consumption constraint for large-scale computing encourages scientists to revise the architecture design of hardware but also applications, algorithms, as well as the underlying working/ storage precision. We introduce an approach to address the issue of sustainable computations from the perspective of computer arithmetic tools. We employ the variable precision backend (VPREC) to identify parts of code that can benefit from smaller floating-point formats. Finally, we show preliminary results on several proxy applications.

[00426] Variational methods for thin structures and free-boundary problems

Session Time & Room :

00426 (1/3) : 4C (Aug.24, 13:20-15:00) @F312

00426 (2/3) : 4D (Aug.24, 15:30-17:10) @F312

00426 (3/3) : 4E (Aug.24, 17:40-19:20) @F312

Type : Proposal of Minisymposium
Abstract : Thin structures are classically studied using variational methods and PDEs, and they may be described both by surfaces and by free interfaces. On one hand, surfaces appear for modeling soap films and biological membranes minimizing suitable energy functionals, like area and Canham-Helfrich functionals. On the other hand, free interfaces separate a domain whose boundary is free: it is not known a priori and it depends on the solution of a PDE. Such a free-boundary problems naturally arise in many different models in Physics and Engineering, like for instance the Bernoulli one-phase problem.
Organizer(s) : Giulia Bevilacqua, Luca Lussardi
Classification : 49J45, 49Q05, 49Q10, 35R35, 76D27
Minisymposium Program :

00426 (1/3) : 4C @F312 [Chair: Luca Lussardi]

[03469] On the Kircchoff-Plateau problem: critical points and regularity

Format : Talk at Waseda University
Author(s) : Giulia Bevilacqua (Università di Pisa)
Abstract : In this talk I will discuss some generalization of the Plateau problem, which in its classical form asks if it exists a surface of minimal area spanning a given boundary. First-order necessary conditions and regularity properties are studied when a thick rod (with non vanishing thickness) and/or an elastic curve are assigned as the boundary spanned by the surface.

[02176] On Stationary Points of Polyconvex Functionals

Format : Talk at Waseda University
Author(s) : Riccardo Tione (MPI MiS Leipzig)Camillo De Lellis (Institute for Advanced Study)Guido De Philippis (Courant Institute of Mathematics)Antonio De Rosa (University of Maryland)Jonas Hirsch (Universität Leipzig)Bernd Kirchheim (Universität Leipzig)
Abstract : Quasi- and polyconvex energies arise naturally in modeling physical phenomena related to elasticity. From the mathematical viewpoint, a challenging question concerns the regularity of critical/stationary points and minimizers of these energies. My talk focuses on recent results in this direction concerning stationary points, i.e. critical points subject to outer and inner variations. I also address the application of this question to geometric measure theory.

[04199] Minimization of the Canham-Helfrich within generalised Gauss graphs

Format : Talk at Waseda University
Author(s) : Anna Kubin (Politecnico di Torino)Luca Lussardi (Politecnico di Torino)Marco Morandotti (Politecnico di Torino)
Abstract : The Canham-Helfrich functional is the most widely used functional to study the equilibrium of biological membranes as a result of the competition between mean curvature and Gaussian curvature.
In this talk, we review some approaches to the minimisation problem for this functional and present novel results in the setting of generalised Gauss graphs.
This is joint work with Anna Kubin and Luca Lussardi.

[03181] A capillarity theory approach to the analysis of soap films

Format : Online Talk on Zoom
Author(s) : Salvatore Stuvard (University of Milan)Darren King (New York University)Francesco Maggi (University of Texas at Austin)Antonello Scardicchio (Abdus Salam ICTP)
Abstract : I will present a variational model, based on Gauss' theory of capillarity, which describes soap films as sets of finite perimeter enclosing a prescribed volume of fluid and satisfying a spanning condition of homotopic type, rather as minimal surfaces. I will discuss the corresponding existence theory, the sharp regularity properties of the minimizers, their asymptotic behavior in the vanishing volume limit, and I will attempt a qualitative description of their local and global geometry.

00426 (2/3) : 4D @F312 [Chair: Marco Morandotti]

[04117] Stable Möbius bands obtained by isometrically deforming circular helicoids

Format : Talk at Waseda University
Author(s) : Eliot Fried (Okinawa Institute of Science and Technology)Vikash Chaurasia (Okinawa Institute of Science and Technology)
Abstract : We consider a variational problem for finding an isometric deformation from a (circular helicoid to a stable Möbius band. Helicoids with certain specific numbers of turns yield stable bands with (n=2k+1), (k\ge1), half twists and (n)-fold rotational symmetry. Each such band has the least energy of any stable competitor with the same number of half twists. Helicoids with other numbers of turns yield two stable bands with equal energy but different numbers of half twists.

[02967] Rectifiability for flat singularities of higher codimension area minimizers

Format : Talk at Waseda University
Author(s) : Camillo De Lellis (Institute for Advanced Study)
Paul Minter (Princeton University)
Anna Skorobogatova (Princeton University)
Abstract : Integral currents provide a natural setting in which to study the Plateau problem, but permit the formation of singularities in area-minimizers. The problem of determining the size and structure of the interior singular set of an area-minimizer in this setting has been studied in great detail since the 1960s, with many ground-breaking contributions. When the codimension is higher than 1, due to the presence of singular points with high multiplicity flat tangent cones, little progress has been made since Almgren's celebrated (m-2)-Hausdorff dimension bound on the singular set, the proof of which has since been simplified by De Lellis and Spadaro.

In this talk I will discuss joint work with Camillo De Lellis and Paul Minter, in which we achieve (m-2)-rectifiability for the singular set.

[03455] Interior regularity for stationary two-dimensional multivalued maps

Format : Talk at Waseda University
Author(s) : Jonas Hirsch (University of Leipzig)Luca Spolaor (UCSD)
Abstract : Q-valued maps minimizing a suitably defined Dirichlet energy were introduce by Almgren in his proof of the optimal regularity of area minimizing currents in any dimension and codimension. In this talk I will discuss the extension of Almgren's result to stationary Q-valued maps in dimension 2. This is joint work with Jonas Hirsch (Leipzig).

[03306] Transport of currents and geometric Rademacher-type theorems

Format : Online Talk on Zoom
Author(s) : Paolo Bonicatto (University of Warwick)
Abstract : Given a vector field b on $\mathbb{R}^d$, one usually studies the transport/continuity equation drifted by b looking for solutions in the class of functions or at most in the class of measures. I will talk about recent efforts, motivated by the modeling of defects in crystalline materials, aimed at extending the previous theory to the case when the unknown is instead a family of k-currents in $\mathbb{R}^d$.

00426 (3/3) : 4E @F312 [Chair: Giulia Bevilacqua]

[02741] Long time behavior and stability of surface diffusion flow

Format : Talk at Waseda University
Author(s) : Antonia Diana (Scuola Superiore Meridionale)
Abstract : We present a long-time existence and stability result for the surface diffusion flow in the flat torus.
According to this flow, smooth hypersurfaces move with the outer normal velocity given by the Laplacian of their mean curvature.
We show that if the initial set is sufficiently `close'' to a stable critical set for the volume-constrained Area functional, then the flow exists for all times and asymptotically converges to a`translation" of the critical set.

[03626] Graphical solutions to one-phase problems

Format : Talk at Waseda University
Author(s) : Hui Yu (National University of Singapore)Max Engelstein (University of Minnesota-Twin Cities)Xavier Fernandez-Real (Ecole Polytechnique Federale de Lausanne)
Abstract : The free boundaries of solutions (critical points of the functional) to the one-phase problem can have rich geometry. Such richness can be reduced by imposing the graphical condition.

In this talk, we show that if homogeneous minimizers are trivial in dimension k, then graphical solutions are trivial in dimension k+1. This works for both the classical one-phase problem as well as its thin counterpart.

This talk is based on a joint work with Max Engelstein (Minnesota) and Xavier Fernandez-Real (EPFL).

[04656] Regularity of the optimal shapes for a class of integral functionals

Format : Online Talk on Zoom
Author(s) : Bozhidar Velichkov (Università di Pisa)
Abstract : This talk is dedicated to the regularity of solutions to the following variational problem
$\min\Big\{J(\Omega)\ :\ \Omega\subset D\Big\}$,
where $D\subset\mathbb{R}^d$ is a given bounded open set and J is a functional of the form
$J(\Omega)=\int_\Omega j(x,u_\Omega)\,dx+|\Omega|\,,$
where $j:D\times\mathbb{R}\to\mathbb{R}$ is a given "cost function" and u_Ω is the solution to
$-\Delta u_\Omega=f(x)\quad\text{in}\quad\Omega\,,\qquad u_\Omega\in H^1_0(\Omega)\,,$
where $f:D\to\mathbb{R}$ is a fixed function. We will discuss the case $j(x,u_\Omega)=-g(x)u_\Omega$, which leads to a free boundary system of the form
\begin{align}
-\Delta u\Omega=f(x)&\quad\text{in}\quad\Omega\
-\Delta v\Omega=g(x)&\quad\text{in}\quad\Omega\
u\Omega=v\Omega=0&\quad\text{on}\quad\partial \Omega\
|\nabla u\Omega||\nabla v\Omega|=1&\quad\text{on}\quad\partial \Omega
\end{align}
We will show that, if the functions f and g are positive and comparable, and if the dimension d of the ambient space is 2, 3, or 4, then any optimal set Ω is $C^{1,\alpha}$ smooth (and solves the above system in the classical sense). The talk is based on joint works with Giorgio Tortone (University of Pisa) and Francesco Paolo Maiale (Scuola Normale Superiore), and on a joint work with Giuseppe Buttazzo (University of Pisa), Francesco Paolo Maiale (Scuola Normale Superiore), Dario Mazzoleni (University of Pavia), and Giorgio Tortone (University of Pisa).

[04579] Min-max minimal surfaces with contact angle conditions

Format : Online Talk on Zoom
Author(s) : Luigi De Masi (University of Padova)
Abstract : Existence and regularity of minimal surfaces (i.e. stationary points for area functional) has been an active topic of research for the last decades. When minimizing strategies produce just trivial solutions, min-max methods may be successfully used.
In this talk, based on a joint work with G. De Philippis, I will discuss min-max construction of a minimal surface Σ in a container $\mathcal{M}\subset\mathbb{R}^3$ which meets $\partial\mathcal{M}$ with a fixed angle.

[00432] Empirically Driven Deep Learning Theory

Session Time & Room :

00432 (1/2) : 2D (Aug.22, 15:30-17:10) @E812

00432 (2/2) : 2E (Aug.22, 17:40-19:20) @E812

Type : Proposal of Minisymposium
Abstract : Deep learning has become increasingly popular recently due to its superior performance on a variety of tasks. However, understanding the mathematical foundations of deep networks is challenging because they are highly parameterized and built using complex computational heuristics.

This session features recent works in mathematical deep learning theory based on empirically-driven, phenomenological approaches: the works first reveal prevalent phenomena observed across multiple deep learning settings; then, they propose new mathematical explanations for these phenomena. These mathematical results give important insights into the generalization of deep nets, the efficiency of their optimization, and their robustness to adversarial noise and data imbalance.
Organizer(s) : X.Y. Han, Weijie Su

00432 (1/2) : 2D @E812 [Chair: X.Y Han & Weijie Su]

[02983] How different optimizers select the global minimizer in deep learning

Format : Talk at Waseda University
Author(s) : Weinan E (Peking University)
Abstract : It has been observed in deep learning that different optimization process converges to different global minimum.
We analyze this process by studying the stability of the minimum for the optimization algorithm. We find numerically that in practice, the numerical solutions often live at the so-called "edge of stability". We also study the relationship between the "sharpness" and "non-uniformity" of the global minimum. We present arguments that confirm the hypothesis that flat solution tends to generalize better. This is joint work with Chao Ma of Stanford University and Lei Wu of Peking University.

[03263] A Law of Data Separation in Deep Learning

Format : Talk at Waseda University
Author(s) : Hangfeng He (University of Rochester)Weijie Su (University of Pennsylvania)
Abstract : While deep learning has enabled significant advances in many areas of science, its black-box nature hinders architecture design for future artificial intelligence applications and interpretation for high-stakes decision makings. We addressed this issue by studying the fundamental question of how deep neural networks process data in the intermediate layers. Our finding is a simple and quantitative law that governs how deep neural networks separate data according to class membership throughout all layers for classification. This law shows that each layer improves data separation at a constant geometric rate, and its emergence is observed in a collection of network architectures and datasets during training. This law offers practical guidelines for designing architectures, improving model robustness and out-of-sample performance, as well as interpreting the predictions.

[03057] Neural Collapse in Deep Learning

Format : Talk at Waseda University
Author(s) : Vardan Papyan (University of Toronto)
Abstract : In this talk, we'll delve into Neural Collapse - a recently discovered phenomenon in deep learning that emerges in the final phase of model training. Additionally, we'll explore how this phenomenon relates to the interpretability, robustness, and generalization performance of deep learning models.

[03168] Memorization-Dilation: A Novel Model for Neural Collapse in Deep Neural Network Classifiers

Format : Online Talk on Zoom
Author(s) : Gitta Kutyniok (LMU Munich)Duc Anh Nguyen (---)Ron Levie (Technion)Julian Lienen (University of Paderborn)Eyke Hüllermeier (LMU Munich)
Abstract : The notion of neural collapse refers to several emergent phenomena that have been empirically observed across various canonical classification problems. In this talk, we introduce a more realistic mathematical model than the classical layer-peeled model, which takes both the positivity of the features and the limited expressivity of the network into account. For this, we then show results about the performance of the trained network in the sense of generalization properties.

00432 (2/2) : 2E @E812 [Chair: X.Y. Han & Weijie Su]

[04878] Understanding Deep Learning Through Optimization Geometry

Format : Talk at Waseda University
Author(s) : Nathan Srebro (TTIC)
Abstract : I will survey the approach emerging in recent years for understanding deep learning through the optimization geometry in function space induced by the architecture. To appreciate this view, its ability to explain empirical phenomena, and also its limitations, we will see how many phenomena can be understood through a detailed study of optimization geometry in a simple deep linear model.

[04289] Feature Learning in Two-Layer Neural Networks

Format : Talk at Waseda University
Author(s) : Murat Erdogdu (University of Toronto)
Abstract : We study the effect of gradient-based optimization on feature learning in two-layer neural networks. We consider the non-asymptotic setting, and we show that a network trained via SGD exhibits low-dimensional representations, with applications in learning a monotone single-index model.

[03006] On the Implicit Geometry of Deep-net Classifiers

Format : Talk at Waseda University
Author(s) : Tina Behnia (University of British Columbia)Ganesh Ramachandra Kini (University of California, Santa Barbara)Vala Vakilian (University of British Columbia)Christos Thrampoulidis (University of British Columbia)
Abstract : The talk will address the following questions:

What are the unique structural properties of models learned by deep-net classifiers?
Is there an implicit bias towards solutions of a certain geometry and how does this vary across architectures and data?
Specifically, how does this implicit geometry change under label imbalances, and is it possible to use this information to design better loss functions for learning with imbalances?

[05316] Does the loss function matter in overparameterized models?

Format : Online Talk on Zoom
Author(s) : Vidya Muthukumar (Georgia Institute of Technology)
Abstract : Recent years have seen substantial interest in a first-principles theoretical understanding of the behavior of overparameterized models that interpolate noisy training data, based on their surprising empirical success. In this talk, I compare classification and regression tasks in the overparameterized linear model. On the one hand, we show that with sufficient overparameterization, solutions obtained by training on the squared loss (minimum-norm interpolation) typically used for regression, are identical to those produced by training on exponential and polynomially-tailed losses, typically used for classification. On the other hand, we show that there exist regimes where these solutions are consistent when evaluated by the 0-1 test loss function, but inconsistent if evaluated by the mean-squared-error test loss function. Our results demonstrate that: a) different loss functions at the training (optimization) phase can yield similar solutions, and b) a significantly higher level of effective overparameterization admits good generalization in classification tasks as compared to regression tasks.

[00435] Multiscale Numerical Methods for Complex Fluids

Session Time & Room :

00435 (1/3) : 4C (Aug.24, 13:20-15:00) @D101

00435 (2/3) : 4D (Aug.24, 15:30-17:10) @D101

00435 (3/3) : 4E (Aug.24, 17:40-19:20) @D101

Type : Proposal of Minisymposium
Abstract : Focus of this mini-symposium will be on the modelling and computational aspects of multiscale coupling strategies and hybrid techniques -continuum, mesoscopic, atomistic- specifically applied to complex fluids, such as colloidal suspensions, granular media, polymeric systems and/or multiphase flows. The goal is, on one hand, to share state-of-the-art results on multiscale approaches in fluids, on the other to discuss technical issues on their computational modelling. We believe that this mini-symposium will foster new collaborations and contribute to further advances in the field.
Organizer(s) : Giulio Giusteri, Takashi Taniguchi, Marco Ellero

Minisymposium Program :

00435 (1/3) : 4C @D101 [Chair: Takashi Taniguchi]

[05277] Multi-Physics Simulations of Flow, Friction, and Reactions in Solid/Liquid Interface

Format : Talk at Waseda University
Author(s) : Momoji Kubo (Tohoku University)
Abstract : In recent years, due to strong demands for energy saving and carbon neutrality, maximizing energy utilization efficiency in automobiles, airplanes, etc. is required. Therefore, it is essential to establish the technologies for the super-low friction. In the present study, we employed our supercomputer “MASAMUNE-IMR” and successfully applied our large-scale molecular dynamics code “Laich” to clarifying the multi-physics processes of the flow, friction, and chemical reactions in the solid/liquid interfaces for realizing the super-low friction system.

[02346] Numerical modeling of viscoelastic flows with high elasticity

Format : Talk at Waseda University

Author(s) : Laura Moreno (Universita degli Studi di Padova)Joan Baiges (Universitat Politecnica de Catalunya)Ramon Codina (Universitat Politecnica de Catalunya)

Abstract : Computing the viscoelastic fluid flow involves a wide range of difficulties, in particular when elasticity becomes dominant. These difficulties are considered one of the biggest challenges in computational rheology; this is known as the High Weissenberg Number Problem.This work presents different strategies to deal with the shortcomings that appear when the fluid is particularly elastic. These are carried out in the Finite Element framework and by using the Variational Multiscale formulation as a stabilization approach.

[02354] DPD Simulation of Ultrasound Propagation through Liquid Water

Format : Talk at Waseda University

Author(s) : Petra Papež (National Institute of Chemistry, Ljubljana)Matej Praprotnik (National Institute of Chemistry, Ljubljana)

Abstract : We present a dissipative particle dynamics simulation of ultrasound propagation through liquid water. The effects of frequency and thermostat parameters are studied and discussed. We show that frequency and thermostat parameters affect not only the attenuation but also the computed speed of sound. The present study paves the way for development and optimization of a virtual ultrasound machine for large-scale biomolecular simulations.

[04595] Machine-Learning for Accelerated Multi-Scale Polymer Flow Simulations

Format : Talk at Waseda University

Author(s) : John Jairo Molina (Kyoto University)Souta Miyamoto (Kyoto University)Yoshiki Ueno (Kyoto University)Takashi Taniguchi (Kyoto University)

Abstract : We develop a Bayesian Machine-Learning approach, based on a Gaussian Process Regression, to accelerate Multi-Scale Simulations (MSS) of polymer melt flows. In particular, we are able to learn the constitutive relation of entangled polymer melts (within the Doi-Takimoto model), which are then used within macroscopic flow solvers, drastically reducing the computational cost. We also show how ML can be used to reduce the statistical variance of a full MSS, significantly enhancing its computational efficiency.

00435 (2/3) : 4D @D101 [Chair: Giulio Giusteri]

[03437] Simulation of micro-scale particulate motion in gases

Format : Talk at Waseda University

Author(s) : Duncan Lockerby (University of Warwick)Josiah Jordan (University of Warwick)

Abstract : Low-speed gas flow around micro-scale particles (e.g. soot and other pollutants), and through suspensions of particles, are rich in physics and challenging to simulate. The hydrodynamic reach of a single particle is broad, making application of conventional approaches (e.g. finite-volume CFD) computationally expensive. Furthermore, their scale renders the conventional Navier-Stokes equations, and associated boundary conditions, inaccurate. In this talk we discuss recent developments in simulating micro-scale particulate flows using the Method of Fundamental Solutions.

[03686] Synchronized Molecular-Dynamics simulation of the thermal lubrication of an entangled polymer melt

Format : Talk at Waseda University

Author(s) : Shugo Yasuda (University of Hyogo)

Abstract : The thermo-rheological property of an entangled polymer melt in wall-driven shear flows is investigated by using a multiscale hybrid method, coupling molecular dynamics and hydrodynamic. The temperature of the polymeric liquid rapidly increases due to viscous heating once the drive force exceeds a certain threshold value, and the rheological properties drastically change at around the critical drive force. A remarkable observation is the re-entrant transition in the stress–optical relation at this threshold point.

[03368] Simulation of multiphase flows based on Lagrangian methods

Format : Talk at Waseda University

Author(s) : Xin Bian (Zhejiang University)

Abstract : We study dynamics of a solid particle, a droplet, a vesicle, and a red blood cell (RBC) suspended in a Newtonian fluid, respectively. These four systems share common features, while distinct behaviors are also very

apparent. We employ the smoothed particle hydrodynamics (SPH) method to solve the matrix fluid universally, but deal with the suspended object differently. We investigate their rich behaviors in Couette/Poiseuille flows.

[03717] Lagrangian Heterogeneous Multiscale Methods: A generalized multiphysics model for complex fluids with memory

Format : Talk at Waseda University
Author(s) : Nicolas Moreno (Basque Center for Applied Mathematics)Marco Ellero (Basque Center for Applied Mathematics)
Abstract : We present a Lagrangian multiscale/multiphysics framework for modeling complex fluids in various flow configurations. Our method employs Smoothed Dissipative Particle Dynamics (SDPD) to model fluids at both micro and macro scales, allowing us to incorporate complex physical models such as polymer solutions and multiphase flows. The method accurately captures stresses and enables the simulation of mixed flows. We validate the framework with benchmark configurations for Newtonian and non-Newtonian fluids, demonstrating its effectiveness in modeling complex fluids at both scales. Our methodology provides a natural link between macro and microscales and accounts for memory effects, resulting in a richer fluid response at the continuum.

00435 (3/3) : 4E @D101 [Chair: Momoji Kubo]

[05555] Moisture-induced weakening of adhesion between polymers and metals

Format : Talk at Waseda University
Author(s) : Shuji Ogata (Nagoya Institute of Technology)
Abstract : Adhesive bonding has attracted renewed interest from the manufacturing industry due to its role in creating composite materials and multimaterial designs with the desired arrangements of polymers and metals. In the present work, we theoretically addressed a fundamental problem of the moisture-induced adhesion weakening between polymers (or resin) and metal from a novel viewpoint of (de)protonation of them in water.

[03509] Modelling and Simulation of Capillary Origami in Three Dimensions

Format : Talk at Waseda University
Author(s) : Zhixuan Li (National University of Singapore)Weiqing Ren (National University of Singapore)
Abstract : Capillary origami involves folding a planar object into a 3D structure using capillary force, and has many important applications such as the fabrication of microelectromechanical systems. In this work, we propose a three-dimensional model of the droplet-on-sheet system with a pinned contact line. The system energy consists of interfacial energies caused by surface tensions and the elastic energy of the thin sheet given by nonlinear Koiter's model. We derive the governing equations of the static equilibrium using a variational approach. We then propose a numerical algorithm to find the equilibrium via a relaxation dynamics. We use the subdivision element method for discretization of the sheet, which provides $C^1 \cap H^2$ basis functions, and a modified area-minimizing functional for maintaining the mesh quality of the discrete droplet surface. Our numerical simulations demonstrate first-order and second-order convergence in time and space, respectively, and are in good agreement with physical experiments. Specifically, for a triangular sheet, we present phase diagrams of folding, which exhibit rich and fully three-dimensional behaviors not captured by previous two-dimensional models. Our results provide new insights into the mechanics of capillary folding and can inform the design of microfabrication techniques.

[04590] Multiscale simulation of a polymer melt flow between two coaxial cylinders under nonisothermal conditions

Format : Talk at Waseda University
Author(s) : Takashi Taniguchi (Kyoto University)Takeshi Sato (Kyoto University)Yuji Hamada (Kyoto University)
Abstract : We successfully extend a multiscale simulation (MSS) method to nonisothermal wellentangled polymer melt flows between two coaxial cylinders. In the multiscale simulation, the macroscopic flow system is connected to a number of microscopic systems through the velocity gradient tensor, stress tensor and temperature. At the macroscopic level, in addition to the momentum balance equation, we consider the energy balance equation, where heat generation plays an important role not only in the temperature distribution but also in the flow profile.

[05592] Flow-type dependent rheologies and multiscale simulations

Format : Talk at Waseda University
Author(s) : Giulio Giuseppe Giusteri (University of Padua)Francesca Tedeschi (University of Padua)Maria Lukácová-Medvid'ová (Johannes Gutenberg University of Mainz)Leonid Yelash (Johannes Gutenberg University of Mainz)
Abstract : The importance of taking into consideration the dependence on the local flow type of the response of non-Newtonian fluids in multiscale data-driven simulations will be highlighted. A framework to organize data in mixed flows and reconstruct the stress tensor will be reviewed. Then, an algorithm to take into account the flow-type dependence in a consistent way will be presented by discussing paradigmatic planar flows implied by data obtained with a FENE-type model for polymer chains.

[00436] Coupled dynamical systems: from data analysis to biomathematics

Session Time & Room : 2C (Aug.22, 13:20-15:00) @F308

Type : Proposal of Minisymposium
Abstract : This minisymposium presents recent results in the study of coupled systems, from small groups of elements (neurons, cardiomyocytes, chemical reactions, and so on) to large ones. We propose different lines of study from data analysis techniques to dynamical systems theory approaches to deal with these problems from isolated systems to coupled systems .

Organizer(s) : Roberto Barrio, Hiroyuki Kitajima, Valeriy Makarov, Ivan Tyukin
Classification : 37Cxx, 34Cxx, 92B05, Dynamical systems; Biomathematics
Minisymposium Program :

00436 (1/1) : 2C @F308 [Chair: Roberto Barrio]

[03097] Fractal dimension of multidimensional biological recordings

Format : Talk at Waseda University
Author(s) : Valeri A. Makarov (Universidad Complutense de Madrid)
Abstract : A linear mixture model can describe multisite LFPs, EEG, and MEG recordings. The fractal dimension (FD) of such multidimensional data can measure the complexity of different brain states. However, the local stationarity, the data's high dimension, and noise limit the assessment of FD from raw data. We discuss theoretical principles and methods derived from the model enabling accurate estimation of the FD, and illustrate them on synthetic and biological data.

[03895] Lyapunov-like characterization of ghost and weak attractors in complex dynamical systems

Format : Talk at Waseda University
Author(s) : Ivan Y Tyukin (King's College London)Alexander N Gorban (University of Leicester)Roqaiah Alsolami (University of Leicester)Tatiana Tyukina (University of Leicester)
Abstract : In this talk we discuss the problem of identifying and formally characterizing ghost and weak attractors in complex dynamical systems governed by systems of coupled nonlinear ordinary differential equations. We present a set of conditions enabling to determine if an equilibrium is a weak attractor in terms of the corresponding Jacobian and Hessian matrices. We show how these results can be used to constructively define and determine the existence of ghost attractors in such systems.

[03442] Flip-flip bifurcations in mathematical cardiac systems with and without symmetry

Format : Talk at Waseda University
Author(s) : Hiroyuki Kitajima (Kagawa University)
Abstract : We study the intersection of double-flip (period-doubling) bifurcations in a parameter plane. We derive normal forms for discrete-time and continuous-time systems. Using these normal forms, we clarify the bifurcation structure around the flip-flip bifurcation point. We apply these analytical results to a system of coupled ventricular cell models. We make the simplest model for generating discordant alternans and clarify that two parameters play key roles in generating discordant alternans.

[03235] Generation of early afterdepolarizations in cardiomyocytes: Fast-slow and bifurcation analysis

Format : Talk at Waseda University
Author(s) : Roberto Barrio (University of Zaragoza, Spain)Jorge Jover-Galtier (University of Zaragoza)M. Angeles Martinez (University of Zaragoza)Lucia Perez (University of Oviedo)Sergio Serrano (University of Zaragoza)Esther Pueyo (University of Zaragoza)
Abstract : We analyze the dynamical mechanisms underlying the formation of arrhythmogenic early afterdepolarizations (EADs) in the cardiomyocyte models of Sato et al. (a biophysically detailed model of dimension 27) and Luo-Rudy (dimension 3). Based on a comparison of the two models, with detailed bifurcation analysis using continuation techniques and using a fast-slow decomposition in the simple model and numerical explorations in the complex model, we propose a conjectured scheme of the formation of EADs that fits well with electrophysiological experimental data on EAD generation.

[00437] Climate Risks: From Modelling to Applications

Session Time & Room :

00437 (1/2) : 3D (Aug.23, 15:30-17:10) @A510

00437 (2/2) : 3E (Aug.23, 17:40-19:20) @A510

Type : Proposal of Minisymposium
Abstract : There is an increasing awareness of the urgency required to combat climate change and environmental pollution from central governments, researchers, and the industry around the world. Over 130 countries have committed to carbon neutrality targets in various forms, representing approximately 80% of the world population and 90% of the world's GDP. This shift in public attention is particularly relevant to our economic and financial systems in several aspects. This minisymposium discusses how to model and measure climate risks, their implications for corporate decisions, credit risks, and supply chain risks, how to green investing, and how to regulate the climate emissions market. Overall, these progresses allow researchers, regulators, and other stakeholders to improve their insights into the climate transitional risk to the economy, which will enable society to design policies and strategies to help allocate resources for carbon-neutral goals.

[01677] Optimal ecological transition path of a credit portfolio distribution, based on Multidate Monge-Kantorovich formulation

Format : Talk at Waseda University
Author(s) : Emmanuel Gobet (Ecole Polytechnique)Clara Lage (Ecole polytechnique and Univ. Lyon1)
Abstract : Accounting for climate transition risks is one of the most important challenges in the transition to a low-carbon economy. Banks are encouraged to align their investment portfolios to CO2 trajectories fixed by international agreements, showing the necessity of a quantitative methodology to implement it. We propose a mathematical formulation for this problem and a multistage optimization criterion for a transition between the current bank portfolio and a target one. The optimization problem combines the Monge-Kantorovich formulation of optimal transport, for which the cost is defined according to the financial context, and a credit risk measure. We show that the problem is well-posed, and can be embedded into a saddle-point problem for which Primal-Dual algorithms can be used. We design a numerical scheme that is able to solve the problem in available time, with nice scalability properties according to the number of decision times; its numerical convergence is analysed. Last we test the model using real financial data, illustrating that the optimal portfolio alignment may differ from the naive interpolation between the initial portfolio and the target.

[01674] Optimal Dynamic Contracts and Environmental Pollution

Format : Talk at Waseda University

Author(s) : Jerome Detemple (Boston University)Hao Xing (Boston University)

Abstract : We examine optimal dynamic contracts when production generates harmful pollution. We derive optimal consumption, effort and environmental investment of the agent and solve for the optimal contract offered by the principal. We then solve for a stationary pollution equilibrium in an economy with a continuum of
polluting firms. The optimal contract rewards for financial performance and self-pollution mitigation. We study the impact of model parameters on contractual structure, managerial decisions, and the stationary pollution distribution.

[05305] Optimal Impact Portfolios with General Dependence and Marginals

Format : Talk at Waseda University

Author(s) : Andrew Lo (MIT)Lan Wu (Peking University)Ruixun Zhang (Peking University)Chaoyi Zhao (Peking University)

Abstract : Impact investing typically involves ranking and selecting assets based on a non-financial impact factor, such as the environmental, social, and governance (ESG) score and the prospect of developing a disease-curing drug. We develop a framework for constructing optimal impact portfolios and quantifying their financial performances. Under general bivariate distributions of the impact factor and residual returns from a multi-factor asset-pricing model, the construction and performance of optimal impact portfolios depend critically on the dependence structure (copula) between the two. We derive a general representation theorem to characterize the distribution of induced order statistics (returns of impact-ranked assets), which allows us to explicitly and efficiently compute the optimal portfolio weights under any copula. The optimal weights depend on the tail characteristics of the copula, as well as whether the marginal distribution of residual returns is skewed or heavy-tailed. Our framework requires the estimation of only a constant number of parameters as the number of assets grows, providing a more regularized and robust approach compared to traditional Markowitz portfolios.

[01585] Using NLP to Analyze Corporate Communication

Format : Online Talk on Zoom

Author(s) : Markus Leippold (University of Zurich)

Abstract : Corporate climate disclosures are considered an essential prerequisite to managing climate-related financial risks. At the same time, current disclosures are imprecise, inaccurate, and greenwashing-prone. We introduce a deep learning approach to enable comprehensive climate disclosure analyses by fine-tuning the climateBert model. From 14,584 annual reports of the MSCI World index firms from 2010 to 2020, we extract the amount of cheap talk, defined as the share of precise versus imprecise climate commitments. We then test various hypotheses by linking three different climate initiatives, namely the Task Force on Climate-Related Financial Disclosure, the Science-Based Targets Initiative, and the Climate Action 100+, to the economic channels of signaling, credibility, and active engagement. In particular, we ask whether these initiatives decrease cheap talk by disciplining companies in how they define and disclose actionable climate commitments in their annual reports.

00437 (2/2) : 3E @A510 [Chair: Emmanuel Gobet, Ruixun Zhang, Florian Bourgey]

[01328] When Green Investors Are Green Consumers

Format : Talk at Waseda University

Author(s) : Olivier David Zerbib (EDHEC)Maxime Sauzet (Boston University)

Abstract : We introduce investors with preferences for green assets to a general equilibrium setting in which they also prefer consuming green goods. Their preference for green goods induces consumption premia on expected returns, which counterbalance the green premium stemming from their preferences for green assets. Because they provide a hedge when green goods become expensive, brown assets command lower consumption premia, while green investors allocate a larger share of their portfolios towards them. Empirically, the green-minus-brown consumption premia differential reached 30-40 basis points annually, and contributes to explaining the limited impact of green investing on the cost of capital of polluting firms.

[01612] Bridging Shared Socioeconomic Pathways of GHG Emission and Credit Risk

Format : Talk at Waseda University

Author(s) : Florian Bourgey (Bloomberg L.P.)

Abstract : We investigate the impact of transition risk on a firm's low-carbon production. As the world is facing global climate change, the Intergovernmental Panel on Climate Change has set the idealized carbon-neutral scenario around

2050. In the meantime, many carbon reduction scenarios, known as Shared Socioeconomic Pathways (SSPs) have been proposed in the literature for different production sectors in a more comprehensive socio-economic context. We consider, on the one hand, a firm that aims to optimize its emission level under the double objectives of maximizing its production profit and respecting the emission mitigation scenarios. Solving the penalized optimization problem provides the optimal emission according to a given SSP benchmark. On the other hand, such transitions affect the firm's credit risk. We model the default time by using the structural default approach. We are particularly concerned with how, by following different SSPs scenarios, the adopted strategies may influence the firm's default probability. We then show how to incorporate physical risk and extend the previous framework to a large-sized portfolio.

[01683] On some initial climate change impact models in actuarial science

Format : Online Talk on Zoom
Author(s) : Stephane Loisel (ISFA, Universite Lyon 1)
Abstract : In this talk, we start by presenting the main sources of uncertainty about the impact of climate change in the insurance industry, and the approaches proposed to model them. We then focus on the impact of physical risk on biometric risks for life insurance and on claims frequency risk in non-life insurance and present work in progress on these two topics.

[05370] Optimal carbon tax in the Golosov et al. 2014 DGSE central planning model

Format : Online Talk on Zoom
Author(s) : Stéphane Crépey (Université Paris Cité / LPSM)Dounia Essaket (Université Paris Cité / LPSM)Florian Bourgey (Bloomberg L.P.)Noufel Frokha (Université Paris 1)Gauthier Vermandel (Ecole Poytechnique)
Abstract : We provide a full analytical solution to the Golosov et al. 2014 optimal control formulation of the carbon tax problem in a DGSE central planning setup. Whereas the original paper was only solving the problem in terms of first order necessary conditions, we derive the value function itself. This gives a direct access to the carbon tax as the derivative of the value function with respect to the Lagrangian parameter associated with the labor constraint.

[00441] Intersection between financial economics and optimal control

Session Time & Room :

00441 (1/2) : 1E (Aug.21, 17:40-19:20) @D502

00441 (2/2) : 2C (Aug.22, 13:20-15:00) @D502

Type : Proposal of Minisymposium
Abstract : Optimal control is widely applied to understand strategic behavior of agents in financial economics. For example, an investor or a household makes investment and consumption decisions, a firm decides production, investment, and financing policies. Optimal control helps to understand these problems in a random environment facing constraints, risk, and uncertainties. Meanwhile, financial applications motivate new forms of control problems. This mini-symposium presents the latest developments in the applications of optimal control in financial economics.
Organizer(s) : Scott Robertson, Hao XingSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.
Classification : 91-10, 91G50, 91G10
Minisymposium Program :

00441 (1/2) : 1E @D502 [Chair: Hao Xing]

[05612] Asset Pricing with Misallocation

Format : Talk at Waseda University
Author(s) : Yan Ji (HKUST)
Abstract : We develop an endogenous growth model with heterogeneous firms facing financial frictions, in which misallocation emerges explicitly as a crucial state variable. In equilibrium, misallocation endogenously generates long-run uncertainty about economic growth by distorting innovation decisions, leading to significant welfare losses and risk premia in capital markets. Macroeconomic shocks that affect misallocation are likely to have overly persistent effects on aggregate growth. Using an empirical misallocation measure motivated by the model, we find evidence showing that

misallocation captures low-frequency variations in both aggregate growth and stock returns. Empirically, a two-factor model with market and misallocation factors prices size, book-to-market, momentum, and bond portfolios with an R-squared and a mean absolute pricing error close to the Fama-French three-factor model.

[03797] An optimal consumption and investment problem for general factor models : Epstein-Zin recursive utility case.

Format : Talk at Waseda University
Author(s) : Hiroaki Hata (Hitotsubashi University)
Abstract : We consider an optimal consumption and investment problem with Epstein-Zin recursive utility on the finite time horizon. The returns and volatilities of the assets depend on nonlinearly on the factor processes modeled as diffusion process. The problem becomes a standard control problem. We derive the Hamilton-Jacobi-Bellman (HJB) equation and study its solutions. Under some conditions we construct a suitable pair of sub- and super-solution. And, we prove the existence and uniqueness of solution for this HJB equation.
Finally, we show the verification theorem.

[05413] Patience is a virture: optimal investment in the presence of limit order book

Format : Talk at Waseda University
Author(s) : Nan Chen (The Chinese University of Hong Kong)Qiheng Ding (The Chinese University of Hong Kong)Chen Yang (The Chinese University of Hong Kong)
Abstract : We study an optimal investment problem of a CARA investor trading in a market operated with a limit order book (LOB). The model synergizes three key features of market microstructure: the bid-ask spread, the market depth, and a finite market resilience. Under a Bachelier process for the dynamic of the fundamental value of the asset, we manage to develop explicit characterization through a system of variational inequalities on the investor's optimal trading strategy. A patience index is derived to highlight the importance of trading timing in reconciling several competing goals such as achieving the current optimal risk exposure, incorporating the trading signals about the future, and minimizing trading impact costs.

[05411] Why is Cash U-Shape in Firm Size?

Format : Talk at Waseda University
Author(s) : Hao Xing (Boston University)Ali Kakhbod (UC Berkeley)Anders Max Reppen (Boston University Questrom School of Business)Tarik Umar (Rice University)
Abstract : Cash holdings are U-shaped in firm size. To rationalize this finding, we develop a model of firm dynamics with costly financing allowing for heterogeneous size} Cash is U-shaped in firm size because of decreasing returns to scale and hedging incentives. When a firm is small, cash decreases with size because investment opportunities are better resulting in more aggressive investing. Investing slows as the firm grows, and eventually, cash increases with firm size to hedge larger-scale cash flow shocks. Our model likewise explains why in the data issuance amounts (payout rates) are U-shaped (hump-shaped) in firm size.

00441 (2/2) : 2C @D502 [Chair: Hao Xing]

[02868] Debt Maturity Management

Format : Talk at Waseda University
Author(s) : Chao Ying (Chinese University of Hong Kong)Yunzhi Hu (UNC)Felipe Varas (Duke)
Abstract : This paper studies how a borrower issues long- and short-term debt in response to shocks to the enterprise value. Our theory highlights the tradeoff between commitment and hedging. Short-term debt protects creditors from future dilution and forces the borrower to reduce leverage after negative shocks. Long-term debt postpones default and allows the borrower time to recover after a downturn, thereby providing hedging in the upturn.

[05611] Nonlinear Dependence and Households' Portfolio Decisions over the Life Cycle

Format : Online Talk on Zoom
Author(s) : Wei Jiang (HKUST)Shize Li (HKUST)Jialu Shen (University of Missouri)
Abstract : This paper uncovers the nonlinear relationship between earning risk and stock returns, as measured by the between-squares correlation. By incorporating this between-squares correlation into a life-cycle model, we demonstrate that it lowers households' participation rate and generates moderate risky asset holdings. We identify two pathways through which the between-squares correlation affects portfolio choices: the skewness and kurtosis channels. The extent to which these channels dominate each other depends on the level of between-squares correlation, leading to a nonlinear

relationship between this variable and household decisions. Our empirical studies support the model's predictions. Moreover, we find that ignoring between-squares correlations leads to substantial welfare loss and contributes to increasing wealth inequality.

[04014] Dynamic Equilibrium with Insider Information and General Uninformed Agent Utility

Format : Online Talk on Zoom
Author(s) : Scott Robertson (Boston University)Jerome Detemple (Boston University)
Abstract : In this talk, we establish the existence of equilibrium in the presence of both asymmetric information and general preferences for the uninformed agent. Specifically, there is an insider who possesses a private signal about the terminal value of the traded asset, and an uninformed agent who possesses no private signal. While the insider has CARA (exponential) preferences, the uninformed agent's preferences are described by a general utility function defined for positive wealth. The terminal value of the traded asset is a function of a time homogeneous diffusion. In this setting, and under mild conditions on the diffusion, terminal payoff function, and uninformed preferences, we establish existence of a partially revealing equilibrium, where a market signal is communicated to all agents at time zero. Additionally, the equilibrium is a rational expectations equilibrium in the univariate case. As the uninformed agent preferences are general, we are able to obtain sensitivity of the asset price, volatility, and market price of risk, to the uninformed agent's initial endowment, as we will show through examples. This is joint work with Jerome Detemple of Boston University.

[00444] Complex Systems: Advances in Theory and Applications

Session Time & Room :

00444 (1/2) : 1C (Aug.21, 13:20-15:00) @G304

00444 (2/2) : 1D (Aug.21, 15:30-17:10) @G304

Type : Proposal of Minisymposium
Abstract : Many social, biological, and technological networks display non-trivial features, with complicated structures patterns of connection. Well-known classes of complex networks are scale-free and small-world networks. The study of complex networks is growing and many new aspects of network structures attract attention in mathematics, physics, electric power systems, biology, climate, computer science, sociology, epidemiology, and others. There is also a wide range of practical issues including Coupled networks and cyber-physical networks; Networked control; Multi-agent systems: Synchronization phenomena; Complex engineering design, including communication networks, power grids, electronic circuits, biomedical systems, software systems; Biological systems, neural networks, disease transmission.

[01282] Time Series Analysis with Machine Learning

Format : Talk at Waseda University
Author(s) : Michael Small (University of Western Australia)Braden John Thorne (University of Western Australia)Eugene Tan (University of Western Australia)Débora Corrêa (University of Western Australia)Ayham Zaitouny (University of Western Australia)Thomas Stemler (University of Western Australia)
Abstract : Machine learning is widely applied to model dynamical systems and make predictions. Instead of doing this, We will introduce the concept of Reservoir Time Series Analysis - using a particular flavour of machine learning (reservoir computing) to represent the state of a dynamical system and characterise the dynamical evolution of that state. How much can we infer about the changing behaviour of a system from the internal representation of these states within a reservoir machine learning model? A second strategy within machine learning for time series analysis is to use the machine learning model as a proxy for the original dynamics - but how well do such models capture chaotic dynamics? I will show via some short examples that persistent homology can be used as an effective tool to quantify that structure. These methods will be illustrated with applications to machine vibration and pump cavitation in industrial processes.

[01306] On constructing directed networks from multivariate time series

Format : Talk at Waseda University

Author(s) : Tomomichi Nakamura (University of Hyogo)Toshihiro Tanizawa (Toyota)

Abstract : We consider a problem of constructing networks for multivariate time series. To construct networks from multivariate time series, we first need to detect relationships among them. However, it is difficult, because the relationships among multivariate time series are diverse. The time series might contain components that have large differences in the amplitude and the time scales of the fluctuations. We consider this problem using the transfer entropy, one of the common techniques for detecting causal relationships and Reduced Auto-Regressive (RAR) model, an information theoretic reduction of auto-regressive model.

[05563] Optimal network synchronization and a higher-order topological approach

Author(s) : Maciej Ogorzalek (Jagiellonian University)Guanrong (Ron) Chen (City University of Hong Kong)

Abstract : In this talk, we will discuss the optimal network synchronization problem. The totally homogenous network approach will be reviewed, and a higher-order topological approach will be introduced, with some preliminary results reported.

[01273] Evaluating the Network Robustness: A Convolutional Neural Network Approach

Format : Online Talk on Zoom

Author(s) : Yang Lou (Osaka University)Junli Li (Sichuan Normal University)Guanrong Chen (City University of Hong Kong)

Abstract : Evaluating network robustness by attack simulations is computationally time-consuming. In this talk, a convolutional neural network (CNN)-based robustness estimation is presented, which has three schemes, including the straightforward scheme, the learning feature-assisted scheme, and the pyramid pooling-assisted scheme. Experimental studies demonstrate that: 1) the prediction error is low; 2) the runtime is significantly lower than that of attack simulations; and 3) it provides a good indicator for robustness, better than the classical spectral measures.

00444 (2/2) : 1D @G304 [Chair: Maciej Ogorzalek]

[01264] Adaptive Finite-Time Output Consensus for Fractional-Order Complex Networks With Multiple Output Derivative Couplings

Format : Talk at Waseda University

Author(s) : Chenguang Liu (Beihang University)Qing Gao (Beihang University)Jinhu Lu (Beihang University)

Abstract : This paper delves into the adaptive fifinite-time output consensus (FTOC) problem for a multiple output derivative coupled fractional-order complex network (MODCFOCN). Based on the properties of the Gamma function and the fractional derivetive, a FTOC criterion for the MODCFOCN is derived by designing an appropriate adaptive output-feedback controller. Finally, a numerical example is utilized to substantiate the effectiveness of the acquired FTOC results and the devised adaptive output-feedback controller.

[01255] Optimizing 3D Complex Networks on chip

Format : Talk at Waseda University

Author(s) : Maciej Ogorzalek (Jagiellonian University)Katarzyna Grzesiaak-Kopec (Jagiellonian University)

Abstract : Current generations of integrated circuits can contain billions of transistors and extremely complicated interconnect network the length of which goes into dozens of kilometers – all these placed in an extremely small physical volume.
For the correct operation of the circuit placement of elements and building blocks and design of interconnect has to be done in optimal or quasi-optimal way satisfying also several types of constraints. Mathematical models of complex networks can play a significant role in the design and AI-based methodologies can be used for finding good/quasi-optimal solution in reasonable time.

[01268] Machine Learning for Detecting Internet Traffic Anomalies

Format : Online Talk on Zoom

Author(s) : Ljiljana Trajkovic (Simon Fraser University)Ljiljana Trajkovic (Simon Fraser University)

Abstract : Border Gateway Protocol (BGP) enables the Internet data routing. BGP anomalies may affect the Internet connectivity and cause routing disconnections, route flaps, and oscillations. Hence, detection of anomalous BGP routing dynamics is a topic of great interest in cybersecurity. Various anomaly and intrusion detection approaches based on

machine learning have been employed to analyze BGP update messages collected from RIPE and Route Views collection sites. Survey of supervised and semi-supervised machine learning algorithms for detecting BGP anomalies and intrusions is presented. Deep learning, broad learning, and gradient boosting decision tree algorithms are evaluated by creating models using collected datasets that contain Internet worms, power outages, and ransomware events.

[01280] Model for estimating unconfirmed COVID-19 cases and multiple waves of pandemic progression

Format : Talk at Waseda University
Author(s) : Choujun Zhan (South China Normal University)Chi K. Tse (City University of Hong Kong)
Abstract : The novel coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has unique epidemiological characteristics that include presymptomatic and asymptomatic infections, resulting in a large proportion of infected cases being unconfirmed, including patients with clinical symptoms who have not been identified by screening. These unconfirmed infected individuals move and spread the virus freely, presenting difficult challenges to the control of the pandemic. To reveal the actual pandemic situation in a given region, a simple dynamic susceptible-unconfirmed-confirmed-removed (D-SUCR) model is developed taking into account the influence of unconfirmed cases, the testing capacity, the multiple waves of the pandemic, and the use of nonpharmaceutical interventions. Using this model, the total numbers of infected cases in 51 regions of the USA and 116 countries worldwide are estimated, and the results indicate that only about 40% of the true number of infections have been confirmed. In addition, it is found that if local authorities could enhance their testing capacities and implement a timely strict quarantine strategy after identifying the first infection case, the total number of infected cases could be reduced by more than 90%. Delay in implementing quarantine measures would drastically reduce their effectiveness.

[00448] Particle based methods

Session Time & Room :

00448 (1/2) : 1C (Aug.21, 13:20-15:00) @E818

00448 (2/2) : 1D (Aug.21, 15:30-17:10) @E818

Type : Proposal of Minisymposium
Abstract : Predictions of the state or parameter of a system of interest that is subject to some type of stochastic noise are typically achieved by estimating the associated density. Yet this approach becomes highly challenging for extended state and parameter spaces and if the unknown density is non-parametric. State of the art methods are designed to use a Monte Carlo type empirical estimation often referred to as an ensemble or particle filter. Here we will explore theoretical and algorithmic advances of these methods in the context of data assimilation and classical inverse problems.
Organizer(s) : Matei Hanu, Jana de Wiljes
Classification : 68Txx, 60Gxx, 62Fxx, Data assimilation, Inverse Problems, Machine Learning
Minisymposium Program :

00448 (1/2) : 1C @E818 [Chair: Jana de Wiljes]

[02827] Constrained sampling

Format : Talk at Waseda University
Author(s) : Xin Tong (National University of Singapore)
Abstract : Sampling-based inference and learning techniques, especially Bayesian inference, provide an essential approach to handling uncertainty in machine learning (ML). As these techniques are increasingly used in daily life, it becomes essential to safeguard the ML systems with various trustworthyrelated constraints, such as fairness, safety, interpretability. We propose a family of constrained sampling algorithms which generalize Langevin Dynamics (LD) and Stein Variational Gradient Descent (SVGD) to incorporate a moment constraint or a level set specified by a general nonlinear function. By exploiting the gradient flow structure of LD and SVGD, we derive algorithms for handling constraints, including a primal-dual gradient approach and the constraint controlled gradient descent approach.We investigate the continuous-time mean-field limit of these algorithms and show that they have O(1/t) convergence under mild conditions.

[03107] Subsampling in ensemble kalman inversion

Format : Talk at Waseda University
Author(s) : Matei Hanu (Free University of Berlin)Jonas Latz (Heriot-Watt-University)Claudia Schillings (Free University of Berlin)
Abstract : The Ensemble Kalman Inversion (EKI) is an efficient, gradient-free optimisation method to estimate

unknown parameters in an inverse setting. For large data sets, the EKI becomes computationally infeasible as the data misfit needs to be evaluated for each particle in each iteration.
Randomised algorithms can successfully overcome this issue by using only a random subset of the data in each iteration, so-called subsampling techniques.
In this talk we present subsampling-techniques within Ensemble Kalman Inversion.

[03842] Ensemble Inference Methods for Models with Noisy and Expensive Likelihoods

Format : Talk at Waseda University
Author(s) : Marie-Therese Wolfram (University of Warwick)Andrew Stuart (California Institute of Technology)Andrew Duncan (Imperial College London)Oliver Dunbar (California Institute of Technology)
Abstract : This talk concerns interacting particle systems to solve inverse problems where the forward model evaluations present rapid fluctuations over the smoothly varying quantity of interest. After comparing the performance of ensemble Kalman methods (EKS) and Langevin-based methods (ELS) using formal multiscale analysis, we introduce a new class of algorithms, named ensemble Gaussian process samplers, which combine the main benefits of both approaches while avoiding their flaws.

[04379] Projected ensemble data assimilation

Format : Talk at Waseda University
Author(s) : Svetlana Dubinkina (VU Amsterdam)Jana de Wiljes (University of Potsdam)
Abstract : Ensemble data assimilation is unable to reduce the error estimate for high-dimensional systems when used with a small ensemble. A typical remedy is dimesion reduction by localization. Though localization reduces the error substantially for both linear and nonlinear data-assimilation methods, the former ones considerably outperform the latter ones in quasi-linear regimes. We propose a further dimension reduction based on projection and show numerically considerable error decrease when used with small ensemble.

00448 (2/2) : 1D @E818 [Chair: Matei Hanu]

[04587] Alternatives to Monte Carlo based sampling and high dimensional integration

Format : Talk at Waseda University
Author(s) : Sahani Pathiraja (University of New South Wales)
Abstract : Monte Carlo is a fundamental component of popular methods for uncertainty quantification and Bayesian inference. However, Monte Carlo based techniques are often inefficient in high dimensions, representing distributional tails and in complex time-dependent systems. This is in part due to the reliance on points (i.e. delta functions) to approximate distributions. We numerically and analytically investigate the performance of various sampling techniques that make use of alternatives to delta functions and compare to standard Monte Carlo.

[05018] Mixtures of Gaussian Process Experts with SMC^2

Format : Talk at Waseda University
Author(s) : Lassi Roininen (LUT University)
Abstract : Gaussian processes are a key component of many flexible statistical and machine learning models. However, they exhibit cubic computational complexity and high memory constraints due to the need of inverting and storing a full covariance matrix. To circumvent this, mixtures of Gaussian process experts have been considered where data points are assigned to independent experts, reducing the complexity by allowing inference based on smaller, local covariance matrices. Moreover, mixtures of Gaussian process experts substantially enrich the model's flexibility, allowing for behaviors such as non-stationarity, heteroscedasticity, and discontinuities. In this work, we construct a novel inference approach based on nested sequential Monte Carlo samplers to simultaneously infer both the gating network and Gaussian process expert parameters. This greatly improves inference compared to importance sampling, particularly in settings when a stationary Gaussian process is inappropriate, while still being thoroughly parallelizable.

[05073] Eulerian calibration for stochastic transport models

Format : Talk at Waseda University
Author(s) : Oana Andrea Lang (Imperial College London)
Abstract : In this talk I will talk about a new probabilistic approach for calibrating a general class of stochastic nonlinear fluid dynamics models. A key step for ensuring the successful application of the combined stochastic parameterisation and data assimilation procedure is the “correct” calibration of stochastic model parameters. Currently, most methodologies are based on Lagrangian particle trajectories which are simulated starting from each point on both the physical grid and its refined version. Then the differences between the particle positions are used to calibrate the noise.

This is computationally expensive and not fully justified from a theoretical perspective. We currently explore an Eulerian approach based on calibrating the amplitude of the individual noises to obtain an approximate representation of uncertainty that uses a finite set of individual noises, and in this talk I will report on the current advances.
This is joint work with Prof Dan Crisan and Dr Alexander Lobbe (Imperial College London).

[05209] Can possibility theory help with uncertainty quantification for neural networks?

Format : Talk at Waseda University
Author(s) : Jeremie Houssineau (University of Warwick)
Abstract : We consider an alternative to the Gaussian version of the stochastic weight averaging method (SWAG), an approach to uncertainty quantification in neural networks. It is well accepted that the uncertainty in the parameters of the network is epistemic rather than being induced by randomness, which motivates the use of possibility theory. We will see how possibility theory helps to overcome difficulties with standard Bayesian neural networks and how it leads to an alternative to SWAG.

[00449] Atomistic simulations in the exascale era

Session Time & Room :

00449 (1/3) : 4C (Aug.24, 13:20-15:00) @D407

00449 (2/3) : 4D (Aug.24, 15:30-17:10) @D407

00449 (3/3) : 4E (Aug.24, 17:40-19:20) @D407

Type : Proposal of Minisymposium
Abstract : The world's very first exascale computer has finally arrived. The first generation of exascale machines will predominantly rely on hybrid architectures where massive numbers of CPUs, GPUs, and specialized hardware accelerators, coexist. Realizing the full potential of such architectures is a formidable task that requires an in-depth rethinking of current approaches. In this mini-symposium, we address the challenges faced by computational materials and chemical science communities. We specifically explore novel techniques, algorithms, and methodologies that can extend the time and length scales of atomistic simulations using exascale hardware.
Organizer(s) : Joshua Finkelstein, Danny Perez, Emanuel Rubensson, Tony Lelièvre

[01608] Quantum Materials Simulations at the Nexus of Exascale Computing, Artificial Intelligence, and Quantum Computing

Format : Talk at Waseda University
Author(s) : Aiichiro Nakano (University of Southern CaliforniaUniversity of Southern California)
Abstract : Computing landscape is evolving rapidly. Exascale computers have arrived, and quantum supremacy has been demonstrated for several problems, while artificial intelligence (AI) is transforming every aspect of science and engineering. Atomistic simulations at the exa-quantum-AI nexus are revolutionizing quantum materials research. I will describe research and education on atomically thin two-dimensional and other quantum materials using our AI and quantum-computing enabled exascale materials simulator (AIQ-XMaS). Specifically, I will describe (1) self-assembly of layered material metastructures for scalable and robust manufacturing of quantum emitters for future quantum information science and technology; and (2) excited-state neural-network quantum molecular dynamics (NNQMD) trained by first-principles nonadiabatic quantum molecular dynamics (NAQMD) to prove the exciting concept of picosecond optical, electrical and mechanical control of symmetric breaking in topological ferroelectric skyrmion and skyrmionium for emerging ultralow-power polar topotronics. This research was supported by NSF Future Manufacturing Program, Award 2036359, NSF Cybertraining Program, Award 2118061, and Sony Research Award. Simulations were performed at Argonne Leadership Computing Facility under DOE INCITE and Aurora Early Science programs and at Center for Advanced Research Computing of the University of Southern California.

[01950] Large scale quantum chemistry with Tensor Processing Units

Format : Online Talk on Zoom
Author(s) : Ryan Pederson (University of California, Irvine)John Kozlowski (University of California, Irvine)Ruyi Song (Duke University)Jackson Beall (SandboxAQ)Martin Ganahl (SandboxAQ)Markus Hauru (Alan Turing Institute)Adam Lewis (SandboxAQ)Shrestha Basu Mallick (Google LLC)Volker Blum (Duke University)Guifre Vidal (Google LLC)
Abstract : We demonstrate the use of Googles cloud-based Tensor Processing Units (TPUs) to accelerate and scale up conventional (cubic-scaling) density functional theory (DFT) calculations. Utilizing 512 TPU cores, we accomplish the largest such DFT computation to date, with $247,848$ orbitals, corresponding to a cluster of $10,327$ water molecules with $103,270$ electrons, all treated explicitly. Our work thus paves the way toward accessible and systematic use of conventional DFT, free of any system-specific constraints, at unprecedented scales.

[02042] Quantum molecular dynamics using Tensor cores

Format : Talk at Waseda University
Author(s) : Joshua Finkelstein (Los Alamos National Laboratory)Emanuel H Rubensson (Uppsala)Susan M Mniszewski (Los Alamos National Laboratory)Christian F. A. Negre (Los Alamos National Laboratory)Anders M Niklasson (Los Alamos National Laboratory)
Abstract : Tensor cores represent a new form of hardware acceleration specifically designed for deep neural network calculations. They provide extraordinary speed and efficiency but were designed for low-precision tensor contractions. Despite this, we demonstrate how Tensor cores can be applied with high efficiency to the challenging and numerically sensitive problem of quantum-based Born–Oppenheimer molecular dynamics, which requires highly accurate electronic structure optimizations and conservative force evaluations.

[02949] Recent algorithmic improvements in parallel long-time molecular dynamics

Format : Talk at Waseda University
Author(s) : Danny Perez (Los Alamos National Laboratory)
Abstract : The temporal reach of molecular dynamics is limited by poor parallel strong-scaling: even on exascale computers, direct simulation is expected to remain limited to microseconds. We explore alternative time-wise parallelization schemes that target long-time simulations where multiple trajectory segments are evolved simultaneously and assembled into a unique dynamically correct trajectory. We discuss recent speculative execution and resource-allocation schemes that suggest significant potential scalability enhancements, leading to increased simulation timescales when deployed on massively-parallel computers.

00449 (2/3) : 4D @D407 [Chair: Danny Perez]

[03771] Adaptive parareal method for the simulation of atomistic defects

Format : Online Talk on Zoom
Author(s) : Olga Gorynina Tony Lelievre (Ecole des Ponts)Frederic Legoll (Ecole des Ponts)Danny Perez (Los Alamos National Laboratory)
Abstract : Molecular dynamics simulations demand extensive computational resources to accurately calculate ensemble averages and dynamical quantities over long trajectories. In this study, we employ an adaptive parareal algorithm to enhance the speed of MD simulations by breaking down time calculations into smaller segments. We focus on the diffusion of a self-interstitial atom in a body-centered cubic tungsten lattice, utilizing LAMMPS molecular dynamics software and employing machine-learned spectral neighbor analysis potentials (SNAP) and embedded-atom method potentials (EAM). The adaptive parareal algorithm, which iteratively refines approximate solutions using parallel fine solvers, demonstrates significant computational gains. The goal of the talk is to highlight the potential of the adaptive parareal algorithm for accelerating MD simulations.

[04027] Fast, Accurate and Large-scale Ab-initio Calculations for Materials Modeling

Format : Talk at Waseda University
Author(s) : Vikram Gavini (University of Michigan)Sambit Das (University of Michigan)Phani Motamarri (Indian Institute of Science)
Abstract : This talk will present our recent advances towards the development of computational methods and numerical algorithms for conducting fast and accurate large-scale DFT calculations using adaptive finite-element discretization, which form the basis for the recently released DFT-FE open-source code (https://github.com/dftfeDevelopers/dftfe). The

computational efficiency, scalability and performance of DFT-FE will be presented. Some application problems that highlight the utility of DFT-FE in tackling complex aperiodic systems will be demonstrated.

[04848] The Chunks and Tasks Matrix Library

Format : Talk at Waseda University
Author(s) : Emanuel Rubensson (Uppsala University)
Abstract : We present the Chunks and Tasks Matrix Library, which is a parallel sparse matrix library able to dynamically take advantage of data locality in matrices to avoid movement of data. The library uses a sparse quadtree representation of sparse matrices and is implemented using the Chunks and Tasks programming model. We demonstrate the scaling capabilities for operations used in large-scale electronic structure calculations, including sparse matrix-matrix multiplication and algorithms for inverse factorization.

[05282] From Langevin dynamics to kinetic Monte Carlo: mathematical foundations of accelerated dynamics algorithms

Format : Online Talk on Zoom
Author(s) : Tony LELIEVRE (Ecole des Ponts ParisTech)
Abstract : We will discuss models used in classical molecular dynamics, and some mathematical questions raised by their simulations. In particular, we will present recent results on the connection between a metastable Markov process with values in a continuous state space (satisfying e.g. the Langevin or overdamped Langevin equation) and a jump Markov process with values in a discrete state space. This is useful to analyze and justify numerical methods which use the jump Markov process underlying a metastable dynamics as a support to efficiently sample the state-to-state dynamics (accelerated dynamics techniques à la A.F. Voter). It also provides a mathematical framework to justify the use of transition state theory and the Eyring-Kramers formula to build kinetic Monte Carlo or Markov state models.

00449 (3/3) : 4E @D407 [Chair: Anders Niklasson]

[05409] Quantum-Mechanical Shadow Born-Oppenheimer Molecular Dynamics for Distributed Computing

Format : Talk at Waseda University
Author(s) : Anders Niklasson (LANL)
Abstract : We present recent developments of quantum-mechanical shadow Born-Oppenheimer molecular dynamics for simulations with tens-of-thousands of atoms using distributed, linear scaling, graph-based electronic structure calculations [Negre, Wall, and Niklasson, J. Chem. Phys. 158, 074108 (2023)].

[05380] Compressing, resampling and forecasting atomic simulations with descriptor vectors

Format : Online Talk on Zoom
Author(s) : Thomas D Swinburne (CNRS)
Abstract : We show atomic descriptor functions give a metric latent space for atomic simulations, where sparse snapshots can be interpolated and complex transitions (e.g. yeilding) can be linearly classified. When descriptors are unimodal, latent trajectories can be resampled and forecasted by a vector autoregressive model, with a Mahalanobis extrapolation grade. The approach is applied to challenging, large-scale simulations of dislocation plasticity. A strategy to optimise resources is proposed, maximising the estimated information yield of additional effort.

[05479] Structure modeling with large-scale DFT and machine-learning methods

Format : Talk at Waseda University
Author(s) : Tsuyoshi Miyazaki (National Institute for Materials Science (NIMS))
Abstract : To overcome the size limitation of DFT calculations, we have developed a large-scale and linear-scaling DFT code CONQUEST. Using CONQUEST, we can investigate the atomic and electronic structures of large and complex materials containing many thousands of atoms. In this talk, I introduce the recent progress of CONQUEST, together with a newly proposed method to analyze the local atomic structures observed in the DFT-MD simulations of complex systems.

[00455] Recent Development of Theory and Algorithms of Scientific Machine Learning

Session Time & Room :

00455 (1/3) : 1E (Aug.21, 17:40-19:20) @E804

00455 (2/3) : 2C (Aug.22, 13:20-15:00) @E804

00455 (3/3) : 2D (Aug.22, 15:30-17:10) @E804

Type : Proposal of Minisymposium
Abstract : The “unreasonable effectiveness” of deep learning for massive datasets posed numerous mathematical and algorithmic challenges along the path towards gaining deeper understandings of new phenomena in machine learning. This minisymposium aims at bringing together applied mathematicians interested in the mathematical aspects of deep learning, with diverse background and expertise to modeling high-dimensional scientific computing problems and nonlinear physical systems; the talks reflect the collaborative, multifaceted nature of the mathematical theory and applications of deep neural networks.

Organizer(s) : Chunmei Wang, Haizhao Yang

[05474] Monte Carlo neural networks: Stochastic gradient descent learns random variables

Format : Online Talk on Zoom
Author(s) : Sebastian Becker (ETH Zurich)Arnulf Jentzen (The Chinese University of Hong Kong, Shenzhen & University of Münster)Marvin Müller (2Xideas Switzerland AG)Philippe von Wurstemberger (ETH Zurich & The Chinese University of Hong Kong, Shenzhen)
Abstract : In financial engineering, prices of financial products are computed approximately many times each trading day with (slightly) different parameters in each calculation. Here we introduce a new approximation strategy for such parametric approximation problems where we employ stochastic gradient descent not to train parameters of standard neural networks (NNs) but instead to learn random variables appearing in Monte Carlo approximations. The proposed approach achieves in the tested examples much high approximation precisions than standard NNs.

[01329] Deep adaptive basis Galerkin method for evolution equations

Format : Online Talk on Zoom
Author(s) : Yiqi Gu (University of Electronic Science and Technology of China)Michael K. NG (The University of Hong Kong)
Abstract : We study deep neural networks (DNNs) for solving high-dimensional evolution equations. Unlike other existing methods (e.g., the least square method) that simultaneously deal with time and space variables, we propose a deep adaptive basis approximation structure. On the one hand, orthogonal polynomials are employed to form the temporal basis to achieve high accuracy in time. On the other hand, DNNs are employed to form the adaptive spatial basis for high dimensions in space.

[01635] Identifying reaction channels via reinforcement learning

Format : Talk at Waseda University
Author(s) : Senwei Liang (Lawrence Berkeley Laboratory)
Abstract : Reactive trajectories between metastable states are rare yet important in studying reactions. This talk introduces a new method to identify the reaction channels where reactive trajectories occur frequently via reinforcement learning (RL). The action function in RL learns to seek the connective configurations based on reward from simulation. We characterize the reactive channels by data points sampled by shooting from the located connective configurations. These data points bridge stable states and cover most transition regions of interest, enabling us to study reaction mechanism on narrowed regions rather than entire configuration space.

[03340] Finite Expression Methods for Discovering Pyhsical Laws from Data

Format : Online Talk on Zoom
Author(s) : chunmei wang (University of Florida)
Abstract : The speaker will present the finite expression method (FEX) for discovering the governing equations of data. By design, FEX can provide physically meaningful and interpretable formulas for physical laws compared to black-box deep learning methods. FEX only requires a small number of predefined operators to automatically generate a large class of mathematical formulas. Therefore, compared to existing symbolic approaches, FEX enjoys favorable memory cost and can discover a larger range of governing equations while other methods fail, as shown by extensive numerical tests.

00455 (2/3) : 2C @E804 [Chair: Chunmei Wang]

[03345] Approximation Theory for Sequence Modelling

Format : Talk at Waseda University
Author(s) : Qianxiao Li (National University of Singapore)
Abstract : In this talk, we present some recent results on the approximation theory of deep learning architectures for sequence modelling. In particular, we formulate a basic mathematical framework, under which different popular architectures such as recurrent neural networks, dilated convolutional networks (e.g. WaveNet), encoder-decoder structures, and transformers can be rigorously compared. These analyses reveal some interesting connections between approximation, memory, sparsity and low rank phenomena that may guide the practical selection and design of these network architectures.

[03154] Finite Expression Method: A Symbolic Approach for Scientific Machine Learning

Format : Talk at Waseda University
Author(s) : Haizhao Yang (University of Maryland College Park)
Abstract : Machine learning has revolutionized computational science and engineering with impressive breakthroughs, e.g., making the efficient solution of high-dimensional computational tasks feasible and advancing domain knowledge via scientific data mining. This leads to an emerging field called scientific machine learning. In this talk, we introduce a new method for a symbolic approach to solving scientific machine learning problems. This method seeks interpretable learning outcomes in the space of functions with finitely many analytic expressions and, hence, this methodology is named the finite expression method (FEX). It is proved in approximation theory that FEX can avoid the curse of dimensionality in discovering high-dimensional complex systems. As a proof of concept, a deep reinforcement learning method is proposed to implement FEX for learning the solution of high-dimensional PDEs and learning the governing equations of raw data.

[01880] Discretization Invariant Operator Learning for Solving Inverse Problems

Format : Talk at Waseda University
Author(s) : Yong Zheng Ong (National University of Singapore)
Abstract : Discretization invariant learning aims at learning in the infinite-dimensional function spaces with the capacity to process heterogeneous discrete representations of functions as inputs and/or outputs of a learning model. This talk presents a novel deep learning framework based on integral autoencoders, IAE-Net, for discretization invariant learning. Using IAE-Net, an adaptive training scheme is proposed with different loss functions to train the model. The proposed model is tested with various applications.

[03159] Deep Adaptive Basis Galerkin Method for Evolution Equations

Format : Talk at Waseda University
Author(s) : Yiqi Gu (University of Electronic Science and Technology of China)
Abstract : We study deep neural networks (DNNs) for solving high-dimensional evolution equations. Unlike other existing methods (e.g., the least square method) that simultaneously deal with time and space variables, we propose a deep adaptive basis approximation structure. On the one hand, orthogonal polynomials are employed to form the temporal basis to achieve high accuracy in time. On the other hand, DNNs are employed to form the adaptive spatial basis for high dimensions in space.

00455 (3/3) : 2D @E804 [Chair: Haizhao Yang]

[03467] Multi-scale Neural Networks for High Frequency Problems in Regressions and PDEs

Format : Talk at Waseda University
Author(s) : Wei Cai (Southern Methodist University)Lizuo Liu (Southern Methodist University)Bo Wang (LCSM(MOE), School of Mathematics and Statistics, Hunan Normal University, Changsha, Hunan, 410081, P. R. China.)
Abstract : In this talk, we will introduce multiscale deep neural networks (MscaleDNNs) in order to overcome the spectral bias of deep neural networks when approximating functions with wide-band frequency information. The MscaleDNN uses a radial scaling in the frequency domain, which converts the problem of learning high frequency contents in regression problems or PDE's solutions to one of learning lower frequency functions. As a result, the MscaleDNN achieves fast uniform convergence over multiple scales as demonstrated in solving regression problems and highly oscillatory Navier-Stokes flows. Moreover, a diffusion equation model in the frequency domain is obtained based on the neural tangent kernel, which clearly shows how the multiple scales in the MscaleDNN improves the convergence of the training of neural networks over wider frequency ranges with more scales, compared with a traditional fully connected neural network.

[05449] Implicit bias in deep learning based PDE solvers

Format : Talk at Waseda University
Author(s) : Tao Luo (Shanghai Jiao Tong University)Qixuan Zhou (Shanghai Jiao Tong University)
Abstract : We will discuss some recent development on the theory of deep learning based PDE solvers. We would like to mention some new ideas on modeling and analysis of such algorithms, especially some related phenomenon observed during the training process. For the theorectical part, both optimization and approximation will be considered.

[00462] Mathematical and applicable studies on quantum walks

Session Time & Room :

00462 (1/2) : 2C (Aug.22, 13:20-15:00) @D405

00462 (2/2) : 2D (Aug.22, 15:30-17:10) @D405

Type : Proposal of Minisymposium
Abstract : Eigenvalue problems for matrices and spectral theory for unitary operators and self-adjoint operators are important research area of quantum walks. In fact, spectra of time-evolution operators of quantum walks determine the dynamics of quantum walkers. In this minisymposium, we are going to have eight talks on the scattering and the spectral theory for quantum walks as well as eigenvalue problems on quantum walks on finite graphs and related topics. Some of them are going to introduce studies of quantum walks in view of theoretical physics and laser engineering.
Organizer(s) : Hisashi Morioka, Etsuo Segawa
Classification : 81Q35, 15A18, 47A75, 81Q10, 05C25
Minisymposium Program :

00462 (1/2) : 2C @D405 [Chair: Akito Suzuki]

[01759] The Ihara expression of graph zeta functions

Format : Talk at Waseda University
Author(s) : Ayaka Ishikawa (Yokohama National University)
Abstract : Konno and Sato showed that the Grover walk corresponds to the Sato zeta function. They also gave the characteristic polynomial of the transition matrix of the Grover walk, using the Ihara expression of the Sato zeta function.
We define the graph zeta function related to the Szegedy walk on a finite graph and give the Ihara expression. The Ihara expression will extend Konno-Sato's result to the Szegedy walk.

[02778] Topological stability of quantum walks and related

Format : Talk at Waseda University
Author(s) : Chris Bourne (Nagoya University)
Abstract : Quantum walks with additional symmetries may possess topologically protected bound states, meaning these bound states are robust against small perturbations and changes. I will give a gentle mathematical introduction to this phenomenon, which borrows ideas from so-called topological phases of matter. I will also explain how the existence of topological bound states can be detected using a winding number-like formula.

[03296] Spectral mapping theorem for quantum walks on graphs

Format : Talk at Waseda University
Author(s) : Kei Saito (Kanagawa University)
Abstract : Quantum walks (QWs) are well known as a quantum version of random walks, and their time evolution is described by a unitary operator. Segawa, Suzuki(2019) show that the spectrum of the QW is given by that of a self-adjoint operator on the underlying graph. In this talk we reconsider such a spectral mapping theorem from a different perspective and present a relation between the spectrum of QWs and the weighted line matrix.

[05096] The Segawa-Suzuki spectral mapping theorem, revisited

Format : Talk at Waseda University
Author(s) : Yohei Tanaka (Gakushuin University)
Abstract : The Segawa-Suzuki spectral mapping theorem for chiral unitaries is particularly useful when studying spectral properties of chiral symmetric quantum walks. For example, it states that topologically protected bound states can be characterised by elements of the so-called birth and inherited eigenspaces. The purpose of this talk is to show that this characterisation has a yet another interpretation in terms of the real part of a chiral unitary.

00462 (2/2) : 2D @D405 [Chair: Yohei Tanaka]

[03456] Resonance expansion for quantum walks

Format : Talk at Waseda University
Author(s) : Kenta Higuchi (Ehime University)
Abstract : We study long time behavior of "open" quantum walks by introducing resonances and the resonance expansion. Eigenvalues on the unit circle characterize the localization of quantum walkers. However, an open quantum walk does not have eigenvalues but may have resonances inside the unit circle. Then the decay rate of the quantum walker in any bounded region is described by the modulus of resonances. The eigenstate expansion is generalized to the resonance expansion.

[04207] Spectral scattering theory for quantum walks

Format : Talk at Waseda University
Author(s) : Akito Suzuki (Shinshu university)
Abstract : Spectral scattering theory works to understand the dynamics of quantum walks and obtain the limit distribution of the asymptotic velocity of the walker, which gives a quantum version of the central limit theorem. In this talk, I would like to talk about the recent development of spectral scattering theory for one-dimensional quantum walks.

[04051] Quantum Walk-Based Maze-Solving with Absorbing Holes

Format : Talk at Waseda University
Author(s) : Leo Matsuoka (Hiroshima Institute of Technology)Kenta Yuki (Freelancer)Hynek Lavicka (STTech GmbH)Etsuo Segawa (Yokohama National University)
Abstract : We propose a strategy for finding the shortest path on a bipartite graph maze using a discrete-time quantum walk with absorbing holes. Our numerical analysis shows that the chain of maximum trapped densities detects the

shortest paths in most cases. Furthermore, we discuss the speed of the algorithm and propose a strategy for accelerating it using numerical analysis. Our results offer a potential model for autonomous maze-solving optimization by harnessing natural phenomena.

[03689] Distinguishability and Complexity in Non-Unitary Boson Sampling Dynamics

Format : Online Talk on Zoom
Author(s) : Ken Mochizuki (RIKEN)
Abstract : We show that quantum walks of many photons are closely related to the boson sampling problem and computational complexity. In addition, we consider non-unitary quantum walks, which correspond to photonic dynamics in open quantum systems with post selection. We clarify that the distribution of photons can approach that of distinguishable particles in the long time limit, which makes the non-unitary boson sampling problem easy.

[00465] Linear and Non-linear Approximation of Curves and Surfaces

Session Time & Room :

00465 (1/3) : 1C (Aug.21, 13:20-15:00) @E507

00465 (2/3) : 1D (Aug.21, 15:30-17:10) @E507

00465 (3/3) : 1E (Aug.21, 17:40-19:20) @E507

Type : Proposal of Minisymposium
Abstract : Approximation techniques are used in problems in which it's required to find unknown functions from a set of known data. This problem appears in physics (solution of hyperbolic PDEs), medicine (medical imaging treatment) or topography (Digital Elevation Models) etc.

Reconstruction based on linear schemes, like splines, have proved to be useful in different application (DEM). However they become ineffective for approximating piecewise smooth functions (shocks in solution of hyperbolic PDEs) or edge-dominated images. For such families, nonlinear schemes may improve the approximation performance.

This MS brings together researchers from the two different communities, with the aim to generate scientific dialogue.

[01862] Stable nonlinear inversion : a general framework for interface reconstruction from cell-average

Format : Talk at Waseda University
Author(s) : Albert Cohen (Sorbonne Universite)
Abstract : In this lecture, we present a general framework for solving inverse problem using nonlinear approximation spaces. The main principles build up on the so called Parametrized Background Data Weak method (PBDW) which can be thought as a linear counterpart. As a main and motivating application we discuss the reconstruction of sharp interfaces from cell average at coarse resolutions for which linear methods are known to be uneffective. We discuss the convergence rates of these reconstructions and their optimality.

[02134] Adaptive Multi-Quadric Interpolation: Applications in Image Compression.

Format : Talk at Waseda University
Author(s) : Rosa Donat (Universitat de Valencia)Francesc Aràndiga (Universitat de Valènciacia)Daniela Schenone (Leonardo Sistemi Integrati S.L.R.)
Abstract : Multi-Quadric interpolation techniques depend on a shape parameter that has a direct influence on its

accuracy. The computation of the shape parameter can be performed using 'linear' (e.g. data-independent) estimates or by incorporating adaptive techniques, similar to those used in ENO/WENO schemes to maximize the region of accuracy when using piecewise polynomial interpolatory techniques.

We design 2D Prediction operators within Harten's Multiresolution Framework based on non-separable multi-quadric approximation that incorporates a WENO-type selection of the local shape parameter. We explore the compression properties of the resulting MR transformation, and also the combination of these techniques with the construction of edge maps of the image.

[01772] Reconstructing a Digital Elevation Model from C2 quasi-interpolation

Format : Talk at Waseda University
Author(s) : Domingo Barrera (University of Granada)Salah Eddargani (University of Rome Tor Vergata)Juan Francisco Reinoso (University of Granada)
Abstract : Quasi-interpolation spline in the Bernstein basis is a low-cost computational method for approximating functions or data in one or several variables. Although linked to the degree, regularity and exactness are parameters available to the user. In this contribution we propose to define a one-dimensional quasi-interpolation operator that achieves the optimal approximation order and provides C2 continuous approximants. It will be used to reconstruct a Digital Elevation Model using a tensor product type scheme.

[01766] Low-degree quasi-interpolation in the Bernstein basis

Format : Talk at Waseda University
Author(s) : María José Ibáñez (University of Granada)Salah Eddargani (University of Rome Tor Vergata)Sara Remogna (University of Torino)
Abstract : Spline quasi-interpolation is an effective tool for approximating functions or data. Usually, the quasi-interpolant is defined as a linear combination of the B-splines of a basis of the linear space in which the approximant is to be constructed. In this contribution we present a procedure for constructing quasi-interpolants by directly defining the coefficients of the expression in the Bernstein basis of its restriction to each subinterval induced by a uniform partition of the real line.

00465 (2/3) : 1D @E507 [Chair: Rosa Donat]

[01326] A Nonlinear B-spline quasi-interpolation method,

Format : Talk at Waseda University
Author(s) : Francesc Aràndiga (Universitat de València)
Abstract : Quasi-interpolation based on B-spline approximation methods are used in numerous applications.
However, we observe that the Gibbs phenomenon appears when approximating near
discontinuities. We present nonlinear modifications, based on weighted essentially non-oscillatory (WENO) techniques, of well-known quasi-interpolant methods to avoid this phenomena near discontinuities and, at the same time, maintain the high-order accuracy in smooth regions.

[01853] Edge adaptive schemes and machine learning for image super-resolution

Format : Talk at Waseda University
Author(s) : Agustin Somacal (Sorbonne University)
Abstract : In image processing Edge-adapted methods are used to reconstruct high-resolution images from coarser cell averages. When images are piece-wise smooth functions, interfaces can be approximated by a pre-specified functional class through optimization LVIRA or specific preprocessing ENO-EA. We extend the ENO-EA approach to polynomials, show two methods to treat vertices and compare with learning-based methods in which an artificial neural network is used to attain the same goal.

[01411] Univariate subdivision schemes based on local polynomial regression

Format : Talk at Waseda University
Author(s) : Dionisio F. Yanez (UV)
Abstract : The generation of curves and surfaces from given data is a well-known problem in Computer-Aided Design that can be solved by means of subdivision schemes. They are a powerful tool that allows obtaining new data from the initial one using simple calculations. In some real applications, the initial data are given with noise and interpolatory schemes are not adequate to process them. In this talk, we present some new families of binary univariate linear subdivision schemes using weighted local polynomial regression. We study their properties, such as convergence, monotonicity and polynomial reproduction and show some examples.

[01410] Linear and nonlinear approximation rules arising from optimal denoising

Format : Talk at Waseda University
Author(s) : Sergio López-Ureña (Universitat de València)
Abstract : We explore the design of new linear filter-like methods based on the minimization of the noise variance. But linear methods, when applied to data with large gradients, may lead to some kind of Gibbs phenomenon. To overcome this problem, we combine some of these linear methods in a WENO style to obtain a nonlinear denoising method which handles properly large gradients in the data. Some examples are performed to validate the theoretical results.

00465 (3/3) : 1E @E507 [Chair: Domingo Barrera]

[01560] A totally C^2 quartic splines defined on mixed macro-structures

Format : Online Talk on Zoom
Author(s) : Salah Eddargani (University of Rome "Tor Vergata")Domingo Barrera (University of Granada)María José Ibáñez (University of Granada)
Abstract : This work deals with the construction of normalized B-splines of degree four and C^2 smooth everywhere on triangulations endowed with mixed splits. The main splits involved herein are Powell-Sabin (6-), and Modified Morgan-Scott (10-) splits. With the help of Marsden identity, a family of C^2 quartic quasi-interpolation splines of optimal orders has been provided.

[01502] Construction of quadratic and cubic orthogonal wB-spline wavelets

Format : Online Talk on Zoom
Author(s) : Mohamed Ajeddar (MISI Laboratory, Faculty of Sciences and Technology, University Hassan First, Settat, Morocco.)
Abstract : The definition and basic properties of ωB-splines, frequently used as primal scaling functions, are introduced, as well as their refinement equation. Then, a method for constructing orthogonal wavelets using $\mathcal{C}^1$ and $\mathcal{C}^2$ ωB-splines is presented.

[01492] Algebraic Hyperbolic spline interpolation by means of integral values.

Format : Online Talk on Zoom
Author(s) : Mohammed Oraiche (Department of Mathematics, University Hassan First, Settat, Morocco.)
Abstract : In this paper, a cubic Hermite spline interpolating scheme reproducing both linear polynomials and hyperbolic functions is considered. The interpolating scheme is mainly defined by means of integral values over the subintervals of a partition of the function to be approximated, rather than the function and its first derivative values. The scheme provided is C^2 everywhere and yields optimal order. We provide some numerical tests to illustrate the good performance of the novel approximation scheme.

[00467] Volatility modeling in finance

Session Time & Room :

00467 (1/3) : 4C (Aug.24, 13:20-15:00) @D502

00467 (2/3) : 4D (Aug.24, 15:30-17:10) @D502

00467 (3/3) : 4E (Aug.24, 17:40-19:20) @D502

Type : Proposal of Minisymposium
Abstract : Volatility is the single most important factor driving the dynamics of financial assets. Volatility modeling has been a very active field of research in the past years. Recent developments include in particular rough volatility, path-dependent volatility, including signature models, as well as designing models that jointly calibrate to S&P 500 and VIX options. This minisymposium aims to present in one place, compare, and bridge different new approaches on volatility modeling. It is our hope that fruitful ideas and collaborations can emerge from it.
Organizer(s) : Julien GuyonSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.
Classification : 91-XX, 60-XX, 62-XX, Quantitative finance
Minisymposium Program :

00467 (1/3) : 4C @D502 [Chair: Julien Guyon]

[05137] Volatility is (Mostly) Path-Dependent

Author(s) : Julien Guyon (Ecole des Ponts ParisTech)Jordan Lekeufack Sopze (University of California, Berkeley)

Abstract : Using data, we show that volatility is mostly path-dependent: 90% of the implied volatility of equity indexes is explained endogenously by past index returns thanks to a simple linear model that combined weighted sums of past daily returns and squared returns with different time-shifted power-law weights. It thus suggests a continuous-time Markovian path-dependent volatility model. This model captures key stylized facts of volatility, and fits SPX and VIX smiles well, solving joint SPX/VIX smile calibration problem.

[05626] The 4-Factor Path-Dependent Volatility Model

Author(s) : Julien Guyon (Ecole des Ponts ParisTech)

Abstract : The natural Markovian continuous-time version of the empirical path-dependent volatility (PDV) uncovered in [Guyon and Lekeufack, Volatility Is (Mostly) Path-Dependent, 2022] is the 4-Factor PDV model. Two factors describe the short and long dependence of volatility on recent returns (trend), while the two other factors describe the short and long dependence of volatility on recent returns squared (historical volatility). We show that this model, which is inferred from the empirical joint behavior of returns and volatility, captures all the important stylized facts of volatility: leverage effect, volatility clustering, large volatility spikes followed by a slower decrease, roughness at the daily scale, very realistic SPX and VIX smiles, joint calibration, Zumbach effect and time-reversal asymmetry. Being Markovian in low dimension, the model is very easy and fast to simulate. It can easily be enhanced with stochastic volatility (PDSV) to account for exogenous shocks. This is joint work with Jordan Lekeufack.

[01960] A theoretical analysis of Guyon's toy volatility model

Format : Talk at Waseda University

Author(s) : Ofelia Bonesini (Imperial College London)Antoine Jacquier (Imperial College London)Chloé Lacombe (Morgan Stanley)

Abstract : We provide a thorough analysis of a path-dependent volatility model introduced by Guyon,
proving existence and uniqueness of a strong solution, characterising its behaviour at boundary points,
providing asymptotic closed-form option prices as well as deriving small-time behaviour estimates.

[05614] Prediction through Path Shadowing Monte-Carlo

Format : Online Talk on Zoom

Author(s) : Julien Guyon (Ecole des Ponts ParisTech)Rudy Morel (Ecole Normale Superieure)

Abstract : We introduce a Path Shadowing Monte-Carlo method, which provides prediction of future paths, given any generative model. At a given date, it averages future quantities over generated price paths whose past history matches, or “shadows”, the actual (observed) history. We test our approach using paths generated from a maximum entropy model of financial prices, based on a recently proposed multi-scale analogue of the standard skewness and kurtosis called “Scattering Spectra”. This model promotes diversity of generated paths while reproducing the main statistical properties of financial prices, including stylized facts on volatility roughness. Our method yields state-of-the-art predictions for future realized volatility. It also allows one to determine conditional option smiles for the S&P500. These smiles depend only on the distribution of the price process, and are shown to outperform both the current version of the Path Dependent Volatility model and the option market itself.

00467 (2/3) : 4D @D502 [Chair: Julien Guyon]

[04506] Understanding how market impact shapes rough volatility

Author(s) : Mathieu Rosenbaum (École Polytechnique)Gregoire Szymanski (Ecole Polytechnique)

Abstract : We explain the subtle connection between the shape of market impact curves and the rough behavior of the volatility. We particularly focus on the celebrated square-root law and on the role of the participation rate in the price and volatility formation process.

[04065] Pricing in affine forward variance models

Format : Talk at Waseda University

Author(s) : Jim Gatheral (Baruch College, CUNY)

Abstract : In affine forward variance (AFV) models, the moment generating function may be expressed as the convolution of the forward variance curve and the solution of an associated convolution integral equation. In the case of the rough Heston model, this convolution integral equation may be solved numerically using the Adams scheme and approximately using a rational approximation. We show that in the general case, AFV models may be simulated

efficiently using a hybrid version of Andersen's QE scheme. We illustrate convergence of the scheme numerically in the special case of the rough Heston model.

[02829] The rough Hawkes Heston model

Format : Talk at Waseda University
Author(s) : Sergio Andres Pulido Nino (ENSIIE-LaMME, Evry)Alessandro Bondi (Scuola Normale Superiore di Pisa)Simone Scotti (Universita di Pisa)
Abstract : We introduce an extension of the Heston stochastic volatility model that incorporates rough volatility and jump clustering phenomena. In our model, the spot variance is a rough Hawkes-type process proportional to the intensity process of the jump component appearing in the dynamics of the spot variance itself and the log returns. The model belongs to the class of affine Volterra models. In particular, the Fourier-Laplace transform of the log returns and the square of the volatility index can be computed explicitly in terms of solutions of deterministic Riccati-Volterra equations, which can be efficiently approximated using a multi-factor approximation technique. Prices of options on the underlying and its volatility index can then be obtained using Fourier-inversion techniques. We show that a parsimonious setup, characterized by a power kernel and an exponential law for the jumps, is able to simultaneously capture the behavior of the implied volatility smile for both S&P 500 and VIX options. Our findings demonstrate the relevance, under an affine framework, of rough volatility and self-exciting jumps in order to jointly calibrate S&P 500 and VIX smiles.

[05086] Recent advances on rough volatility

Format : Talk at Waseda University
Author(s) : Antoine Jacquier (Imperial College London)
Abstract : Empirical evidence has recently highlighted that volatility of financial markets was not Markovian, giving rise to a new paradigm called "rough volatility". In this talk, we consider several recent advances in the topic, from a modelling point of view (suggesting interesting extensions of fractional Brownian motion) and from numerical aspects.

00467 (3/3) : 4E @D502 [Chair: Julien Guyon]

[04764] Does the Term-Structure of Equity At-the-Money Skew Really Follow a Power Law?

Format : Talk at Waseda University
Author(s) : Mehdi El Amrani-Zirifi (Bloomberg LP)Julien Guyon (Ecole des Ponts ParisTech)
Abstract : Using two years of S&P 500, Eurostoxx 50, and DAX data, we empirically investigate the term-structure of the at-the-money-forward (ATM) skew of equity indexes. While a power law (2 parameters) captures the term-structure well away from short maturities, the power law fit deteriorates considerably when short maturities are included. By contrast, 3-parameter shapes such as time-shifted or capped power laws, are shown to fit well regardless of whether short maturities are included or not.

[04899] Fast exact joint S&P 500/VIX smile calibration in discrete and continuous time

Format : Talk at Waseda University
Author(s) : Florian Bourgey (Bloomberg L.P.)Julien Guyon (Ecole des Ponts ParisTech)
Abstract : We introduce the Newton--Sinkhorn and implied Newton algorithms which significantly speed up the Sinkhorn algorithm that (Guyon, Risk, April 2020) used to build the first arbitrage-free model exactly consistent with S&P 500 and VIX market data. Using a purely forward Markov functional model, we show how to build a continuous-time extension of the previous discrete-time model. We also compute model-free bounds on S&P 500 options that show the importance of taking VIX smile information into account. Extensive numerical tests are conducted.

[03758] Joint calibration to SPX and VIX options with signature-based models

Format : Talk at Waseda University
Author(s) : Christa Cuchiero (University of Vienna)Guido Gazzani (University of Vienna)Janka Möller (University of Vienna)Sara Svaluto-Ferro (University of Verona)
Abstract : We consider a stochastic volatility model where the dynamics of the volatility are described by linear functions of the signature of a primary process. Under the assumption that this process is polynomial, we can express the log-price and the VIX squared as linear functions of the signature of an (augmented) primary process. This feature can be efficiently used for calibration purposes since the signature samples can be easily precomputed. We also propose a Fourier approach for VIX and SPX options exploiting that the signature of the augmented primary process is an infinite dimensional affine process.

[03638] Neural Joint SPX/VIX Smile Calibration

Format : Talk at Waseda University
Author(s) : Scander Mustapha (Princeton University)Julien Guyon (CERMICS, Ecole des Ponts ParisTech)
Abstract : We calibrate neural stochastic differential equations jointly to S&P 500 smiles, VIX futures, and VIX smiles. Drifts and volatilities are modeled as neural networks. Minimizing a suitable loss allows us to fit market data for multiple S&P 500 and VIX maturities. A one-factor Markovian stochastic local volatility model is shown to fit both smiles and VIX futures within bid-ask spreads. The joint calibration actually makes it a pure path-dependent volatility model, confirming the findings in [Guyon, 2022, The VIX Future in Bergomi Models: Fast Approximation Formulas and Joint Calibration with S&P 500 Skew].

[00468] Stochastic Modelling in Finance

Session Time & Room : 4D (Aug.24, 15:30-17:10) @D505

Type : Proposal of Minisymposium
Abstract : The mini-symposium is devoted to the recent developments in stochastic modelling in finance. It will include stochastic modelling of big data in finance, portfolio optimization problems in incomplete stochastic volatility financial markets, driven by both Brownian motion and a jump processes, as well as a Heston 1/2 component and a 3/2 component the state-of-the-art 4/2 stochastic volatility models, and also new modelling involving Parrondo's paradox and its financial applications.
Organizer(s) : Anatoliy Swishchuk
Classification : 91G15, 91B24, 60H10, 60K15, 60F05
Minisymposium Program :

00468 (1/1) : 4D @D505 [Chair: Anatoliy Swishchuk, University of Calgary, Calgary, AB, Canada]

[01313] Portfolio optimization in the family of 4/2 stochastic volatility models.

Format : Online Talk on Zoom
Author(s) : Marcos Escobar-Anel (Western University, Department of Statistical and Actuarial Sciences.)
Abstract : The state-of-the-art 4/2 stochastic volatility model was recently proposed by Grasselli in 2017 and has gained great attention ever since. This model is a superposition of a Heston (1/2) component and a 3/2 component, bringing the best of the two nested models. This talk gives an overview of recent progress in the application of the model, as well as a multivariate generalization, to portfolio optimization, in particular within expected utility theory. The work includes the study of CRRA and HARA utilities, the presence of consumption, as well as considerations about complete/incomplete markets and ambiguity-aversion. All is complemented with the analysis of wealth-equivalent losses to gain insight into popular suboptimal strategies.

[01486] Parrondo's paradox and financial applications

Format : Online Talk on Zoom
Author(s) : Bruno N Remillard (HEC Montreal)
Abstract : In this talk, I will start by giving an introduction to Parrondo's paradox, then I will present recent results on this topic, and finally I will talk about financial applications.

[01304] Optimal portfolio analysis on finite and small-time horizons

Format : Online Talk on Zoom
Author(s) : Indranil SenGupta (North Dakota State University)
Abstract : In this presentation, we consider the portfolio optimization problem in a financial market under a general utility function. We consider an incomplete stochastic volatility market model that is driven by both Brownian motion and jump process. We obtain a closed-form formula for an approximation to the optimal portfolio in a small-time horizon. This is obtained by finding the associated Hamilton-Jacobi-Bellman integro-differential equation and then approximating the value function by constructing appropriate supersolution and subsolution.

[01292] Stochastic Modelling of Big Data in Finance

Format : Talk at Waseda University
Author(s) : Anatoliy Swishchuk (University of Calgary)
Abstract :
This talk will review some recent results in stochastic modelling of big data in finance, including semi-Markov

modelling, modelling with Hawkes processes, multivariate modelling, to name a few. Numerical results are used to explain, visualize and justify the proposed models, and are based on real data such as LOBster, CISCO, Xetra and Francfurt markets stocks and other data.

[00471] Recent Advancements in Electrical Impedance Tomography

Session Time & Room :

00471 (1/2) : 4C (Aug.24, 13:20-15:00) @D515

00471 (2/2) : 4D (Aug.24, 15:30-17:10) @D515

Type : Proposal of Minisymposium
Abstract : Electrical impedance tomography is an imaging modality based on solving the inverse conductivity problem, in which known boundary voltages and currents are used to reconstruct information about an object's interior. The inversion process is known to be both highly nonlinear and highly ill-posed, and thus provides researchers with an ongoing wealth of interesting problems. The cutting edge of research in EIT includes both theoretical and computational developments, and is relevant to a wide variety of medical and industrial applications. This minisymposium will gather leading experts in EIT along with young researchers to share their new results and insights.
Organizer(s) : Melody Alsaker, Samuli Siltanen
Classification : 92C55, 35R30, 78A46
Minisymposium Program :

00471 (1/2) : 4C @D515 [Chair: Samuli Siltanen]

[04879] A Multithreaded Implementation of the D-bar Algorithm for 2D Functional EIT Imaging

Format : Talk at Waseda University
Author(s) : Melody Alsaker (Gonzaga University)
Abstract : D-bar algorithms for Electrical Impedance Tomography have high computational complexity. Previous attempts at fast D-bar implementations had some limitations: these methods used a parallelization strategy which caused a time delay between data acquisition and reconstruction, and they used coarse spatial meshes with large numbers of CPU cores. Furthermore, data acquisition speed of modern EIT systems has increased, making previously published runtimes out-of-date. In this talk, we present a new multithreaded solution which addresses these problems.

[02729] New insight into EIT reconstruction using virtual X-rays

Format : Talk at Waseda University
Author(s) : Siiri Rautio (University of Helsinki)
Abstract : We introduce a new reconstruction algorithm for EIT, which provides a connection between EIT and X-ray tomography. We divide the ill-posed and nonlinear inverse problem of EIT into separate steps. We start by calculating “virtual” X-ray projection data from the DN map. Then, we perform algebraic operations and integration, ending up with a blurry Radon sinogram. We use neural networks to deconvolve the sinogram and finally, we compute a reconstruction using the inverse Radon transform.

[04009] Combining electrical impedance tomography and machine learning for stroke classification

Format : Talk at Waseda University
Author(s) : Juan Pablo Agnelli (National University of Córdoba)
Abstract : There are two main types of stroke: ischemic and hemorrhagic. In both cases the symptoms are the same, but treatments very different, so a cost-effective and portable classification device is needed.
In (Agnelli et al. 2020) a methodology for classifying stroke was proposed. The methodology combines the use of EIT data, the computation of VHED functions (Greenleaf et al. 2018) that have a geometric interpretation of the EIT data and finally machine learning applied to these VHED functions for the stroke classification. In this talk we continue this research line and extend the previous results to a more realistic scenario.

[03129] Recent developments on integral equation approaches for Electrical Impedance Tomography

Format : Talk at Waseda University

Author(s) : Cristiana Sebu (University of Malta)

Abstract : The talk is focused on recent developments of reconstruction algorithms that can be used to approximate admittivity distributions in Electrical Impedance Tomography. The algorithms are non-iterative and are based on linearized integral equation formulations to allow reconstructions of the conductivity and/or permittivity distributions of two and three-dimensional domains from boundary measurements of both low and high-frequency alternating input currents and induced potentials. Reconstructions from noisy simulated data are obtained from single-time, time-difference and multiple-times data.

00471 (2/2) : 4D @D515 [Chair: Melody Alsaker]

[04744] Monitoring of hemorrhagic stroke using Electrical Impedance Tomography

Format : Talk at Waseda University

Author(s) : Ville Kolehmainen (Department of Technical Physics, University of Eastern Finland)

Abstract : In this talk, we present recent progress in development of electrical impedance tomography (EIT)
based bedside monitoring of hemorrhagic stroke. We present the practical setup and pipeline for this novel application of EIT and the image reconstruction method we have developed for it.
Feasibility of the approach is studied with simulated data from anatomically highly accurate simulation models and experimental phantom data from a laboratory setup

[04874] Exploration of deep generative modelling approaches to electrical impedance tomography

Format : Talk at Waseda University

Author(s) : Valentina Candiani (University of Genoa)

Abstract : Reconstruction of conductivity images in electrical impedance tomography (EIT) requires the solution of a nonlinear inverse problem on noisy data. This problem is typically ill-conditioned and solution algorithms need either simplifying assumptions or regularization based on a priori knowledge.
In this work we study the applicability, the challenges and the limitations of some relatively new deep generative models such as score-based generative diffusion models and normalising flows, for both image reconstruction and medical anomaly detection. This talk will present some preliminary results obtained with such approaches in the application of EIT to the detection of stroke.

[04904] Fast CGO-based absolute reconstructions for 3D EIT

Format : Talk at Waseda University

Author(s) : Peter Muller (Villanova University)Sarah Hamilton (Marquette University)

Abstract : Complex geometrical optics (CGO)-based methods for 3-D electrical impedance tomography are presented. Calderón's method and the $\mathbf{t}^{\mathrm{exp}}$ method are adapted for reconstructions from 3-D electrode data. These are the first absolute images to be produced from these methods for 3-D electrode data, both simulated and experimental. Some benefits of these CGO-based methods are that they provide real-time imaging and are shown to be robust to modelling errors such as electrode location and domain size.

[05054] Use of reference measurements in electrical tomography

Format : Talk at Waseda University

Author(s) : Aku Seppänen (University of Eastern Finland)Laura E. Dalton (Duke University)Mikko Räsänen (University of Eastern Finland)Moe Pourghaz (North Carolina State University)

Abstract : Reconstruction methods in electrical resistance/capacitance tomography are often divided into classes of absolute and difference methods. While absolute reconstructions are based on data from a single time instant, difference reconstructions use reference data, to image the change of conductivity/permittivity from the reference state qualitatively. In this talk, we demonstrate that absolute reconstructions can also benefit from the use of reference data, when available, especially because it improves their tolerance to modeling errors.

[00475] Variational methods and periodic solutions in the n-body problem

Session Time & Room :

00475 (1/3) : 1C (Aug.21, 13:20-15:00) @E819

00475 (2/3) : 1D (Aug.21, 15:30-17:10) @E819

00475 (3/3) : 1E (Aug.21, 17:40-19:20) @E819

Type : Proposal of Minisymposium
Abstract : The n-body dynamics have been studied by many prominent mathematicians and physicists for centuries. With the developments of mathematical and computational tools, there has been exciting progress during the past two decades. This progress includes variational approaches, stability, chaotic phenomenon, integrability, central configurations, solar system, space mission designs, and planetary formations, among many others. In this minisymposium, we aim to provide a forum for researchers to share the latest developments and exchange ideas.

[04108] Regularizing Fuel-Optimal, Multi-Impulse Trajectories with Second-Order Derivatives

Format : Talk at Waseda University
Author(s) : Kenta Oshima (Hiroshima Institute of Technology)
Abstract : The present work implements analytical second-order derivatives for a direct multiple shooting-based regularized method of minimizing the fuel expenditure for spacecraft trajectories. The high-order dynamical information, such as the state transition tensor, expresses the Hessian matrix of the Lagrange function in the nonlinear programming problem. The result is an efficient tool for robustly and accurately computing fuel-optimal, multi-impulse trajectories in the regularized framework of removing singularities associated with null thrust impulses.

[04642] Floquet Mode-Based Transfer between Halo Orbits Using Solar Sails

Format : Talk at Waseda University
Author(s) : Toshihiro Chujo (Tokyo Institute of Technology)
Abstract : Transfer between halo orbits around the sun-Earth L2 using solar sails is discussed in the circular restricted three-body problem. The path planning and the corresponding tilting angle of the sail are determined based on the Floquet mode, such that the coefficient of the center manifold for transition to another family of the halo orbit is maximized while that of the unstable manifold is suppressed under a certain threshold.

[04549] Low-energy Transfer to the Earth-Moon Periodic Orbit: CubeSat Application

Format : Talk at Waseda University
Author(s) : Takuya Chikazawa (The University of Tokyo)
Abstract : This work investigates trajectories design for the ride-share spacecraft that begin with the Moon swing-by. In this type of trajectory design, mission designers need to consider uncertainties under limited propulsion capability. To aid trajectories design, established theory, such as manifold from periodic orbit in circular restricted three-body system, are often used. We demonstrate how to use such theory in actual mission design and operation phases.

[04028] Transfer between Resonances via Lobe Dynamics in the Standard Map

Format : Talk at Waseda University
Author(s) : Naoki Hiraiwa (Kyushu University)Isaia Nisoli (Universidade Federal do Rio de Janeiro)Yuzuru Sato (Hokkaido University)Mai Bando (Kyushu University)Shinji Hokamoto (Kyushu University)
Abstract : Lobe dynamics is a useful structure to reveal phase space transport of chaotic trajectories by stable and unstable manifolds of resonant orbits. Based on lobe dynamics, this study formulates the transfer problem between two quasi-periodic orbits to find the optimal lobe sequence. Especially, the lobe dynamics of resonant orbits of the standard map are extracted and used to solve the problem. Applications to spacecraft trajectory design are also discussed.

00475 (2/3) : 1D @E819 [Chair: Guowei Yu]

[03973] Distance estimates for action-minimizing solutions of the n-body problem

Format : Talk at Waseda University
Author(s) : Bo-Yu Pan (National Chung-Hsing University)
Abstract : In this talk we estimate mutual distances of action minimizing solutions for the n-body problem. We will present some quantitative estimates for these solutions, including their action values and bounds for their mutual distances. These estimates will facilitate numerical explorations to locate and search new orbits effectively.

[04970] Some progress on the N-center problem by variational methods

Format : Talk at Waseda University
Author(s) : Kuo-Chang Chen (National Tsing Hua University)
Abstract : Since Chenciner-Montgomery's construction of the figure-8 orbit for the 3-body problem, in the past 20+ years variational methods have succeeded in discovering new solutions for the N-body and N-center problems, within certain symmetry of topological classes. I will briefly outline recent progress, main ideas and obstacles, and some ongoing research topics for the N-center problem. In particular, I will outline variational construction of satellite orbits for N=2, and recent joint works with Guowei Yu on periodic and chaotic orbits for N>2.

[04318] Periodic solutions bifurcated from the figure-eight choreography: non-planar eight and non-symmetric eight

Format : Talk at Waseda University
Author(s) : Hiroshi Fukuda (Kitasato University)Toshiaki Fujiwara (Kitasato University)Hiroshi Ozaki (Tokai University)
Abstract : The figure-eight choreography of equal mass three bodies under the homogeneous potential $-1/r^{\alpha}$ and under the Lennard-Jones type potential $1/r^{12} - 1/r^{6}$, bifurcates in power α and in period T, respectively, where r is a distance between bodies. We found two interesting bifurcation solutions: a figure-eight choreography with an orbit having no spatial symmetry, and a non-planar figure-eight solution which is unfortunately not choreographic.

[04797] Variational structures for infinite transition orbits of monotone twist maps

Format : Talk at Waseda University
Author(s) : Yuika Kajihara (Kyoto university)
Abstract : There is a lot of study on the dynamics of area-preserving maps, and Poincare and Birkhoff's works are well-known. In this talk, we define a special class of area-preserving maps called monotone twist maps to consider the variational structures of area-preserving maps. Variational structures determined from twist maps can be used for constructing characteristic trajectories of twist maps. Our goal is to define the variational structure such as giving infinite transition orbits through minimizing methods.

00475 (3/3) : 1E @E819 [Chair: Kuo-Chang Chen]

[03812] Periodic and homo/heteroclinic solutions of the restricted three-body problem

Format : Talk at Waseda University
Author(s) : Mitsuru Shibayama (Kyoto University)
Abstract : The restricted three-body problem is an important research area that deals with significant issues in celestial mechanics, such as analyzing asteroid movement behavior and orbit design for space probes. We aim to show the existence of periodic and heteroclinic orbits in the planar circular R3BP. To find these orbits, we adopt a variational approach and symmetry.

[04714] Existence of transit orbits in the restricted three-body problem

Format : Talk at Waseda University
Author(s) : Taiga Kurokawa (Kyoto University)Mitsuru Shibayama (Kyoto University)
Abstract : We discuss the existence of transit orbits with fixed energy in the planar circular restricted three-body problem. In 2005, Moeckel provided sufficient conditions for the existence of transit orbits using the Maupertuis functional. In this talk, we give another sufficient condition using the Lagrange functional. This is joint work with Mitsuru Shibayama.

[03894] regularizable collinear periodic solutions in the n-body problem with arbitrary masses

Format : Talk at Waseda University
Author(s) : Guowei Yu (Nankai University)
Abstract : For n-body problem with arbitrary positive masses, we prove there are regularizable collinear periodic solutions for any ordering of the masses, going from a simultaneous binary collision to another in half of a period with half of the masses moving monotonically to the right and the other half monotonically to the left. When the masses satisfy certain equality condition, the solutions have extra symmetry. This also gives a new proof of the Schubart orbit, when n=3.

[03430] Braids and periodic solutions of the planar N-body problem

Format : Talk at Waseda University
Author(s) : EIKO KIN (Osaka University)Yuika Kajihara (Kyoto University)Mitsuru Shibayama (Kyoto University)
Abstract : Periodic solutions of the planar N-body problem determine braids through the trajectory of N bodies. Braids fall into three types: periodic, reducible and pseudo-Anosov. The last type is significant for the study of dynamical systems. In this talk I discuss a family of braid types obtained from periodic solutions, simple choreographies of the chain types by Guowei Yu and multiple choreographic solutions of the planar 2n-body problem by Shibayama.

[00479] Advances in clinically-driven AI image reconstruction and processing

Session Time & Room : 1E (Aug.21, 17:40-19:20) @E818

Type : Proposal of Minisymposium
Abstract : The application of Artificial Intelligence methods, particularly in medical imaging, attracts huge interest from the mathematics and computer science community. Often, AI-based methods provide solutions surpassing image quality metrics compared to traditional methods. However, it's not always obvious if improved image quality metrics necessarily translate to improved clinically-relevant questions such as diagnosis and prognosis. This minisymposium focuses on applied AI methodologies that are clinically-oriented and incorporate direct measures and uses of clinical metrics in the learning or evaluation sections. We will cover topics including advances in model-based learned reconstruction, AI-based inverse problems, regularisation, generative models and their clinical applications.
Organizer(s) : Ander Biguri, Lorena Escudero
Classification : 68Txx, 92Cxx
Minisymposium Program :

00479 (1/1) : 1E @E818 [Chair: Ander Biguri & Lorena Escudero]

[05254] The impact of model-based ML driven CT reconstruction on tumor segmentation and clinical diagnosis

Format : Talk at Waseda University
Author(s) : Ander Biguri (University of Cambridge)Carola-Bibiane Schönlieb (University of Cambridge)Lorena Escudero (University of Cambridge)
Abstract : Machine learning has recently found success in tomographic image reconstruction, particularly CT. This work explores its impact on image quality, but most importantly, how (or if) that image quality translates to clinically relevant parameters, in this case radiomics. The evaluation of the reconstruction quality thus is moved from image quality metrics like SSIM or PSNR to clinically relevant metrics like predictive power of radiomics based tumour analysis.

[03919] Bringing research advances in imaging sciences into the clinic

Format : Talk at Waseda University
Author(s) : Ozan Öktem (KTH Royal Institute of Technology)Lorena Escudero (University of Cambridge)Thomas Buddenkotte (Jung Diagnostics GmbH)Cathal McCague (University of Cambridge)Carola-Bibiane Schönlieb (University of Cambridge)Evis Sala (University of Cambridge)
Abstract : The talk will survey both scientific and practical challenges associated with making state-of-the-art deep learning methods available to clinicians. It will showcase these challenges in an ambitious setting where one seeks to use an end-to-end deep learning based approach for joint reconstruction and downstream post-processing task, the latter being specific for a clinical use case.

[02867] Spectral Normalisation of Depthwise Separable Convolutions for Medical Applications

Format : Talk at Waseda University
Author(s) : Christina Runkel (University of Cambridge)Christian Etmann (University of Cambridge)Michael Moeller (University of Siegen)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : An increasing number of models require the control of the spectral norm of convolutional layers of a neural network. While there is an abundance of methods for estimating and enforcing upper bounds on those during training, they are typically costly in either memory or time. In this talk, we introduce a very simple method for spectral normalisation of depthwise separable convolutions, which introduces negligible computational and memory overhead - allowing to control spectral norms for practical relevant applications like medical imaging.

[05266] Mice PET/CT Dataset Augmentation using a 3D Single Image GAN

Format : Online Talk on Zoom
Author(s) : Jeremy Kim (Stanford University)Jonathan Fisher (Stanford University)Craig Levin (Stanford University)
Abstract : In this study, we applied GANs for 3D mice PET/CT data augmentation; these synthetic mice will be used in deep learning (DL) based preclinical research. The lack of available datasets makes it difficult for researchers to apply DL to solve tasks that involve small-animal datasets, such as emission-based attenuation correction for small-animals PET/MR. We applied the Single-Image GAN (SinGAN) Framework to generate multiple realistic synthetic PET/CT scans of mice from a limited number of examples.

[00484] Matrix Analysis and Applications

Session Time & Room :

00484 (1/4) : 4C (Aug.24, 13:20-15:00) @G306

00484 (2/4) : 4D (Aug.24, 15:30-17:10) @G306

00484 (3/4) : 4E (Aug.24, 17:40-19:20) @G306

00484 (4/4) : 5B (Aug.25, 10:40-12:20) @G306

Type : Proposal of Minisymposium
Abstract : The goal of the minisymposium is to stimulate research and foster interaction of researchers. It scope includes any topics in matrices and their applications. Matrix analysis is widely used in mathematics with applications in control and systems theory, image processing, operations research, scientific computing, statistics, and engineering. This minisymposium has multiple sessions which provide an opportunity for researchers to exchange ideas and recent developments in this active area of research. Participants are from Canada, China, Japan, Macau, Norway, Pakistan, Portugal, Singapore, South Korea, and USA.
Organizer(s) : Luyining Gan, Tin-Yau Tam, Qing-Wen Wang, Yang Zhang
Classification : 15AXX
Minisymposium Program :

00484 (1/4) : 4C @G306 [Chair: Tin-Yau Tam]

[01267] Combinatorial Perron Parameters and Classes of Trees

Format : Talk at Waseda University
Author(s) : Enide Cascais Andrade (CIDMA, University of Aveiro, Portugal)Lorenzo Ciardo (University of Oxford)Geir Dahl (University of Oslo)
Abstract :
The main goal of this talk is to present recent results related with the combinatorial Perron
parameters
introduced in previous papers for certain classes of trees, and related bounds for these parameters.
These parameters are related to algebraic connectivity of trees and corresponding centers.

[01379] Poset matrices and associated algebras

Format : Talk at Waseda University
Author(s) : Gi-Sang Cheon (Sungkyunkwan University)
Abstract : We introduce the constructions of poset matrices by defining several partial compositions on the species of poset matrices. Some of these partial composition operations are shown to define a set operad structure. We also obtain various matrix algebras obtained from incidence algebras of Riordan posets.

[01266] Majorization orders for $(0, \pm 1)$-matrices

Format : Talk at Waseda University
Author(s) : Geir Dahl (University of Oslo)Alexander Guterman (Bar-Ilan University)Pavel Shteyner (Bar-Ilan University)
Abstract : Matrix majorization is a generalization of classical majorization for vectors; an important notion in many areas of mathematics. The talk gives some majorization background, and then presents a study of matrix majorization for $(0, \pm 1)$-matrices, i.e., matrices whose entries are restricted to 0, 1 and -1. In particular, we characterize when the zero vector is weakly majorized by a matrix, and discuss related results. Different connections are discussed, and characterizations of majorization are given.

[00830] The ranks and decompositions of quaternion tensors

Format : Talk at Waseda University
Author(s) : Yang Zhang (University of Manitoba)Yungang Liang (University of Manitoba)
Abstract : Quaternion tensors have attracted more and more attentions in recent years. Many applications have been found in various areas. In this talk, we discuss the maximal ranks of quaternion tensors, in particular, the third-order case. We also investigate the canonical forms, CP and Tucker decompositions of some quaternion tensors.

00484 (2/4) : 4D @G306 [Chair: Yang Zhang]

[03621] Log-majorization and inequalities of power means

Format : Talk at Waseda University
Author(s) : Sejong Kim (Chungbuk National University)
Abstract : As non-commutative versions of the quasi-arithmetic mean, we consider the Lim-Palfia's power mean, Renyi right mean, and Renyi power mean of positive definite matrices. We see that the Lim-Palfia's power mean of negative order converges increasingly to the log-Euclidean mean with respect to the weak log-majorization. Furthermore, we establish the weak log-majorization relationships between power means and provide the boundedness of Renyi power mean.

[00868] Matrix Problems in International Economics

Format : Talk at Waseda University
Author(s) : Konstantin Kucheryavyy (University of Tokyo)
Abstract : Analyzing properties of general equilibrium models in economics amounts to analyzing properties of nonlinear systems of equations. The standard questions asked in this context are about existence and uniqueness of solutions to a nonlinear system of equations, characterization of multiplicity of solutions, and behavior of solutions in response to changes in parameters. One approach to address these questions is to formulate them in terms of matrix algebra. This approach has been especially fruitful when applied to classes of models arising in international economics. Such models often give rise to matrices with striking properties, but formally proving the observed properties usually

constitutes a challenge. In my presentation, I will consider several matrix problems that arise in the international economics context and sketch related proofs. I will also discuss open questions in this literature.

[01404] Spectral inequalities for Kubo-Ando and Heinz means

Format : Talk at Waseda University
Author(s) : Rute Correia Lemos (CIDMA, University of Aveiro)Graça Soares (CMAT-UTAD, University of Trás-os Montes e Alto Douro)
Abstract : In this talk, spectral inequalities, involving Kubo-Ando operator connections and means of positive semidefinite matrices, are surveyed. Some Log-majorization type results are presented. Singular values inequalities for Heinz mean of matrices, which are not of Kubo-Ando type, and its 'harmonic' variant are also given.

[00800] Limit of the induced Aluthge transformations

Format : Talk at Waseda University
Author(s) : Takeaki Yamazaki (Toyo University)
Abstract : Let $\mathcal{H}$ and $B(\mathcal{H})$ be a complex Hilbert space and the algebra of all bounded linear operators on $\mathcal{H}$, respectively. For $T \in B(\mathcal{H})$ with the polar decomposition $T = U|T|$, Aluthge transformation is known as $\Delta(T) := |T|^{1/2}U|T|^{1/2}$. In this talk, we shall introduce a generalization of Aluthge transformations and limit point of its iterations.

00484 (3/4) : 4E @G306 [Chair: Sejong Kim]

[01263] Geometric inequalities for contraction matrices

Format : Talk at Waseda University
Author(s) : Tin-Yau Tam (University of Nevada, Reno)
Abstract : Given two $n \times n$ contraction matrices W and Z, i.e., $I - WW^* \geq 0$ and $I - ZZ^* \geq 0$, L.K. Hua's inequalities (1955) assert that

$$\det(I - WW^*) \det(I - ZZ^*) \leq |\det(I - WZ^*)|^2 \leq \det(I + WW^*) \det(I + ZZ^*). \tag{2}$$

In this talk we will present geometry behind Hua's inequalities in the context of elliptical and hyperbolic geometry.

[01307] The generalized quaternion matrix equation

Format : Talk at Waseda University
Author(s) : Xin Liu (Macau University of Science and Technology)Cui E Yu (Macau University of Science and Technology)
Abstract : We consider the matrix equation $AXB + CX^{\star}D = E$ over the generalized quaternions, where $X^{\star}$ is one of X, X^*, the η-conjugate or the η-conjugate transpose of X with $\eta \in \{i, j, k\}$. We define two new real representations of a generalized quaternion matrix, then we derive the solvability conditions for the mentioned matrix equation. Moreover, we also discuss the existence of $X = \pm X^{\star}$ solutions to the generalized quaternion matrix equation $AXB + CXD = E$.

00484 (4/4) : 5B @G306 [Chair: Yang Zhang]

[01222] Some new results on matrix and tensor equations

Format : Online Talk on Zoom
Author(s) : Qing-Wen Wang (Shanghai University, China)
Abstract : In this talk, we mainly introduce some new developments of matrix and tensor equations over the quaternion algebra.

[01920] Matrix inequalities and properties of means on positive definite matrices

Format : Online Talk on Zoom
Author(s) : Luyining Gan (University of Nevada Reno)
Abstract : In this talk, we will introduce the study of the relations between the weighted metric geometric mean, the weighted spectral geometric mean and the weighted Wasserstein mean of the positive definite matrices in terms of

(weak) log-majorization relation. In addition, we will also introduce some new properties of means, like geodesic property and tolerance relation.

[05621] How to chesk D-stability: a simple determinantal test

Format : Online Talk on Zoom
Author(s) : Volha Y. Kushel (Shanghai University)
Abstract : The concept of matrix D-stability, introduced in 1958 by Arrow and McManus is of major importance due to the variety of its applications. However, characterization of matrix D-stability for dimensions $n > 4$ is considered as a hard open problem. In this talk, we propose a simple way for testing matrix D-stability, in terms of the inequalities between
principal minors of a matrix. The conditions are just sufficient but they allow to test matrices of an arbitrary size n, are easy to verify and can be used for the analysis of parameter-dependent models.

[00488] Eigenvector-Dependent Nonlinear Eigenvalue Problems: Theory, Algorithms and Applications

Session Time & Room :

00488 (1/2) : 1E (Aug.21, 17:40-19:20) @E603

00488 (2/2) : 2C (Aug.22, 13:20-15:00) @E603

Type : Proposal of Minisymposium
Abstract : Nonlinear eigenvalue problems fall into two major categories in terms of eigenvalue-dependency or eigenvector-dependency, short-named NEP and NEPv, respectively. NEPv is the next natural topic after NEP. The most well-known origin of NEPv is from Kohn-Sham density functional theory in electronic structure calculations, but most recent sources are various machine learning models in the form of optimization on matrix manifolds, core-periphery detection in networks, rate-splitting multiple access in wireless communication, among others. In this minisymposium, speakers will present recent advancements in algorithms, numerical analysis and applications of NEPv and discuss emerging challenges.

Organizer(s) : Zhaojun Bai, Ren-Cang Li, Ding Lu
Classification : 65F15, 65H17, 90C25
Minisymposium Program :

00488 (1/2) : 1E @E603 [Chair: Zhaojun Bai]

[03905] A Self-Consistent-Field Iteration for OCCA

Format : Talk at Waseda University
Author(s) : Leihong Zhang (Soochow University)Li Wang (University of Texas at Arlington)Zhaojun Bai (University of California, Davis)Rencang Li (University of Texas at Arlington)
Abstract : In this talk, we propose an efficient algorithm for solving the orthogonal canonical correlation analysis (OCCA). Within an alternating optimization scheme, a customized self-consistent-field (SCF) iteration for a core trace-fractional sub-maximization over orthogonality constraint is devised and analyzed. The SCF iteration is further extended to deal with the multi-view OCCA. Experiments on real-world applications of multi-view learning will be reported.

[04633] Mathematical Analysis and Numerical Approximations of Density Functional Theory Models for Metallic Systems

Format : Talk at Waseda University
Author(s) : Xiaoying Dai (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk, we will introduce our study on the energy minimization model arising in the ensemble Kohn-Sham density functional theory for metallic systems, in which a pseudo-eigenvalue matrix and a general smearing approach are involved. We investigate the invariance of the energy functional and

the existence of the minimizer of the ensemble Kohn-Sham model. We propose an adaptive two-parameter step size strategy and the corresponding preconditioned conjugate gradient methods to solve the energy minimization model. Under some mild but reasonable assumptions, we prove the global convergence for the gradients of the energy functional produced by our algorithms. Numerical experiments show that our algorithms are efficient, especially for large scale metallic systems. In particular, our algorithms produce convergent numerical approximations for some metallic systems, for which the traditional self-consistent field iterations fail to converge. This is a joint work with Dr. Bin Yang and Prof. Aihui Zhou.

[05119] Convergence of SCF Iteration for Eigenvector-dependent Nonlinear Eigenvalue Problems

Format : Talk at Waseda University
Author(s) : Ding Lu (University of Kentucky)
Abstract : The self-consistent field (SCF) iteration is a widely used method for solving eigenvector-dependent nonlinear eigenvalue problems (NEPv). Despite its simplicity, SCF is prone to slow convergence and can even fail to converge entirely. Extensive research has been devoted to analyzing the algorithm's convergence, and in this talk, we will share new insights on the local convergence analysis of SCF. First, for NEPv with a unitarily-invariant coefficient matrix, we will establish a precise estimation of the local convergence factor of SCF. This estimation enables us to prove the convergence of a level-shift scheme, which can help address the convergence issues of SCF. Second, for a class of NEPv without the unitary invariance property, we will show how to transform the problem into a unitarily invariant NEPv locally at the eigenbasis of interest. We will then establish the convergence rate of SCF based on this transformed problem. This work is a joint effort with Zhaojun Bai and Ren-Cang Li.

[04225] Geometric inexact Newton method for generalized singular values

Format : Online Talk on Zoom
Author(s) : Weiwei Xu (Nanjing University of Information Science and Technology)Michael K. Ng (The University of Hong Kong)Zhengjian Bai (Xiamen University)
Abstract : We give new model formulations for computing arbitrary generalized singular value of a Grassmann matrix pair or a real matrix pair, where we need to solve matrix optimization problems with unitary constraints or orthogonal constraints. We propose a geometric inexact Newton-CG method for solving these optimization problems. Under some mild assumptions, we establish the global and quadratic convergence of the proposed method for the complex case. We illustrate its effectiveness by some numerical examples.

00488 (2/2) : 2C @E603 [Chair: Ding Lu]

[05381] Nonlinear spectral graph theory: an overview of graph properties

Format : Online Talk on Zoom
Author(s) : Francesco Tudisco (Gran Sasso Science Institute)Dong Zhang (Peking University)Piero Deidda (Gran Sasso Science Institute)
Abstract : It is well-known that a variety of combinatorial graph quantities are approximated by the spectrum of relevant graph matrices, such as the Laplacian or the adjacency matrix. While very useful and widely used, these approximations are far from being tight. A generalization of the graph spectrum can be defined by considering nonlinear eigenvalue problems defined in terms of pairs of homogeneous convex functions. For quadratic functions, this definition boils down to the standard linear (matrix) eigenvalue problem. In this talk, we review several basic definitions and properties of nonlinear eigenproblems defined in terms of generic homogeneous pairs, and we then show how the corresponding eigenvalues can be used to provide tight approximations to fundamental graph quantities, including the multi-way Cheeger constant, the graph packing radius, the graph's max and min cuts, and graph's modularity.

[05445] Solving Non-Convex Problems without Relaxation: Unexpected Usefulness of NEPv on Optimization Theory

Format : Online Talk on Zoom
Author(s) : Jeonghun Park (Yonsei University)
Abstract : Non-convex optimization problems arise in many applications of wireless communications and signal processing. To solve this, one typical principle is relaxing the original problem, obtaining a "convexified" solution, and repeat the process until convergence. In this talk, breaking away from this conventional approach, we develop an unorthodox method called spectral method. We also show that in some applications, this new approach offers significantly better performances with less complexity.

[05390] Trace Minimization Principles on Matrix Manifolds

Format : Talk at Waseda University
Author(s) : Xin Liang (Tsinghua University)Ren-Cang Li (University of Texas at Arlington)Li Wang (University of Texas at Arlington)Leihong Zhang (Soochow University)
Abstract : This talk is concerned with establishing a trace minimization principle for two Hermitian matrix pairs: when is $\inf_X$ trace$(\widehat{A}X^{\mathrm{H}}AX)$ subject to $\widehat{B}X^{\mathrm{H}}BX = I$ finite? Sufficient and necessary conditions are obtained and, when the infimum is finite, an explicit formula for it is presented in terms of the finite eigenvalues of the matrix pairs.

[05272] Bound states in the continuum for a class of infinite matrices

Format : Talk at Waseda University
Author(s) : Ya Yan Lu (City University of Hong Kong)
Abstract : For certain infinite matrix A, the equation $Ax = \lambda x$ may represent a boundary value problem (BVP) for λ in a real interval C. Such an equation models the scattering of incident waves by some objects. Without the incident waves, $Ax = \lambda x$ is still an eigenvalue problem. A bound state in the continuum (BIC) is a special eigenpair with the eigenvalue $\lambda \in C$. In that case, the BVP for the same λ has no uniqueness. A nonlinear version is $(A + D(x))x = \lambda x$, where $D(x)$ is a diagonal matrix with the (i, i) entry being $d_i|x_i|^2$. In this talk, we discuss linear and nonlinear BICs for a class of infinite matrices.

[00496] Recent development in Quantum Simulation and Stochastic Methods

Session Time & Room :

00496 (1/3) : 3C (Aug.23, 13:20-15:00) @G704

00496 (2/3) : 3D (Aug.23, 15:30-17:10) @G704

00496 (3/3) : 3E (Aug.23, 17:40-19:20) @G704

Type : Proposal of Minisymposium
Abstract : This mini-symposium aims to bring together mathematicians and scientists working on quantum simulation and related topics to exchange ideas and share recent results. It highlights how the recent developments in computational tools, such as stochastic methods, quantum computing, fast algorithms, etc., make the simulation of large-scale or multiscale quantum systems feasible and thus expand the scope of quantum simulation. It also serves as a platform for presenting challenging quantum problems, which still call for novel methodologies to alleviate simulation costs.

Classification : 35Q40, 81-08, 68Q12, 65C20
Minisymposium Program :

00496 (1/3) : 3C @G704 [Chair: Zhiwen Zhang]

[02786] Orthogonalization and Orthogonalization-free Algorithms

Format : Talk at Waseda University
Author(s) : Weiguo Gao (Fudan University)
Abstract : This talk consists of two parts. Orthogonalization algorithms are discussed in the first part. And we extend the error analysis result for shiftedCholeskyQR3 algorithm in oblique inner product and show that the new error bound is optimal. We also discuss the loss of orthogonality and verify our conclusions through numerical experiments. This is joint work with Rentao Xu. In the second part, orthogonalization-free algorithms are proposed to solve extreme eigenvalue problems. These algorithms achieve eigenvectors instead of eigenspace. Global convergence and local linear convergence are discussed. Efficiency of new algorithms are demonstrated on random matrices and matrices from computational chemistry. This is joint work with Yingzhou Li and Bichen Lu.

[01872] Frozen Gaussian Sampling for mixed quantum-classical dynamics

Format : Talk at Waseda University

Author(s) : Zhennan Zhou (Peking University)Zhen Huang (University of California, Berkeley)Limin Xu (Tsinghua University)

Abstract : In this article, we propose a Frozen Gaussian Sampling (FGS) algorithm for simulating nonadiabatic quantum dynamics at metal surfaces with a continuous spectrum. This method consists of a Monte-Carlo algorithm for sampling the initial wave packets on the phase space and a surface-hopping type stochastic time propagation scheme for the wave packets. We prove that to reach a certain accuracy threshold, the sample size required is independent of both the semiclassical parameter and the number of metal orbitals, which makes it one of the most promising methods to study nonadiabatic dynamics. The algorithm and its convergence properties are also validated numerically. Furthermore, we carry out numerical experiments including exploring the nuclei dynamics, electron transfer, and finite-temperature effects, and demonstrate that our method captures the physics which can not be captured by classical surface hopping trajectories.

[02280] The Random Feature Method for Time-dependent Problems

Author(s) : Jingrun Chen (University of Science and Technology of China)Weinan E (Peking University)Yixin Luo (Suzhou Institute for Advanced Research, University of Science and Technology of China)

Abstract : We propose to solve time-dependent partial differential equations in the framework of random feature method. The approximate solution is constructed using space-time partition of unity and random feature functions, and is proved to enjoy the universal approximation property. The resulting least-squares problem can be solved using two different strategies, and the corresponding error estimates are provided.

[02728] Numerical methods for disordered NLS

Format : Talk at Waseda University

Author(s) : Xiaofei Zhao (Wuhan University)

Abstract : In this talk, I will consider the numerical solution for the disordered nonlinear Schrodinger equation (NLS). The model is a standard cubic NLS with a spatial random potential. The roughness and/or randomness of the potential brings some numerical difficulties. The performance of some classical time integrators will reviewed, and the low-regularity integrator will be applied to tackle the possible roughness. Then, a quasi-Monte Carlo time-splitting method will be considered to tackle the randomness and improve the sampling accuracy. The full error bound will be presented and numerically verified.

00496 (2/3) : 3D @G704 [Chair: Zhennan Zhou]

[02819] Asymmetric transport and topological invariants

Format : Talk at Waseda University

Author(s) : Guillaume Bal (University of Chicago)

Abstract : Transport asymmetries along interfaces separating insulating bulks have a topological origin. The talk proposes a classification of partial differential systems with topological invariant computed explicitly by a Fedosov-Hörmander formula. Asymmetric transport is associated to another topological invariant whose calculations is less direct. A bulk-edge correspondence states that the two invariants in fact agree. The theory is applied to graphene-based topological insulators. Time permitting, the above spectral analysis will be contrasted with a temporal picture.

[02812] Asymmetric transport computations in Dirac models of topological insulators

Format : Talk at Waseda University

Author(s) : Zhongjian Wang (Nanyang Technological University)Guillaume Bal (University of Chicago)Jeremy Hoskins (University of Chicago)

Abstract : We will present a fast algorithm for computing transport properties of two-dimensional Dirac operators with linear domain walls, which model the macroscopic behavior of the robust and asymmetric transport observed at an interface separating two two-dimensional topological insulators. Our method is based on reformulating the partial differential equation as a corresponding volume integral equation, which we solve via a spectral discretization scheme.
We demonstrate the accuracy of our method by confirming the quantization of an appropriate interface conductivity modeling transport asymmetry along the interface, and moreover, confirm that this quantity is immune to local perturbations. We also compute the far-field scattering matrix generated by such perturbations
and verify that while asymmetric transport is topologically protected the absence of back-scattering is not.

[01869] Quantum Orbital Minimization Method for Excited States Calculation on Quantum Computer

Format : Talk at Waseda University
Author(s) : Yingzhou Li (Fudan University)
Abstract : We propose a quantum-classical hybrid variational algorithm, the quantum orbital minimization method (qOMM), for obtaining the ground state and low-lying excited states of a Hermitian operator. Given parametrized ansatz circuits representing eigenstates, qOMM implements quantum circuits to represent the objective function in the orbital minimization method and adopts a classical optimizer to minimize the objective function with respect to the parameters in ansatz circuits. The objective function has an orthogonality constraint implicitly embedded, which allows qOMM to apply a different ansatz circuit to each input reference state. We carry out numerical simulations that seek to find excited states of H2, LiH, and a toy model consisting of four hydrogen atoms arranged in a square lattice in the STO3G basis with UCCSD ansatz circuits. Comparing the numerical results with existing excited states methods, qOMM is less prone to getting stuck in local minima and can achieve convergence with more shallow ansatz circuits.

[02283] Bloch decomposition based method for Schroedinger equation with random inputs

Format : Talk at Waseda University
Author(s) : Zhongyi Huang (Tsinghua University)
Abstract : In this talk, we focus on the analysis and numerical methods for the Schroedinger equation with lattice potential and random inputs. Here we recall the well-known Bloch decomposition-based split-step pseudo-spectral method where we diagonalize the periodic part of the Hamilton operator so that the effects from dispersion and periodic lattice potential are computed together. Meanwhile, for the random non-periodic external potential, we utilize the generalize polynomial chaos with Galerkin procedure to form an ODE system which can be solved analytically. Furthermore, we analyse the convergence theory of the stochastic collocation method for the linear Schroedinger equation with random inputs. We provide sufficient conditions on the random potential and initial data to ensure the spectral convergence.

[02028] On Quantum Speedups for Nonconvex Optimization via Quantum Tunneling Walks

Format : Online Talk on Zoom
Author(s) : Yizhou Liu (MIT)Weijie J. Su (University of Pennsylvania)Tongyang Li (Peking University)
Abstract : Classical algorithms are often not effective for solving nonconvex optimization problems where local minima are separated by high barriers. In this paper, we explore possible quantum speedups for nonconvex optimization by leveraging the global effect of quantum tunneling. Specifically, we introduce a quantum algorithm termed the quantum tunneling walk (QTW) and apply it to nonconvex problems where local minima are approximately global minima. We show that QTW achieves quantum speedup over classical stochastic gradient descents (SGD) when the barriers between different local minima are high but thin and the minima are flat. Based on this observation, we construct a specific double-well landscape, where classical algorithms cannot efficiently hit one target well knowing the other well but QTW can when given proper initial states near the known well. Finally, we corroborate our findings with numerical experiments.

[02822] Quantum dynamics simulation and its application to Hamiltonian learning

Format : Online Talk on Zoom
Author(s) : Di Fang (Duke University)
Abstract : Recent years have witnessed tremendous progress in developing and analyzing quantum algorithms for quantum dynamics simulation (Hamiltonian simulation). The accuracy of quantum dynamics simulation is usually measured by the error of the unitary evolution operator in the operator norm, which in turn depends on the operator norm of the Hamiltonian. However, the operator norm measures the worst-case scenario, while practical simulation concerns the error with respect to a given initial vector or given observables at hand. In this talk, we will discuss a few ways to weaken the strong operator norm dependence in quantum simulation tasks by taking into account the the initial condition and observables. We then discuss how such analysis can be applied in the setting of Hamiltonian learning. Using a Hamiltonian reshaping technique, we propose a first learning algorithm to achieve the Heisenberg limit for efficiently learning an interacting N-qubit local Hamiltonian.

[00497] Advances in numerical methods for nonlinear optics

Session Time & Room :

00497 (1/2) : 4D (Aug.24, 15:30-17:10) @D404

00497 (2/2) : 4E (Aug.24, 17:40-19:20) @D404

Type : Proposal of Minisymposium
Abstract : Nonlinear optics is the area of optics that studies the interaction of light with matter in the regime where the response of the material system to the applied electromagnetic field is nonlinear in the amplitude of this field. Here, we are concerned with numerical modeling of nonlinear optical phenomena. Of particular interest to this minisymposium are recent advances on general numerical methods such as finite difference methods, finite element methods, discontinuous Galerkin methods, etc. that have been tailored to the mathematical models of nonlinear optics with emphasis on achieving high order accuracy, adaptivity and efficient handling of multiscale features.
Organizer(s) : Vrushali A. Bokil, Camille Carvalho, Stéphane Lanteri, Claire Scheid
Classification : 78-10
Minisymposium Program :

00497 (1/2) : 4D @D404 [Chair: Stéphane Lanteri]

[03183] High-Order Accurate Approaches for Maxwell's Equations with Nonlinear Active Media on Overlapping Grids

Format : Talk at Waseda University
Author(s) : Jeffrey Banks (Rensselaer Polytechnic Institute)Gregor Kovacic (Rensselaer Polytechnic Institute)William Henshaw (Rensselaer Polytechnic Institute)Donald Schwendeman (Rensselaer Polytechnic Institute)Qing Xia (KTH Royal Institute of Technology)Alexander Kildeshev (Purdue University)Ludmila Prokopeva (Purdue University)
Abstract : Here I discuss efficient numerical methods for Maxwell's equations in nonlinear active media. Complex geometry is treated with overlapping grids, and interfaces between different materials are accurately and efficiently treated using compatibility coupling conditions. A novel hierarchical modified equation (ME) approach leads to an explicit scheme that does not require nonlinear iteration, and also gives local update equations without any tangential coupling along interfaces that would otherwise occur using a traditional high-order ME time stepper.

[02203] Energy stability and active Q-factor control in numerical models of nonlinear electromagnetic resonance effects

Format : Online Talk on Zoom
Author(s) : Lutz Angermann (Clausthal University of Technology)
Abstract : The talk deals with the modeling and some properties of mathematical models to describe the excitation of a nonlinear material by electromagnetic waves, including typical questions such as the existence and uniqueness of a solution, the derivation of energy laws or estimates, the evaluation of the resonance quality and the transfer of these properties to numerical models.

[02291] Energy stable finite element method for nonlinear Maxwell's equations

Format : Talk at Waseda University
Author(s) : Maohui Lyu (Beijing University of Posts and Telecommunications)Vrushali Bokil (Oregon State University)Yingda Cheng (Michigan State University)Fengyan Li (Rensselaer Polytechnic Institute)Weiying Zheng (LSEC, Chinese academy of sciences)
Abstract : In this talk, we consider the time-domain nonlinear Maxwell's equations in multi-dimensions. With special discretizations for the nonlinear terms, we introduce a class of provably energy stable finite element method. Numerical experiments are provided to validate the performance of the proposed methods.

[03742] High Order Energy Stable FDTD Methods for Maxwell Duffing models in Nonlinear Photonics

Format : Talk at Waseda University
Author(s) : Vrushali A Bokil (Oregon State University)Daniel Appelo (Michigan State University)Yingda Cheng (Michigan State University)Fengyan Li (Rensselaer Polytechnic Institute)
Abstract : We present electromagnetic models that describe nonlinear optical phenomenon in which the nonlinear polarization is driven by the electric field
and modeled as an anharmonic oscillator(s). The models for the nonlinear polarization are given by Duffing equations and incorporate both nonlinearity and dispersion. Using the auxiliary differential equation approach, we present discretizations of the coupled Maxwell-Duffing models which are high order and energy stable methods based on finite difference time domain (FDTD) techniques.

00497 (2/2) : 4E @D404 [Chair: Vrushali A Bokil]

[05175] Local time-integration for wave equations

Format : Online Talk on Zoom
Author(s) : Constantin Carle (Karlsruhe Institute of Technology)Marlis Hochbruck (Karlsruhe Institute of Technology)
Abstract : For the spatially discretized acoustic wave equation, stability of explicit time integration schemes such as the leapfrog scheme can only be guaranteed under a CFL condition. In the case of locally refined meshes, this condition is the main bottleneck for the efficiency of explicit schemes.

To overcome this issue, we introduce local time-stepping and locally implicit schemes and present a rigorous error analysis.

[02186] Discontinuous Galerkin Time-Domain methods for nonlinear active media on unstructured grids

Format : Talk at Waseda University
Author(s) : Stéphane Descombes (Université Côte d'Azur, CNRS, Inria, LJAD)Stéphane Lanteri (Université Côte d'Azur, Inria, CNRS, LJAD)Cédric Legrand (Université Côte d'Azur, Inria, CNRS, LJAD)
Abstract : We present a Discontinuous Galerkin Time-Domain method for solving the system of Maxwell equations coupled to the rate equations modeling light interaction with gain media.

[00498] Approximation and modeling with manifold-valued data

Session Time & Room :

00498 (1/3) : 4C (Aug.24, 13:20-15:00) @A615

00498 (2/3) : 4D (Aug.24, 15:30-17:10) @A615

00498 (3/3) : 4E (Aug.24, 17:40-19:20) @A615

Type : Proposal of Minisymposium
Abstract : Application problems that involve data on differentiable manifolds are at the interface of numerical analysis and differential geometry. Researchers approach such tasks for various reasons: some make general efforts to transfer established methods from the Euclidean setting to nonlinear manifolds. Others are motivated by a specific application that requires one to work with manifold data.
This minisymposium aims at bringing together researchers working on approximation and modeling problems on Riemannian manifolds. A particular focus is on interpolation methods and applications in model reduction.
We aspire to create synergies and bridge the gap between different communities in this fascinating research field.

[05470] Implicit integration along the low-rank manifold for stiff and nonlinear equations

Format : Online Talk on Zoom
Author(s) : Aaron Charous (MIT)Pierre F. J. Lermusiaux (MIT)
Abstract : We introduce a family of implicit integration methods for the dynamical low-rank approximation: the alternating-implicit dynamically orthogonal Runge-Kutta (ai-DORK) schemes. By alternating over the row and column space of the approximate solution, an efficient iterative low-rank linear solver is developed. To evaluate nonlinearities, we propose a local/piecewise polynomial approximation with adaptive clustering, and on-the-fly reclustering may be performed efficiently in the coefficient space. We demonstrate the proposed schemes on ill-conditioned, nonlinear, and realistic systems.

[04268] Stochastic modeling of model uncertainties through Riemannian reduced-order representations

Format : Online Talk on Zoom
Author(s) : Hao Zhang (Duke University)Johann Guilleminot (Duke University)
Abstract : Molecular Dynamics (MD) simulations are widely used in computational materials science to explore the conformational space of atomistic systems, to analyze microscopic processes, and to evaluate macroscopic properties of interest. At the core of all MD simulations stands the selection of interatomic potentials, which can be calibrated by means of first-principles calculations or by solving inverse problems based on experimental observations. Such potentials are not uniquely defined in general, which raises the question of model uncertainties and their impact on MD-informed multiscale predictions. In this work, we propose a new probabilistic framework that enables the seamless integration of model-form uncertainties in atomistic computations. The approach relies on a stochastic reduced-order model involving a randomized Galerkin projection operator. An information-theoretic probabilistic model is specifically constructed on the tangent space to the manifold, taking advantage of Riemannian projection and retraction operators. We also explore statistical inference with a view toward inverse identification. We show, in particular, that the Fréchet mean can be constrained by solving a quadratic programming problem. Various applications are finally presented to demonstrate the relevance of the method, including toy examples in the Euclidean space and multiscale simulations on single layer graphene sheets. The proposed method offers key advantages, including a simple and interpretable low-dimensional parameterization, the ability to constraint the mean on the underlying manifold, and ease of implementation and propagation through multiscale operators.

[05113] On approximation and representation of manifold-valued functions

Format : Talk at Waseda University
Author(s) : Nir Sharon (Tel Aviv University)
Abstract : Recent years have given rise to exciting developments in methods for approximating manifolds and manifold-valued objects. This talk will review recent work concerning manifold-valued approximation via refinement and quasi-interpolation operators and their close connection to multiscaling.

00498 (2/3) : 4D @A615 [Chair: Ralf Zimmermann]

[05093] Multivariate Hermite Intepolation On Riemannian Manifolds

Format : Talk at Waseda University
Author(s) : Ralf Zimmermann (University of Southern Denmark)Ronny Bergmann (NTNU, Trondheim)
Abstract : We consider two methods for multivariate Hermite interpolation of manifold-valued functions.
On the one hand, we approach the problem via computing weighted Riemannian barycenters. This approach is intrinsic in the sense that it does not depend on local coordinates.
As an alternative, we consider straightforward Hermite interpolation in a tangent space. Here, the actual interpolation is conducted via classical vector space operations.
Both approaches are illustrated by means of numerical examples.

[01628] Approximations and learning in the Wasserstein space

Format : Talk at Waseda University
Author(s) : Caroline Moosmueller (University of North Carolina at Chapel Hill)Alexander Cloninger (University of California, San Diego)Varun Khurana (University of California, San Diego)Harish Kannan (University of California, San Diego)Keaton Hamm (University of Texas at Arlington)
Abstract : Detecting differences and building classifiers between distributions, given only finite samples, are important tasks in a number of scientific fields. Optimal transport and the Wasserstein distance have evolved as the most natural concept in dealing with such tasks, but they also have some computational drawbacks.

In this talk, we describe an approximation framework through local linearizations that significantly reduces both the computational effort and the required training data in supervised learning settings.

[05075] On multiscale quasi-interpolation of scattered scalar- and manifold-valued functions

Format : Talk at Waseda University
Author(s) : Nir Sharon (Tel Aviv University)Holger Wendland (University of Bayreuth)
Abstract : In this talk, we introduce and analyze a combination of kernel-based quasi-interpolation and multiscale approximations for both scalar- and manifold-valued functions. We are particularly interested in the improvements coming from such a combination over simply using quasi-interpolation processes alone. We provide ample numerical evidence that multiscale quasi-interpolation has superior convergence to quasi-interpolation. In addition, we will provide examples showing that the multiscale quasi-interpolation approach offers a powerful tool for data analysis tasks.

[03824] The de Casteljau algorithm on symmetric spaces

Format : Online Talk on Zoom
Author(s) : Fátima Silva Leite (Institute of Systems and Robotics, University of Coimbra)Knut Huper (Institute of Mathematics, Julius-Maximilians-Universitat Wurzburg)
Abstract : An important task for interpolation problems in many areas of science and technology is the computation of smooth
curves connecting two data points in a Riemannian symmetric space. For instance, the de Casteljau algorithm on manifolds, which is a geometric procedure to generate smooth polynomial splines, is based on recursive geodesic interpolation. Also in statistics, the efficient computation of (geometric) means of data in a symmetric space, as well as the computation of midpoints of smooth curves connecting two data points, is particularly important. While closed form solutions for the so called endpoint geodesic problem on general symmetric spaces are well known, often explicit exponentiation of matrices and/or SVD computations are still required. In most cases, these computations are rather expensive. We present much simpler closed form expressions for the particular case of Grassmannians, where only constant, linear and quadratic functions in the data points and scalar trigonometric functions are involved. This represents an important step in the implementation of the de Casteljau algorithm. We also comment on the general idea putting other important symmetric spaces, compact and noncompact ones, into perspective.

00498 (3/3) : 4E @A615 [Chair: Nir Sharon]

[04608] Structure-preserving Model Order Reduction on Manifolds

Format : Talk at Waseda University
Author(s) : Patrick Buchfink (University of Stuttgart)Silke Glas (University of Twente)Bernard Haasdonk (University of Stuttgart)Benjamin Unger (University of Stuttgart)
Abstract : Approximation on manifolds has become a highly researched field in Model Order Reduction (MOR) for problems with slowly decaying Kolmogorov n-widths. However, many MOR techniques do not respect the structure of the underlying equations during the reduction.
In this talk, we present a new differential geometric formulation of MOR on pseudo-Riemannian manifolds. It allows us to geometrically understand and unify existing structure-preserving MOR techniques for Hamiltonian and Lagrangian systems.

[03709] The Difference of Convex Algorithm on Riemannian Manifolds

Format : Online Talk on Zoom
Author(s) : Ronny Bergmann (NTNU, Trondheim)Orizon Pereira Ferreura (IME/UFG, Goiâna)Elisanderson Meneses Santos (Instituto Federal de Educação, Ciência e Tecnologia do Maranhão, Barra do Corda)João Carlos de Oliveira Souza (Department of Mathematics, Federal University of Piauí, Teresina)
Abstract : In this talk we propose a difference of convex algorithm (DCA) on Riemannian manifolds to solve optimisation problems involving a difference of two functions.
We establish both its relation to recently introduced Fenchel duality on manifolds, and its wwell-posedness. On Hadamard manifolds, we prove that every cluster point of the sequence generated by the algorithm is a cluster point.
Finally, we illustrate that several optimisation problems can be written as difference of convex (DC) functions on manifolds, and that some Euclidean problems that are differences of non-convex problems become DC problems when rephrased on a manifold. Numerical examples illustrate that such a rephrasing even for DC problems is beneficial numerically.

[02950] Symplectic model order reduction via Riemannian optimization

Format : Talk at Waseda University
Author(s) : Bin Gao (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Numerous problems in optics, quantum physics, stability analysis, and control of dynamical systems can be brought to an optimization problem with matrix variable subjected to the symplecticity constraint. As this constraint nicely forms a so-called symplectic Stiefel manifold, Riemannian optimization is preferred, because one can borrow ideas from unconstrained optimization methods after preparing necessary geometric tools. Retraction is arguably the most important one which decides the way iterates are updated given a search direction. Two retractions have been constructed so far: one relies on the Cayley transform and the other is designed using quasi-geodesic curves. In this talk, we propose a new retraction that is based on an SR matrix decomposition. We prove that its domain contains the open unit ball which is essential in proving the global convergence of the associated gradient-based optimization algorithm. Moreover, we consider the symplectic model order reduction of Hamiltonian systems with various examples. The extensive numerical comparisons reveal the strengths of the proposed optimization algorithm.

[05465] Hirotugu Akaike's Analysis of Gradient Descent: 70 years later

Format : Talk at Waseda University
Author(s) : Pok Yin Thomas Yu (Drexel University)
Abstract : It is very well known that when the exact line search gradient descent method is applied to a convex quadratic objective, the worst-case rate of convergence (among all seed vectors) deteriorates as the condition number of the Hessian of the objective grows.
By an elegant analysis by H. Akaike in 1959, it is generally believed -- but not proved -- that in the ill-conditioned regime the ROC for almost all initial vectors, and hence also the average ROC, is close to the worst case ROC. We complete Akaike's analysis using the theorem of center and stable manifolds. Our analysis also makes apparent the effect of an intermediate eigenvalue in the Hessian by establishing the following somewhat amusing result: In the absence of an intermediate eigenvalue, the average ROC gets arbitrarily fast -- not slow -- as the Hessian gets increasingly ill-conditioned.

We discuss in passing some contemporary applications of exact line search GD to polynomial optimization problems arising from imaging and data sciences and, if time allows, formulate an open problem related to accelerated GD methods.

[00505] Structured matrices with applications in sciences and engineering

Session Time & Room :

00505 (1/3) : 5B (Aug.25, 10:40-12:20) @G305

00505 (2/3) : 5C (Aug.25, 13:20-15:00) @G305

00505 (3/3) : 5D (Aug.25, 15:30-17:10) @G305

Type : Proposal of Minisymposium
Abstract : The main purpose of this MS is to present recent developments on some special structured matrices that are of interest in different areas of mathematics, as well as in more applied areas like operations research, social sciences and computation. Problems arising in these fields are considered and techniques from matrix theory, numerical linear algebra and combinatorics, among others, are explored to solve them.

[02264] Reciprocal Matrices, Ranking and the Relationship with Social Choice

Format : Online Talk on Zoom
Author(s) : Charles R Johnson (William and Mary)
Abstract : There is a close connection between the use of efficient vectors for reciprocal (pairwise comparison) matrices, used
in business project ranking schemes, and social choice/voting rules from political science and economics. However,

the two seem not to have been discussed together before. We explore this connection, as well as advance the theory of reciprocal matrices. In addition, there seem to be natural connections with other parts of economic theory.

[01723] A matrix approach to the study of efficient vectors in priority setting methodology

Format : Talk at Waseda University
Author(s) : Susana Furtado (Faculdade de Economia do Porto and CEAFEL)Charles Johnson (College of William and Mary)
Abstract : The Analytic Hierarchy Process is a much discussed method in ranking business alternatives based on empirical and judgemental information.
Here we use a matrix approach to study the key component of efficient vectors for a reciprocal matrix of pairwise comparisons. In particular, we give new efficient vectors for a reciprocal matrix, which we compare numerically with other known efficient vectors.

[00811] Singular matrices whose Moore-Penrose inverse is tridiagonal.

Format : Talk at Waseda University
Author(s) : Maria Isabel Bueno Cachadina (University of California Santa Barbara)Susana Borges Furtado (Faculdade de Economia do Porto and CEAFEL)
Abstract : A variety of characterizations of nonsingular matrices whose inverse is tridiagonal (irreducible or not) have been widely investigated in the literature. One well-known such characterization is stated in terms of semiseparable matrices. In this talk, we consider singular matrices A and give necessary and sufficient conditions for the Moore-Penrose inverse of A to be tridiagonal. Our approach is based on bordering techniques, as given by Bapat and Zheng (2003). In addition, we obtain necessary conditions on A analogous to the semiseparability conditions in the nonsingular case, though in the singular case they are not sufficient, as illustrated with examples. We apply our results to give an explicit description of all the 3×3 real singular matrices and 3×3 Hermitian matrices whose Moore-Penrose inverse is irreducible and tridiagonal.

[03060] Spectral geometric mean versus geometric mean by generalized Kantorovich constant

Format : Talk at Waseda University
Author(s) : Shigeru Furuichi (Nihon University)
Abstract : In this talk, we give two different operator inequalities between the weighted spectral geometric mean and the weighted geometric mean. We also study the mathematical properties for the generalized Kantorovich constant. Applying the obtained inequalities on the generalized Kantorovich constant, we give the ordering of two inequalities between the weighted spectral geometric mean and the weighted geometric mean.
In addition, we give some inequalities such as Ando type inequality, Kantorovich type inequality, and Ando-Hiai type inequality with the weighted spectral geometric mean and the generalized Kantorovich constant.

00505 (2/3) : 5C @G305 [Chair: Fernando Teran]

[05539] Bundles of matrix pencils under strict equivalence

Format : Talk at Waseda University
Author(s) : FERNANDO DE TERÁN (Universidad Carlos III de Madrid)Froilán Martínez Dopico (Universidad Carlos III de Madrid)
Abstract : Bundles of matrix pencils are sets of pencils having the same Kronecker canonical form, up to the eigenvalues (namely, they are a union of orbits under strict equivalence). This notion was introduced in the 1990's, following the one for matrices under similarity (from Arnold, 1971). In this talk, we provide a characterization for the inclusion relation between closures of bundles and prove that bundles are open in their closure (in the standard topology) .

[05542] Row completion of polynomial matrices

Format : Talk at Waseda University
Author(s) : Alicia Roca (Universitat Politècnica de València / IMM, Valencia, Spain)Agurtzane Amparan (Universidad del País Vasco UPV/EHU)Itziar Baragaña (Universidad del País Vasco UPV/EHU)Silvia Marcaida (University of the Basque CountryUniversidad del País Vasco UPV/EHU)
Abstract : Perturbation problems arise frequently in applications, as in structural changes of the dynamics of a system or in pole placement problems in control theory.

Perturbation problems of matrices are closely related to completion problems. We present a solution to the row-completion problem of a polynomial matrix, prescribing the eigenstructure of the resulting matrix and maintaining the degree.

[01819] Computational Techniques for the Mittag-Leffler Function of a Matrix Argument

Format : Talk at Waseda University
Author(s) : João R. Cardoso (Polytechnic Institute of Coimbra – ISEC)
Abstract : It is well-known that the two-parameter Mittag-Leffler function plays a key role in Fractional Calculus. In this talk, we address the problem of computing this function, when its argument is a square matrix. Effective methods for solving this problem involve the computation of successive derivatives or require the use of mixed precision arithmetic. We provide an alternative method that is derivative-free and can work entirely using IEEE standard double precision arithmetic. Our method starts with a reordered Schur decomposition of the argument matrix, so that the problem reduces to the computation of the Mittag-Leffler function of a triangular matrix with ``close'' eigenvalues. Theoretical and numerical issues regarding the performance of the method are investigated. A set of numerical experiments show that our novel approach is competitive with the existing ones, in terms of accuracy and computational cost.

[02170] A reduction algorithm for reconstructing periodic pseudo-Jacobi matrices

Format : Online Talk on Zoom
Author(s) : Natalia Bebiano (Department of Mathematics, Coimbra University)
Abstract : For the given signature operator $\mathcal{H} = I_r \oplus -I_{n-r}$, a pseudo-Jacobi matrix is a self-adjoint matrix relatively to a symmetric bilinear form $\langle \cdot, \cdot \rangle_{\mathcal{H}}$. In this talk, we consider recent inverse eigenvalue problems for this class of matrices. Necessary and sufficient conditions under which the problems have solution are presented. Numerical algorithms are designed according to the obtained theoretical results. Illustrative numerical examples are given to test the reconstructive algorithms.

00505 (3/3) : 5D @G305 [Chair: Susana Furtado]

[05469] A Low-Cost Algorithm to Determine Orbital Trajectories

Format : Talk at Waseda University
Author(s) : Sirani M. Perera (Embry-Riddle Aeronautical University)David Canales (Embry-Riddle Aeronautical University)Atahan Kurttisi (Embry-Riddle Aeronautical University)Brian Baker-McEvilly (Embry-Riddle Aeronautical University)
Abstract : The increasing demand for effective methods to propagate trajectories in the circular restricted three-body problem (CR3BP) is driven by heavy traffic in the region. This presentation introduces a
novel approach that utilizes interpolation for determining orbital trajectories. We present a novel algorithm for determining orbital motion in the CR3BP, which is specifically applied to different
Cislunar trajectories. Our findings demonstrate a 50% reduction in time complexity compared to the existing methods.

[00506] Inverse Problems for Anomalous Diffusion

Session Time & Room :

00506 (1/3) : 3E (Aug.23, 17:40-19:20) @G808

00506 (2/3) : 4C (Aug.24, 13:20-15:00) @G808

00506 (3/3) : 4D (Aug.24, 15:30-17:10) @G808

Type : Proposal of Minisymposium
Abstract : Anomalous diffusion has received a lot of attention recently due to its extraordinary capability for describing nonstandard diffusion processes arising in multiple physical sciences and engineering. The relevant mathematical models often involve a fractional-order derivative in time or space. The nonlocality of the model substantially changes the analytical behaviour of the mathematical models when compared with the standard counterpart. This has also big impact on the behaviour of related inverse problems, which has witnessed many exciting and important developments in the last few years. In this mini-symposium, we aim at gathering researchers working on the topic to discuss recent advances on mathematical and numerical analysis of inverse problems for anomalous diffusion, in order to further promote the developments of the topic.

[01356] Coefficient identification space-fractional equation with Abel type operators

Format : Online Talk on Zoom
Author(s) : Barbara Kaltenbacher (University of Klagenfurt)
Abstract : We consider the inverse problem of recovering an unknown, spatially-dependent coefficient $q(x)$ from the fractional order equation $\mathbb{L}_\alpha u = f$ defined in a two-dimensional spatial domain from boundary information.
Here $\mathbb{L}_\alpha = D_x^{\alpha_x} + D_y^{\alpha_y} + q(x)$ contains fractional derivative operators based on the Abel fractional integral.
We develop uniqueness and reconstruction results and show how the ill-conditioning of this inverse problem depends on the geometry of the region and the fractional powers α_x and α_y.

[04481] Inverse problems for simultaneous determination of several scalar parameters and source factors in anomalous diffusion equations

Format : Online Talk on Zoom
Author(s) : Jaan Janno (Tallinn University of Technology)
Abstract : We consider inverse problems for anomalous diffusion equations where unknowns are orders of multiterm fractional time derivatives/multiterm fractional Laplacians or kernels of distributed fractional time derivatives/distributed fractional Laplacians. Along with these quantities an unknown is also a space-dependent or time-dependent source factor. We prove uniqueness for simultaneous determination of these quantities form final or boundary data.

[03427] Parameter inverse problem for coupled time-fractional diffusion systems

Format : Talk at Waseda University
Author(s) : Yikan Liu (Hokkaido University)
Abstract : This talk is concerned with determining fractional orders in a coupled system of time-fractional diffusion equations. Defining the mild solution, we first establish fundamental unique existence of the solution, which mostly inherit those of a single equation. Owing to the coupling effect, we obtain the uniqueness for determining all orders by the single point observation of a single component of the solution.

[04183] Identification of potential in diffusion equations from terminal observation

Format : Online Talk on Zoom
Author(s) : Zhidong Zhang (Sun Yat-sen University)
Abstract : We consider an inverse potential problem in a (sub)diffusion equation. We construct a monotone operator, one of whose fixed points is the unknown potential. The uniqueness of the identification is proved. Next, a fixed point iteration is applied to reconstruct the potential. We prove the linear convergence of the iterative algorithm and present a thorough error analysis for the reconstructed potential. Numerical experiments are provided to illustrate and complement our theoretical analysis.

[04736] Classical Unique Continuation Property for Time Fractional Evolution Equations

Format : Talk at Waseda University
Author(s) : Gen Nakamura (Hokkaido University)Ching-Lung LIn (National Cheng Kung University)
Abstract : Let $q_j = q_j(x),\ 2 \le j \le m$ with $q_1 = 1$ and let $2 > \alpha = \alpha_1 > \alpha_2 > \cdots > \alpha_m > 0$.
Then, the classical unique continuation property of solutions in $H^{\alpha,2}((0,T) \times \Omega)$ holds for the time fractional evolution equation (tfEE) whose leading part given as
$\sum_{j=1}^{m} q_j \partial_t^{\alpha_j} u(t,y) - L\,u(t,y)$ over a domain $\Omega \subset \mathbb{R}^n$
with a time dependent strongly eilliptic operator L of oder 2, where $\partial_t^{\alpha_j}$ is the Caputo derivative whenever $\alpha_j \notin \mathbb{Z}$.
See C-L. Lin and G. Nakamura, Math. Ann. 385 (2023), pp. 551–574 for the details.

[02704] The Calderón problem for nonlocal parabolic operators

Format : Talk at Waseda University
Author(s) : Yi-Hsuan Lin (Department of Applied Mathematics, National Yang Ming Chiao Tung University)
Abstract : We investigate inverse problems in the determination of leading coefficients for nonlocal parabolic operators, by knowing the corresponding Cauchy data in the exterior space-time domain. The key contribution is that
we reduce nonlocal parabolic inverse problems to the corresponding local inverse problems with the lateral boundary Cauchy data. In addition, we derive a new equation and offer a novel proof of the unique continuation property for this new equation. We also build both uniqueness and non-uniqueness results for both nonlocal isotropic and anisotropic parabolic Calder´on problems, respectively.

[02699] Inverse Problems for Subdiffusion from Observation at an Unknown Terminal Time

Format : Talk at Waseda University
Author(s) : Bangti Jin (The Chinese University of Hong Kong)Yavar Kian (Aix Marseille University)Zhi Zhou (The Hong Kong Polytechnic University)
Abstract : Time-fractional subdiffusion equations represent an important class of mathematical models with a broad range of applications. The related inverse problems of recovering space-dependent parameters, e.g., initial condition, space dependent source or potential coefficient, from the terminal observation have been extensively studied in recent years. However, all existing studies have assumed that the terminal time at which one takes the observation is exactly known. In this talk, we present uniqueness and stability results for three canonical inverse problems, e.g., backward problem, inverse source and inverse potential problems, from the terminal observation at an unknown time. The subdiffusive nature of the problem indicates that one can simultaneously determine the terminal time and space-dependent parameter.

[04403] Numerical Recovery of Multiple Parameters from One Lateral Boundary Measurement

Format : Talk at Waseda University
Author(s) : Siyu Cen (The Hong Kong Polytechnic University)Bangti Jin (Chinese University of Hong Kong)Yikan Liu (Hokkaido University)Zhi Zhou (The Hong Kong Polytechnic University)
Abstract : This talk is concerned with numerically recovering multiple parameters in a partly unknown subdiffusion model from one lateral measurement on the boundary. We prove that the boundary measurement uniquely determines the fractional order and the polygonal support of the diffusion coefficient, without knowing either the initial condition or the source. We present an algorithm for recovering the fractional order and diffusion coefficient which combines small-time asymptotic expansion, analytic continuation and the level set method.

00506 (3/3) : 4D @G808 [Chair: Yikan Liu]

[04435] Long-Short time asymptotic estimates for time-fractional diffusion-wave equation

Format : Talk at Waseda University
Author(s) : Xinchi HUANG (Tokyo Institute of Technology)Xinchi Huang (Tokyo Institute of Technology)Yikan Liu (Hokkaido University)
Abstract : In this talk, we consider the time-fractional diffusion-wave equations and show the long-time asymptotic estimate of the solution, which can be used to prove the long-time strict positivity of the solution and the uniqueness for

an inverse source problem of determining the time-varying factor. Besides, we discuss the short-time asymptotic behavior and provide an application to the determination of the spatial varying factor in the source.

[04612] Numerical identification of conductivity in (sub)diffusion equations from terminal measurement

Format : Online Talk on Zoom
Author(s) : Bangti Jin (Chinese University of Hong Kong)Xiliang Lu (Wuhan University)Qimeng Quan (Wuhan University)Zhi Zhou (The Hong Kong Polytechnic University)
Abstract : This talk focuses on the inverse diffusion problems in (sub)diffusion equation. Typically, we employ Tikhonov strategy and discretize the regularized model by finite element methods. One critical issue is to establish a priori error estimate on the concerned parameter. In this talk, the speaker will discuss their recent study of recovering a space-dependent diffusion coefficient from terminal observation by a novel conditional stability.

[00507] Stochastic Dynamical Systems and Applications

Session Time & Room :

00507 (1/4) : 3D (Aug.23, 15:30-17:10) @G802

00507 (2/4) : 3E (Aug.23, 17:40-19:20) @G802

00507 (3/4) : 4C (Aug.24, 13:20-15:00) @G802

00507 (4/4) : 4D (Aug.24, 15:30-17:10) @G802

Type : Proposal of Minisymposium
Abstract : The objective of this special minisymposium is to bring together experts from multiple disciplines with complementary views and approaches to stochastic dynamics in the context of applications. The topics include but not limited to: Theoretical advances in stochastic dynamical systems and stochastic partial differential equations, connection with non-equilibrium statistical physics, non-Gaussian noise and nonlocal partial differential operators, dynamical indicators for phase transition and abrupt change, most probable transition pathways and early warning time, tools for predicting rare events or extreme events, machine learning tools for examining stochastic dynamics, multi-scale stochastic simulation algorithms, multiscale multiphase flow simulation and homogenization problems.
Organizer(s) : Yanjie Zhang
Classification : 37A50, 35R60, 60H17
Minisymposium Program :

00507 (1/4) : 3D @G802

[04264] Three-dimensional numerical study on wrinkling of vesicles in elongation flow

Format : Talk at Waseda University
Author(s) : Wang Xiao (Huazhong University of Science and Technology)
Abstract : We study the wrinkling dynamics of three-dimensional vesicles in time-dependent elongation flow by utilizing an immersed boundary method. The numerical results well match the predictions of perturbation analysis for a quasi-spherical vesicle. The parallel simulation can compute 512^3 Eulerian fluid grids and save the computation cost by at least an order of magnitude compared with the CPU algorithm. In addition, the parallel simulation can be directly extended to study other initial vesicles and external flows.

[04452] Energetic Variation associated with nonlinear Schrödinger equations with Anderson Hamiltonian

Format : Talk at Waseda University
Author(s) : Qi Zhang (Yau Mathematical Sciences Center, Tsinghua University, China/Yanqi Lake Beijing Institute of Mathematical Sciences and Applications, China)
Abstract : We study the variation problem associated with nonlinear Schrödinger equations with Anderson Hamiltonian in 2-dimensional torus. Under the paracontrolled distribution framework from singular SPDEs theory, we obtain the existence of the ground state solution by considering the minimization problem of the corresponding energy functional

with L^2 constraints. We also obtain the tail estimate on the distribution of the principal eigenvalue via the variational representation. This is joint work with Prof. Jinqiao Duan.

[04457] Macroscopic approximation for stochastic N-particle system with small mass

Format : Talk at Waseda University
Author(s) : Wei Wang (Nanjing University)
Abstract : In this talk we present a small mass limit approximation on macroscopic scale for stochastic N-particle system.
On macroscopic scale we have a slow-fast system and then by coupling the system on microscopic scale, an averaging approach is applied to derive the small mass limit. We also present this method to several different systems.

[04557] Effective wave factorization for a stochastic Schrodinger equation

Format : Talk at Waseda University
Author(s) : Ao Zhang (Central South University)
Abstract : We study the homogenization of a stochastic Schrodinger equation with a large periodic potential in solid state physics. Under a generic assumption on the spectral properties of the associated cell problem, we prove that the solution can be approximately factorized as the product of a fast oscillating cell eigenfunction and of a slowly varying solution of an effective equation. Our method is based on two-scale convergence and Bloch waves theory.

00507 (2/4) : 3E @G802

[04528] Approximation of nonlinear filtering for multiscale McKean-Vlasov stochastic differential equations

Format : Talk at Waseda University
Author(s) : Huijie Qiao (Southeast University)Wanlin Wei (Southeast University)
Abstract : The work concerns approximation of nonlinear filtering for multiscale McKean-Vlasov stochastic differential equations. First of all, by a Poisson equation we prove an average principle. Then we define nonlinear filtering of the origin multiscale equations and the average equation, and again by the Poisson equation show approximation between nonlinear filtering of the slow part for the origin multiscale equations and that of the average equation.

[04629] On the WKB approximation of confluent hypergeometric systems

Format : Talk at Waseda University
Author(s) : Xiaomeng Xu
Abstract : This talk studies the WKB approximation of the linear meromorphic systems of Poncaré rank 1 via the isomonodromy approach. It gives a characterization of the WKB approximation via the periods on the underlying spectral curves. It also unveils a relation between the WKB approximation, the Cauchy interlacing inequality, cluster algebras and so on. It is based on a joint work with Anton Alekseev, Andrew Neitzke and Yan Zhou.

[04570] Global stability of stochastic functional differential equations

Format : Talk at Waseda University
Author(s) : Xiang Lyu (Shanghai Normal University)
Abstract : This paper gives a criterion for the existence of a stationary solution for a class of semilinear stochastic functional differential equations with additive white noise and its global stability. To be more precise, we show that the infinite-dimensional stochastic flow possesses a unique globally attracting random equilibrium in the state space of continuous functions, which produces the globally stable stationary solution.

[04648] Averaging principle for slow-fast systems of stochastic PDEs with rough coefficients

Format : Online Talk on Zoom
Author(s) : Yichun Zhu (University of Maryland, College Park)Sandra Cerrai (University of Maryland, College Park)
Abstract : In this paper, we consider a class of slow-fast systems of stochastic partial differential equations where the nonlinearity in the slow equation is not continuous and unbounded.
We first provide conditions that ensure the existence of a martingale solution. Then we prove that the laws of the slow motions are tight, and any of their limiting points is a martingale solution for a suitable averaged equation. Our results apply to systems of

stochastic reaction-diffusion equations where the reaction term in the slow equation is only continuous and has polynomial growth.

00507 (3/4) : 4C @G802

[04756] Mean Asymptotic Behavior for Stochastic Kuramoto-Sivashinshy Equation in Bochner Spaces

Format : Online Talk on Zoom
Author(s) : Xiaopeng Chen (Shantou University)
Abstract : In this talk we mainly present some asymptotic behavior of the Kuramoto-Sivashinshy equation with stochastic perturbation. We define the mean random dynamical systems for the stochastic Kuramoto-Sivashinshy equation in Bochner spaces. Then we consider the so-called weak pullback mean random attractor and invariant manifold for the stochastic Kuramoto-Sivashinshy equation with odd initial conditions.

[04325] The Poisson Equation and Application to Multi-Scale SDEs with State-Dependent Switching

Format : Online Talk on Zoom
Author(s) : Xiaobin Sun (Jiangsu Normal University)
Abstract : In this talk, we discuss the Poisson equation associated with a Markov chain. By investigating the differentiability of the corresponding transition probability matrix with respect to parameters, we establish the regularity of the Poisson equation solution. As an application, we further study the averaging principle for a class of multi-scale stochastic differential equations with state-dependent switching, ultimately achieving an optimal strong convergence order of 1/2. This talk is based on a joint work with Yingchao Xie.

[04954] A stochastic fractional Schrodinger equation with multiplicative noise

Format : Talk at Waseda University
Author(s) : Yan jie Zhang (Zhengzhou University)Yanjie Zhang (Zhengzhou University)
Abstract : We establish the stochastic Strichartz estimate for the fractional Schr"odinger equation with multiplicative noise. With the help of the deterministic Strichartz estimates, we prove the existence and uniqueness of a global solution to the stochastic fractional nonlinear Schr"odinger equation
in $L_2(\mathbb{R}^n)$ and $H^1(\mathbb{R}^n)$, respectively. In addition, we also prove a general blow up result by deriving a localized virial estimate and the generalized Strauss inequality with $E[u_0] < 0$.

[05083] The most probable dynamics of receptor-ligand binding on cell membrane

Format : Online Talk on Zoom
Author(s) : Xi Chen (Xi'an University of Finance and Economics)
Abstract : We devise a method for predicting receptor-ligand binding behaviors, based on stochastic dynamical modelling. We consider the receptor and ligand perform different motions and are thus modeled by stochastic differential equations with Gaussian noise or non-Gaussian noise. We use neural networks based on Onsager-Machlup function to compute the probability of the receptor diffusing to the cell membrane. In this way, we conclude with some indication about where the ligand will most probably encounter the receptor.

00507 (4/4) : 4D @G802

[00509] Recent developments in stochastic optimization

Session Time & Room :

00509 (1/2) : 3E (Aug.23, 17:40-19:20) @A201

00509 (2/2) : 4C (Aug.24, 13:20-15:00) @A201

Type : Proposal of Minisymposium
Abstract : Optimization problems involving stochastic models or randomized algorithms are at the core of various applications areas such as machine learning, finance, energy production, signal processing, telecommunications, and medical imaging. Modern applications involve complex models and large dimensions. They require sophisticated analysis and algorithmic tools to obtain efficiently reliable solutions. This minisymposium will feature several advances illustrating the fertile interface between stochastic analysis and optimization through talks presented by junior and senior researchers. It will cover theoretical advances, as well as practical applications in finance, optimal control, inverse problems, optimal transportation, and petroleum production.

[00650] Random activations in primal-dual splittings for monotone inclusions with a priori information

Format : Talk at Waseda University
Author(s) : Luis Briceño-Arias (Universidad Técnica Federico Santa María)
Abstract : In this paper, we propose a numerical approach for solving composite primal-dual monotone inclusions with a priori information. The underlying a priori information set is represented by the intersection of fixed point sets of a finite number of operators, and we propose an algorithm that activates the corresponding set by following a finite-valued random variable at each iteration. Our formulation is flexible and includes, for instance, deterministic and Bernoulli activations over cyclic schemes, and Kaczmarz-type random activations. The almost sure convergence of the algorithm is obtained by means of properties of stochastic Quasi-Fejér sequences. We also recover several primal-dual algorithms for monotone inclusions without a priori information and classical algorithms for solving convex feasibility problems and linear systems. In the context of convex optimization with inequality constraints, any selection of the constraints defines the a priori information set, in which case the operators involved are simply projections onto half spaces. By incorporating random projections onto a selection of the constraints to classical primal-dual schemes, we obtain faster algorithms as we illustrate by means of a numerical application to a stochastic arc capacity expansion problem in a transport network.

[01376] New results on Carathéodory integral functions, applications to stochastic optimization

Format : Talk at Waseda University
Author(s) : Minh Nhut Bui (Universität Graz)Patrick L. Combettes (North Carolina State University)
Abstract : We present new results on Carath'eodory integral functions and discuss applications to stochastic optimization.

[03790] Adaptive partition-based method for 2-stage stochastic linear programming

Format : Talk at Waseda University
Author(s) : Eduardo Moreno (Universidad Adolfo Ibañez)Ivana Ljubic (ESSEC Business School)
Abstract : The Generalized Adaptive partition-based method for solving 2-stage stochastic linear problems is based on iteratively and automatically aggregating the uncertainty space into scenarios and disaggregating them based on the dual subproblem variables. It can be seen as a Benders-like method, where optimality cuts are adaptively aggregated based on the dual solutions. Computational experiments show significant improvements compared to classical methods, including the possibility of solving problems in continuous probability spaces using discrete optimization.

[03978] Multistage optimization of a partially observed petroleum production system

Format : Talk at Waseda University
Author(s) : Jean-Philippe Chancelier (CERMICS -- Ecole des Ponts ParisTech)Pierre Carpentier (UMA, ENSTA PARIS)Michel De Lara (CERMICS - Ecole des Ponts ParisTech)Cyrille Vessaire (CERMICS -- Ecole des Ponts ParisTech)Alejandro Rodriguez-Martinez (Total Energies, SE Pau)

Abstract : An oil production network is composed of one or more reservoirs (geological formations containing oil) connected through a network of wells and pipes. At the beginning of the reservoir exploitation, we have only partial knowledge of the content of the reservoir, namely a probability distribution of the initial state of the reservoir.

We propose a formulation of the management of an oil production network where the reservoir is a partially observed controlled dynamical system. This approach leads to a well-known class of problems: Partially Observed Markovian Decision Process (POMDP). However, general POMDPs are often untractable due to the curse of dimensionality. In the case of the proposed formulation, we consider a subclass of POMDPs: deterministic-POMDPs (deterministic transition and observation). We highlight and exploit structure in the deterministic-POMDP formulation to push back the curse of dimensionality. Then, we are able to use Dynamic Programming to find the optimal production planning.

Finally, we present numerical applications.

00509 (2/2) : 4C @A201 [Chair: Patrick Combettes]

[05112] Convex stochastic optimization

Format : Talk at Waseda University
Author(s) : Teemu August Pennanen (King's College London)Ari-Pekka Perkkiö (Ludwig-Maximilian University of Munich)
Abstract : We study dynamic programming, duality and optimality conditions in general convex stochastic optimization problems introduced by Rockafellar and Wets in the 70s. We give a general formulation of the dynamic programming recursion and derive an explicit dual problem in terms of two dual variables, one of which is the shadow price of information while the other one gives the marginal cost of a perturbation much like in classical Lagrangian duality. Existence of primal solutions and the absence of duality gap are obtained without compactness or boundedness assumptions. In the context of financial mathematics, the relaxed assumptions are satisfied under the well-known no-arbitrage condition and the reasonable asymptotic elasticity condition of the utility function. We extend classical portfolio optimization duality theory to problems of optimal semi-static hedging. Besides financial mathematics, we obtain several new results in stochastic programming and stochastic optimal control.

[00517] Numerical Modelling of Highly Flexible Structures for Industrial Applications

Session Time & Room : 3C (Aug.23, 13:20-15:00) @E606

Type : Proposal of Minisymposium
Abstract : Highly flexible slender structures like yarns, cables, hoses or ropes are essential parts of high-performance engineering systems. The complex response of such structures in real operational conditions is far beyond the capabilities of current modelling tools that are at the core of modern product development cycles. The European Training Network THREAD, see https://thread-etn.eu/, addresses this problem class by novel methods for modelling and numerical simulation and their application in medical engineering, ropeway system design, civil engineering and automotive industry. Three groups of the THREAD network report on modelling aspects and tailored geometric time integration methods in these fields of application.

[02070] Augmented Lagrangian contact formulation of the 2D Euler elastica

Format : Talk at Waseda University
Author(s) : Martina Stavole (Friedrich-Alexander-Universität Erlangen-Nürnberg)Rodrigo Takuro Sato Martín de Almagro (Friedrich-Alexander-Universität Erlangen-Nürnberg)Olivier Brüls (Université de Liège)Sigrid Leyendecker (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : In this work we show an application of an augmented Lagrangian formulation to simulate contact between an elastic curve and a narrow environment with rigid walls. Our goal is to provide fast and accurate simulations of endoscopic procedures.

[02324] The velocity-based formulation for static and dynamic analysis of non-linear three-dimensional frames

Format : Talk at Waseda University
Author(s) : Dejan Zupan Sudhanva Kusuma Chandrashekhara (Unversity of Ljubljana)Eva Zupan (University of Ljubljana)
Abstract : The choice of primary interpolated variables is highly important in numerical formulations of three-dimensional frame-like structures. The crucial idea exploited in our approach is to employ velocities and angular velocities as the primary unknowns, which enables us the use of standard additive interpolation without violating the properties of configuration space. The main advantage of the proposed solution method is in its simplicity, robustness and long-term stability.

[02419] Half-explicit time integration of constrained mechanical systems on Lie groups

Format : Online Talk on Zoom
Author(s) : Martin Arnold (Martin Luther University Halle-Wittenberg)
Abstract :
Recently, there has been new interest in the local coordinates approach to Lie group time integration. The present paper contributes a novel half-explicit Lie group integrator to this field of research. This half-explicit integrator combines an explicit Runge-Kutta Munthe-Kaas method with the index-2 formulation of the equations of motion for constrained mechanical systems. We construct methods of order up to $p = 5$ and illustrate their favourable properties by numerical test results.

[02155] Frequency-dependent damping as forcing on multisymplectic integrators

Format : Online Talk on Zoom
Author(s) : Rodrigo Takuro Sato Martín de Almagro (FAU - Lehrstuhl für Technische Dynamik)Sigrid Leyendecker (FAU - Lehrstuhl für Technische Dynamik)
Abstract : Multisymplectic integrators are geometric integration methods with interesting conservation properties. However, for the temporal integration of flexible structures it may be desirable to dampen high-frequency modes. In this talk we propose a simple frequency-dependent damping model which can be considered as additional forcing. We implement it together with multisymplectic integrators and compare its performance with the generalized alpha method, a popular numerical method for this application due to its frequency-dependent numerical damping.

[00521] Recent advances on non-convex optimization in inverse problems, imaging and machine learning

Session Time & Room :

00521 (1/5) : 3D (Aug.23, 15:30-17:10) @A206

00521 (4/5) : 4D (Aug.24, 15:30-17:10) @A206

00521 (5/5) : 4E (Aug.24, 17:40-19:20) @A206

Type : Proposal of Minisymposium
Abstract : Non-convex optimization has become increasingly important for modern data science applications, with many unsolved challenging open problems. Due to the absence of convexity, the well- developed paradigms convex optimization cannot be fully extended here, leading to the current situation that the theory of non-convex optimization is way behind the practice. In this mini-symposium, we focus on recent advances in non-convex optimization, including the analysis and understanding of the fundamental nature of the non-convex optimization, algorithmic bias/implicit regularization of gradient-based algorithms, fast convergent algorithms in non-convex problems, and their applications in inverse problems, imaging and machine learning and many others.

[02446] Convergence rate analysis of a Dykstra-type projection algorithm

Format : Talk at Waseda University
Author(s) : Xiaozhou Wang (The Hong Kong Polytechnic University)Ting Kei Pong (The Hong Kong Polytechnic University)
Abstract : We extend the Dykstra's projection algorithm to find projections onto the intersection of linear preimages of closed convex sets. The algorithm only makes use of projections onto the latter sets and operations by the linear maps and their adjoints in every iteration. Explicit convergence rate is derived when each set is $C^{1,\alpha}$-cone reducible for some $\alpha \in (0,1]$, under standard relative interior conditions. Concrete examples are constructed to illustrate the necessity of some of our assumptions.

[04336] Critical points of the projection onto the set of low rank tensors

Format : Talk at Waseda University
Author(s) : Shenglong Hu (Hangzhou Dianzi University)
Abstract : In 2009, SIAM von Neumann prize-winner Yousef Saad proposed the open problem on characterizing the convergence rate of the classical alternating polar decomposition method for low rank orthogonal tensor approximation problem. Actually, this problem was initiated by Gene Golub in 2001 for the rank one case, and received considerable study in the past twenty years. In 2015, concrete examples were given showing that the convergence rate may be sublinear, linear and superlinear. In this talk, we show that for a generic tensor, the algorithm converges linearly without any further assumption by studying the critical points of the projection onto the set of low rank tensors.

[05256] Nonconvex Semi-algebraic Optimization: From Exact to Convergent Conic Program Relaxations

Format : Talk at Waseda University
Author(s) : Jeya Jeyakumar (UNSW Sydney)
Abstract : Semi-algebraic optimization is the study of optimization problems where the feasible set is defined in terms of polynomial inequalities, called a semi-algebraic set. In addition to the usual tools of nonlinear optimization, such as convex analysis and linear algebra, powerful techniques of real algebraic geometry, such as representation theorems for polynomials, and conic programming methods, such as semi-definite programming and copositive programming, can be employed to study these problems. In this talk, I will describe the key results in this area, highlighting our recent work on the development of exact conic programming relaxations and convergent hierarchy of conic programming relaxations for classes of semi-algebraic optimization problems.

00521 (2/5) : 3E @A206 [Chair: Guoyin Li]

[01258] Global convergence of the gradient method for functions definable in o-minimal structures

Format : Talk at Waseda University
Author(s) : Cedric Josz (Columbia University)
Abstract : We consider the gradient method with variable step size for minimizing functions that are definable in o-minimal structures on the real field and differentiable with locally Lipschitz gradients. A sufficient condition ensuring global convergence is discussed, with implications for the convergence rate and convergence to a local minimum. Applications include principal component analysis, matrix sensing, and linear neural networks.

[04681] Convergence theory for mean-field optimization methods

Format : Talk at Waseda University
Author(s) : Atsushi Nitanda (Kyushu Institute of Technology)Denny Wu (University of Toronto)Taiji Suzuki (The University of Tokyo)
Abstract : Optimization of mean-field models recently attracts attention due to its connection to training two-layer neural networks under the mean-field regime. To analyze the optimization dynamics of mean-field models, we have established the theory of convex analysis and have derived several optimization methods. In this talk, we present recent advances in the theory for mean-field optimization methods.

[03322] Convergence Theorem for Deep Neural Network with ReLU Activation

Format : Talk at Waseda University

Author(s) : Gue Myung Lee (Department of Applied Mathematics, Pukyong National University)Jae Hyoung Lee (Department of Applied Mathematics, Pukyong National University)Kwang Baik Lee (Department of Applied Mathematics, Pukyong National University)

Abstract : Deep Neural Network (Deep Learning) is an artificial neural network which consists of input layer, output layer and many hidden layers between them. The gradient descent algorithm is the key one in the learning system for the deep neural network. So, for understanding the learning system, we should know the convergence for the descent algorithm for the cost function of L-layers neural network. The cost function is a composition of weight variables, biases variables and activation functions.

In this talk, we consider the convergence theorem for the descent algorithm for the cost function of L-layers neural network with ReLU function(:$\sigma(z) = \max\{0, z\}$) as its activation function.
First, we show that the cost function is semi-algebraic and locally Lipschitz.
Secondly, we show that the sequence, which was generated by the descent algorithm with Clarke generalized gradient, globally converges to a stationary point (critical point) under certain assumptions.
Thirdly, we prove that the set of critical values of the cost function is finite.

[05068] Theoretical and practical applications of signomial rings to polynomial optimization

Format : Talk at Waseda University

Author(s) : Mareike Dressler (UNSW Sydney)

Abstract : Signomials generalize polynomials by allowing arbitrary real exponents, at the expense of restricting the resulting function to the positive orthant. In this talk, I present a signomial Positivstellensatz based on conditional "sums of arithmetic-geometric exponentials" (SAGE). The Positivstellensatz applies to compact sets which need not be convex or even basic semi-algebraic. In the first part of the talk, I explain how this result is derived through the newly-defined concept of signomial rings. Then I show how the same concept leads to a novel convex relaxation hierarchy of lower bounds for signomial optimization. These relaxations (which are based on relative entropy programming) can be solved more reliably than those arising from earlier SAGE-based Positivstellensätze. Moreover, this increase in reliability comes at no apparent cost of longer solver runtimes or worse bounds. Numerical examples are provided to illustrate the performance of the hierarchy on a problem in chemical reaction networks.
This talk is based on joint work with Riley Murray.

00521 (3/5) : 4C @A206 [Chair: Jingwei Liang]

[04380] Proximal methods for nonsmooth and nonconvex fractional programs: when sparse optimization meets fractional programs

Format : Talk at Waseda University

Author(s) : Guoyin Li (University of new south wales)Radu Ioan Bot (University of Vienna)Minh Dao (Royal Melbourne Institute of Technology)

Abstract : Nonsmooth and nonconvex fractional programs are ubiquitous and also highly challenging. It includes the composite optimization problems studied extensively lately, and encompasses many important modern optimization problems arising from diverse areas such as the recent proposed scale invariant sparse signal reconstruction problem in signal processing, the robust Sharpe ratio optimization problems in finance and the sparse generalized eigenvalue problem in discrimination analysis. In this talk, we will introduce extrapolated proximal methods for solving nonsmooth and nonconvex fractional programs and analyse their convergence behaviour. Interestingly, we will show that the proposed algorithm exhibits linear convergence for sparse generalized eigenvalue problem with either cardinality regularization or sparsity constraints. This is achieved by identifying the explicit desingularization function of the Kurdyka-Lojasiewicz inequality for the merit function of the fractional optimization models. Finally, if time permits, we will present some preliminary encouraging numerical results for the proposed methods for sparse signal reconstruction and sparse Fisher discriminant analysis.

[03321] Error bounds based on facial residual functions

Format : Talk at Waseda University
Author(s) : Bruno Lourenço (Institute of Statistical Mathematics)Scott B. Lindstrom (Curtin University)Ting Kei Pong (The Hong Kong Polytechnic University)
Abstract : In this talk, we overview some recent error bound results obtained under the framework of facial residual functions.
This includes new tight error bounds for optimization problems with constraints involving
exponential cones, p-cones and others. Time allowing, we will briefly illustrate the applications of such results in proving precise convergence rates of certain algorithms and in determining automorphism groups of cones.

[02798] Doubly majorized algorithm for sparsity-inducing optimization problems with regularizer-compatible constraints

Format : Talk at Waseda University
Author(s) : Tianxiang Liu (Tokyo Institute of Technology)Ting Kei Pong (The Hong Kong Polytechnic University)Akiko Takeda (The University of Tokyo)
Abstract : We consider a class of sparsity-inducing optimization problems whose constraint set is regularizer-compatible. By exploiting absolute-value symmetry and other properties in the regularizer, we propose a new algorithm, called the Doubly Majorized Algorithm (DMA). Without invoking any commonly used constraint qualification conditions, we show that the sequence generated by DMA clusters in a new stationary point inspired by the notion of L-stationarity. Finally, numerical performance of DMA on variants of ordered LASSO is also illustrated.

00521 (4/5) : 4D @A206 [Chair: Jingwei Liang]

[04271] Differentiating Nonsmooth Solutions to Parametric Monotone Inclusion Problems

Format : Talk at Waseda University
Author(s) : Antonio José Silveti-Falls (Université Paris-Saclay, CentraleSupélec, INRIA OPIS, France)Edouard Pauwels (Université Toulouse 3 Paul Sabatier)Jérôme Bolte (Université Toulouse Capitole, Toulouse School of Economics)
Abstract : Understanding the differentiability and regularity of the solution to a monotone inclusion problem is an important question with consequences for convex optimization, machine learning, signal processing, and beyond. Past attempts have been made either under very restrictive assumptions that ensure the solution is continuously differentiable or using mathematical tools that are incompatible with automatic differentiation. In this talk, we discuss how to leverage path differentiability and a recent result on nonsmooth implicit differentiation calculus to give sufficient conditions ensuring that the solution to a monotone inclusion problem will be path differentiable and provide formulas for computing its generalized gradient. Our approach is fully compatible with automatic differentiation and comes with assumptions which are easy to check, roughly speaking: semialgebraicity and strong monotonicity. We illustrate the scope of our results by considering three fundamental composite problem settings: strongly convex problems, dual solutions to convex minimization problems and primal-dual solutions to min-max problems.

[01315] Optimal Neural Network Approximation of Wasserstein Gradient Direction via Convex Optimization

Format : Online Talk on Zoom
Author(s) : Yifei Zack Wang (Stanford University)Peng Chen (Georgia Institute of Technology)Mert Pilanci (Stanford University)Wuchen Li (University of South Carolina)
Abstract : The computation of Wasserstein gradient direction is essential for posterior sampling problems and scientific computing. For finite samples, we approximate the score function in the family of two-layer networks with squared-ReLU activations. We derive a semi-definite programming (SDP) relaxation of the variational problem, which can be efficiently solved by standard interior point method. Numerical experiments including PDE-constrained Bayesian inference and parameter estimation in COVID-19 modeling demonstrate the effectiveness of the proposed method.

[01537] Data-informed deep optimization

Format : Talk at Waseda University
Author(s) : Lulu Zhang (Shanghai Jiao Tong University)
Abstract : Motivated by the impressive success of deep learning, we explore the application of deep learning into a specific class of optimization problems lacking explicit formulas for both objective function and constraints. In this work, we propose a data-informed deep optimization (DiDo) approach emphasizing on the adaptive fitting of the the feasible region. To demonstrate the effectiveness of our DiDo approach, we consider a practical design case in industry and a 100-dimension toy example.

00521 (5/5) : 4E @A206 [Chair: Jingwei Liang]

[02734] Continuous Newton-like Methods featuring Inertia and Variable Mass

Format : Talk at Waseda University
Author(s) : Camille Castera (University of Tübingen)Hedy Attouch (IMAG, Université Montpellier, CNRS)Jalal Fadili (ENSICAEN, Normandie Université, CNRS, GREYC)Peter Ochs (University of Tübingen)
Abstract : Towards designing new algorithms that benefit from the best of both first- and second-order optimization methods, we introduce a new dynamical system, called VM-DIN-AVD, at the interface between second-order dynamics with inertia and Newton's method. This system extends the class of inertial Newton-like dynamics by featuring a time-dependent parameter in front of the acceleration, called variable mass. For strongly convex optimization, we provide guarantees on how the Newtonian and inertial behaviors of the system can be non-asymptotically controlled by means of this variable mass. A connection with the Levenberg-Marquardt --or regularized Newton's-- method is also made. We then show the effect of the variable mass on the asymptotic rate of convergence of the dynamics, and in particular, how it can turn the latter into an accelerated Newton method. We present numerical experiments supporting our findings.

[01611] Inertial quasi-Newton methods for monotone inclusion

Format : Talk at Waseda University
Author(s) : Shida Wang (Universität Tübingen)Jalal Fadili (Normandie Univ, ENSICAEN)Peter Ochs (Universität Tübingen)
Abstract : We introduce an inertial quasi-Newton Forward-Backward Splitting Algorithm to solve a class of monotone inclusion problems. While the inertial step is computationally cheap, in general, the bottleneck is the evaluation of the resolvent operator. A change of the metric makes its computation hard even for (otherwise in the standard metric) simple operators. In order to fully exploit the advantage of adapting the metric, we develop a new efficient resolvent calculus for a low-rank perturbed standard metric, which accounts exactly for quasi-Newton metrics. Moreover, we prove the convergence of our algorithms, including linear convergence rates in case one of the two considered operators is strongly monotone. Beyond the general monotone inclusion setup, we instantiate a novel inertial quasi-Newton Primal-Dual Hybrid Gradient Method for solving saddle point problems. The favourable performance of our inertial quasi-Newton PDHG method is demonstrated on several numerical experiments in image processing.

[05250] Extrapolated Proximal Algorithms for Nonconvex and Nonsmooth Min-max problems

Format : Talk at Waseda University
Author(s) : Peter Wu (UNSW)Guoyin Li (The University of New South Wales)Minh Dao (RMIT)
Abstract : In this talk, we consider an extrapolated proximal algorithm for solving nonsmooth and nonconvex minmax problems. We establish convergence of the full sequence to a stationary point under some gentle assumptions. If time permits, numerical experiment on its application to multi-domain robust sparse learning will be presented.

[05578] Global stability of first-order methods for coercive tame functions

Format : Talk at Waseda University
Author(s) : Cédric Josz (Columbia University)Lexiao Lai (Columbia University)
Abstract : We consider first-order methods with constant step size for minimizing locally Lipschitz coercive functions that are tame in an o-minimal structure on the real field. We prove that if the method is approximated by subgradient trajectories, then the iterates eventually remain in a neighborhood of a connected component of the set of critical points. Under suitable model-dependent regularity assumptions, this result applies to the random reshuffling and momentum and the random-permutations cyclic coordinate descent method.

[00523] Implicit methods for hyperbolic problems and their extensions and applications

Session Time & Room :

00523 (1/3) : 3C (Aug.23, 13:20-15:00) @A618

00523 (2/3) : 3D (Aug.23, 15:30-17:10) @A618

00523 (3/3) : 3E (Aug.23, 17:40-19:20) @A618

Type : Proposal of Minisymposium
Abstract : Hyperbolic partial differential equations and their numerical solutions play an important role in several fields of applied mathematics. Many interesting applications of related PDEs are stiff in nature, so implicit time discretizations with enhanced stability properties are good candidates for their numerical solution. The minisymposium shall discuss important aspects of such methods like higher order accuracy, non-oscillatory behavior, well-balancing, asymptotic-preserving, efficient solvers, and combinations with explicit schemes.
Organizer(s) : Peter Frolkovič, Pep Mulet, Carlos Parés
Classification : 35L04

00523 (1/3) : 3C @A618 [Chair: Carlos Parés]

[04131] Semi-implicit schemes for a convection-diffusion-reaction model of sequencing batch reactors

Format : Talk at Waseda University
Author(s) : Raimund Bürger (Universidad de Concepción)Julio Careaga (Radboud University)Stefan Diehl (Lund University)Romel Pineda (Universidad de Concepción)
Abstract : Sequencing batch reactors are used in wastewater treatment for the settling of solid biomass particles simultaneously with biochemical reactions with nutrients dissolved in the liquid. This unit can be modeled as a moving-boundary problem for a degenerating convection-diffusion-reaction system. This model is transformed to a fixed computational domain and is discretized by an explicit and semi-implicit monotone schemes. Both variants obey an invariant region property. Numerical examples illustrate that the semi-implicit variant is more efficient.

[01691] High resolution well-balanced compact implicit numerical scheme for numerical solution of the shallow water equations

Format : Talk at Waseda University
Author(s) : Michal Žeravý (Slovak University of Technology in Bratislava)Peter Frolkovič (Slovak University of Technology in Bratislava)
Abstract : In this talk, we deal with the numerical solution of shallow water equations with topography in one-dimensional case using a high resolution well-balanced compact implicit numerical scheme. The upwind scheme uses the fractional step method with the fast sweeping method. Consequently, the Jacobian matrix of the discrete system of nonlinear algebraic equations is always either a lower or upper triangular matrix.

[01692] Numerical solution of scalar hyperbolic problems using the third order accurate compact implicit scheme

Format : Talk at Waseda University
Author(s) : Dagmar Zakova (Slovak University of Technology in Bratislava)Peter Frolkovic (Slovak University of Technology in Bratislava)
Abstract : This work presents compact implicit numerical schemes for solving scalar hyperbolic problems. We propose details of the third-order accurate scheme using the finite volume method. To avoid unphysical oscillations in the case of nonsmooth solution, we modify the scheme using ENO and WENO approximation in space. Applications to one-dimensional conservation laws are shown.

[05425] High-fidelity multiderivative time integration for compressible flows

Format : Talk at Waseda University
Author(s) : Arjun Thenery Manikantan (Hasselt University)Jochen Schütz (Hasselt University)Jonas Zeifang (Hasselt University)
Abstract : We present a high-order parallel-in-time implicit multiderivative time-stepping scheme for Navier Stokes equations spatially discretized with the Discontinuous Galerkin Spectral element method. The time-stepping starts with a predicted solution, and the correction steps increase the order of accuracy up to the order of the underlying quadrature rule. Implicit non-linear(linear) equations are solved using Newton's and the general minimal residual methods. Extensive numerical results are shown for convergence, parallel efficiency, and other scheme features.

00523 (2/3) : 3D @A618 [Chair: Pep Mulet]

[01684] Implicit and semi-implicit well-balanced finite volume methods for general 1d systems of balance laws

Format : Talk at Waseda University
Author(s) : Carlos Parés (University of Málaga)Irene Gómez-Bueno (University of Málaga)Manuel Jesús Castro (University of Málaga)Sebastiano Boscarino (University of Catania)Giovanni Russo (University of Catania)
Abstract : In this work a general family of implicit and semi-implicit well-balanced finite volume numerical methods for nonlinear hyperbolic systems of balance laws will be presented. These methods are obtained by extending a general strategy introduced by some of the authors to design high-order well-balanced explicit methods. This strategy, based on the computation of local steady states, will be combined with implicit RK or IMEX solvers in time. Different applications will be shown.

[01665] SHALLOW-WATER MODEL: IMPLICIT FULLY WELL-BALANCED METHODS IN THE LAGRANGE-PROJECTION FRAMEWORK

Format : Talk at Waseda University
Author(s) : Celia Caballero Cárdenas (Universidad de Málaga)Manuel Jesús Castro Díaz (Universidad de Málaga)Tomás Morales de Luna (Universidad de Malaga)María de la Luz Muñoz-Ruiz (Universidad de Málaga)Christophe Chalons (Université Versailles Saint-Quentin-en-Yvelines)
Abstract : We propose fully well-balanced Lagrange-Projection finite volume schemes for the shallow-water model. This two-step approach separates acoustic and transport phenomena, allowing for implicit-explicit and large time step schemes with CFL restriction based on slower transport waves.

[01664] Hyperbolic systems with stiff relaxation: asymptotic-preserving and well-balanced schemes

Format : Talk at Waseda University
Author(s) : Irene Gómez-Bueno (University of Málaga)Sebastiano Boscarino (University of Catania)Manuel Jesús Castro Díaz (University of Málaga)Carlos Parés (University of Málaga)Giovanni Russo (University of Catania)
Abstract : We consider hyperbolic systems depending on a stiff parameter ε: when ε is small, numerical schemes may produce spurious results. Implicit-explicit Runge–Kutta schemes have been widely used for their time evolution. Our goal is to design high-order asymptotic-preserving methods which are at the same time well-balanced for the asymptotic limit system.

[01673] MIRK methods and applications in RRMHD and neutrino transport equations

Format : Talk at Waseda University
Author(s) : Isabel Cordero-Carrión (University of Valencia)Samuel Santos-Pérez (University of Valencia)Martin Obergaulinger (University of Valencia)
Abstract : We present the Minimally-Implicit Runge-Kutta (MIRK) methods for the numerical resolution of hyperbolic equations with stiff source terms. We apply these schemes to the resistive relativistic magnetohydrodynamic (RRMHD) and the M1 neutrino transport equations. Previous approaches rely on Implicit-Explicit Runge-Kutta schemes. The MIRK methods are able to deal with stiff terms producing stable numerical evolutions and their computational cost is similar to the standard explicit methods.

00523 (3/3) : 3E @A618 [Chair: Peter Frolkovič]

[03904] Implicit-explicit schemes for Cahn-Hilliard-Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Pep Mulet (University of Valencia)
Abstract : Navier-Stokes-Cahn-Hilliard equations are a system of fourth-order partial differential equations that model the evolution of compressible mixtures of binary fluids (e.g. foams, solidification processes, fluid–gas interface) under gravitational effects. Our aim is to use implicit-explicit time-stepping schemes to avoid the severe restriction posed by the high order terms for the efficient numerical solution of problems with these equations.

[00524] Lie Symmetries, Solutions and Conservation laws of nonlinear differential equations

Session Time & Room :

00524 (1/4) : 1C (Aug.21, 13:20-15:00) @A201

00524 (2/4) : 1D (Aug.21, 15:30-17:10) @A201

00524 (3/4) : 1E (Aug.21, 17:40-19:20) @A201

00524 (4/4) : 2C (Aug.22, 13:20-15:00) @A201

Type : Proposal of Minisymposium
Abstract : This mini-symposium is devoted to all research areas that are related to nonlinear differential equations and their applications in science and engineering. The main focus of this mini-symposium is on the Lie symmetry analysis, conservation laws and their applications to ordinary and partial differential equations. These differential equations could originate from mathematical models of diverse disciplines such as architecture, chemical kinetics, civil engineering, ecology, economics, engineering, fluid mechanics, biology and finance. Other approaches in finding exact solutions to nonlinear differential equations will also be discussed. This includes, but not limited to, asymptotic analysis methodologies, bifurcation theory, inverse scattering transform techniques, the Hirota method, the Adomian decomposition method, and others.

[02723] Conservation laws and variational structure of damped nonlinear wave equations

Format : Talk at Waseda University
Author(s) : Almudena P. Márquez (University of Cadiz)Stephen Anco (Brock University)Tamara M. Garrido (University of Cadiz)María L. Gandarias (University of Cadiz)
Abstract : All low-order conservation laws are found for a general class of nonlinear wave equations in one dimension with linear damping which is allowed to be time-dependent. Such equations arise in numerous physical applications and have attracted much attention in analysis. The conservation laws describe generalized momentum and boost momentum, conformal momentum, generalized energy, dilational energy, and light-cone energies. Both the conformal momentum and dilational energy have no counterparts for nonlinear undamped wave equations in one dimension. All of the conservation laws are obtainable through Noether's theorem, which is applicable because the damping term can be transformed into a time-dependent self-interaction term by a change of dependent variable. For several of the conservation laws, the corresponding variational symmetries have a novel form which is different than any of the well known variation symmetries admitted by nonlinear undamped wave equations in one dimension.

[03330] Constructing mass-conserving cnoidal wave solutions for the KdV equation

Format : Talk at Waseda University
Author(s) : Carel Petrus Olivier (North-West University)Frank Verheest (Universiteit Gent)
Abstract : Nonlinear periodic travelling wave solutions of the Korteweg-deVries (KdV) equation in the form of cnoidal wave solutions are investigated. The general cnoidal wave solution does not ensure that the mass of the undisturbed medium is conserved. In this paper, a framework is provided to construct mass-conserving cnoidal wave solutions., and the resulting solutions are analyzed. It is shown that these solutions are consistent with linear solutions in the small amplitude limit.

[04290] Conservation laws and symmetries of a Generalized Drinfeld-Sokolov system

Format : Talk at Waseda University
Author(s) : Tamara M. Garrido (University of Cadiz)Rafael De La Rosa (University of Cadiz)Elena Recio (University of Cadiz)Almudena P. Márquez (University of Cadiz)
Abstract : The generalized Drinfeld-Sokolov system is a widely-used model that describes wave phenomena in various contexts. Many properties of this system, such as Hamiltonian formulations and integrability, have been extensively studied, and exact solutions have been derived for specific cases. In this paper, we apply the direct method of multipliers to obtain all low-order local conservation laws of the system. These laws correspond to physical quantities that remain constant over time, such as energy and momentum, and we provide a physical interpretation for each of them. Additionally, we investigate the Lie point symmetries and first-order symmetries of the system. Through the point symmetries and constructing the optimal systems of one-dimensional subalgebras, we are able to reduce the system of partial differential equations to ordinary differential systems.

[02959] Lie symmetry analysis of flow and pressure inside horizontal chamber

Format : Talk at Waseda University
Author(s) : Tanki Motsepa (University of Mpumalanga)Modisawatsona Lucas Lekoko (North-West University)Gabriel Magalakwe (North-West University)
Abstract : Exact solutions improve industrial processes by giving operators greater grasp of how systems operate. The study aims to find exact momentum and pressure solutions during the unsteady filtration process. Lie symmetry analysis is used to transform a system of PDEs representing the case study into solvable ODEs. The ODEs are then solved to obtain velocity and pressure solutions. Effects of parameters resulting from the dynamics are examined to identify the parameters that yield maximum outflow.

00524 (2/4) : 1D @A201 [Chair: Tanki Motsepa]

[03457] Closed-form solutions and conservation laws of the fifth-order strain wave equation in microstructured solids

Format : Online Talk on Zoom
Author(s) : Mduduzi Thabo Lephoko (North-West University, Mafikeng Campus)Chaudry Masood Khalique (North-West University, South Africa)
Abstract : In this presentation, we examine the dynamics of soliton waves associated with higher-order nonlinear partial differential equations, which have applications in various fields of science and engineering. Our focus is on the fifth-order strain wave equation, for which we employ the Lie group theory of differential equations to obtain analytic solutions. Specifically, we use this technique to systematically generate the Lie point symmetries spanned by the equation, which we then use to reduce it to ordinary differential equations that can be solved to obtain closed-form solutions. The ordinary differential equations are solved by direct integration and the engagement of two methods, the simplest method and generalized tanh-function method. We successfully identify soliton solutions, including dark and singular period solitons, and depict them graphically to better understand their physical meaning. We then use the multiplier method to obtain conserved vectors. Our analysis sheds light on the wave structures associated with the strain wave equation and provides insight into the physical implications of the soliton solutions.

[02308] Symmetry solutions and conservation laws of the derivative nonlinear Schrodinger equation

Format : Online Talk on Zoom
Author(s) : Karabo Plaatjie (North-West University, Mafikeng Campus)Chaudry Masood Khalique (North-West University, South Africa)
Abstract : In this talk we study the derivative nonlinear Schrodinger equation.This equation has many applications, for example in the propagation of circular polarized nonlinear Alfven waves in plasmas. We present general and special solutions of this equation using Lie group theory. We also derive conservation laws for the underlying equation.

[03449] Lie symmetry analysis of new 3-D fifth-order nonlinear Wazwaz equation

Format : Online Talk on Zoom
Author(s) : Oke Davies Adeyemo (North-West University, Mafikeng Campus)
Abstract : In this talk, we present the analytical examination of a new (3+1)-dimensional fifth-order nonlinear Wazwaz equation with third-order dispersion terms in ocean physics and other nonlinear sciences. We apply Lie group analysis to obtain various infinitesimal generators admitted by the equation. The generators are used to reduce the understudy

equation to achieve copious group-invariant solutions. Thus, various closed-form solutions are obtained for the equation. We further construct its conservation laws.

00524 (3/4) : 1E @A201 [Chair: C M KHALIQUE]

[03451] Lie group analysis of the nonlinear 3D KP-BBM equation

Format : Online Talk on Zoom

Author(s) : Jonathan Lebogang Bodibe (North-West University, Mafikeng Campus)Chaudry Masood Khalique (North-West University, South Africa)

Abstract : In this talk, we present Lie group analysis of the nonlinear (3+1)-dimensional Kadomtsev Petviashvili Benjamin Bona Mahony equation. We find exact solutions of the equation using Lie symmetry method together with Kudryashov's and (G'/G)-expansion methods. Moreover, we derive the conservation laws for the equation using the multiplier and Ibragimov's methods.

00524 (4/4) : 2C @A201 [Chair: C M KHALIQUE]

[04488] Integrable equations and Riemann-Hilbert problems

Format : Talk at Waseda University

Author(s) : Wen-Xiu Ma (University of South Florida)

Abstract : This talk covers the zero curvature formulation and the Riemann-Hilbert technique. Nonlocal integrable equations are derived from conducting group reductions. The associated matrix spectral problems are used to build a kind of Riemann-Hilbert problems, whose reflectionless cases generate soliton solutions.

[04064] A study of 3D generalized nonlinear wave equation in fluids

Format : Talk at Waseda University

Author(s) : Chaudry Masood Khalique (North-West University, South Africa)

Abstract : In this talk we study a (3+1)-dimensional generalized nonlinear wave equation of fluids. Using Lie symmetry methods, we transform the underlying equation into a nonlinear ordinary differential equation. We deduce periodic, trigonometric bright soliton together with singular soliton solutions. Moreover, some soliton solutions are secured via the simplest equation method in the form of Jacobi elliptic functions. The dynamics of the solutions are depicted using suitable graphs. Furthermore, we construct conservation laws of the equation by employing Ibragimov's theorem.

[04126] Burgers' nth Partial Differential Equation Hierarchy

Format : Talk at Waseda University

Author(s) : Sameerah Jamal (University of the Witwatersrand)

Abstract : We present some recent advances of the applications of one-parameter Lie group transformations of famous partial differential equations. In particular, we discuss the Burgers' equation, which are often the benchmarks in the study of differential equations. We exploit the link between the equation and a recursion operator and show how the full hierarchy may be solved.

[03471] Nonclassical Potential Symmetries for the transient heat transfer equation

Format : Talk at Waseda University

Author(s) : Mpho Nkwanazana (Sefako Makgatho Health Science Universitye)Raseelo Moitsheki (University of the Witwatersrand)

Abstract : In this article we consider the one dimensional transient heat conduction
equation. The diffusivity term and internal heat generator are given by the
power law. The objective is to employ nonclassical and nonlocal approach to
generate nonclassical potential symmetries.

[00528] High order and well-balanced methods and stability analysis for non-linear hyperbolic systems

Session Time & Room :

00528 (1/2) : 1C (Aug.21, 13:20-15:00) @G606

00528 (2/2) : 1D (Aug.21, 15:30-17:10) @G606

Type : Proposal of Minisymposium
Abstract : Many complex physical phenomena may be modeled by means of non-linear hyperbolic systems. When approximating such systems, one requires the use of efficient, accurate and stable numerical schemes. On the one hand, the use of high-order methods will be necessary in order to reduce the numerical diffusion inherent to the numerical approach. On the other hand, it is common for these systems the existence of some particular steady-state solutions that should be preserved, which will need the use of a well-balanced scheme.

The goal of this mini-symposium is the discussion and presentation of state-of-the-art computational and numerical methods of high-order well-balanced schemes with applications to hyperbolic systems.

[01682] High order well-balanced finite volume and discontinuous Galerkin schemes for a first order hyperbolic reformulation of the coupled Einstein-Euler system in 3+1 general relativity

Format : Talk at Waseda University
Author(s) : Michael Dumbser (University of Trento)
Abstract : We present new well-balanced finite volume and discontinuous Galerkin schemes for the solution of a new first order hyperbolic Z4 formulation of the Einstein-Euler system of general relativity. Nonlinear involutions are accounted for via a covariant GLM cleaning technique. We introduce a new, simple and efficient type of well-balancing that automatically applies to any numerical discretization and arbitrary equilibria in multiple space dimensions. We show numerical results for vacuum spacetimes and for a TOV star.

[01699] Numerical approximation of non-convex relativistic hydrodynamics

Format : Talk at Waseda University
Author(s) : Susana Serna (Universitat Autonoma de Barcelona)Antonio Marquina (Universidad de Valencia)
Abstract : We explore the rich and complex dynamics that a phenomenological equation of state (EoS) with non-convex regions in the pressure-density plane may develop as a result of genuinely relativistic effects. We study the parameter space of the EoS to ensure its causality and thermodynamical consistency. We approximate the non-conventional dynamics developed in the evolution of relativistic blast waves by means of a high order shock capturing scheme.

[01720] Recovering primitive variables in special relativistic hydrodynamics

Format : Talk at Waseda University
Author(s) : Antonio Marquina (Universidad de Valencia)Susana Serna (Universitat Autonoma de Barcelona)Jose M Ibanez (Universidad de Valencia)
Abstract : We study an iterative procedure based on fixed-point strategy to recover primitive variables
in each time step of the evolution of Special Relativistic Hydrodynamic equations. Given a set of three conserved values we start the iteration by prescribing an initial zero pressure so that if the first iterate
is strictly positive, then, the fixed-point iteration monotonically converges to the unique
pressure associated to the conserved variables.

[01290] Well-Balanced High-Order Discontinuous Galerkin Methods for Systems of Balance Laws

Format : Talk at Waseda University
Author(s) : Ernesto Guerrero Fernández (National Oceanic and Atmospheric Administration (NOAA))Cipriano Escalante Sanchez (Universidad de Málaga)Manuel Castro Díaz (Universidad de Málaga)
Abstract : This work introduces a general strategy to develop well-balanced high-order Discontinuous Galerkin (DG) numerical schemes for systems of balance laws. The essence of our approach is a local projection step that guarantees the exactly well-balanced character of the resulting numerical method for smooth stationary solutions. The strategy can be adapted to some well-known different time marching DG discretisations. Particularly, in this article, Runge--Kutta DG and ADER DG methods are studied. Additionally, a limiting procedure based on a modified WENO approach is described to deal with the spurious oscillations generated in the presence of non-smooth solutions, keeping the well-balanced properties of the scheme intact. The resulting numerical method is then exactly well-balanced and high-order in space and time for smooth solutions. Finally, some numerical results are depicted using different systems of balance laws to show the performance of the introduced numerical strategy.

00528 (2/2) : 1D @G606 [Chair: Ernesto Guerrero Fernández]

[01687] Structure preserving high order discontinuous Galerkin schemes for general relativity

Format : Talk at Waseda University
Author(s) : Elena Gaburro (Inria)Michael Dumbser (University of Trento)Ilya Peshkov (University of Trento)Olindo Zanotti (University of Trento)Manuel J. Castro (University of Malaga)
Abstract : In this talk we present a novel first order hyperbolic reformulation of the coupled Einstein-Euler system allowing robust and long-time stable simulations for the joint evolution of matter and space-time in general relativity. Among our numerical results we have long-time evolution of TOV neutron stars and accretion disks and a black holes collision. This is obtained through high order discontinuous Galerkin schemes endowed with subcell finite volume limiter, well balanced techniques and GLM curl cleaning.

[01663] Multidimensional approximate Riemann solvers for hyperbolic nonconservative systems

Format : Talk at Waseda University
Author(s) : José M. Gallardo (University of Málaga)
Abstract : This work deals with the development of efficient incomplete multidimensional Riemann solvers for hyperbolic systems. We present a general strategy for constructing genuinely two-dimensional Riemann solvers, that can be applied for solving systems including source and coupling terms. Two-dimensional effects are taken into account through the approximate solutions of 2d Riemann problems arising at the vertices of the computational mesh. Applications to magnetohydrodynamics and shallow water equations are presented.

[01841] A fully-well-balanced hydrodynamic reconstruction

Format : Talk at Waseda University
Author(s) : Christophe Berthon (Nantes Université)Victor Michel-Dansac (INRIA)
Abstract : The present work concerns the numerical approximation of the weak solutions of the shallow-water model. To address such an issue, the well-known hydrostatic reconstruction is adopted. Such a relevant technique easily gives numerical schemes able to exactly capture the steady states at rest. Here, necessary conditions are stated on the reconstruction process in order to also capture the moving steady states. An example of suitable hydrodynamic reconstruction is presented and tested.

[01690] A well-balanced scheme for landslide models

Format : Talk at Waseda University
Author(s) : Manuel J. Castro (Universidad de Malaga)Cipriano Escalante Sanchez (Universidad de Málaga)José Garres-Díaz (Universidad de Córdoba, Spain)Tomas Morales de Luna (Universidad de Malaga)
Abstract : When landslide models in the shallow water framework, special care has to be taken with the stationary solutions. Indeed, motion of the material only begins when the slope of the material is bigger than that of the repose angle. Preserving such steady states is not a trivial task. We present here different strategies to design well-balance high-order finite volume schemes.

[00529] Numerical approximation of geophysical flows

Session Time & Room :

00529 (1/2) : 1E (Aug.21, 17:40-19:20) @G606

00529 (2/2) : 2C (Aug.22, 13:20-15:00) @G606

Type : Proposal of Minisymposium
Abstract : Hyperbolic PDE systems naturally appear in many real-world applications, particularly in geophysical flow models. They are of essential importance for understanding natural phenomena and for their prediction.

This mini-symposium focuses on geophysical flows with a particular interest in the shallow water framework and related applications such as sediment transport, tsunami hazards, and viscoplastic flows.

The objective will be to discuss and presents new trends in computational and numerical methods for shallow flows and their applications.

[01506] Monotonicity-preserving interpolation in multilevel schemes for balance laws

Format : Talk at Waseda University
Author(s) : Antonio Baeza (University of Valencia, Spain)Rosa Donat (University of Valencia)Anna Martínez-Gavara (University of Valencia)
Abstract : This work deals with the problem of developing cost-effective multilevel schemes for balance laws, in particular for the shallow water equations in 1D and 2D. We focus on the application of monotonicity-preserving interpolatory techniques as a tool for the recursive computation of the numerical divergence in the different grids, which is a key step on multilevel schemes. Numerical tests confirm that this technique leads to a more robust multilevel code while improving its efficiency.

[01433] Entropy-stable, positivity-preserving and well-balanced Godunov-type schemes for multidimensional shallow-water system

Format : Talk at Waseda University
Author(s) : Agnes Chan (CEA Cesta - Université de Bordeaux)Gérard Gallice (CEA Cesta)Raphaël Loubère (Université de Bordeaux)Pierre-Henri Maire (CEA Cesta)Alessia Del Grosso (CEA Cesta - Université de Bordeaux)
Abstract : An entropy stable, positivity preserving Godunov-type scheme for multidimensional hyperbolic systems of conservation laws on unstructured grids was presented by Gallice et al. in 2022. A specific feature of their Riemann solver is coupling all cells in the vicinity of the current one, making their solver no longer 1D across one edge.
We extend their work to handle source terms, specifically for shallow water equations. The scheme we obtain is well-balanced in 1D and 2D.

[01511] Numerical solution of a system of conservation laws with discontinuous flux modelling flotation with sedimentation

Format : Talk at Waseda University
Author(s) : Raimund Bürger (Universidad de Concepción)Stefan Diehl (Lund University)Carmen Marti Raga (Universitat de València)Yolanda Vásquez (Universidad de Concepción)
Abstract : Froth flotation is a unit operation used in mineral processing to separate valuable mineral particles from worthless gangue particles in finely ground ores. In this talk, we will present a model for froth flotation, including the drainage of liquid that occurs at the top of the column. We will detail the construction of steady-state solutions and present some results that show the ability of the model to capture steady operation of the flotation device.

[01508] Implicit and IMEX Lagrange Projection schemes for Ripa model

Format : Talk at Waseda University

Author(s) : Celia Caballero Cárdenas (Universidad de Málaga)Manuel Jesús Castro Díaz (Universidad de Málaga)Tomas Morales de Luna (Universidad de Málaga)María Luz Muñoz-Ruiz (Universidad de Málaga)

Abstract : We consider the one-dimensional system of shallow equations with horizontal temperature gradients, i.e., the Ripa system. We present a numerical approximation of this system based on a Lagrange-Projection type finite volume scheme. We shall consider fully implicit and implicit-explicit versions of the scheme for the Lagrangian step, while the Projection step will always be done explicitly. Several numerical experiments are included in order to illustrate the good behavior of the proposed schemes.

[01400] Vertical discretizations of Euler systems and application to bedload problems

Format : Talk at Waseda University

Author(s) : José Garres-Díaz (Universidad de Córdoba)Tomas Morales de Luna (Universidad de Malaga)Cipriano Escalante Sanchez (Universidad de Málaga)Manuel Castro Díaz (Universidad de Málaga)

Abstract : Shallow water type systems are very popular in numerical simulation of geophysical flows, mainly due to their low computational cost. However, these systems share an important drawback: the vertical information of the flow is lost. In this talk, we present a general framework for vertical discretizations of free-surface Euler system, that generalizes the moment and multilayer techniques. It is called multilayer-moment approach. Several tests are presented, pointing out advantages/disadvantages of each approach, and their efficiency.

[01507] Numerical methods for viscoplastic flows : balancing precision and acceleration

Format : Talk at Waseda University

Author(s) : Clément Berger (UMPA CNRS UMR 5669, ENS de Lyon)

Abstract : We consider here equations for yield stress flows formulated as variational inequalities. The reason is that it allows the best numerical computation of the interfaces between fluid zones and rigid zones. In this talk, we compare multiple optimization methods, from proximal algorithms to second-order cone programming. The compromise between precision and speed differs from one method to another. We will also comment on each associated convergence criteria.

[01504] Digital Twins (DT) on geophysical extreme hazards. Using Tsunami-HySEA numerical model as DT for tsunami hazards.

Format : Talk at Waseda University

Author(s) : Jose Manuel Gonzalez-Vida (Dpt. Applied Mathematics. University of Malaga)Jorge Macías (Dpt. Mathematical Analysis, Statistics and Applied Mathematics)Manuel J. Castro (Dpt. Mathematical Analysis, Statistics and Applied Mathematics)Alex González (Dpt. Mathematical Analysis, Statistics and Applied Mathematics)

Abstract : A Digital Twin (DT) for GEOphysical extremes (DT-GEO) is an European project that aims to analyse and forecast the impact of tsunamis, earthquakes, volcanoes, and anthropogenic seismicity. This work address tsunami hazard phenomena to conduct precise data-informed early warning systems, forecasts, and tsunami-hazard assessments across multiple time scales.

[01513] Novel schemes for overdetermined thermodynamically compatible hyperbolic systems

Format : Online Talk on Zoom

Author(s) : Saray Busto (Universidade de Vigo)Michael Dumbser (University of Trento)

Abstract : We introduce a novel efficient general class of thermodynamically compatible, HTC, semi-discrete finite volume and discontinuous Galerkin schemes for overdetermined HTC systems. The approach is based on the discretization of the entropy being the total energy conservation a direct consequence of the HTC discretization. The obtained schemes are provably marginally stable in the energy norm, satisfy a discrete entropy inequality by construction and are assessed using classical benchmarks for turbulent shallow water and compressible flows.

[00533] Recovery and robustness of geometric fingerprints for point clouds and data

Session Time & Room :

00533 (1/3) : 1C (Aug.21, 13:20-15:00) @F412

00533 (2/3) : 1D (Aug.21, 15:30-17:10) @F412

00533 (3/3) : 1E (Aug.21, 17:40-19:20) @F412

Type : Proposal of Minisymposium
Abstract : The aim of our mini-symposium is to connect communities interested in the problem of condensing information from a dataset to a less complex geometric/statistical "summary", sometimes called a fingerprint. We will concentrate especially on, Distance histograms, Persistence diagrams, as well as spectral fingerprints and other geometric fingerprints. Questions relevant to applications, including topics such as resistence or stability to noise/error of a given fingerprint ("robustness" problems), or injectivity of the fingerprint (relevant for "recovery" problems) will be our focus during the minisymposium.

Organizer(s) : Mircea Petrache, Rodolfo Viera
Classification : 53C23, 55N31, 68T09, 52C35, 68R12, Distance histograms, Persistence diagrams, Fourier fingerprints
Minisymposium Program :

00533 (1/3) : 1C @F412 [Chair: Petrache Mircea]

[04178] Recovering discrete Fourier spectra from random perturbations

Format : Online Talk on Zoom
Author(s) : Mircea Petrache (Pontificia Catolica Universidad de Chile)Rodolfo Viera (Pontificia Universidad Católica de Chile)
Abstract : In this talk I will discuss the behaviour of the Fourier Transform of (quasi-)periodic sets under random perturbations. We will see that for i.i.d random perturbations of a quasi-periodic set X in the Euclidean space, the effect of the perturbations is almost surely that of multiplying the Fourier Transform of X by a weight which depends on the law of the perturbation. Also we will see quantitative versions of the previous discussion in finite groups which we will use to obtain, after passing to the limit, the almost sure recovery of the Fourier Transform of lattices in some non-abelian instances, such as the Heisenberg group.

[04956] An information-theoretic perspective on the turnpike and beltway problems

Format : Online Talk on Zoom
Author(s) : Shuai Huang (Emory University)
Abstract : Reconstructing a set of points on a line or a loop from their unlabelled pairwise distances is known as the turnpike or beltway problem. Some point configurations are easy to reconstruct, while others are more difficult. We show that the difficulty of problem can be characterized by the mutual information $I(X;Y)$ between the point variable X and distance variable Y. Experiments show that $I(X;Y)$ decreases when there are more repeated distances.

[04313] Curvature sets and curvature measures over persistence diagrams

Format : Talk at Waseda University
Author(s) : Facundo Memoli (Ohio State University)
Abstract : We study an invariant (i.e. a feature) of compact metric spaces which combines the notion of curvature sets introduced by Gromov in the 1980s together with the notion of Vietoris-Rips persistent homology. For given integers k≥0 and n≥1 these invariants arise by considering the degree k Vietoris-Rips (VR) persistence diagrams of all finite point clouds with cardinality at most n sampled from a given metric space. We call these invariants \emph{persistence sets}. This family of invariants contains the usual VR persistence diagram of the original space (when n is large enough). We argue that for a certain range of values of parameters n and k, (1) the family of these invariants 'sees' information not detected by the VR persistence diagrams of the whole space and (2) computing these invariants is significantly easier than computing the usual VR persistence diagrams.

We establish stability results for our persistence sets and also precisely characterize some of them in the case of spheres with geodesic and Euclidean distances. We identify a rich family of metric graphs for which the invariant determined by n=4 and k=1 fully recovers their homotopy type. Along the way we prove some novel properties of VR persistence diagrams.

[05121] Learning with persistence diagrams

Format : Talk at Waseda University
Author(s) : Jose Perea (Northeastern University)Iryna Hartsock (University of Florida)Alex Elchesen (Colorado State University)Tatum Rask (Colorado State University)
Abstract : Persistence diagrams are common descriptors of the topological structure of data appearing in various classification and regression tasks. They can be generalized to Radon measures supported on the birth-death plane and endowed with an optimal transport distance. Examples of such measures are expectations of probability distributions on the space of persistence diagrams. In this talk, I will present methods for approximating continuous functions on the space of Radon measures supported on the birth-death plane, as well as their utilization in supervised learning tasks.

00533 (2/3) : 1D @F412 [Chair: Petrache Mircea]

[04676] Persistent cycle registration and topological bootstrap

Format : Online Talk on Zoom
Author(s) : Yohai Reani (Viterbi Faculty of Electrical Engineering, Technion - Israel Institute of Technology)Omer Bobrowski (Viterbi Faculty of Electrical Engineering, Technion - Israel Institute of Technology)
Abstract : In this talk we present a novel approach for comparing the persistent homology representations of two spaces (filtrations) directly in the data space. We do so by defining a correspondence relation between such representations and devising a method, based on persistent homology variants, for its efficient computation. We demonstrate our new framework in the context of topological inference, where we use statistical bootstrap-like methods to differentiate between real phenomena and "noise" in point cloud data.

[05127] The Density Fingerprint of a Periodic Set and Persistent Homology

Format : Online Talk on Zoom
Author(s) : Herbert Edelsbrunner (Institute of Science and Technology Austria)Teresa Heiss (Institute of Science and Technology Austria)Vitaliy Kurlin (University of Liverpool)Philip Smith (University of Liverpool)Mathijs Wintraecken (Institute of Science and Technology Austria)
Abstract : Modeling a crystal as a periodic point set, we present a fingerprint consisting of density functions. The density fingerprint is invariant under isometries, continuous, and complete in the generic case, which are necessary features for reliable comparison of crystals. The fingerprint has a fast algorithm based on Brillouin zones and related inclusion-exclusion formulae, which we have implemented. I will discuss the connection with persistent homology, suggesting a possible extension of the fingerprint.

[04866] Reconstruction of manifolds from point clouds and inverse problems

Format : Talk at Waseda University
Author(s) : Matti Lassas (University of Helsinki)Charles Fefferman (Princeton University)Sergei Ivanov (Steklov Institute of Mathematics)Hariharan Narayanan (Tata Institute for Fundamental Research)Jinpeng Lu (University of Helsinki)
Abstract : We consider a geometric problem on how a Riemannian manifold can be constructed to approximate a given discrete metric space. This problem is closely related to invariant manifold learning, where a Riemannian manifold (M,g) needs to be approximately constructed from the noisy distances $d(X_j,X_k)+\eta_{jk}$ of points $X_1,X_2,\dots,X_N$, sampled from the manifold M. Here, $d(X_j,X_k)$ are the distance of the points $X_j,X_k\in M$ and η_{jk} are random measurement errors. The values $d(X_j,X_k)$ can be considered as distance fingerprints of the manifold M.
We also consider applications of the results in inverse problems encountered in medical and seismic imaging. In these problems, an unknown wave speed in a domain needs to be determined from indirect measurements. Moreover, we discuss a problem analogous to the above one, where distances are measured from points in a small subset $U\subset M$ to points in a discrete subset of M and the errors are deterministic.

00533 (3/3) : 1E @F412

[00534] Topological and geometric data analysis: theory and applications

Session Time & Room :

00534 (1/2) : 2C (Aug.22, 13:20-15:00) @F412

00534 (2/2) : 2D (Aug.22, 15:30-17:10) @F412

Type : Proposal of Minisymposium
Abstract : In recent decades, topological data analysis "TDA" and geometric data analysis "GDA" have provided great impacts on data science, characterizing valuable information on “shape of data”. In this series of mini-symposia, we present recent progresses of theory and applications of TDA and GDA, including persistent homology, optimal transportation, filling radius, Reeb graph, graph embeddings, flow data analysis, dimensionality reduction, geometric deep learning, Hodge Laplacian, discrete exterior calculus, and their various applications in materials, chemistry, biology, and data sciences.

00534 (1/2) : 2C @F412 [Chair: Yasuaki Hiraoka]

[01514] Vietoris-Rips persistent homology, injective metric spaces, and the filling radius

Format : Talk at Waseda University
Author(s) : Sunhyuk Lim (Max Planck Institute for Mathematics in the Sciences)Facundo Memoli (The Ohio State University)Osman Berat Okutan (Florida State University)
Abstract : In the applied algebraic topology community, the persistent homology induced by the Vietoris-Rips simplicial filtration is a standard method for capturing topological information from metric spaces. In this paper, we consider a different, more geometric way of generating persistent homology of metric spaces which arises by first embedding a given metric space into a larger space and then considering thickenings of the original space inside this ambient metric space. In the course of doing this, we construct an appropriate category for studying this notion of persistent homology and show that, in a category theoretic sense, the standard persistent homology of the Vietoris-Rips filtration is isomorphic to our geometric persistent homology provided that the ambient metric space satisfies a property called injectivity.
As an application of this isomorphism result we are able to precisely characterize the type of intervals that appear in the persistence barcodes of the Vietoris-Rips filtration of any compact metric space and also to give succinct proofs of the characterization of the persistent homology of products and metric gluings of metric spaces. Our results also permit proving several bounds on the length of intervals in the Vietoris-Rips barcode by other metric invariants, for example the notion of spread introduced by M. Katz.
As another application, we connect this geometric persistent homology to the notion of filling radius of manifolds introduced by Gromov and show some consequences related to (1) the homotopy type of the Vietoris-Rips complexes of spheres which follow from work of M. Katz and (2) characterization (rigidity) results for spheres in terms of their Vietoris-Rips persistence barcodes which follow from work of F. Wilhelm.
Finally, we establish a sharp version of Hausmann’s theorem for spheres which may be of independent interest.

[01746] Reeb Order Method and its Application to Topological Flow Data Analysis

Format : Talk at Waseda University
Author(s) : Tomoki UDA (Tohoku University)
Abstract : Sakajo and Yokoyama have classified the topology of streamlines and characterised them by unique tree representations, called Cyclically Ordered rooted Tree (COT) representations. The author realised the practical application of their theory to data science, called Topological Flow Data Analysis (TFDA), utilising Reeb graphs and their discretised version, Reeb order. In this talk, we briefly introduce TFDA theory and its application to meteorology and oceanography.

[04575] Topological Node2vec: Graph Embeddings via Persistent Homology

Format : Talk at Waseda University

Author(s) : Killian Meehan (Kyoto University)

Abstract : Node2vec is a machine learning framework which specializes in transforming graph into euclidean data. However, we demonstrate that with very simple examples we see a high destruction of topological information during the embedding process. Our project builds on top of the original Node2vec framework and introduces a topological loss function derived from optimal transport which forces this new machine learning network to maximally preserve graph information while checking topological loss at every step.

[04694] Data, Geometry, and homology

Format : Talk at Waseda University

Author(s) : Wojciech Chacholski (KTH, Royal Institute of Technology)Jens Agerberg (KTH, Royal Institute of Technology and Ericsson)Ryan Ramanujam (Karolinska Institutet (Dept. of Clinical Neuroscience) and Datanon Corporation)Francesca Tombari (KTH, Royal Institute of Technology)

Abstract : For a successful analysis a suitable representation of data by objects amenable for statistical methods is fundamental.

There has been an explosion of applications in which homological representations of data played a significant role. I will present one such representation called stable rank and introduce various novel ways of using it to encode geometry, and then analyse, data. I will provide several illustrative examples of how to use stable ranks to find meaningful results.

00534 (2/2) : 2D @F412 [Chair: Kelin Xia]

[04865] Topological Representation Learning for Biomedical Image Analysis

Format : Talk at Waseda University

Author(s) : Chao Chen (Stony Brook University)

Abstract : Modern analytics is facing highly complex and heterogeneous data. While deep learning models have pushed our prediction power to a new level, they are not satisfactory in some crucial merits such as transparency, robustness, data-efficiency, etc. In this talk, I will focus on our recent work on combining topological reasoning with learning to solve problems in biomedical image analysis. In biomedicine, we encounter various complex structures such as neurons, vessels, tissues and cells. These structures encode important information about underlying biological mechanisms. To fully exploit these structures, we propose to enhance learning pipelines through the application of persistent homology theory. This inspires a series of novel methods for segmentation, generation, and analysis of these topology-rich biomedical structures. Complex structures also arise in many other contexts beyond biomedicine. We will also briefly introduce how topological reasoning can be used to strengthen graph neural networks and to improve the robustness of deep neural networks against noise and against backdoor attacks.

[05110] New Algorithms for Random Graph Embeddings

Format : Talk at Waseda University

Author(s) : Jason H Cantarella (University of Georgia)Clayton Shonkwiler (Colorado State University)Henrik Schumacher (Technische Universitat Chemnitz)Tetsuo Deguchi (Ochanomizu University)Erica Uehara (Kyoto University)

Abstract : We discuss the problem of randomly embedding graphs in R^d, which often arises in machine learning. Given an arbitrary probability distribution on each edge, we condition the joint distribution on the graph type (loops of edges must close). The key idea is to use an unusual version of cohomology to encode embedding data. Our method is particularly well suited to embeddings with fixed edge lengths, which arise in polymer science and robotics.

[05318] Topological Deep Learning: Going Beyond Graph Data

Format : Talk at Waseda University

Author(s) : Mustafa Hajij (university of San Francisco)Ghada Zamzmi (University of South Florida)Theodore Papamarkou (University of Manchester)Nina Miolane (University of Californian Santa Barbara)Aldo Saenz (IBM)Karthikeyan Natesan Ramamurthy (IBM)Tolga Birdal (Imperial College London)Tamal Krishna Dey (Purdue University)Soham Mukherjee (Purdue University)Shreyas Samaga (Purdue University)Neal Livesay (Northeastern University)Robin Walters (Northeastern University)Paul Rosen (University of Utah)Michael Schaub (RWTH Aachen University)

Abstract : Topological deep learning is a rapidly growing field that pertains to the development of deep learning models for data supported on topological domains such as simplicial complexes, cell complexes, and hypergraphs, which generalize many domains encountered in scientific computations. In this paper, we present a unifying deep learning framework built upon a richer data structure that includes widely adopted topological domains.

Specifically, we first introduce combinatorial complexes, a novel type of topological domain. Combinatorial complexes

can be seen as generalizations of graphs that maintain certain desirable properties. Similar to hypergraphs, combinatorial complexes impose no constraints on the set of relations. In addition, combinatorial complexes permit the construction of hierarchical higher-order relations, analogous to those found in simplicial and cell complexes. Thus, combinatorial complexes generalize and combine useful traits of both hypergraphs and cell complexes, which have emerged as two promising abstractions that facilitate the generalization of graph neural networks to topological spaces.
Second, building upon combinatorial complexes and their rich combinatorial and algebraic structure, we develop a general class of message-passing combinatorial complex neural networks (CCNNs), focusing primarily on attention-based CCNNs. We characterize permutation and orientation equivariances of CCNNs, and discuss pooling and unpooling operations within CCNNs in detail.
Third, we evaluate the performance of CCNNs on tasks related to mesh shape analysis and graph learning. Our experiments demonstrate that CCNNs have competitive performance as compared to state-of-the-art deep learning models specifically tailored to the same tasks. Our findings demonstrate the advantages of incorporating higher-order relations into deep learning models in different applications.

[01521] Topological approaches to higher-order interaction networks

Format : Online Talk on Zoom
Author(s) : Jie Wu Wu (Yanqi Lake Beijing Institute of Mathematical Sciences and Applications (BIMSA))
Abstract : In this talk, guided by the applications to higher-order interaction network, we will discuss some topological approaches to graphs and hypergraphs beyond TDA, including GLMY homology of digraphs introduced by S. T. Yau et al, and their generalizations such as embbed homology of hypergraphs, which is an extension of simplicial homology. We will also report some of our recent works on the topic, including a frame work for introducing a new theory which unifies various aspects of topological approaches for data science, by being applicable both to point cloud data and to graph datas.

[00538] Mathematical modeling, analysis, and simulation for complex neural systems

Session Time & Room :

00538 (1/2) : 5C (Aug.25, 13:20-15:00) @A511

00538 (2/2) : 5D (Aug.25, 15:30-17:10) @A511

Type : Proposal of Minisymposium
Abstract : Mathematical neuroscience exploits applied mathematics tools, e.g., modeling, analysis and scientific computing, to understand the structure, dynamics, and function of the brain. Many neuroscience phenomena are intriguing but extremely complicated, with features of high dimensionality, nonlinearity, multi-scale, and complex dynamics. Therefore, developing effective theoretical and computational methods becomes increasingly significant to understand the mechanism underlying neuroscience phenomena, as well as to advance experimental neuroscience. This mini-symposium focuses on novel ideas and advanced approaches in mathematical neuroscience, with an emphasis on prominent neuroscience phenomena including hierarchical structure, oscillatory and attractor dynamics, and functions of learning and memory.
Organizer(s) : Songting Li, Douglas Zhou
Classification : 92-10, 37Nxx, 62Pxx
Minisymposium Program :

00538 (1/2) : 5C @A511 [Chair: Songting Li]

[04042] Learning optimal models of statistical events in spontaneous neural activity

Format : Talk at Waseda University
Author(s) : Toshitake Asabuki (Imperial College London)Tomoki Fukai (Okinawa Institute of Science and Technology)
Abstract : The brain is thought to learn an internal model of the statistical environment for improved cognitive performance. Evidence suggests that spontaneous cortical activity represents such a model, or prior distribution, by replaying stimulus-evoked activity patterns with the probabilities that these stimuli were experienced. Here, we present a principle to robustly learn replay activity patterns in spiking recurrent neural networks and demonstrate how such spontaneous replay biases animals' perceptual decision making.

[03841] The hierarchical organization of the Drosophila connectome

Format : Talk at Waseda University

Author(s) : Kresimir Josic (University of Houston)Alexander B. Kunin (Creighton University)Jiahao Guo (University of Houston)Kevin E. Bassler (University of Houston)Xaq Pitkow (Rice University)

Abstract : The Hemibrain is the largest published connectome to date. It is the result of a dense reconstruction of over twenty thousand neurons and ten million synapses spanning the fruit fly Drosophila central brain. I will describe a novel approach to uncovering the hierarchical community structure of this connectome. This approach allows us to recover previously known and reveal novel features of the organization within the fly brain. Methods such as these will be essential to interpret the forthcoming connectomics data due to its size and complexity.

[01437] The mechanism of abnormal beta-oscillation generated in striatum

Format : Talk at Waseda University

Author(s) : Douglas Zhou (Shanghai Jiao Tong University)

Abstract : combining simulations of a neural network model and the analysis of the corresponding reduced neural mass model, we demonstrate how the cellular architecture and network dynamics of the ChAT - iMSN close loop in the striatum efficiently yield exaggerated beta oscillations. We find that beta oscillations can emerge from inhibitory interactions among iMSNs. And a slow inhibitory dynamic in iMSNs could be the underpinning of beta oscillations.

[03947] Maturation of neurons reconciles flexibility and stability of memory: dual structural plasticity in the olfactory system

Format : Talk at Waseda University

Author(s) : Bennet Sakelaris (Northwestern University)Hermann Riecke (Northwestern University)

Abstract : It is essential for the brain to flexibly form new memories without overwriting and jeopardizing the stability of existing ones. Using a computational model of the olfactory bulb (OB) that captures several experimental observations, we investigate how the characteristic structural plasticity of the OB addresses this flexibility-stability tradeoff. We demonstrate that the evolution of the timescales of synaptic plasticity associated with the aging of adult-born cells allows the OB to strike a harmonious balance between the competing demands of flexibility and stability.

00538 (2/2) : 5D @A511 [Chair: Douglas Zhou]

[01409] Mathematical mechanism underlying hierarchical timescales in the primate neocortex

Format : Talk at Waseda University

Author(s) : Songting Li (Shanghai Jiao Tong University)

Abstract : In the neocortex, while early sensory areas encode and process external inputs rapidly, higher-association areas are endowed with slow dynamics to benefit information accumulation over time. Such a hierarchy of temporal response windows along the cortical hierarchy naturally emerges in an anatomically based model of primate cortex. The emergent property raises the question of why diverse temporal modes are well segregated rather than being mixed up across the cortex, despite high connection density and an abundance of feedback loops. In this talk, we will address this question by mathematically analyzing the primate cortical model and identifying crucial conditions of synaptic excitation and inhibition that give rise to timescale segregation in a hierarchy. In addition, we will discuss the mathematical relation between timescales segregation and signal propagation in the cortex.

[04184] Computation with Adaptive Continuous Attractor Neural Networks

Format : Online Talk on Zoom

Author(s) : SI WU (Peking University)

Abstract : Continuous attractor neural networks (CANNs) are a canonical model for neural information representation, storing, retrieving and manipulation. Adaptation is a general feature of neural systems referring to a negative feedback process when neuronal activity is high. When two of them are combined together, the neural network exhibits rich dynamical behaviors. In this talk, I will introduce the rich dynamical properties of adaptive CANNs and their potential roles in brain functions.

[03884] Learning biological neuronal networks with artificial neural networks: Neural oscillations

Format : Online Talk on Zoom
Author(s) : Louis Tao (Peking University)Ruilin Zhang (Peking University)Zhongyi Wang (Peking University)Tianyi Wu (New York University)Yuhang Cai (University of California at Berkeley)Zhuo-cheng Xiao (New York University)Yao Li (University of Massachusetts)
Abstract : First-principles-based models have been extremely successful in providing crucial insights and predictions for complex biological functions and phenomena. However, they can be hard to build and expensive to simulate for complex living systems. On the other hand, modern data-driven methods thrive at modeling many types of high-dimensional and noisy data. Still, the training and interpretation of these data-driven models remain challenging. Here, we combine the two types of methods to model stochastic neuronal network oscillations. Specifically, we develop a class of first-principles-based artificial neural networks to provide faithful surrogates to the high-dimensional, nonlinear oscillatory dynamics produced by neural circuits in the brain. Furthermore, when the training data set is enlarged within a range of parameter choices, the artificial neural networks become generalizable to these parameters, covering cases in distinctly different dynamical regimes. In all, our work opens a new avenue for modeling complex neuronal network dynamics with artificial neural networks.

[01458] Reconstruction of Evolving Percepts in Binocular Rivalry Using Novel Model Network Dynamics

Format : Online Talk on Zoom
Author(s) : Victor Barranca (Swarthmore College)
Abstract : When the two eyes are presented with distinct stimuli, our percept irregularly switches between the monocular images, giving rise to binocular rivalry. We investigate mechanisms for rivalry through stimulus reconstructions based on the activity of a two-layer neuronal network model with competing downstream pools driven by disparate monocular images. To estimate the dynamic percept, we derive an embedded input-output mapping and iteratively apply compressive sensing techniques, generating percept reconstructions that agree with key experimental observations.

[00539] Extreme value theory and statistical analysis

Session Time & Room : 4D (Aug.24, 15:30-17:10) @F412

Type : Proposal of Minisymposium
Abstract : Huge disasters, such as earthquake and flood occur rarely but their damage is extremely terrible and the countermeasures against them are urgent social task.
Extreme value theory (EVT) deals with rare events mathematically or statistically and is applied to risk management for not only disasters but also various fields, for example, finance, insurance and life span of industrial products.
We present 4 researches. Asymptotic theory for extreme value generalized additive model, statistical inference for sample maximum distribution, nonparametric statistical inference related to several economic topics and statistical management for multivariate risk for financial institutions.

Organizer(s) : Takaaki SHIMURA
Classification : 60G70, 62G32, 62E20, 62G08, 62H05

00539 (1/1) : 4D @F412 [Chair: Takuma Yoshida]

[03480] Asymptotic theory for extreme value generalized additive model

Format : Talk at Waseda University
Author(s) : Takuma Yoshida (Kagoshima University)
Abstract : The classical approach to analyzing extreme value data is the generalized Pareto distribution (GPD). When the GPD is used to explain a target variable with the large dimension of covariates, the shape and scale function of covariates included in GPD are sometimes modeled using the generalized additive models (GAM). In contrast to many results of application, there are no theoretical results on the hybrid technique of GAM and GPD, which motivates us to develop its asymptotic theory. We provide the rate of convergence of the estimator of shape and scale functions, as well as its local asymptotic normality.

[03597] Comparative study on accuracy of sample maximum distribution estimators in IID settings

Format : Online Talk on Zoom
Author(s) : Taku Moriyama (Yokohama City University)
Abstract : Comparative study on the accuracy of sample maximum distribution estimators in IID settings will be reported. The distribution of sample maximum is approximated by the generalized extreme value distribution. However, the approximation accuracy heavily depends on the tail index. This study investigates a nonparametric estimator as the alternative approach and compares the accuracies both theoretically and numerically. Future prospects of the study will also be discussed.

[02777] Subsampling inference for nonparametric extremal conditional quantiles

Format : Talk at Waseda University
Author(s) : Daisuke Kurisu (The University of Tokyo)Taisuke Otsu (London School of Economics)
Abstract : In this talk, we study asymptotic properties of the local linear (LL) quantile estimator under the extremal-order quantile asymptotics and develop a practical inference method for conditional quantiles in extreme tail areas. The asymptotic distribution of the LL quantile estimator is derived as a minimizer of certain functional of a Poisson point process. We also propose a subsampling inference method for conditional extreme quantiles based on a self-normalized version of the LL estimator.

[03093] Measuring non-exchangeable tail dependence using tail copulas

Format : Talk at Waseda University
Author(s) : Takaaki Koike (Hitotsubashi University)Shogo Kato (Institute of Statistical Mathematics)Marius Hofert (The University of Hong Kong)
Abstract : We propose a novel framework of quantifying and comparing the degree of tail dependence using tail copula. Our proposed measures have clear probabilistic interpretations, and capture various features of non-exchangeable tail dependence depending on the purpose of the analysis. Analytical forms of the proposed measures are derived for various parametric copulas. A real data analysis reveals striking tail dependence and tail non-exchangeability of the return series of stock indices, particularly in periods of financial distress.

[00545] Waves in complex and multiscale media

Session Time & Room :

00545 (1/3) : 5B (Aug.25, 10:40-12:20) @G406

00545 (2/3) : 5C (Aug.25, 13:20-15:00) @G406

00545 (3/3) : 5D (Aug.25, 15:30-17:10) @G406

Type : Proposal of Minisymposium
Abstract : Characterizing wave propagation in complex and multiple-scale media is important for modelling and simulating the propagation of acoustic, electromagnetic, elastic and water waves in heterogeneous media. This minisymposium demonstrates the ubiquity of mathematical techniques by bringing together researchers from all of these application areas. The talks will illustrate a variety of the current methods and the challenges that remain. The session will represent a cross section of applied mathematics, ranging from applied analysis to large-scale numerical simulation schemes. A central aim of the minisymposium is to promote the exchange of ideas and knowledge between the different application areas.
Organizer(s) : Bryn Davies, Luke Bennetts

[03757] Effective waves in random particulate media: introduction and numerical validation

Format : Talk at Waseda University
Author(s) : ARTUR LEWIS GOWER (University of Sheffield)Stuart Hawkins (Macquarie University)Gerhard Kristensson (Lund University)
Abstract : Describing how waves scattering between a large set of particles is challenging. There are accurate numerical methods, but they lack intuition and can be slow. Effective theory is a method to replace the particles with a homogeneous media which leads to greater intuition and is quick to calculate. One drawback is often that effective theory is only accurate for long wavelengths. In this talk, I will show how we overcame the challenges to extend effective theory for a large range of wavelengths ($0 < k a < 2$) and material properties (particle type and volume fractions) for waves in a random particulate material.

[04234] Scattered wavefield in the stochastic homogenization regime

Format : Talk at Waseda University
Author(s) : Laure Giovangigli (ENSTA Paris)Quentin Goepfert (ENSTA Paris)Pierre Millien (Institut Langevin, ESPCI)Josselin Garnier (Ecole Polytechnique)
Abstract : This work aims at modelling and studying the propagation and diffusion of ultrasounds in complex multi-scale media such as biological tissues or composite materials. We consider in the free space a homogeneous bounded medium in which lie randomly distributed inhomogeneities that are small compared to the wavelength. In order to characterize the response of this medium to an incident plane wave, we perform an asymptotic expansion of the scattered wave with respect to the size of the inhomogeneities using stochastic homogenisation techniques. The difficulties lie in the transmission conditions at the boundary of the medium. We derive quantitative error estimates given that the random distribution of inhomogeneities verifies mixing properties. Finally we present numerical simulations to illustrate and validate our results.

[04262] Waves on Graphs

Format : Talk at Waseda University
Author(s) : Gregor Tanner (University of Nottingham)Stephen C Creagh (University of Nottingham)Cerian Brewer (University of Nottingham)
Abstract : We consider the wave dynamics on networks or graphs carrying both propagating and evanescent modes on each edge. This is an extension of quantum graph theory and occurs naturally when considering networks of plates or beams with different mode types (flexural, longitudinal and shear waves) propagating on each connecting structure. The local vertex scattering matrices and the global transfer operator are no longer unitary with interesting consequences for secular equations and the Weyl law.

[04615] Designing large-scale acoustic scattering systems using structural optimization and multiple scattering theory

Format : Talk at Waseda University
Author(s) : Kei Matsushima (The University of Tokyo)Takayuki Yamada (The University of Tokyo)
Abstract : In this talk, we present a numerical scheme for designing large-scale acoustic scattering systems based on a multiple scattering theory and shape/topology optimization. We first solve exterior Helmholtz problems using the T-matrix method. This formulation allows us to evaluate a design sensitivity of multiple scattering systems using the adjoint variable method. We will demonstrate that the proposed scheme can design an omnidirectional acoustic cloak.

00545 (2/3) : 5C @G406 [Chair: Luke Bennetts]

[04940] Bounds on the Quality-factor of Two-phase Quasi-static Metamaterial Resonators and Optimal Microstructure Designs

Format : Talk at Waseda University
Author(s) : Kshiteej Deshmukh (University of Utah)Graeme Milton (University of Utah)
Abstract : Material resonances are fundamentally important in the field of nano-photonics and optics. So it is of great interest to
know what are the limits to which they can be tuned. The bandwidth of the resonances in materials is an important
feature which is commonly characterized by using the quality (Q) factor. We present bounds on the quality factor of
two-phase quasi-static metamaterial resonators evaluated at a given resonant frequency by introducing an alternative definition for the Q-factor in terms of the complex effective permittivity of the composite material. Optimal metamaterial microstructure designs achieving points on these bounds are presented. The most interesting optimal microstructure,
is a limiting case of doubly coated ellipsoids, consisting of a dilute suspension of ellipsoids near resonance

sandwiched between layers. It attains points on the lower bound for the Q-factor. We also obtain bounds on Q for three dimensional, isotropic, and fixed volume fraction two-phase quasi-static metamaterials. Some almost optimal isotropic microstructure geometries are identified.

[04245] Band structure and Dirac points of real-space quantum optics in periodic media

Format : Talk at Waseda University
Author(s) : Erik Orvehed Hiltunen (Yale University)John Schotland (Yale University)Michael Weinstein (Columbia University)Joseph Kraisler (Columbia University)
Abstract : The field of photonic crystals is almost exclusively based on a Maxwell model of light. While often an effective model, it is natural to study such systems under a quantum-mechanical photon model instead. In the real-space parametrization, interacting photon-atom systems are governed by a system of \emph{nonlocal} partial differential equations. In this talk, we study resonant phenomena of such systems. Using integral equations, we phrase the resonant problem as a nonlinear eigenvalue problem. In a setting of high-contrast atom inclusions, we obtain fully explicit characterizations of resonances, band structure, and Dirac cones. Additionally, we present a strikingly simple relation between the Green's function of the nonlocal equation and that of the local (Helmholtz) equation. Based on this, we are able to achieve highly efficient numerical calculations of band structures of interacting photon-atom systems.

[03889] Mathematics of in-gap interface modes in photonic/phononic structures in one dimension

Format : Talk at Waseda University
Author(s) : Hai Zhang (HKUST)Junshan Lin (Auburn University)
Abstract : The developments of topological insulators have provided a new avenue for creating interface modes (or edge modes) in photonic/phononic structures. Such created modes have the distinct property of being topologically protected and are stable with respect to perturbations in certain classes. In this talk, we will report recent results on the existence of an in-gap interface mode that is bifurcated from a Dirac point in a photonic/phononic structure in one dimension.

[04807] Recent advances in the theory of field patterns

Format : Talk at Waseda University
Author(s) : Ornella Mattei (San Francisco State University)Vincenzo Gulizzi (University of Palermo)
Abstract : Field pattern materials are spatial composites whose properties are modulated in time in such a way that disturbances propagate along locally periodic networks of characteristic lines, called field patterns. Depending on the material properties, modes can be propagating or can blow up (decay) in time. Here we show how to design the spatial geometry of one- and two-dimensional field pattern materials, so that modes are always stable.

00545 (3/3) : 5D @G406 [Chair: Bryn Davies]

[05192] Water wave resonances between floating vessels: fundamentals to applications

Format : Talk at Waseda University
Author(s) : Hugh Wolgamot (University of Western Australia)Wenhua Zhao (University of Western Australia)
Abstract : The narrow gap formed between floating vessels in close proximity supports resonances. This leads to a variety of problems of both theoretical and practical interest. In this talk the resonant structure of the coupled motion of the vessels and fluid is first investigated using linear potential flow theory for simple geometries. The interaction of prismatic vessels spanning a channel (a common experimental set-up) is then considered. Interaction with practical mechanical constraints (mooring) is discussed.

[03152] Broadband energy capture by an array of heaving buoys

Format : Talk at Waseda University
Author(s) : Amy-Rose Westcott (The University of Adelaide)Luke Bennetts (The University of Adelaide)Benjamin Cazzolato (The University of Adelaide)Nataliia Sergiienko (The University of Adelaide)
Abstract : Broadband energy capture is sought by grading the resonant properties of an array of heaving buoy-type wave energy converters (WECs) in 2D. Linear potential-flow theory is applied and WEC interactions are modelled using multiple-wave scattering theory. The resonant properties of WECs are tuned via a linear spring-damper power take-off mechanism to manipulate the complex-frequency zeros. The resulting graded array captures near-perfect absorption (>97% of incident energy) from a targeted band of wavelengths spanning 1.5 times the array's length.

[04111] Graded arrays for spatial frequency separation and amplification of water waves

Format : Talk at Waseda University
Author(s) : Malte A Peter (University of Augsburg)Luke G Bennetts (University of Adelaide)Richard V Craster (Imperial College London)
Abstract : Wave-energy converters extracting energy from ocean waves are known to suffer from poor efficiency. We propose structures substantially amplifying water waves over a broad range of frequencies at selected locations, with the idea of enhanced energy extraction. Using linear potential-flow theory, it is shown that the energy carried by a plane incident wave is amplified within specified locations. Transfer-matrix analysis is used for the analysis and results from wave-flume experiments confirm the amplification in practice.

[00550] Multi-scale analysis in random media and applications

Session Time & Room :

00550 (1/3) : 1E (Aug.21, 17:40-19:20) @G502

00550 (2/3) : 2C (Aug.22, 13:20-15:00) @G502

00550 (3/3) : 2D (Aug.22, 15:30-17:10) @G502

Type : Proposal of Minisymposium
Abstract : A rich variety of models in mechanics are heterogenous and multi-scale in nature, and the derivation of „averaged“ or „effective“ behaviours on large-scales are well-known to be challenging and of particular interest. The complexity of the micro-structure often requires stochastic modeling and advanced methods, combining tools from PDE and probability, to understand and compute such effective properties. The purpose of this mini-symposium is to offer an overview of recent developments on the theory of stochastic homogenization and its applications in several areas of applied mathematics, ranging from fluids mechanics, wave propagation, nonlinear elasticity and statistical mechanics.
Organizer(s) : Nicolas Clozeau, Laure Giovangigli, Lihan Wang

00550 (1/3) : 1E @G502 [Chair: Laure Giovangigli]

[04699] Recent advances in quantitative stochastic homogenisation of nonlinear models

Format : Talk at Waseda University
Author(s) : Nicolas Clozeau (Institute of science and technology Austria)Antoine Gloria (Sorbonne Université)Mathias Schäffner (Uni Halle)Julian Fischer (Institute of science and technology Austria)Antonio Agresti (Institute of science and technology Austria)
Abstract : I will present recent advances on the quantitative homogenisation of stochastic nonlinear models. First, I will discuss
the case of convex variational models described by its Euler-Lagrange equation, taking the form of a nonlinear elliptic equation in divergence form with monotone and random coefficients. I will present the quantitative homogenisation theory in current development with Antoine Gloria and Mathias Schäffner, aiming at describing the oscillations and fluctuations of solutions at the microscopic scale as well as the large-scale regularity theory of the random nonlinear operator. Second, I will discuss the case of non-convex variational models of Griffith type in fracture mechanics and a quantitative result concerning the convergence of the cell formula recently obtained in collaboration with Julian Fischer and Antonio Agresti.

[04559] Quantitative Homogenization for Nondivergence Form Equations

Format : Talk at Waseda University
Author(s) : Jessica Lin (McGill University)
Abstract : In this talk, I will first give an overview of stochastic homogenization for nondivergence form equations (from the PDE perspective) and quenched invariance principles for nonreversible diffusion processes (from the probability perspective). I will then present various quantitative stochastic homogenization results and discuss challenges specific to the homogenization of nondivergence form equations. This talk is based on joint work with Scott Armstrong (NYU) and Benjamin Fehrman (Oxford).

[04584] Quantitative homogenization of elliptic system with periodic and high contrast coefficients

Format : Talk at Waseda University

Author(s) : Wenjia Jing (Tsinghua University)Xin Fu (Tsinghua University)

Abstract : We present several results about the quantitative estimates of the homogenization of elliptic systems in high contrast periodic media. The periodically distributed high contrast parts have physical parameters that are either extremely large or extremely small compared to those in the background. We develop a method that is somewhat unified and can treat both types of high contrast limits. We obtain quantitative convergence rates with proper correctors, uniform Lipschitz regularity for the solutions of the heterogeneous equations and, as an application, a quantitative description of the spectral convergence for the double-porosity problem. We also discuss possible extensions of the method to some other systems, e.g., linear elasticity, with richer high contrast structures.

00550 (2/3) : 2C @G502 [Chair: Nicolas Clozeau]

[05476] On the lower spectrum of heterogeneous acoustic operators

Format : Online Talk on Zoom

Author(s) : Mitia Duerinckx (Université Libre de Bruxelles)

Abstract : In this talk, we describe a quantitative link between homogenization and Anderson localization for heterogeneous acoustic operators: we draw consequences on the spatial spreading of eigenstates in the lower spectrum (if any) from the long-time homogenization of the wave equation, through dispersive estimates. This yields an alternative proof (avoiding Floquet theory) that the lower spectrum of the acoustic operator is purely absolutely continuous in case of periodic coefficients, and it further provides nontrivial quantitative lower bounds on the spatial spreading of potential eigenstates in case of quasiperiodic and random coefficients. This is based on joint work with Antoine Gloria.

[03179] Boundary effects in radiative transfer of acoustic waves in a randomly-fluctuating medium delimited by boundaries

Format : Talk at Waseda University

Author(s) : Adel Messaoudi (Aix-Marseille université)Régis Cottereau (CNRS)Christophe Gomez (Aix-Marseille université)

Abstract : This presentation discusses the derivation of radiative transfer equations for acoustic waves propagating in a randomly-fluctuating half-space and slab in the weak-scattering regime, and the study of boundary effects. These radiative transfer equations allow to model the transport of wave energy density, taking into account the scattering by random heterogeneities. The approach builds on an asymptotic analysis of the Wigner transform of the wave solution and the method of images.

[05197] Bloch analysis extended to weakly disordered periodic media

Format : Online Talk on Zoom

Author(s) : Régis Cottereau (CNRS)Yilun Li (CentraleSupélec)Bing Tie (CNRS)

Abstract : The dispersion properties of periodic metamaterials can be tailored in order to obtain desirable effects, for instance band gaps over chosen frequency ranges. However, these patterns are sometimes completely destroyed by the small (random) defects introduced by the manufacturing processes, and the induced loss of periodicity of the metamaterials. This contribution explores the extension of the classical Bloch-Floquet theory to problems that are weakly non-periodic, using asymptotic analysis and a random mapping of the properties to a periodic reference.

00550 (3/3) : 2D @G502 [Chair: Nicolas Clozeau]

[04385] Gamma-convergence and stochastic homogenisation for phase-transition models

Format : Talk at Waseda University

Author(s) : Roberta Marziani (TU Dortmund)

Abstract : In this talk we discuss the gamma-convergence of general phase-transition functionals of Modica-Mortola type whose integrands depend both on the space variable and on the regularization parameter (which represents the characteristic length scale of phase transition). In particular we show that the limit is a surface functional whose integrand is characterized by the limit of a suitable cell formula. We then extend our analysis to the case of stochastic homogenization and prove a gamma-convergence result for stationary random integrands.

[05141] Anomalous diffusion of a passive tracer advected by the curl of the GFF in 2D

Format : Talk at Waseda University
Author(s) : Peter Morfe (Max Planck Institute, Leipzig)Georgiana Chatzigeorgiou (Max Planck Institute, Leipzig)Lihan Wang (Max Planck Institute, Leipzig)Felix Otto (Max Planck Institute, Leipzig)
Abstract : I will discuss the long-time asymptotics of the displacement of a passive tracer in a (time-independent) turbulent flow, where the velocity field equals the curl of the GFF, in two dimensions. Physicists long ago predicted that the mean-squared displacement scales like time with a logarithmic correction. In our contribution, we prove that this is indeed the case via a novel iterative argument that exploits fundamental ideas from the theory of stochastic homogenization.

[04734] Variance reduction methods in random homogenization by using surrogate models

Format : Online Talk on Zoom
Author(s) : Frederic Legoll (Ecole des Ponts ParisTech and Inria)Sebastien Brisard (Ecole des Ponts ParisTech)Michael Bertin (Ecole des Ponts ParisTech and Inria)
Abstract : We consider the homogenization of elliptic PDEs with random coefficients. The associated corrector problem is set on the entire space, and is thus practically intractable. A standard approximation consists in restricting this problem to a large but bounded domain. The obtained effective coefficients are random. It is thus natural to consider several realizations.

To improve the accuracy on the expectation of the effective coefficients, we introduce a variance reduction approach based on a surrogate model.

[00552] Homogenization theory and applications

Session Time & Room : 5D (Aug.25, 15:30-17:10) @G501

Type : Proposal of Minisymposium
Abstract : The aim of this mini-symposium is to overview contemporary theory and applications on homogenization by specialists from various areas.
Short time behavior of particles in inhomogeneous media may depend on the location of particles, whereas their long time behavior often tends to be homogeneous due to the averaging effects. Such an averaging process is called homogenization.
Homogenization has been a very active research area in mathematics and applied mathematics for a long time. We invite specialists from several fields, including PDE, probability, analysis and applied mathematics. We exchange ideas and discuss various aspects on homogenization.

[01750] On the rate of convergence in homogenization of time fractional Hamilton-Jacobi equations

Format : Talk at Waseda University
Author(s) : Hiroyoshi Mitake (University of Tokyo)
Abstract : In this talk, we consider periodic homogenization for time fractional Hamilton-Jacobi equations. By using the perturbed test function method, we establish the convergence, and give estimates on the rate of convergence. A main difficulty is the incompatibility between the function used in the doubling variable method, and the non-locality of the Caputo derivative. Our approach is to provide a lemma to prove the rate of convergence without the doubling variable method with respect to the time variable, which is a key ingredient. This is a joint work with Shoichi Sato (U. Tokyo).

[01811] Discrete approximation of higher degree Laplacians

Format : Talk at Waseda University
Author(s) : Jun Masamune (Tohoku University)Hiroki Fukagawa (DeepFlow Inc)
Abstract : In this talk, we review some basic ideas in the theory of homogenization and discuss recent progress in the theory and applications of discrete approximation of equations involving, possibly higher degree, Laplacian. The talk is based on a collaborative effort with Hiroki Fukagawa from DeepFlow Inc.

[03559] Homogenization of the rate-independent evolution of a random heterogeneous, elasto-plastic spring network

Format : Talk at Waseda University
Author(s) : Stefan Neukamm (TU Dresden)
Abstract : We consider a periodic network composed of elasto-plastic spring with stationary and ergodic coefficients, described as a evolutionary rate independent system (ERIS) and derive a homogenized, continuum model as evolutionary Gamma-limit. The limit can be described as a generalized Prandtl-Ishlinskii hysteresis model and we analyse a corresponding RVE approximation.

[00554] Pattern dynamics appearing in mathematical biology

Session Time & Room : 4E (Aug.24, 17:40-19:20) @G406

Type : Proposal of Minisymposium
Abstract : Biological phenomenon have promoted the mathematical studies of pattern dynamics, such as Turing's pattern formation and traveling wave. We will introduce some of the recent progress around this topic which offer new viewpoints. We hope this is going to be the starting point to discuss the future perspective.
Organizer(s) : Chiun-Chuan Chen, Yoichiro Mori, Hirokazu Ninomiya, Toshiyuki Ogawa
Classification : 35B32, 35B36, 35K55, 35K57
Minisymposium Program :

00554 (1/1) : 4E @G406 [Chair: Toshiyuki Ogawa, Hirokazu Ninomiya]

[01234] Turing's instability by equal diffusion

Format : Talk at Waseda University
Author(s) : Hirokazu Ninomiya (Meiji University)
Abstract : In 1952, Turing proposed the mechanism of pattern formation in which a stable equilibrium of some kinetic system is destabilized by diffusion. In the case of two-component reaction-diffusion systems, however, the diffusion coefficients should be different. This talk presents an example of a two-component kinetic system with a asymptotically stable equilibrium, while the corresponding reaction-diffusion system has a family of unstable stationary solutions that is arbitrarily close to the homogeneous stationary solution.

[01275] Reaction-diffusion fronts in funnel-shaped domains

Format : Talk at Waseda University
Author(s) : Mingmin Zhang (Universite Toulouse III - Paul Sabatier)
Abstract : We study large-time dynamics of entire solutions to bistable equations in funnel-shaped domains emanating from a planar front in the straight part and moving into the conical part. We prove a dichotomy between blocking and spreading, and show that any spreading solution is a transition front whose level sets have roughly expanding spherical shapes at large times. We provide sufficient conditions on geometry of the domains, under which the solution is blocked or spreads completely.

[01442] Traveling wave solution in a macroscopic traffic model

Format : Talk at Waseda University
Author(s) : Kota Ikeda (Meiji UniversityMeiji University)
Abstract : Various subjects in traffic dynamics have long posed a challenge. Theoretical approaches have revealed the localized and extended forms of congestion with the propagation velocity of stop-and-go waves in models. In 2001, Lee et

al. derived a macroscopic traffic model from an OV model and numerically showed that a traveling pulse appears under a relatively high density of cars. We prove the existence of such a traveling pulse rigorously via a phase plane method.

[03160] Bistable pulsating fronts in showling oscillating environments

Format : Talk at Waseda University
Author(s) : Weiwei Ding (South China Normal University)
Abstract : In this talk, I will present some progress on reaction-diffusion fronts in spatially periodic bistable media. The results include: existence of pulsating fronts with large periods, existence of and an explicit formula for the limit of front speeds as the spatial period goes to infinity, convergence of pulsating front profiles to a family of front profiles associated with spatially homogeneous equations. This talk is based on joint work with Francois Hamel and Xing Liang.

[00555] Advanced Numerical Methods for PDEs with Applications

Session Time & Room :

00555 (1/2) : 4C (Aug.24, 13:20-15:00) @E705

00555 (2/2) : 4D (Aug.24, 15:30-17:10) @E705

Type : Proposal of Minisymposium
Abstract : Numerical modeling and algorithms are fundamental building blocks in computational science and engineering that provide accurate and efficient solution methods to the model equations. As applications become more complex, the model equations become more difficult and sophisticated. New and efficient numerical techniques are hence needed to solving the physical equations. The goal of this mini-symposium is to present the recent developments of computational methods for applications. The topics include numerical methods for PDEs, fast solvers, adaptive methods, and software developments. The mini-symposium will emphasize both the design and analysis of numerical algorithms as well as applications in science and engineering.

[02041] Numerical Methods for PDEs and Mesh Generation

Format : Talk at Waseda University
Author(s) : Justin Wan (University of Waterloo)Connor Tannahill (University of Waterloo)
Abstract : We will start with an overview of the mini-symposium. Then, in this talk, we will present a novel optimization-based approach for variational mesh adaptation based on MMPDE methods, combined with recent techniques for solving large-scale nonlinear constraint problems in parallel. The resulting method resembles meshing algorithms based on the spring analogy while producing high-quality adaptive meshes. We demonstrate the advantages of our method over standard MMPDE methods for generating two and three-dimensional meshes in parallel.

[01595] PDAEs redux

Format : Talk at Waseda University
Author(s) : Uri Michael Ascher (University of BC)
Abstract : We re-examine computational principles for solving constrained PDEs in large applications.
One involves simulation of friction and contact effects in deformable object motion arising in graphics and robotics.
The need to flexibly engage such constraints in differentiable models prompts introducing penalty methods,
despite some additional complexity and minor potential instability.
The other project investigates, in the context of neural ODEs,
different stabilization methods for differential equations with invariants arising from elimination of algebraic constraints.

[02132] Optimized Schwarz domain decomposition for surface intrinsic positive Helmholtz equations

Format : Talk at Waseda University

Author(s) : Alireza Yazdani (Simon Fraser University)Ronald Haynes (Memorial University of Newfoundland)Steven Ruuth (Simon Fraser University)

Abstract : We consider the convergence of optimized Schwarz iterations for the surface intrinsic positive Helmholtz equation $(c - \Delta_S)u = f, c > 0$, for smooth, simple closed 1-manifolds where periodicity is inherent in the geometry. We prove convergence results for the unequal-sized subdomain case with an arbitrary number of subdomains, and find an explicit formula for the optimal Robin parameter. Connections to a particular discretization, the closest point method, are provided as are numerical experiments verifying our results.

[02719] DD approaches for surface PDEs solved by the closest point method

Format : Online Talk on Zoom

Author(s) : Ronald Haynes (Memorial University of Newfoundland and Labrador)

Abstract : The solution of surface intrinsic PDEs using the closest point method will be proposed. For efficiency we have designed and analyzed domain decomposition solvers and preconditioners to solve the resulting discrete system of equations. Numerical results for model test examples will be presented.

00555 (2/2) : 4D @E705 [Chair: Justin Wan]

[02811] TVD property of second order method for two-dimensional scalar conservation laws

Format : Talk at Waseda University

Author(s) : Lilia Krivodonova (University of Waterloo)Alexey Smirnov (University of Waterloo)

Abstract : The total variation diminishing (TVD) property plays a crucial role in ensuring the stability and convergence of numerical solutions for one-dimensional scalar conservation laws. It was established in 1985 that in the two-dimensional space, a TVD method can be at most first order accurate. We consider a new definition of TV and propose a condition on scheme coefficients for a second-order method to be TVD for nonlinear scalar conservation laws.

[02206] Using Adaptive Time-Steppers to Explore Stability Domains

Format : Talk at Waseda University

Author(s) : Mary Pugh (University of Toronto)

Abstract : Stability domains for ODE time-steppers are well-understood when the linearized system is diagonalizable. I'll discuss an implicit-explicit time-stepper for which the linearized system isn't diagonalizable. An adaptive time-stepper can be used to explore the stability domain. I'll present a system whose stability domain has a discontinuous boundary; a small change in a parameter can cause a jump in the time-step-size stability threshold. This is joint work with my former PhD student, Dave Yan.

[02320] Extended Statistical Modelling and Advanced Computational Approaches for Disperse Multiphase Flows

Format : Talk at Waseda University

Author(s) : Lucian Ivan (Canadian Nuclear Laboratories)Benoit Allard (University of Ottawa)Francois Forgues (Canadian Nuclear Laboratories)James McDonald (University of Ottawa)

Abstract : This talk presents an Eulerian-based polydisperse Gaussian-moment model (PGM) family for the description of particle-laden multiphase flows. The modelling approach leads to a set of first-order, robustly-hyperbolic balance laws that provide a direct treatment for local higher-order statistics, such as covariances between particle distinguishable properties (e.g., diameter, temperature, etc.) and particle velocity. A massively parallel discontinuous-Galerkin-Hancock framework is employed to efficiently obtain computational PGM-solutions for a range of flows, including bio-aerosol dispersion and fuel sprays.

[02260] tost.II: A temporal operator splitting template library for deal.II

Format : Talk at Waseda University

Author(s) : Raymond Spiteri (University of Saskatchewan)Kevin Green (University of Saskatchewan)

Abstract : Operator splitting is a popular and often necessary means for solving
PDEs. Software that implements operator splitting, however, generally

only allows specific splitting methods, with only specific sub-integrators, and only for specific problems. In this talk, I describe the tost.II temporal operator splitting library built on the deal.II finite-element library. tost.II enables easy experimentation with splittings for an arbitrary number of operators and with arbitrary order of convergence, including methods with negative or complex coefficients.

[00558] Bifurcations, periodicity and stability in fluid-structure interactions

Session Time & Room :

00558 (1/3) : 1C (Aug.21, 13:20-15:00) @E820

00558 (2/3) : 1D (Aug.21, 15:30-17:10) @E820

00558 (3/3) : 1E (Aug.21, 17:40-19:20) @E820

Type : Proposal of Minisymposium

Abstract : This minisymposium connects rigorous mathematical theory with empirically observed time-periodic phenomena arising in fluid-structure interactions. Scenarios of interest include: aeroelastic resonances and flutter instabilities, e.g., bridge deck and flight-structure instabilities, and nonlinear phenomena such as von Karman vortex sheets, and the various approaches which have been developed such as spectral analyses and theories of weak solutions. Theoretical advances are complemented by progress in numerical simulation. We facilitate the connections between experts of various mathematical backgrounds for the development of new strategies exploiting the interplay between different approaches. Lastly, we wish to emphasize open problems in this challenging and exciting area.

[04678] Weak solutions in fluid-structure interactions: Cauchy and periodic problems

Format : Talk at Waseda University

Author(s) : Boris Muha (University of Zagreb)Sebastian Schwarzacher (Charles University and Uppsala University)Justin Thomas Webster (University of Maryland, Baltimore County)

Abstract : In this talk, we will provide an overview of the latest developments in the theory of weak solutions to fluid-structure interaction problems. We will specifically explore the difficulties and distinctions that arise when moving from the Cauchy problem to that of obtaining periodic solutions. We will examine a simple heat-wave system, which serves as a representative example for a fluid-structure interactions; for this system, we present some new existence results for periodic solutions.

[02192] Modelling and analysis of solids floating in a viscous fluid

Format : Talk at Waseda University

Author(s) : Marius Tucsnak (University of Bordeaux)

Abstract : We describe some recent advances on the mathematical modelling of the interaction of water waves with floating objects. The main applications we have in mind are point absorber type devices for producing marine energy and floating platforms used to support wind turbines. The mathematical challenge here is the existence of two free boundaries: the free surface of the fluid and the solid-fluid interface. The presentation is essentially devoted to wellposedness and large time behavior issues.

[02207] Time-periodic solutions to an interaction problem between a compressible fluid and a viscoelastic structure

Format : Talk at Waseda University
Author(s) : Srđan Trifunović (Faculty of Sciences, University of Novi Sad)Šárka Nečasová (Institute of Mathematics AS CR)Ondřej Kreml (Institute of Mathematics AS CR)Václav Mácha (Institute of Mathematics AS CR)
Abstract : In this lecture, I will talk about the problem of interaction between a compressible fluid and a viscoelastic beam under the influence of time-periodic external forces in 2D. For this problem, at least one weak solution is constructed which is periodic in time and perserves the mass which is a given constant. The approximate solution is obtained via a decoupling scheme in finite bases for time and space.

[02722] Artificial boundary conditions for time-periodic flow past a body

Format : Talk at Waseda University
Author(s) : Thomas Eiter (Weierstrass Institute for Applied Analysis and Stochastics)
Abstract : Consider the time-periodic viscous flow past an obstacle. Numerical implementations require to reduce the problem to a bounded domain by introducing an artificial boundary. In this talk, we study a choice of associated boundary conditions such that this perturbed problem suitably approximates the original one. These boundary conditions reflect the asymptotic behavior of the flow, which is studied in terms of new representation formulas relying on time-periodic fundamental solutions to the linearized Navier-Stokes equations.

00558 (2/3) : 1D @E820 [Chair: Justin Webster]

[04833] On the motion of several small rigid bodies in a viscous incompressible fluid

Format : Talk at Waseda University
Author(s) : Eduard Feireisl (Czech Academy of Sciences)
Abstract : We consider the motion of N rigid bodies immersed in
a viscous incompressible fluid contained in a domain in the Euclidean space Rd, d = 2; 3. We
show the fluid flow is not influenced by the presence of the bodies in the asymptotic limit as
when the radius of the bodies tends to zero sufficiently fast.
The result depends solely on the geometry of the bodies and is independent of their mass
densities. Collisions are allowed and the initial data are arbitrary with finite energy.

[05105] On the motion of a fluid-filled elastic solid

Format : Talk at Waseda University
Author(s) : Giusy Mazzone (Queen's University)
Abstract : Consider the physical system constituted by an elastic solid with an interior cavity entirely filled by a viscous incompressible fluid. The motion of the coupled system is governed by the Navier equations of linear elasticity for the solid, and the Navier-Stokes equations for the fluid. Continuity of stresses and velocities are imposed at the fluid-solid interface, while a zero-traction condition is imposed at the other free boundary of the solid. I will present some results on the existence of strong solutions to the governing equations and discuss their stability properties.

[05124] Gevrey regularity of a certain fluid-structure PDE interaction

Format : Talk at Waseda University
Author(s) : George Avalos (University of Nebraska-Lincoln)
Abstract : In this talk, we present recent results concerning the qualitative behavior of a coupled partial differential equation (PDE) system which describes a certain fluid-structure interaction (FSI), as it occurs in nature. With respect to the associated strongly continuous contraction semigroup for this model, we present our recent results of Gevrey regularity.

[05184] Numerical benchmarking of FSI - efficient discretization and numerical solution

Format : Online Talk on Zoom
Author(s) : Jaroslav Hron (Charles University, Prague)
Abstract : The lecture will give an overview of the problem of fluid-structure interaction motivated by blood flow in deformable vessels. Possible discretizations by the finite element method and different coupling strategies will be discussed with a focus on the efficient numerical solution of the monolithic problem. We will discuss some simple

benchmark type problems of fluid structure interaction based on finding a suitable simple arrangement with self-induced oscillations.

00558 (3/3) : 1E @E820

[00559] DNB Theory and its Applications

Session Time & Room :

00559 (1/3) : 1C (Aug.21, 13:20-15:00) @G302

00559 (2/3) : 1D (Aug.21, 15:30-17:10) @G302

00559 (3/3) : 1E (Aug.21, 17:40-19:20) @G302

Type : Proposal of Minisymposium
Abstract : The concept of dynamical network biomarker (DNB) was proposed to provide early-warning signals of diseases on the basis of co-dimension 1 local bifurcation in 2012, and then is widely used in various topics and fields of biology and medicine, e.g. dynamical analyses of biological processes in biology and disease prediction/early-diagnoses in medicine. The DNB is a novel type of biomarkers to identify the critical state during disease progression, which quantifies biological systems from a dynamical and network viewpoint, thus providing reliable information on early-warning signals before onset of complex diseases. Many DNB methods as well as applications have been developed. The DNB theory with big biological data is expected to lead to ultra-early precision and preventive medicine. This symposium addresses but not limited to the recent development of theory, methodology and application of DNB in a variety of scientific areas.

00559 (1/3) : 1C @G302

[05641] DNB-based intervention for ultra-early treatment

Format : Talk at Waseda University
Author(s) : Jun-ichi Imura (Tokyo Institute of Technology)
Abstract : The process leading to the onset of disease may be understood as a rapid transition in the complex interactions between genes. This talk proposes a DNB-based intervention approach for preventive treatment just before such transitions, i.e., in the pre-disease state, by combining DNB theory with control theory to build a theory that estimates which nodes of the relevant gene expression network should be intervened and how they should be intervened.

[05637] Alerting for the critical transition of complex systems

Format : Talk at Waseda University
Author(s) : Rui Liu (South China University of Technology)
Abstract : It is a challenging task to accurately predict the future critical state of a short-term time-series. The major difficulty to solve such a task is the lack of the information, which typically results in the failure of most existing approaches due to the overfitting problem of the small sample size. To address this issue, we proposed a computing framework: auto-reservoir neural network, to efficiently and accurately make the multi-step-ahead prediction based on a short-term high-dimensional time-series. Different from traditional reservoir computing whose reservoir is an external dynamical system irrelevant to the target system, ARNN directly transforms the observed high-dimensional dynamics as its reservoir, which maps the high-dimensional/spatial data to the future temporal values of a target variable based on a spatiotemporal information (STI) transformation. Combining with the dynamic network biomarker (DNB), it is possible to detect the early-warning signal of critical transitions of real-world complex systems.

[05638] The algorithm and application of landscape-DNB in complex disease of single sample

Format : Talk at Waseda University
Author(s) : Xiaoping Liu (Hangzhou Institute for Advanced Study)
Abstract : A new model-free method has been developed and termed the landscape dynamic network biomarker (l-DNB) methodology. The method is based on bifurcation theory, which can identify tipping points prior to serious disease deterioration using only single-sample omics data. Here, we show that l-DNB provides early-warning signals of disease deterioration on a single-sample basis and also detects critical genes or network biomarkers (i.e. DNB members) that

promote the transition from normal to disease states. As a case study, l-DNB was used to predict severe influenza symptoms prior to the actual symptomatic appearance in influenza virus infections. The l-DNB approach was then also applied to three tumor disease datasets from the TCGA and was used to detect critical stages prior to tumor deterioration using an individual DNB for each patient. The individual DNBs were further used as individual biomarkers in the analysis of physiological data, which led to the identification of two biomarker types that were surprisingly effective in predicting the prognosis of tumors. The biomarkers can be considered as common biomarkers for cancer, wherein one indicates a poor prognosis and the other indicates a good prognosis.

[05640] DNB based network fluctuation and application to biology and medicine

Format : Talk at Waseda University
Author(s) : Luonan Chen (Chinese Academy of Sciences)
Abstract : I will talk about the recent progress on the DNB methods as well as the applications to biology and medicine. By exploring the original DNB concept, i.e. critical collective fluctuation (CCF) of the observed variables, we developed a network flow entropy, which can quantify the CCF so as to detect the tipping point before the critical transition from one stable equilibrium to another. The applications include the tipping points of various diseases.

00559 (2/3) : 1D @G302

[05343] Change-point detection in temporal complex systems

Format : Talk at Waseda University
Author(s) : Huanfei Ma (Soochow University)
Abstract : We develop a model-free approach, named temporal change-point detection (TCD), and integrate both dynamical and statistical methods to achieve accurate detection of the time instant at which a system changes its internal structures. The proposed approach is able not only to detect the separate change points of the concerned systems without knowing, a priori, any information of the equations of the systems, but also to harvest all the change points emergent in a relatively high-frequency manner.

[05648] Early warning signals for multistage transitions in tipping dynamics on networks

Format : Talk at Waseda University
Author(s) : Neil G. MacLaren (State University of New York at Buffalo)Prosenjit Kundu (State University of New York at Buffalo)Naoki Masuda (State University of New York at Buffalo)
Abstract : Complex dynamical systems for which we want to anticipate sudden regime shifts often form a heterogeneous network. We propose methods to select sentinel nodes in a given network to construct informative early warning signals given that the network may be heterogeneous and show multistage transitions. We show that small subsets of nodes can anticipate transitions as well as or even better than using all the nodes under the proposed node selection method. Informative sentinel nodes depend on the direction of regime shifts, which we also highlight in the talk.

[03348] Modelling single cell multi-omics data

Format : Talk at Waseda University
Author(s) : Yong Wang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk I will introduce combinatorial regulon (cRegulon) to model the combinations among TFs, which can better characterize cell types and serves as the driving forces for cell state transitions. By leveraging rapidly accumulated single multi-omics data, we develop an optimization model to systematically infer cRegulons (i.e., the representative TF modules, their associated regulatory elements and target genes formed regulatory network).

00559 (3/3) : 1E @G302

[00563] PDE's on Mathematical Physics and Biology

Session Time & Room :

00563 (1/2) : 3D (Aug.23, 15:30-17:10) @G709

00563 (2/2) : 3E (Aug.23, 17:40-19:20) @G709

Type : Proposal of Minisymposium

Abstract : This minisymposium will be focused on different models concerning mathematical biology and mathematical physics, both from an analytical and applied point of view.
In the first part, we will give an overview on different problems in population dynamics, such as invasion, spreading of populations and living in regions or in graphs.
The second part will deal with problems involving the Schrödinger operator, coming from mathematical Physics. Precisely, it will be discussed results such as existence of ground state solutions and stability of solutions.

Organizer(s) : Pablo Álvarez-Caudevilla, Cristina Brändle, Eduardo Colorado, Tatsuya Watanabe
Classification : 35Q55, 35Q92, 35J60
Minisymposium Program :

00563 (1/2) : 3D @G709 [Chair: Tatsuya Watanabe]

[04143] The effect of diffusion on principal eigenvalues for Hamilton-Jacobi equations

Format : Talk at Waseda University
Author(s) : Cristina Brändle (U. Carlos III Madrid)
Abstract : We deal with the ergodic problem of viscous Hamilton–Jacobi equations with superlinear Hamiltonian, inward-pointing
drift and a positive potential function that vanishes at infinity. We characterize the generalized principal eigenvalue with respect to diffusion and also specify the necessary and sufficient condition so that the spectral
function contains a plateau.

[03901] Population models with an interface region inside the domain

Format : Talk at Waseda University
Author(s) : Pablo Alvarez-Caudevilla (Universidad Carlos III de Madrid)Pablo Alvarez Caudevilla (Universidad Carlos III de Madrid)
Abstract : We will discuss several models that might be regarded as migration models of populations moving from one part of a domain to the other and becoming part of the population living on the other side. Different situations assuming symmetry of movement between both sides of the domain, following a logistic model in their own environment and assuming spatial heterogeneities, are going to be discussed. Through such a common boundary both populations are coupled, acting as a permeable membrane on which their flow moves in and out.
We will describe the precise interplay between the stationary solutions with respect to the parameters involved in the problem, in particular the growth rate of the populations and the coupling parameter involved on the boundary where the interchange of flux is taking place.

[04005] A bifurcation result for a fractional semilinear Neumann problem

Format : Talk at Waseda University
Author(s) : Luca Vilasi (University of Messina)
Abstract : We will examine a parameterized elliptic problem governed by the Neumann fractional Laplacian on a bounded domain of $\mathbb{R}^N$, $N \geq 1$, with a general nonlinearity. This problem arises, in particular, when looking for steady state solutions to Keller-Segel systems in which the diffusion of the chemical is non-local. By variational arguments we will show the existence of non-trivial solutions, local minima of the corresponding energy functional, that branch off the null one for small values of the parameter. We will also derive some regularity results, as well as other qualitative properties of the solutions.

[04254] Systems of coupled nonlinear Schrödinger equations

Format : Talk at Waseda University
Author(s) : Eduardo Colorado (Universidad Carlos III de Madrid)
Abstract : Along the talk we will see some results about existence of solutions to general coupled systems of nonlinear Schrödinger (NLS) equations (and systems of coupled NLS-nonlinear Korteweg-de Vries equations).

To do so, we will use variational techniques once one pass to the elliptic system obtained by looking for standing solitary wave solutions (or standing-travelling wave solutions) for the NLS coupled system (or the NLS-NKdV coupled system).

00563 (2/2) : 3E @G709 [Chair: Pablo Álvarez-Caudevilla]

[03153] Stable standing waves for a Schrödinger system with nonlinear chi^3 response

Format : Talk at Waseda University
Author(s) : Tatsuya Watanabe (Kyoto Sangyo University)
Abstract : In this talk, we consider standing wave solutions for a certain nonlinear Schrodinger system which appears in nonlinear optics. This two-component system contains a cubic nonlinear term which is called χ^3-interaction, and has a strong coupling on one side only.

Oliveira-Pastor (2021) showed the existence of ground state solutions for the corresponding stationary problems, and investigated their stability and instability. In our study, by considering the solvability of a constraint minimization problem, we show the existence of stable standing wave solutions. We also investigate the correspondence between minimizers and ground state solutions.

This work is based on joint research with Mathieu Colin (University of Bordeaux).

[03664] Critical nonlocal problems driven by the fractional Laplacian

Format : Online Talk on Zoom
Author(s) : Raffaella Servadei (Università degli Studi di Urbino Carlo Bo)
Abstract : Critical problems are particularly relevant for their relations with many applications where a lack of compactness occurs.
The fractional Laplacian operator appears in concrete applications in many different fields. This is one of the reason why, recently, nonlocal fractional problems are widely studied in the literature.
Aim of this talk is to discuss some recent results about existence and multiplicityof solutions for fractional nonlocal equations with critical growth assumptions on the nonlinear term.

[04405] Variational and topological methods on non-compact Randers spaces

Format : Online Talk on Zoom
Author(s) : Giovanni Molica Bisci (University of Urbino Carlo Bo)
Abstract : Motivated by a wide interest in the literature, the leading purpose of this talk is to present some recent abstract results on non-compact Randers spaces and their applications to quasilinear elliptic equations. The main approach is based on novel abstract Sobolev embedding results as well as on some variational and topological methods.

[00570] Title: Machine Learning and Statistical Approaches for PDE Based Inverse Problems in Imaging

Session Time & Room :

00570 (1/2) : 4C (Aug.24, 13:20-15:00) @E503

00570 (2/2) : 4D (Aug.24, 15:30-17:10) @E503

Type : Proposal of Minisymposium
Abstract : In recent years, there is tremendous growth in machine learning and statistical approaches to solve inverse problems involving PDEs. This mini symposium will explore ideas both theoretical and computational to advance understanding of the convergence, consistency, and numerical algorithms to solve PDE based inverse problems. We will focus on inverse problems with applications to imaging including Electrical Impedance Tomography, Diffuse Optical Tomography. The mini symposium is expected to bring experts from theory, computation, and practice to bridge the gap between these areas.
Organizer(s) : Department of Mathematics and Statistics, University of North Carolina at Charlotte, USA

00570 (1/2) : 4C @E503 [Chair: Taufiquar Khan]

[04498] Train Like a (Var)Pro: Efficient Training of DNNs

Format : Talk at Waseda University

Author(s) : Elizabeth Newman (Emory University)Lars Ruthotto (Emory University)Bart van Bloemen Waanders (Sandia National Laboratories)Joseph Hart (Sandia National Laboratories)

Abstract : Deep neural networks (DNNs) have excelled as high-dimensional function approximators and are trained by solving a challenging stochastic optimization problem. In this talk, we will make DNN training easier by exploiting separability of common architectures; i.e., linear in the final weights. We will leverage this linearity by eliminating the weights through variable projection. We will demonstrate the efficacy of this approach through numerical examples and will conclude with a discussion of extensions and new applications.

[05369] Machine Learning for Inverse Problems in Electrical Impedance Tomography

Format : Talk at Waseda University

Author(s) : Hyeuknam Kwon (Yonsei University, Mirae campus)

Abstract : This paper discusses the application of machine learning techniques to solve inverse problems in electric impedance tomography (EIT). EIT is a non-invasive medical imaging technique used to reconstruct the distribution of conductivity within the human body using electrical measurements of surfaces. However, the inverse problem in EIT image reconstruction and its application suffers from various difficulties.The author provides these problems and machine learning techniques to solve them.

00570 (2/2) : 4D @E503 [Chair: Taufiquar Khan]

[04986] Data-Driven Design of Thin-Film Optical Systems using Deep Active Learning

Format : Talk at Waseda University

Author(s) : Youngjoon Hong (Sungkyunkwan University)

Abstract : A deep learning aided optimization algorithm for the design of flat thin-film multilayer optical systems is developed. We introduce a deep generative neural network, based on a variational autoencoder, to perform the optimization of photonic devices. This algorithm allows one to find a near-optimal solution to the inverse design problem of creating an anti-reflective grating, a fundamental problem in material science. As a proof of concept, we demonstrate the method's capabilities for designing an anti-reflective flat thin-film stack consisting of multiple material types. We designed and constructed a dielectric stack on silicon that exhibits an average reflection, which is lower than other recently published experiments in the engineering and physics literature. In addition to its superior performance, the computational cost of our algorithm based on the deep generative model is much lower than traditional nonlinear optimization algorithms. These results demonstrate that advanced concepts in deep learning can drive the capabilities of inverse design algorithms for photonics. In addition, we develop an accurate regression model using deep active learning to predict the total reflectivity for a given optical system. The surrogate model of the governing partial differential equations can then be broadly used in the design of optical systems and to rapidly evaluate their behavior.

[04138] Implicit Solutions of Electrical Impedance Tomography Using Deep Neural Network

Format : Talk at Waseda University

Author(s) : Taufiquar Khan (UNC Charlotte)Thilo Strauss (Bosch)

Abstract : In this talk, we will discuss deep learning approach for the electrical impedance tomography (EIT). In the last several decades, researchers have made significant improvement for image reconstruction for the EIT inverse problem. However, there is still need for much improvement. In this talk, we will discuss a shape reconstruction approach using machine learning. We propose a neural network architecture where the neural network model estimates the probability for a point of whether the conductivity belongs to the background region or to the non-homogeneous region. We present our numerical results to show the performance of the architecture and compare the proposed method with other known algorithms.

[00571] Mathematics in biological pattern formation: modeling, analysis, and applications

Session Time & Room : 3D (Aug.23, 15:30-17:10) @G501

Type : Proposal of Minisymposium

Abstract : This mini-symposium will focus on recent advances in mathematical modeling and analysis of pattern formation problems related to biology. Mainly, we will discuss how to explain pattern formation through the analysis of the evolution equations such as ODE and PDE, which are modeled to fit the context of the biological phenomena. In this mini-symposium, we will invite researchers working on different types of model equations, such as particle systems, reaction-diffusion systems, and Fokker-Planck equations, to introduce a variety of approaches to pattern formation problems in biology.

[04548] Patterning conditions in bilayer reaction-cross-diffusion systems

Format : Talk at Waseda University

Author(s) : Antoine Diez (Kyoto University Institute for the Avanced Study of Human Biology (ASHBi))Andrew L. Krause (Durham University)Philip K. Maini (University of Oxford)Eamonn A. Gaffney (University of Oxford)Sungrim Seirin-Lee (Kyoto University)

Abstract : Various biological systems such as the skin can be modelled by reaction-cross-diffusion networks in a so-called bilayer geometry where two independent reaction-cross-diffusion systems are coupled by a linear transport law. This work considers an arbitrary number of reacting species and gives quantitative theoretical asymptotic conditions, supported by numerical simulations, under which the coupling itself triggers patterning or stabilizes a homogeneous equilibrium.

[04979] Multilevel mathematical modeling methods for morphogenesis of bacterial cell populations

Format : Talk at Waseda University

Author(s) : Sohei Tasaki (Hokkaido University)Madoka Nakayama (Hokkaido University)Masaharu Nagayama (Hokkaido University)Izumi Takagi (Tohoku University)

Abstract : Bacterial cell populations exhibit diverse growth morphologies and collectively form a robust system that can withstand environmental fluctuations. The diversity of macroscopic spatiotemporal patterns and flexible environmental responses in morphogenesis are supported by a variety of cellular states. Therefore, to understand the morphogenesis of bacterial populations, it is necessary to construct and analyze multilevel mathematical models that connect the cellular and tissue levels. Here we propose two multilevel modeling methods.

[04657] A continuous model for bacteria growth with short range interactions, growth and interaction: derivation and analysis of pattern formation

Format : Talk at Waseda University

Author(s) : Sophie Hecht (CNRS, LJLL, Sorbonne Université)

Abstract : We study a mathematical model to describe the spatial evolution of micro-colony growth with bacteria of variable size. This PDE model describes the dynamics of the density of bacteria due to short-range interaction, growth, and division. We first derive the model from a many particles system by performing a large number limit followed by a localization limit. The difficulty in these limits resides in the lack of compactness according to the size variable. We then investigate the process of pattern formation in a two-dimensional domain. We analyse how the cross-diffusion inherent to the model linked to the size variable can impact the formation of spatial patterns such as size sorting.

[03139] Approximation for nonlocal Fokker-Planck equations by a Keller–Segel system

Format : Talk at Waseda University
Author(s) : Yoshitaro Tanaka (Future University Hakodate)Hideki Murakawa (Ryukoku University)
Abstract : To describe biological phenomena such as cell migration and cell adhesion many models with advective nonlocal interaction have been proposed. As an attempt to construct an analysis method for these equations, we approximate the nonlocal Fokker-Planck equation by the combination of a Keller-Segel system. We show that the solution of the nonlocal Fokker-Planck equation with any even continuous integral kernel can be approximated as a singular limit of the Keller-Segel system by controlling parameters.

[00573] Emerging Methods for Shape- and Topology Optimization

Session Time & Room :

00573 (1/2) : 4D (Aug.24, 15:30-17:10) @E605

00573 (2/2) : 4E (Aug.24, 17:40-19:20) @E605

Type : Proposal of Minisymposium
Abstract : Shape and topology optimization has seen considerable progress in multiple areas recently, in particular in regards to the understanding of non-smoothness and higher order methods. A driving problem class for these new developments have been inverse and reconstruction problems. The goal of this mini-symposium is to bridge the gap between these developments and connect new algorithmic developments with applications.

To this end, the first session focuses on the progression from non-smooth shape optimization problems over Quasi-Newton methods to H^1 and H^2 schemes, while the second part focuses on novel applications and emerging new areas of shape and topology optimization.

[02707] Geometry Segmentation with Total Variation Regularization

Author(s) : Lukas Baumgärtner (Humboldt Universität zu Berlin)Ronny Bergmann (NTNU Trondheim)Roland Herzog (Uni Heidelberg)Manuel Weiß (Uni Heidelberg (IWR))Stephan Schmidt (Humboldt-Universität zu Berlin)
Abstract : The total variation has proven as a useful regularizer for various applications in Inverse imaging and Shape optimization problems. For the task of shape segmentation, we consider two models that combine normal vector data of a discrete surface with a total variation penalty that is evaluated in the assignment space and the label space. We show how to solve the model problems using the Chambolle-Pock algorithm and ADMM.

[03021] Topology optimisation with general dilatations via the topological state derivative

Author(s) : Phillip Baumann (TU Wien)Idriss Mazari-Fouquer (CEREMADE, Paris Dauphine Université, PSL)Kevin Sturm (TU Wien)
Abstract : In this work we introduce the topological state derivative, a noval approach to treat PDE-constrained topology optimisation problems. This notion allows to deal with point perturbations as well as more general perturbations like smooth hypersurfaces in a similar way. Furthermore, we draw a connection from the topological state derivative to the asymptotic expansion of the state equation, which is usually derived using boundary layer correctors. Finally, we present numerical results based on these ideas.

[03573] Combining parameterized aerodynamic shape optimization with Sobolev smoothing

Author(s) : Nicolas R. Gauger (University of Kaiserslautern-Landau)Stephan Schmidt (Humboldt University Berlin)Thomas Dick (University of Kaiserslautern-Landau)
Abstract : On the one hand, Sobolev gradient smoothing can considerably improve the performance of aerodynamic shape optimization and prevent issues with regularity. On the other hand, Sobolev smoothing can also be interpreted as an approximation for the shape Hessian. This paper demonstrates, how Sobolev smoothing, interpreted as a shape Hessian approximation, offers considerable benefits, although the parameterization is smooth in itself already. Such an approach is especially beneficial in the context of simultaneous analysis and design, where we deal with inexact flow and adjoint solutions, also called One Shot optimization. Furthermore, the incorporation of the parameterization allows for direct application to engineering test cases, where shapes are always described by a CAD model. The new methodology presented in this paper is used for reference test cases from aerodynamic shape optimization and performance improvements in comparison to a classical Quasi-Newton scheme are shown.

[03630] A combined phase field - Lipschitz method for PDE constrained shape optimization

Author(s) : Michael Hinze (Universität Koblenz)Philip Herbert (Heriot-Watt University)Christian Kahle (Universität Koblenz)
Abstract : Abstract: We present a general shape optimisation framework for PDE constrained shape optimization, which combines phase field methods and the method of mappings in the Lipschitz topology. In a first step the phase field approach determines the topology of the sought shape, and with the zero level set of the phase field simultaneously provides an approximation of the optimal shape. The latter serves as starting point for a sharp interface shape optimization method in the Lipschitz topology. To illustrate our approach we present a selection of PDE constrained shape optimisation problems and compare our findings to results from so far classical Hilbert space methods and recent p-Laplace -approximations.

00573 (2/2) : 4E @E605

[04267] Interface Identification constrained by Local-to-Nonlocal Coupling

Author(s) : Matthias Schuster (Trier University)Christian Vollmann (Trier University)Volker Schulz (Trier University)
Abstract : Models of physical phenomena that use nonlocal operators are better suited for some applications than their classical counterparts that employ partial differential operators.
However, the numerical solution of these nonlocal problems can be quite expensive. Therefore, Local-to-Nonlocal couplings have emerged that combine partial differential operators with nonlocal operators.
In this talk, we make use of an energy-based Local-to-Nonlocal coupling that serves as a constraint for an interface identification problem.

[04673] Total Generalized Variation for Geometric Inverse Problems

Author(s) : Lukas Baumgärtner (Humboldt Universität zu Berlin)Stephan Schmidt (Humboldt University Berlin)Roland Herzog (Heidelberg University)Ronny Bergmann (NTNU, Trondheim)Manuel Weiß (Uni Heidelberg (IWR))Jose Vidal-Nunez (University of Alcal̆a de Henares)
Abstract : The total variation of the outer normal vector of a shape is discussed in the context of triangulated meshes embedded in 3D. This non-smooth regularizer requires an advanced algorithm to be used in (inverse) shape optimization problems. A split
Bregman/ADMM method is used for this purpose. There, the non-smooth objective is split into a smooth shape optimization problem and a simple non-smooth problem. The smooth shape problem is solved by a globalized Newton method. Due to the nature of the regularizer, the first and second-order shape derivatives can not be computed by algorithmic differentiation. Therefore, their analytic form is derived and some of their properties are discussed. Numerical results are presented for mesh denoising problems.

An extension, the total generalized variation of the normal, to counteract the so-called staircasing effect is presented.

[04738] Choice of Inner Product in Shape Gradient Descent

Author(s) : Caitriona Jacqueline McGarry (University of Leicester)Alberto Paganini (University of Leicester)
Abstract : In optimisation problems with infinite dimensional control spaces, the choice of inner product on the control space affects the gradient, the direction of steepest descent wrt the induced norm.

Shape optimisation is no exception, with the control variable in an infinite dimensional function space. We will study the impact on shape optimisation of endowing this space of vector fields with alternatively an H^1 or H^2 inner product, especially regarding adding or removing corners of a shape.

[04786] Image and Shape Registration via Transport Equations

Author(s) : Stephan Schmidt (University of Trier)Lukas Baumgärtner (Humboldt Universität zu Berlin)
Abstract : We consider the use of transport equations as a model for solving inverse and registration problems. Incorporating shape Hessians to facilitate higher order methods have recently made new classes of problems tractable, ranging from the formation of capillary bridges in particle flows to the detection of motion in medical scans as well as mesh registration problems. Special attention is given on how to treat hyperbolic constraints within the setting of moving shapes and images.

[00574] Recent Progress on Stochastic Analysis, Control, and their Applications

Session Time & Room :

00574 (1/2) : 1D (Aug.21, 15:30-17:10) @D514

00574 (2/2) : 1E (Aug.21, 17:40-19:20) @D514

Type : Proposal of Minisymposium
Abstract : This minisymposium features new developments in stochastic analysis, control, and their applications. The invited speakers will be presenting results on impulse control with discontinuous setup costs, deep learning approach for optimal control, optimal control problem for regime-switching processes, and feedback control for switching diffusion systems based on discrete time observations in the first session. The second session will be focused on exponential stability and weak stability of stochastic functional differential equations with impulsive perturbations and a two-time-scale formulation as well as McKean-Vlasov stochastic differential equations. It is anticipated that this minisymposium will help to exchange ideas and stimulate further collaborations.

[03197] Continuous-Review Inventory Systems with Discontinuous Setup Costs

Format : Talk at Waseda University
Author(s) : Dacheng Yao (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk, we will discuss continuous-review inventory systems, in which the setup cost of each order is a discontinuous function of order quantity and the demand process is modeled as a Brownian motion with a positive drift. Assuming the holding and shortage cost to be a convex function of inventory level, we prove that an (s, S) policy is optimal among all admissible policies under the long-run average cost criterion. However, under the discounted cost criterion, we find that although some (s, S)-type policies are indeed optimal in some cases, any (s, S) policy cannot always be optimal for all initial inventory level x∈R in the other cases.

[04097] Deep learning methods in insurance and risk management

Format : Talk at Waseda University
Author(s) : Zhuo Jin (Macquarie University)
Abstract : Recently, deep learning approaches has drawn increasing attention in decision making processes. A type of Markov chain approximation-based iterative deep learning algorithm is developed to study the optimal control problems arising from the insurance industry. The optimal controls are approximated as deep neural networks. The framework of Markov chain approximation plays a key role in building the iterative equations and initialization of the algorithm. Optimal parameters of neural networks are then obtained iteratively.

[04139] Exponential stability of stochastic functional differential equations with impulsive perturbations

Format : Talk at Waseda University
Author(s) : KY QUAN TRAN (SUNY Korea)George Yin (University of Connecticut)
Abstract : This work aims to investigate the moment exponential stability of stochastic functional differential equations subject to
impulsive perturbations and Markovian switching. In contrast to existing literature, we propose new criteria for moment exponential stability and a new method for computing moment Lyapunov exponents. Our analysis also shows that the Euler-Maruyama approximation method can effectively reproduce exponential stability in the mean square, provided that the step sizes are sufficiently small.

[03618] Fully-coupled two-time-scale stochastic functional differential equations with infinite delay

Format : Talk at Waseda University
Author(s) : Fuke Wu (Huazhong University of Science and Technology)
Abstract : This paper examines the fully-coupled two-time-scale stochastic functional differential equations (SFDEs) with infinite delay. The system under consideration involves a slow component and a fast component. This paper aims to establish the averaging principle. To overcome the difficulty due to the infinite delay and the coupling of the segment process, some properties as the Hölder continuity and tightness on a space of continuous functions have to be investigated for the segment process.

00574 (2/2) : 1E @D514 [Chair: Fuke Wu]

[03662] On the weak stability and stabilization of McKean-Vlasov stochastic differential equations

Format : Talk at Waseda University
Author(s) : Chao Zhu (University of Wisconsin-Milwaukee)
Abstract : This work focuses on weak stability and stabilization of a class of McKean-Vlasov stochastic differential equations (SDEs). First, under suitable conditions on the coefficients of the SDE, we derive explicit quantitative contraction rates for the convergence in Wasserstein distances of McKean-Vlasov SDEs using the coupling method. The contraction results are then used to prove a propagation of chaos uniformly in time, which provides quantitative bounds on convergence rate of interacting particle systems, and establishes exponential ergodicity for McKean-Vlasov SDEs. Finally we consider the question of stabilizing in the weak sense an arbitrary McKean-Vlasov SDE using suitable feedback controls with delays.

[05067] Limit Theorems for Distribution Dependent Jump Processes with Random Switching

Format : Online Talk on Zoom
Author(s) : Fubao Xi (Beijing Institute of Technology)Chao Zhu (University of Wisconsin-Milwaukee)
Abstract : We consider distribution dependent jump processes with random switching, where the switching processes may have a countably infinite state space. By virtue of the martingale approach, we first establish the existence and uniqueness theorem of the underlying processes for a special Markovian switching case. Using a martingale function, we then transfer the existence and uniqueness result onto the general state-dependent switching case. Moreover, we establish two limit theorems for the processes with mean field interactions.

[03342] From the optimal singular stochastic control to the optimal stopping for regime-switching processes

Format : Online Talk on Zoom
Author(s) : Jinghai Shao (Tianjin University)Taoran Tian (Tianjin University)
Abstract : This work generalizes the connection between optimal singular control and optimal stopping problem for regime-switching processes. Via optimal singular control, the optimal stopping time and the continuation region are characterized. Moreover, we prove the existence of optimal singular stochastic control for a finite horizon singular control problem with the cost function containing the terminal cost. We prove it directly by the compactification method. Such a problem was left open in Haussmann and Suo (SICON, 1995).

[00575] Factors and Cycles

Session Time & Room : 5B (Aug.25, 10:40-12:20) @G302

Type : Proposal of Minisymposium

Abstract : Factors and cycles are well established subjects in the field of graph theory. They are basic and fundamental problems: for a given graph G, taking a regular graph as a spanning subgraph of G. On the other hand, factors and cycles have several applications in contexts including error correction coding theory, scheduling problems, wireless networking, and many others.

Regardless of efforts by mathematicians, there are many problems on factors and cycles which are not solved yet. This minisymposium intends to bring pioneer researchers to present their very recent discoveries on factors, cycles and related topics.

Organizer(s) : Shoichi Tsuchiya

[02338] On cycles and factors in graphs with large degree sum

Format : Talk at Waseda University

Author(s) : Takamasa Yashima (Seikei University)

Abstract : Numerous researchers have conducted investigations into a Hamiltonian cycle and related objects in both general graphs and bipartite graphs. In this talk, we will focus on two specific topics related to this field. The first topic concerns the problem of finding a spanning subgraph, also known as a factor, that satisfies certain degree constraints. The second topic concerns the problem of finding a Hamiltonian cycle containing a pre-specified set of independent edges, or a matching.

[02275] Toughness and forbidden subgraphs for graphs to be hamiltonian

Format : Talk at Waseda University

Author(s) : Masahiro Sanka (Keio University)

Abstract : We say that a graph G is t-tough if for each vertex cut $S \subset V(G)$, the number of components of $G - S$ does not exceed $\frac{|S|}{t}$. In 1973, Chvátal has conjectured that there exists a constant t_0 such that every t_0-tough graph is hamiltonian. In this talk, we discuss some results on Chvátal's conjecture in R-free graphs for some graph R. In particular, we will present hamiltonicity of $2K_2$-free graphs and $(K_2 \cup kK_1)$-free graphs.

[02216] Recent progress on distance matching extension in graphs on surfaces

Format : Talk at Waseda University

Author(s) : Jun Fujisawa (Keio University)

Abstract : A graph G is said to be distance d matchable if, for any matching M of G in which edges are pairwise at least distance d apart, there exists a perfect matching of G which contains M. If we choose a class of graphs A and an integer d appropriately, then we may observe a phenomenon that every graph in A is distance d matchable. In this talk recent results concerning this phenomenon is introduced.

[02696] Eigenvalues and factors in regular graphs

Format : Talk at Waseda University

Author(s) : Suil Oh (SUNY Korea)

Abstract : In this talk, we investigate spectral conditions for an (r-regular) graph G to guarantee the existence of a certain factor.

[00580] Mathematical Challenges in Current and Future Location Estimation Systems

Session Time & Room : 3E (Aug.23, 17:40-19:20) @E502

Type : Proposal of Minisymposium

Abstract : Location-estimation systems, and in particular Global Navigation Satellite Systems (e.g. GPS), are mature and ubiquitous. Many aspects of modern life are today completely dependent on these systems. However, deriving additional benefits (higher accuracy, resilience to jamming and spoofing) from existing systems and building future systems to fill application gaps require addressing challenging mathematical and computational problems. These challenges revolve around difficult nonconvex optimization problems, some with integer parameters, and some in high dimensions. Effective solutions require a combination of state-of-the-art mathematical tools with application-specific insights. The minisymposium will present both challenges and recent progress towards their solution.

[01325] Local Strong Convexity of Source Localization and Error Bound for Target Tracking under Time-of-Arrival Measurements

Format : Talk at Waseda University

Author(s) : Anthony Man-Cho So (The Chinese University of Hong Kong)Yuen-Man Pun (The Australian National University)

Abstract : We consider a time-varying optimization approach to the problem of tracking a moving target using noisy time-of-arrival {TOA} measurements. To analyze the tracking performance of online gradient descent {OGD}, we first revisit the classic least-squares formulation of the {static} TOA-based source localization problem and elucidate its estimation and geometric properties. Then, we show that the loss function in the formulation, albeit non-convex in general, is locally strongly convex at its global minima. To the best of our knowledge, these results are new and can be of independent interest. By combining them with existing techniques from online strongly convex optimization, we then establish the first non-trivial bound on the cumulative target tracking error of OGD.

[01604] Machine learning techniques for resolving GNSS integer ambiguities

Format : Talk at Waseda University

Author(s) : Xiao-Wen Chang (McGill University)Qincheng Lu (McGill University)

Abstract : A key computational component in high precision GNSS positioning is to resolve carrier phase ambiguities as integers. The optimal method is to solve an integer least squares problem. Since the integer least squares problem is NP-hard, efficiency of traditional algorithms becomes problematic when the dimension of the integer ambiguity vector becomes large. To meet the challenge, we propose some machine learning based algorithms. Numerical results will demonstrate their effectiveness and efficiency.

[01656] Fast and almost unbiased position estimation for location service

Format : Talk at Waseda University

Author(s) : Peiliang Xu (Kyoto University)

Abstract : We propose a bias-corrected weighted LS method for precise location service, which consists of two basic elements: one to automatically correct the bias due to model nonlinearity and the induced biases in squared ranges/pseudoranges and the other to sequentially estimate unknown location parameters by treating equality constraints as a condition adjustment. The method is applied to ranges, squared ranges and the differences of squared rangesand further to pseudoranges, squared pseudoranges and the differences of pseudoranges.

[01296] Robust Location Estimation in Wildlife Tracking Systems

Format : Talk at Waseda University

Author(s) : Sivan Toledo (Tel Aviv University)Eitam Arnon (Tel Aviv University)Shlomo Cain (Tel Aviv University)Assaf Uzan (Tel Aviv University)Ran Nathan (Hebrew University of Jerusalem)Orr Spiegel (Tel Aviv University)

Abstract : The talk will describe new location-estimation algorithms for time-of-arrival transmitter localization systems. The new algorithms use the consensus principle and they detect and discard outlier time-of-arrival observations, which

can be caused by non-line-of-sight propagation, radio interference, clock glitches, or an overestimation of the signal-to-noise ratio. They also detect cases in which two locations are equally consistent with the measurements and can usually select the correct one based on unambiguous estimates shortly before or after.

[00581] Analysis, Methods and Applications in Complex Materials

Session Time & Room :

00581 (1/2) : 5C (Aug.25, 13:20-15:00) @E603

00581 (2/2) : 5D (Aug.25, 15:30-17:10) @E603

Type : Proposal of Minisymposium
Abstract : Materials modeling and simulation is essential in underpinning the discovery and synthesis of new materials and chemicals with novel functionalities in various key areas like energy and biomedicine. Materials science provides a rich source of problems in computational mathematics. Meanwhile, mathematicians are crucial to address fundamental questions with a solid theoretical foundation. The overarching goal of this minisymposium is to promote academic exchanges and collaborations among researchers working in the exciting and rapidly developing field of mathematics in materials science, especially focusing on the mathematical theory in complex materials as well as the applications of state-of-art machine-learning techniques.
Organizer(s) : Xiaoxu Li, Yangshuai Wang
Classification : 65G99, 81V70, 81V55
Minisymposium Program :

00581 (1/2) : 5C @E603 [Chair: Xiaoxu Li]

[04090] A framework for a generalization analysis of MLIPs

Format : Online Talk on Zoom
Author(s) : Yangshuai Wang (University of British Columbia)
Abstract : I will talk about an analytical (as opposed to statistical) approach to demonstrate the generalization of MLIPs and its application on simulating crystalline defects, explaining how the choice of training data and the accuracy of the fit to that training data affect the accuracy of predictions on materials properties.

[04086] A Finite Element Configuration Interaction Method for Wigner Localization

Format : Online Talk on Zoom
Author(s) : Xue Quan (Beijing Normal University)Huajie Chen (Beijing Normal University)
Abstract : This work proposes a numerical algorithm to study the Wigner localization phenomenon which carefully treats the many-body correlations. The main features are three-fold: (i) a finite element discretization of the one-body space such that the sharp localization can be captured; (ii) a good initial state obtained by exploiting the strongly correlated limit; and (iii) a selected configuration interaction method by choosing the Slater determinants from (stochastic) gradients.

[05440] Equivariant Tensor Network Potentials

Format : Talk at Waseda University
Author(s) : Max Hodapp (Materials Center Leoben)Alexander Shapeev (Skoltech)
Abstract : The computational cost of many state-of-the-art machine-learning interatomic (MLIPs) potentials increases exponentially with the number of atomic features. Low-rank tensor networks can overcome exponential growth in complexity, however, it is often not easy to encode the model symmetries. Here, we propose a formalism for rank-efficient equivariant tensor networks (ETNs) that remain invariant under actions of SO(3), and, using ETNs, develop a new class of MLIPs that demonstrate superior performance over existing MLIPs.

[04136] Planewave approximation for electronic structure calculation of incommensurate systems

Format : Talk at Waseda University
Author(s) : Ting Wang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Incommensurate structures come from stacking the single layers of low-dimensional materials on top of one another with misalignment, such as a twist in orientation. While these structures are of significant physical interest, they pose many theoretical challenges due to the loss of periodicity. Under the planewave framework, we provide a numerical scheme to compute the electronic structure of incommensurate systems based on density functional theory.

00581 (2/2) : 5D @E603 [Chair: Ting Wang]

[04088] DeePN2: A Deep Learning-Based Non-Newtonian Hydrodynamic Model

Format : Talk at Waseda University
Author(s) : Lidong Fang (Michigan State University)Pei Ge (Michigan State University)Lei Zhang (Shanghai Jiao Tong University)Weinan E (Peking University)Huan Lei (Michigan State University)
Abstract : A longstanding problem in the modeling of non-Newtonian hydrodynamics of polymeric flows is the availability of reliable and interpretable hydrodynamic models that faithfully encode the underlying microscale polymer dynamics. The main complication arises from the long polymer relaxation time, the complex molecular structure, and the heterogeneous interaction. DeePN2, a deep learning-based non-Newtonian hydrodynamic model, has been proposed and has shown some success in systematically passing the micro-scale structural mechanics information to the macro-scale hydrodynamics for suspensions with simple polymer conformation and bond potential. The model retains a multi-scaled nature by mapping the polymer configurations into a set of symmetry-preserving macro-scale features. The extended constitutive laws for these macro-scale features can be directly learned from the kinetics of their micro-scale counterparts. In this paper, we develop DeePN2 using more complex micro-structural models. We show that DeePN2 can faithfully capture the broadly overlooked viscoelastic differences arising from the specific molecular structural mechanics without human intervention.

[04357] Numerical Analysis of Structural Green's Function in Multiple Scattering Theory

Format : Talk at Waseda University
Author(s) : Xiaoxu Li (Beijing Normal University)Huajie Chen (Beijing Normal University)
Abstract : This work studies the multiple scattering theory, also called Green's function method, in the electronic structure calculations of disordered systems from a mathematical perspective. By analyzing the structural Green's function, which can be viewed as the representation of Green's function in some basis, we will (a) improve the space truncation way to accelerate model convergence; (b) establish a mathematical analysis framework for Green's function and provide a prior error estimate; (c) design two linear-scaling algorithms with systematically controllable error.

[04087] Variational Monte Carlo from a Continuous Viewpoint

Format : Talk at Waseda University
Author(s) : Juerong Feng (Beijing Normal University)Huajie Chen (Beijing Normal University)
Abstract : We study the variational Monte Carlo (VMC) method for quantum many-body problems based on data-driven wavefunction ansatz. We present a continuous stochastic gradient flow formulation for the VMC algorithm and show the large-time asymptotics with an explicit decay bound in terms of the many-body Hamiltonian and the wavefunction parameterization. In particular, we perform a careful analysis of the interactions between the approximation error of the ground state wavefunction and the generalization error of the sampling.

[00584] Advanced Methods for Structured Eigenvalue Problems and Nonlinear Equations

Session Time & Room :

00584 (1/3) : 2D (Aug.22, 15:30-17:10) @E603

00584 (2/3) : 2E (Aug.22, 17:40-19:20) @E603

00584 (3/3) : 3C (Aug.23, 13:20-15:00) @E603

Type : Proposal of Minisymposium
Abstract : Structured eigenvalue problems and nonlinear equations arise from many applications including 3D phononic crystals, medical image processing and phase retrieval. Their structure reflects certain physical properties that need to be preserved during calculations, posing a huge challenge for computational scientists. In recent years, many new methods and algorithms have been achieved, such as Jacobi–Davidson type algorithms, Newton-Noda iteration, GPR parameter prediction method, and multi-symplectic block-Lanczos methods. And theoretical analysis receives new progress on generalized orthogonal flow, nonlinear energy minimization and Davis-Kahan theorem. In this minisymposia, the invited speakers will present their recent advances about such interesting subjects.

00584 (1/3) : 2D @E603

[01505] Eigen-decomposition and Fast Solvers for Maxwell's Equations for 3D Photonic Crystals

Format : Talk at Waseda University
Author(s) : Tiexiang Li (Southeast University)Heng Tian (Sichuan University of Science and Engineering)Xing-Long Lyu (Southeast University)Wen-Wei Lin (National Yang Ming Chiao Tung University)
Abstract : In this article, we propose the Fast Algorithms for Maxwell's Equations FAME package for solving Maxwell's equations for modeling three-dimensional photonic crystals. FAME combines the null-space free method with fast Fourier transform FFT-based matrix-vector multiplications to solve the generalized eigenvalue problems GEPs arising from the oblique Yee's discretization. Numerical results demonstrate the potential of our proposed package to enable large-scale numerical simulations for novel physical discoveries and engineering applications of photonic crystals.

[01246] Projected Gradient Method for Volume-Measure-Preserving Optimal Mass Transportation Problems

Format : Talk at Waseda University
Author(s) : Tsung-Ming Huang (National Taiwan Normal University)Wei-Hung Liao (National Yang Ming Chiao Tung University)Wen-Wei Lin (National Yang Ming Chiao Tung University)Mei-Heng Yueh (National Taiwan Normal University)Shing-Tung Yau (Tsinghua University)
Abstract : Volumetric stretch energy minimization (VSEM) has been widely applied to the computation of volume-/mass-preserving parameterizations of simply connected tetrahedral mesh models. In this talk, based on the VSEM algorithm, we propose a projected gradient method for the computation of the volume/mass-preserving optimal mass transport map with a guaranteed convergence rate of O(1/m). Numerical experiments are presented to justify the theoretical convergence behavior for various examples drawn from known benchmark models. Moreover, these numerical experiments show the effectiveness and accuracy of the proposed algorithm, particularly in the processing of 3D medical MRI brain images.

[01095] Multitask kernel-learning Gaussian process regression parameter prediction method and its application in matrix splitting iteration methods

Format : Talk at Waseda University
Author(s) : Juan Zhang (Xiangtan University)
Abstract : In this talk, we present a multitask kernel-learning Gaussian process regression (GPR) parameter prediction method, and apply it in matrix splitting iteration methods. The first application is developing a general alternating direction implicit (ADI) framework, which can put most existing ADI methods into a unified framework and offer more new ADI approaches. Using the GPR method, the splitting parameter selection of this framework can be solved. The second application is for solving time-dependent linear systems, we give a new matrix splitting Kronecker product method, which can unify the existing Kronecker product schemes. Using the Multitask kernel-learning method, simultaneous multiple splitting parameters prediction and data-driven kernel learning can all be achieved. Based on Bayesian inference, the GPR method only requires a small training data set for learning the regression prediction mapping, and has sufficient accuracy and high generalization capability. We apply our developed methods to solving (time-dependent) convection-diffusion equations and (differential) Sylvester matrix equations. Numerical results illustrate our methods can solve large sparse linear systems more efficiently compared with existing methods.

[01322] Breakdown Avoidance Structure-Preserving Doubling Algorithms for Nonlinear Matrix Equations

Format : Talk at Waseda University
Author(s) : Yueh-Cheng Kuo (National university of Kaohsiung)
Abstract : Structure-Preserving Doubling Algorithms (SDAs) are efficient algorithms for solving Riccati-type matrix equations. However, the breakdown may happen in the SDA. To avoid the breakdown, we first introduce the class of Ω-symplectic forms, Ω-SF, consisting of symplectic matrix pairs with Hermitian parametric matrix Ω. Based on the Ω-SF, we developed modified SDAs, called MSDAs, for solving the Riccati-type equations. The MSDA generates a sequence of symplectic matrix pairs in Ω-SF and can avoid the breakdown by employing a suitable Hermitian matrix Ω. In addition, we show that the Hermitian matrix Ω in MSDAs can be chosen as a real diagonal matrix which can reduce the computational complexity. In this case, MSDA and SDA have the same computational complexity.

00584 (2/3) : 2E @E603

[01293] Newton-Noda iteration for nonlinear eigenvalue problems

Format : Talk at Waseda University
Author(s) : Ching-Sung Liu (National University of Kaohsiung)
Abstract : In this talk, we will introduce nonlinear eigenvalue problems, including tensor eigenvalue problems and nonlinear Schrödinger equations. We present a Newton-Noda iteration (NNI) to find positive eigenvectors of nonlinear problems. A great advantage of this method is that it converges quadratically and maintains positivity, i.e., the vector approximating the Perron vector (or ground state vector) is strictly positive in each iteration.

[01584] Phase Retrieval of Quaternion Signal via Wirtinger Flow

Format : Talk at Waseda University
Author(s) : Junren Chen (University of Hong Kong)Michael Kwok-Po Ng (University of Hong Kong)
Abstract : Quaternion phase retrieval (QPR) is concerned with the recovery of quaternion signal from magnitude of quaternion
linear measurements. We develop the scalable algorithm quaternion Wirtinger flow (QWF) for solving QPR, and establish its linear convergence guarantee. We develop a variant of QWF that can effectively utilize a pure quaternion priori by incorporating a quaternion phase factor estimate into QWF iterations.

[01454] Numerical Methods for the Complete Solution of Multiparameter Eigenvalue Problems

Format : Online Talk on Zoom
Author(s) : Bo Dong (Dalian University of Technology)
Abstract : The linear/nonlinear multiparameter eigenvalue problems appear frequently in the study of multiparameter Sturm-Liouville problems and delay differential equations with some delays. In this talk, I will introduce two classes of numerical methods for solving the multiparameter eigenvalue problems: the method of transforming to silmultaneous eigenvalue problems and the homotopy method. The former is suitable for small-scale and medium-scale problems while the latter tends to be more effective in terms of speed, accuracy and memory storage as the problem size grows. Numerical experiments and applications are presented to show the efficiency of these two classes of methods.

[02763] Perturbation theory for the symmetry eigenvalue problem and singular value decomposition followed by deflation techniques

Format : Online Talk on Zoom
Author(s) : Xiang Wang (Nanchang University)Hongjia Chen (Nanchang University)
Abstract : The calculation of the dominant eigenvalues of a symmetric matrix A together with its eigenvectors, followed by the calculation of the deflation of $A_1 = A - \rho U_k U_k^T$ corresponds to one step of the Wielandt deflation technique, where ρ is a shift and U_k are eigenvectors of A. In this paper, we investigate how the eigenspace of A_1 changes when A_1 is perturbed to $\tilde{A}_1 = A - \rho\tilde{U}_k\tilde{U}_k^T, \tilde{U}_k$ are approximate eigenvectors of U_k. We establish the bounds
for the angle of eigenspaces of A_1 and $\tilde{A}_1$ based on the Davis-Kahan theorem.
Moreover, in the practical implementation for singular value decomposition, once one or several singular triplets converge to a preset accuracy, they should be deflated by $B_1 = B - \gamma W_k V_k^H$ with γ is a shift and W_k and V_k are singular vectors so that they will not be re-computed.
We investigate how the singular subspaces of $B_1 = B - \gamma W V^H$ changes when B_1 is perturbed to $\tilde{B}_1 = B - \gamma\widetilde{W}\widetilde{V}^H$, $\widetilde{W}$ and $\widetilde{V}^H$ are approximate singular vectors.
We also establish the bounds
for the angle of singular subspaces of B_1 and $\tilde{B}_1$ based on the Wedin theorem.

We show, by numerical experiment, the angles of eigenspaces
and the angles of singular subspaces are well--predicted by
these bounds with an appropriable shift.

00584 (3/3) : 3C @E603

[01112] Nonlinear Energy Minimization for Simplicial Manifold Parameterizations

Format : Talk at Waseda University
Author(s) : Mei-Heng Yueh (National Taiwan Normal University)
Abstract : The parameterization problem aims to efficiently compute a diffeomorphism between a simplicial manifold and a specified canonical domain. In this talk, I will introduce the theoretical and computational aspects of nonlinear energy minimization for the computation of parameterizations of simplicial manifolds that preserve the specified geometry property. Applications to manifold registration and image processing will be demonstrated to show the effectiveness of parameterizations.

[01534] Two harmonic Jacobi–Davidson methods for computing a partial GSVD of a large matrix pair

Format : Talk at Waseda University
Author(s) : Jinzhi Huang (Soochow University)Zhongxiao Jia (Tsinghua University)
Abstract : Two harmonic extraction-based Jacobi–Davidson (JD) type algorithms are proposed to compute a partial generalized singular value decomposition (GSVD) of a large regular matrix pair. They are called cross product-free (CPF) and inverse-free (IF) harmonic JDGSVD algorithms, abbreviated as CPF-HJDGSVD and IF-HJDGSVD, respectively. Compared with the standard extraction-based JDGSVD algorithm, the harmonic extraction-based algorithms converge more regularly and suit better for computing GSVD components corresponding to interior generalized singular values. Thick-restart CPF-HJDGSVD and IF-HJDGSVD algorithms with some deflation and purgation techniques are developed to compute more than one GSVD components. Numerical experiments confirm the superiority of CPF-HJDGSVD and IF-HJDGSVD to the standard extraction-based JDGSVD algorithm.

[01473] Harmonic multi-symplectic Lanczos algorithm for quaternion singular triplets

Format : Talk at Waseda University
Author(s) : XUAN LIU (University of Macau)Zhigang Jia (Jiangsu Normal University)Jingfei Zhu (Jiangsu Normal University)Meixiang Zhao (Jiangsu Normal University)
Abstract : The computation of quaternion singular triplets has become one of the core targets of color image processing. A novel harmonic multi-symplectic Lanczos algorithm is presented for approximating extreme quaternion singular triplets. The underlying theory is to preserve an algebraic structure during the partial bidiagonalization, the argumentation, and the restarted bidiagonalization. The proposed algorithm is successfully applied to color video semantic segmentation.

[01319] The asymptotic analysis of generalized orthogonal flows

Format : Talk at Waseda University
Author(s) : Shih-Feng Shieh (National Taiwan Normal University)
Abstract : This talk is concerned with the matrix differential equation approximating the k-dimensional dominant eigenspace of a matrix. The solution of the matrix differential equation is orthogonal and is called generalized orthogonal flow. The existence and uniqueness of the generalized orthogonal flow are guaranteed for all time t∈ R. An orthogonal flow, which has the shortest arc-length, has been constructed and is called the best path of generalized orthogonal flows. We show that the best path is Oja's flow. We also analyze the asymptotic behaviors and the convergence rate of the best path.

[00586] Challenges for Attaining High-performance in Numerical Software

Session Time & Room : 3D (Aug.23, 15:30-17:10) @E603

Type : Proposal of Minisymposium
Abstract : The architectures of the existing top performing systems are undeniable complex, building upon multi-core units and proprietary interconnects, with very high levels of parallelism. These features pose many challenges to numerical library and application developers. In addition, accuracy of numerical computations, which can be an issue for conventional (e.g., BLAS) or complex algorithms (e.g., eigensolvers), should be concerned. In this minisymposium will discuss recent work on Automatic tuning (AT) by using expandable AI, novel approaches for accuracy verification, and iterative eigensolvers that do not enforcing orthogonality on the iterates thus reducing communication.
Organizer(s) : Takahiro Katagiri, Osni Marques, Toshiyuki Imamura
Classification : 65F15, 68T99, 68U99, 65G99, 65F05, Auto-tuning

[03413] Adaptation of XAI to Numerical Libraries: A Case Study for Automatic Performance Tuning

Format : Talk at Waseda University
Author(s) : Takahiro Katagiri (Nagoya University)
Abstract : AI is one of crucial technologies. On the other hand, we have been adapting to auto-tuning (AT) for numerical software. By utilizing AI technology, it is expected to establish AT function for performance tuning on numerical libraries. However, it is difficult to verify correctness for obtained AI model. Adaptation of explainable AI (XAI) is one of solutions. In this presentation, several scenarios for adapted XAI to AT function will be demonstrated.

[03472] Parallel Eigensolvers Based on Minimization Strategies

Format : Talk at Waseda University
Author(s) : Doru Thom Popovici (Lawrence Berkeley National Lab)Osni Marques (Lawrence Berkeley National Laboratory)Mauro Del Ben (Lawrence Berkeley National Laboratory)Andrew Canning (Lawrence Berkeley National Laboratory)
Abstract : This presentation will show recent developments in unconstrained minimization strategies for the solution of eigenvalue problems in electronic structure calculations. These schemes employ a preconditioned conjugate gradient approach that avoids an explicit reorthogonalization of the trial eigenvectors, in contrast to typical iterative eigensolvers, therefore reducing communications and becoming an attractive approach for the solution of very large problems on massively parallel computers. The presentation will also discuss the need to rearrange calculations (sometimes counteractively) to achieve performance, in particular on GPUs.

[03700] Mixed-precision iterative refinement for real-symmetric eigenvalue decomposition with clustered eigenvalues

Format : Talk at Waseda University
Author(s) : Yuki Uchino (Shibaura Institute of Technology)Katsuhisa Ozaki (Shibaura Institute of Technology)Toshiyuki Imamura (RIKEN)
Abstract : Uchino et al. presented two mixed-precision iterative refinement algorithms (herein called Algorithm 1 and 2) for the real-symmetric eigendecomposition based on the algorithm proposed by Ogita and Aishima.
Algorithm 2 offers the same convergence and advantages in terms of computational speed compared to Algorithm 1, as demonstrated through numerical experiments on the supercomputer Fugaku housed at RIKEN R-CCS.
We will also show that Algorithm 2 is much faster than the eigensolver provided in ScaLAPACK.

[04170] Mixed Precision Iterative Refinement with H-matrices

Format : Talk at Waseda University
Author(s) : Thomas Spendlhofer (Tokyo Institute of Technology)Rio Yokota (Tokyo Institute of Technology)
Abstract : It has been shown that the solution to a dense linear system can be accelerated by using mixed precision iterative refinement relying on approximate LU-factorization.
We investigate the usage of both mixed precision and low-rank approximations for obtaining an approximate

factorization. When employing the hierarchical matrix format, we are able to attain results accurate to a double precision solver at a lower complexity of \order$n^2$ for certain matrices.

[00587] Recent Advances in Numerical Methods for Nonlinear Hyperbolic PDEs

Session Time & Room :

00587 (1/2) : 2D (Aug.22, 15:30-17:10) @D401

00587 (2/2) : 2E (Aug.22, 17:40-19:20) @D401

Type : Proposal of Minisymposium
Abstract : Numerically solving hyperbolic systems of conservation and balance laws is a challenging task as their solutions may
develop extremely complicated nonsmooth structures. The number of applications in which such systems arise keeps increasing and most of the existing methods have their restrictions and disadvantages. Therefore, it is extremely important to develop new, highly accurate, stable, and robust numerical methods. The mini-symposium will focus on recent developments in this field of research and will bring together researchers from different countries and provide an opportunity for in-depth scientific discussion and exchange of ideas on the development, analysis, and applications of modern methods.

[01485] A New Locally Divergence-Free Path-Conservative Central-Upwind Scheme for Ideal and Shallow Water Magnetohydrodynamics

Format : Talk at Waseda University
Author(s) : Alina Chertock (North Carolina State University)Alexander Kurganov (Southern University of Science and Technology)Michael Redle (North Carolina State University)Kailang Wu (Southern University of Science and Technology)
Abstract : This talk presents a new second-order unstaggered path-conservative central-upwind scheme for ideal and shallow water MHD equations. The new scheme locally preserves the divergence-free constraint, does not rely on Riemann problem solvers, and robustly produces high-resolution and non-oscillatory results. The derivation of the scheme is based on the Godunov-Powell nonconservative modifications of the studied systems and by augmenting it with the evolution equations for the corresponding derivatives of the magnetic field components.

[01517] Geometric Quasilinearization (GQL) for Bound-Preserving Schemes of Hyperbolic PDEs

Format : Talk at Waseda University
Author(s) : Kailiang Wu (Southern University of Science and Technology)Chi-Wang Shu (Brown University)
Abstract : Solutions to many partial differential equations satisfy certain bounds or constraints. For example, the density and pressure are positive for equations of fluid dynamics, and in the relativistic case the fluid velocity is upper bounded by the speed of light, etc. As widely realized, it is crucial to develop bound-preserving numerical methods that preserve such intrinsic constraints. Exploring provably bound-preserving schemes has attracted much attention and is actively studied in recent years. This is however still a challenging task for many systems especially those involving nonlinear constraints.

Based on some key insights from geometry, we systematically propose a novel and general framework, referred to as geometric quasilinearization (GQL), which paves a way for studying bound-preserving problems with nonlinear constraints. The essential idea of GQL is to equivalently transfer all nonlinear constraints into linear ones, through properly introducing some free auxiliary variables. We establish the fundamental principle and general theory of GQL via the geometric properties of convex regions, and propose three simple effective methods for constructing GQL. We apply the GQL approach to a variety of partial differential equations, and demonstrate its effectiveness and remarkable advantages for studying bound-preserving schemes, by diverse challenging examples and applications which cannot be easily handled by direct or traditional approaches.

[01722] An improved non-hydrostatic shallow-water type model for the simulation of landslide generated tsunamis

Format : Talk at Waseda University

Author(s) : Manuel J Castro Diaz (University of Málaga)Tomas Morales de Luna (Universidad de Malaga)Cipriano Escalante Sanchez (Universidad de Málaga)Jorge Macías Sanchez (University of Málaga)Enrique D Fernandez Nieto (University of Sevilla)

Abstract : In this talk we present an improved version of a non-hydrostatic shallow-water system coupled with a granular landslide shallow-water type model for the numerical simulation of tsunamis generated by landslides. The system is discretized by means of a high-order WB finite volume scheme. Some numerical tests with laboratory experiments and real events will be presented to show the capabilities of the proposed model.

[01949] A New Approach for Designing Well-Balanced Schemes for the Shallow Water Equations

Format : Talk at Waseda University

Author(s) : Remi Abgrall (University of Zurich)Yongle Liu (University of Zurich)

Abstract : In this talk, I will introduce a new approach for constructing robust well-balanced numerical methods for one-dimensional Saint-Venant system. We combine the conservative and non-conservative formulations of the studied hyperbolic system in a natural way. The solution is globally continuous and described by a combination of point values and average values, which will be evolved by two different forms of PDEs. We demonstrate the behavior of the new scheme on a number of challenging examples.

00587 (2/2) : 2E @D401 [Chair: Alina Chertock]

[02636] Error analysis of finite volume methods for the Euler equations via relative energy

Format : Talk at Waseda University

Author(s) : Maria Lukacova (University of Mainz)Bangwei She (Capital Normal University)Yuhuan Yuan (University of Mainz)

Abstract : We present an overview of our recent results for the error analysis of some finite volume
methods for multidimensiona Euler system. To control global error, we apply the relative energy principle and
estimate the L2 norm between a numerical solution and the strong solution.

If time permits, we will present an extension to the error analysis of the random Euler system approximated
by the Monte Carlo finite volume method.

[04782] Flux Globalization Based Well-Balanced Path-Conservative Central-Upwind Schemes

Format : Talk at Waseda University

Author(s) : Alexander Kurganov (Southern University of Science and Technology)

Abstract : The talk will focus on numerical methods for nonconservative hyperbolic systems of balance laws. I will introduce well-balanced path-conservative central-upwind schemes, which are based on the flux globalization: both source and nonconservative product terms are incorporated into the global flux. The resulting quasi-conservative system is numerically solved using a semi-discrete central-upwind scheme with the numerical fluxes are evaluated using the path-conservative technique. Applications to several shallow water models will be demonstrated.

[01953] High order well-balanced and asymptotic preserving WENO schemes for the shallow water equations

Format : Online Talk on Zoom

Author(s) : Yulong Xing (Ohio State University)

Abstract : Shallow water equations (SWEs) with a non-flat bottom topography have been widely used to model flows in rivers and coastal areas. In this presentation, we will talk about the applications of high-order semi-implicit well-balanced and asymptotic preserving (AP) WENO methods to this system. We consider the Froude number ranging from O(1) to 0, which in the zero Froude limit becomes the "lake equations" for balanced flow without gravity waves. We apply a well-balanced finite difference WENO reconstruction, coupled with a stiffly accurate implicit-explicit (IMEX) Runge-Kutta time discretization. The resulting semi-implicit scheme can be shown to be well-balanced, AP and asymptotically accurate at the same time. Both one- and two-dimensional numerical results are provided to demonstrate the high order accuracy, AP property and good performance of the proposed methods in capturing small perturbations of steady state solutions.

[00589] Computational Biomedical Physics and Mechanics

Session Time & Room :

00589 (1/2) : 5B (Aug.25, 10:40-12:20) @D514

00589 (2/2) : 5C (Aug.25, 13:20-15:00) @D514

Type : Proposal of Minisymposium
Abstract : Computational methods play a fundamental role in modern science and health research. This symposium is aimed to provide a platform to get computational experts to share recent simulation efforts in areas of biomedical physics and mechanics. The topics include but are not limited to biomedical fluid dynamics, treatment planning and computational surgery, anatomical modeling from medical imaging, multi-physics modeling of biological processes, medical acoustics applied to hyperthermia and focused ultrasound therapy, ion channels/transporters study by continuum models, kinetic models and molecular dynamics.

[01471] A Multi-Scale Approach to Model K+ Permeation Through the KcsA Channel

Format : Talk at Waseda University
Author(s) : Tzyy-Leng Horng (Feng Chia University)Ren-Shiang Chen (Tunghai University)Maria Vittoria Leonardi (University of Perugia)Fabio Franciolini (University of Perugia)Luigi Catacuzzeno (University of Perugia)
Abstract : K+ channels allow a very efficient passage of K+ ions through the membrane while excluding Na+ ions, which is essential for life. The 3D structure of the KcsA K+ channel allows to address many relevant aspects of K+ permeation and selectivity mechanisms at the molecular level. Using a multi-scale approach, we studied the mechanism of K+ permeation through KcsA channels and reproduced the main permeation properties of the KcsA channel found experimentally.

[02551] Modeling electrohydrodynamic flow through a nanochannel

Format : Talk at Waseda University
Author(s) : Kumar Saurabh (National Health Research Institutes)Maxim A Solovchuk (National Health Research Institutes)
Abstract : Fluid-ion transport through a nanochannel can be described through coupled fourth order-Poisson-Nernst-Planck-Bikerman (4PNPBik) and Navier-Stokes equations. The 4PNPBik model describes ionic and nonionic interactions between particles while accounting for the effect of polarization of the medium, electrostatic correlations, solvation of ions etc. Navier-Stokes equations model the hydrodynamics of the system. Governing equations are discretized using lattice Boltzmann method on GPU. Impact of phenomenon like viscoelectric effect, finite size of particles, velocity slip, non-homogeneous diffusion etc. has been studied.

[02740] Double diffusion for nanofluid

Format : Talk at Waseda University
Author(s) : Yende Chou (National Taiwan University)Maxim A Solovchuk (National Health Research Institutes)Wei-Shien Hwang (National Taiwan University)
Abstract : In double diffusion problems, fluid is driven by temperature and concentration differences within the flow field. By adding nanoparticles into the fluid to form a nanofluid, heat transfer and mass transfer can be enhanced. This study investigates the effect of volume fraction of nanoparticles on heat and mass transfer in a three-dimensional square cavity. The governing equations for this problem are mass conservation, momentum conservation, energy conservation and mass transfer equations. The finite volume method is applied to discretize these equations. Multigrid method is developed for the solution of flow problem to improve computational efficiency.

[03003] GPU Computation of High-Intensity Focused Ultrasound Ablation Under Different Pathways

Format : Talk at Waseda University
Author(s) : Tatiana Filonets (National Taiwan University)Maxim Solovchuk (National Health Research Institutes)
Abstract : High-performance computing is important to accelerate the numerical solutions of partial differential equations which are used for modeling high-intensity focused ultrasound and temperature.
The nonlinear Westervelt equation was coupled with the bioheat equation to model temperature under ultrasound sonication. CUDA program was developed for GPU to speed up computations.
An appropriate scanning pathway can help to ablate a big tumor volume uniformly within a few minutes considering that cavitation can also affect the lesion form.

00589 (2/2) : 5C @D514

[00592] Optimization and Inverse Problems

Session Time & Room :

00592 (1/2) : 1C (Aug.21, 13:20-15:00) @A207

00592 (2/2) : 1D (Aug.21, 15:30-17:10) @A207

Type : Proposal of Minisymposium
Abstract : In an inverse problem, we want to come up with a good description of a phenomenom from bad measurements. Industrial-scale inverse problems include, in particular, medical and biological imaging, structural health monitoring, and process monitoring. Generally the inverse problem takes the form of an ill-posed operator equation, linear or nonlinear. To solve such a problem, often the problem is given a variational formulation to which regularisation is added to promote desirable solution features. The solution of the inverse problem then becomes dependent on efficient optimisation methods. The talks in this minisymposium cover recent research in the area. They present general-purpose optimisation algorithms and numerical techniques, and the application of such methods to inverse problems.

[03137] Sparsity-promoting regularization for inverse problems via statistical learning

Format : Talk at Waseda University
Author(s) : Luca Ratti (University of Bologna)Giovanni S Alberti (University of Genoa)Ernesto De Vito (University of Genoa)Tapio Helin (Lappeenranta-Lahti University of Technology)Matti Lassas (University of Helsinki)Matteo Santacesaria (University of Genoa)
Abstract : In this talk, I will discuss a strategy, based on statistical learning, to design variational regularization functionals for ill-posed linear inverse problems. The proposed approach first restricts the choice to a parametric class of functionals and then searches for the optimal regularizer inside it, combining model-based and data-driven information. I will first recap the main results in the case of generalized Tikhonov functionals, and then focus on a class of sparsity-promotion regularizers.

[03391] Online Optimization for Dynamic Electrical Impedance Tomography

Format : Talk at Waseda University
Author(s) : Jyrki Jauhiainen (University of Helsinki)Tuomo Valkonen (Escuela Politécnica Nacional)Neil Dizon (University of Helsinki)
Abstract : Online optimization generally studies the convergence of optimization methods as more data is introduced into the problem; think of deep learning as more training samples become available. We adapt the idea to dynamic inverse problems that naturally evolve in time. We introduce an improved primal-dual online method specifically suited to these problems, and demonstrate its performance on dynamic monitoring of electrical impedance tomography.

[03177] Primal-Dual Methods with Adjoint Mismatch

Format : Talk at Waseda University
Author(s) : Felix Schneppe (Technische Universität Braunschweig)
Abstract : Primal-dual algorithms are widespread methods to solve saddle-point problems of the form $\min_x \max_y G(x) + \langle Ax, y\rangle - F^*(y)$. However, in practical applications like computed tomography the adjoint operator is often replaced by a computationally more efficient approximation. This leads to an adjoint mismatch in the algorithm.
In this talk, we analyse the convergence of different primal-dual algorithms and prove conditions, under which the existence of a solution can still be guaranteed.

[02036] Material decomposition in multi-energy X-Ray tomography with Inner Product Regularizer

Format : Online Talk on Zoom
Author(s) : Salla Maaria Latva-Äijö (University of Helsinki)
Abstract : Dual-energy X-ray tomography is considered in a context where the target under imaging consists of two or more distinct materials. The materials are assumed to be possibly intertwined in space, but at any given location there is only one material present. Further, the same number of X-ray energies are chosen so that there is a clear difference in the spectral dependence of the attenuation coefficients of the materials.

A novel regularizer is presented for the inverse problem of reconstructing separate tomographic images for the two materials. A combination of two things, (a) non-negativity constraint, and (b) penalty term containing the inner product between the two material images, promotes the presence of at most one material in a given pixel. A preconditioned interior point method is derived for the minimization of the regularization functional.

Numerical tests with digital phantoms suggest that the new algorithm outperforms the baseline method, Joint Total Variation regularization, in terms of correctly material-characterized pixels. While the method is tested only in a two-dimensional setting with two materials and two energies, the approach readily generalizes to three dimensions and more materials. The number of materials just needs to match the number of energies used in imaging.

00592 (2/2) : 1D @A207 [Chair: Tuomo Valkonen]

[05012] Multiscale hierarchical decomposition methods for ill-posed problems

Format : Talk at Waseda University
Author(s) : Tobias Wolf (Klagenfurt University)Elena Resmerita (University of Klagenfurt)Stefan Kindermann (Johannes Kepler University Linz)
Abstract : The Multiscale Hierarchical Decomposition Method (MHDM) is a popular iterative method based on total variation minimization for mathematical imaging. We consider the method in a more general framework and expand existing results to the case when some classes of convex and nonconvex penalties are employed. Moreover, we discuss conditions under which the iterates of the MHDM agree with solutions of Tikhonov regularization corresponding to suitable regularization parameters. We illustrate our results with numerical examples.

[05199] Multiscale hierarchical decomposition methods for images corrupted by multiplicative noise

Format : Talk at Waseda University
Author(s) : Elena Resmerita (University of Klagenfurt)Joel Barnett (UCLA)Wen Li (Fordham University)Luminita Vese (UCLA)
Abstract : Recovering images corrupted by multiplicative noise is a well known challenging task. Motivated by the success of multiscale hierarchical decomposition methods (MHDM) in image processing, we adapt a variety of both classical and new multiplicative noise removing models to the MHDM form. Theoretical and numerical results show that the MHDM techniques are effective in several situations.

[03502] A Lifted Bregman Formulation for the Inversion of Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Xiaoyu Wang (University of Cambridge)Martin Benning (Queen Mary University of London, London)
Abstract : We propose a novel framework for the regularised inversion of deep neural networks. The framework is based on the authors' recent work on the lifted Bregman formulation on training feed-forward neural networks without the differentiation of activation functions. We propose a family of variational regularisations based on Bregman distances,

present theoretical results and support their practical application with numerical examples. In particular, we present the first convergence result (to the best of our knowledge) for the regularised inversion of a single-layer perceptron that only assumes that the solution of the inverse problem is in the range of the regularisation operator, and that shows that the regularised inverse provably converges to the true inverse if measurement errors converge to zero.

[03398] Stable Phase retrieval with mirror descent

Format : Online Talk on Zoom
Author(s) : Jean-Jacques Godeme (Normandie Univ, ENSICAEN, CNRS, GREYC, France)Jalal Fadili (Normandie Univ, ENSICAEN, CNRS, GREYC)Myriam Zerrad (Aix-Marseille Univ, CNRS, Centrale Marseille, Institut Fresnel, Marseille)Claude Amra (Aix-Marseille Univ, CNRS, Centrale Marseille, Institut Fresnel, Marseille)
Abstract : We aim to reconstruct an n-dimensional real vector from m phaseless measurements corrupted by additive noise. We use the mirror descent (or Bregman gradient descent) algorithm to deal with noisy measurements and prove that the procedure is robust to (small enough) noise.

[00593] Advances in Nonlinear Dynamics

Session Time & Room :

00593 (1/3) : 1C (Aug.21, 13:20-15:00) @F308

00593 (2/3) : 1D (Aug.21, 15:30-17:10) @F308

00593 (3/3) : 1E (Aug.21, 17:40-19:20) @F308

Type : Proposal of Minisymposium
Abstract : The aim of dynamical systems theory is to understand the long term behavior of large sets of initial conditions, often
for highly nonlinear models coming from realistic application problems. Due to the importance of nonlinear models, numerical calculations have long played an important role. In this session we bring together experts to discuss problems at the frontiers of our understanding. Some talks will focus on new computational methods, some on attempts to understand more and more realistic models, and some on theoretical issues which inform our approach to computational dynamics.

[02779] Polynomial discretisations of transfer and Koopman operators in chaotic dynamics

Author(s) : Caroline Wormell (The Australian National University)
Abstract : Many long-term statistical properties of chaotic systems are encoded by transfer or Koopman operators. Orthogonal polynomial-based operator discretisations are generally very efficient, and I will show in expanding dynamics these operators are no exception: a Chebyshev discretisation allows fast, very accurate, rigorous estimates of expanding dynamics, even with parabolic fixed points. Furthermore, a theoretical extension to general orthogonal polynomials proves fast convergence of Extended Dynamical Mode Decomposition, a data-driven algorithm commonly used across physical sciences.

[03719] Estimating the spectra for annealed transfer operators of random dynamical systems

Author(s) : Alex Blumenthal (Georgia Tech)Isaia Nisoli (Universidade Federal de Rio de Janeiro)Toby Taylor-Crush (University of Loughborough)
Abstract : I will describe some recent efforts with my collaborators Toby Taylor-Crush and Isaia Nisoli towards the computer-validated estimation of spectra for annealed transfer operators of random dynamical systems. Applications include the study of various stochastic bifurcations associated to the explosion of the support of a stationary measure as some underlying parameter is varied.

[03734] Energy growth in Hamiltonian systems with small dissipation

Author(s) : Marian Gidea (Yeshiva Univesity)
Abstract : We consider a model for an energy harvesting device consisting of a rotator and a pendulum subject to a small perturbation given by a time-periodic Hamiltonian vector field plus a conformally symplectic vector field. In general, the system has energy dissipation. We provide explicit conditions so that the system exhibits energy growth. In theory, this shows Arnold diffusion in Hamiltonian systems with small dissipation. In practice, this translates into continuous generation of electricity.

[03874] A dynamical systems approach to low-damage seismic design

Author(s) : Hinke M Osinga (University of Auckland)
Abstract : An example of low-damage seismic design is the post-tensioned moment-resisting frame, which exhibits geometric nonlinearity under large deformations. Whether the tilt angle of the frame exceeds a prescribed maximum depends on the forcing properties. We show that this failure boundary is organised by so-called grazing orbits, which reach but do not move beyond the design limit of the frame. We consider both harmonic and aperiodic waves with a broader frequency content.

00593 (2/3) : 1D @F308

[03886] Understanding how blenders emerge: weaving a carpet from global manifolds

Author(s) : Dana C'Julio (University of Auckland)Bernd Krauskopf (University of Auckland)Hinke M Osinga (University of Auckland)
Abstract : A blender is a tool for constructing `wild' robust chaotic dynamics in partially hyperbolic systems. We make precise statements about how a blender emerges in a family of 3D Hénon-like maps as parameters are changed. To this end, we employ advanced numerical techniques to determine when the one-dimensional stable manifolds of two saddle points weave through phase space to form an impenetrable carpet, which is the characterising property of a blender.

[03948] A Dynamical Systems Approach for Most Probable Escape Paths over Periodic Boundaries

Author(s) : Emmanuel Fleurantin (George Mason University, University of North Carolina at Chapel Hill)Katherine Slyman (University of North Carolina at Chapel Hill)Blake Barker (Brigham Young University)Christopher K.R.T. Jones (George Mason University, University of North Carolina at Chapel Hill)
Abstract : Analyzing when noisy trajectories, in the two dimensional plane, of a stochastic dynamical system exit the basin of attraction of a fixed point is specifically challenging when a periodic orbit forms the boundary of the basin of attraction. Our contention is that there is a distinguished Most Probable Escape Path (MPEP) crossing the periodic orbit which acts as a guide for noisy escaping paths in the case of small noise slightly away from the limit of vanishing noise. It is well known that, before exiting, noisy trajectories will tend to cycle around the periodic orbit as the noise vanishes, but we observe that the escaping paths are stubbornly resistant to cycling as soon as the noise becomes at all significant. Using a geometric dynamical systems approach, we isolate a subset of the unstable manifold of the fixed point in the Euler-Lagrange system, which we call the River. Using the Maslov index we identify a subset of the River which is comprised of local minimizers. The Onsager-Machlup (OM) functional, which is treated as a perturbation of the Friedlin-Wentzell functional, provides a selection mechanism to pick out a specific MPEP. Much of this talk will be focused on the system obtained by reversing the van der Pol Equations in time (so-called IVDP). Through Monte-Carlo simulations, we show that the prediction provided by OM-selected MPEP matches closely the escape hatch chosen by noisy trajectories at a certain level of small noise.

[04096] On the connectedness and disconnectedness of the Julia set for the Hénon map.

Author(s) : Zin Arai (Tokyo Institute of Technology)
Abstract : We discuss the connectedness and disconnectedness of the Julia set for the complex Hénon map. To prove the disconnectedness of the Julia set, we develop a topological method that uses the plurisubharmonic nature of the Green function. We also construct a hyperbolic complex Hénon map with a connected Julia set. Consequently, we obtain a certain topological property of the connectedness locus of the map. This is a joint work with Yutaka Ishii (Kyushu Univerisity).

[04135] Standard piecewise smooth symplectic maps

Author(s) : Vered Rom-Kedar (The Weizmann Institute)Michal Pnueli (The Weizmann Institute)Alexandra Zobova (The Weizmann Institute)

Abstract : Return maps of near integrable/near quasi-integrable Hamiltonian impact systems are shown to produce piecewise smooth symplectic maps. In the integrable/quasi-integrable limit, these maps reduce to piecewise smooth families of rotations/interval exchange maps. As for the standard map, we introduce simplified models for these return maps and study their dynamics numerically. Regular and singular resonances emerge, as well as transient behavior, leading to conjectures regarding the non-existence of dividing circles in the singularity bands.

00593 (3/3) : 1E @F308

[04300] Optimal linear response for expanding circle maps

Author(s) : Gary Froyland (UNSW Sydney)Stefano Galatolo (University of Pisa)

Abstract : We consider the problem of optimal linear response for deterministic expanding maps of the circle. To each infinitesimal perturbation of a circle map we consider the response of the expectation of an observation function, and the response of isolated spectral points of the transfer operator. Under mild conditions on the set of feasible perturbations we show there is a unique optimal perturbation. We derive expressions for the unique optimum, and devise a Fourier-based computational scheme.

[04937] Finite element approximated manifolds for PDEs by the parameterization method

Author(s) : Jorge Gonzalez (Georgia Tech)Jason Desmond Mireles James (Florida Atlantic University)Necibe Tuncer (Florida Atlantic University)

Abstract : The computation of invariant manifolds for PDEs is significantly challenging over irregular high dimensional domains where the classical Fourier methods are not applicable. This work presents a new framework of interest for practical applications that combines the parameterization method with the classical finite element method. We implement the method for a variety of examples having both polynomial and non-polynomial nonlinearities, on non-convex and not necessarily simply connected polygonal domains.

[05240] Dynamics of a Hill four-body problem with oblate bodies

Author(s) : Wai Ting Lam (Florida Atlantic University)

Abstract : Consider a restricted four body problem with three oblate massive bodies, which are assumed to move in a plane under their mutual gravity, and an infinitestimal fourth body to move in the 3-dimensional space under the gravitational influence of the three heavy bodies, but without affecting them. By performing Hill approximation, we study the dynamics and properties of the infinitesimal body in a neighborhood of the smaller body.

[05259] Parametrisation method for large finite element models of engineering structures

Author(s) : Alessandra Vizzaccaro (University of Exeter)Andrea Opreni (Politecnico di Milano)Giorgio Gobat (Politecnico di Milano)Attilio Alberto Frangi (Politecnico di Milano)Cyril Touze' (ENSTA Paris)

Abstract : In this contribution we present a method to directly compute asymptotic expansion of invariant manifolds of large finite element models from physical coordinates and their reduced order dynamics on the manifold. The focus of hte talk is on engineering structures, whose spectrum around the fixed point is usually composed of complex conjugate pair of eigenvalues with always negative but small real part. This gives rise to rich dynamical behaviour such as internal resonances, parametric resonances, and superharmonic resonances. The accuracy of the reduction on the slow invariant manifold will be shown on selected examples.

[00595] Combinatorial topological dynamics

Session Time & Room :

00595 (1/3) : 5B (Aug.25, 10:40-12:20) @G802

00595 (2/3) : 5C (Aug.25, 13:20-15:00) @G802

00595 (3/3) : 5D (Aug.25, 15:30-17:10) @G802

Type : Proposal of Minisymposium

Abstract : Recent years have seen the rapid development of topological data analysis. Via combinatorial modeling of space, TDA enables the study of the geometry of data using persistent homology. In particular, it may be used to analyze the phase space of a sampled dynamical system, thereby providing a static image. To get a dynamic view, a better understanding of classical topological tools in dynamics in the context of data is needed. The aim of this session is to bring together researchers from TDA and dynamical systems to study dynamic aspects of data via topological tools, in particular Morse and Conley theory.

[05133] Analyzing Network Representations of Dynamical Systems Using Persistent Homology

Format : Online Talk on Zoom

Author(s) : Elizabeth Munch (Michigan State University)

Abstract : Persistent homology, the flagship method of topological data analysis, can be used to provide a quantitative summary of the shape of data. One way to pass data to this method is to start with a finite, discrete metric space (whether or not it arises from a Euclidean embedding) and to study the resulting filtration of the Rips complex. In this talk, we will discuss several available methods for turning a time series into a discrete metric space, including the Takens embedding, and ordinal partition networks. Combined with persistent homology and machine learning methods, we show how this can be used to classify behavior in time series in both synthetic and experimental data.

[01382] Topological Data Analysis of Spatiotemporal Honeybee Aggregation

Format : Online Talk on Zoom

Author(s) : Elizabeth Bradley (University of Colorado)Chad Topaz (Williams College)Golnar Gharooni Fard (University of Colorado)Varad Deshmukh (University of Colorado)Orit Peleg (University of Colorado)Morgan Byers (University of Colorado)

Abstract : We employ topological data analysis to explore honeybee aggregations in the context of trophallaxis: the exchange of food among nestmates. Using synthetic and laboratory data, we build topological summaries called CROCKER plots to capture the shape of the data as a function of both scale and time. Our results show two distinct regimes corresponding to successive dynamical regimes: a dispersed phase before the food is introduced, followed by a food-exchange phase in which clusters form.

[03128] What does Multivector Fields Theory have to offer?

Format : Talk at Waseda University

Author(s) : Michał Lipiński (Polish Academy of Sciences)

Abstract : The theory of Multivector Fields (MVF) is a generalization of Forman vector fields. It has been continuously developed since 2017. MVF theory is equipped with a number of fundamental dynamical concepts and matures into a useful combinatorial model for classical vector fields. In the talk I will present the general idea of the MVF theory, its suitability for the analysis in the spirit of topological data analysis, and its usefulness in understanding continuous dynamical systems.

[03410] A Persistence-like Algorithm for Computing Connection Matrices Efficiently

Format : Talk at Waseda University

Author(s) : Tamal Krishna Dey (Purdue University)

Abstract : Connection matrices are a generalization of Morse boundary operators from the classical Morse theory for gradient vector fields. Developing an efficient computational framework for connection matrices is particularly important in the context of a rapidly growing data science that requires new mathematical tools for discrete data. Toward this goal, the classical theory for connection matrices has been adapted to combinatorial frameworks that facilitate computation. We develop an efficient persistence-like algorithm to compute a connection matrix from a given combinatorial (multi) vector field on a simplicial complex. This algorithm requires a single-pass, improving upon a known algorithm that runs an implicit recursion executing two-passes at each level. Overall, the new algorithm is more

simple, direct, and efficient than the state-of-the-art. Because of the algorithm's similarity to the persistence algorithm, one may take advantage of various software optimizations from topological data analysis.

This is a joint work with Michal Lipinski, Marian Mrozek, and Ryan Slechta

---

00595 (2/3) : 5C @G802 [Chair: Thomas Wanner]

[04935] A combinatorial/homological framework for continuous nonlinear dynamics

Format : Talk at Waseda University
Author(s) : Konstantin Mischaikow (Rutgers University)
Abstract : Computational science and data-driven science suggests the importance of having finite models of dynamics. This raises three questions: 1. How to go from data to appropriate combinatorial models of dynamics. 2. What computations should be performed on these combinatorial models. 3. How to translate the output from the combinatorial models to structures associated with continuous systems. In this talk we will discuss our attempts to provide a coherent approach to addressing these questions.

[04988] Computing the Global Dynamics of Parameterized Systems of ODEs

Format : Talk at Waseda University
Author(s) : Marcio Gameiro (Rutgers University)
Abstract : We present a combinatorial topological method to compute the dynamics of a parameterized family of ODEs. A discretization of the state space of the systems is used to construct a combinatorial representation from which recurrent versus non-recurrent dynamics are extracted. Algebraic topology is then used to validate and characterize the dynamics of the system. We will discuss the combinatorial description and the algebraic topological computations and will present applications to systems of ODEs arising from gene regulatory networks.

[04981] Combinatorics and Topology for Understanding Global Dynamics in Multi-Scale Systems.

Format : Talk at Waseda University
Author(s) : Ewerton Rocha Vieira (Rutgers University)
Abstract : This talk introduces a new approach to analyzing time-varying systems with multi-scale dynamics, which can be challenging due to poorly measured parameters and numerous variables. Traditionally, these systems are modeled using ordinary differential equations (ODE), but this approach can be difficult to apply directly. The proposed approach is based on combinatorics and algebraic topology, and focuses on describing global dynamics in terms of annotated graphs (Morse graphs) and Conley complexes. The method is based on piecewise linear models and offers a more robust, scalable, and computable description of dynamics than classical ODE analysis, with formal mathematical guarantees that extend to a class of ODE with steep sigmoidal nonlinearities. This approach is particularly useful for modeling complex systems, such as biological systems.

[04843] On the identification of cycling motion using topological tools

Format : Talk at Waseda University
Author(s) : Ulrich Bauer (Technical University of Munich)David Hien (Technical University of Munich)Oliver Junge (Technical University of Munich)Konstantin Mischaikow (Rutgers University)
Abstract : Nonlinear dynamical systems often exhibit complicated recurrent behaviour. We propose to decompose recurrent sets into elementary oscillations and the connections between them. To this end, we use topological tools that are flexible enough to be computed from data while still providing a comprehensive description of the oscillations. We demonstrate this through several examples. In particular, we identify and analyze 6 oscillations in a 4d hyperchaotic attractor.

00595 (3/3) : 5D @G802 [Chair: Marian Mrozek]

[03335] Morse-Smale quadrangulations and persistence of vector fields

Format : Talk at Waseda University
Author(s) : Claudia Landi (Università di Modena e Reggio Emilia)Clemens Luc Bannwart (Università di Modena e Reggio Emilia)
Abstract : The goal of this talk is to introduce a persistence barcode for discrete gradient vector fields defined on a combinatorial 2-manifold. The main ingredient is a decomposition of the manifold into quadrangle regions with vertices ordinately given by sinks, saddles, sources, and saddles. We will consider a bottleneck distance and an interleaving distance for such barcodes and we will present results about their stability.

[04607] On the dynamics of the combinatorial model of the real line

Format : Online Talk on Zoom
Author(s) : Pedro J. Chocano (Rey Juan Carlos University)
Abstract : In this talk, we describe the dynamics that appear when we consider a discrete dynamical system defined on the combinatorial model of the real line. Particularly, we show that there are no periodic points of period greater than or equal to 3, which contrasts with the classical setting (Sharkovski theorem). This fact motivates us to introduce multivalued maps to get richer dynamics than the ones obtained from single valued maps. To conclude we provide some examples.

[04886] Topological Inference of the Conley Index

Format : Online Talk on Zoom
Author(s) : Vidit Nanda (University of Oxford)Ka Man Yim (University of Oxford)
Abstract : The Conley index of an isolated invariant set is a fundamental object in the study of dynamical systems. Here we consider smooth functions on closed submanifolds of Euclidean space and describe a framework for inferring the Conley index of any compact, connected isolated critical set of such a function with high confidence from a sufficiently large finite point sample. The main construction of this paper is a specific index pair which is local to the critical set in question. We establish that these index pairs have positive reach and hence admit a sampling theory for robust homology inference. This allows us to estimate the Conley index, and as a direct consequence, we are also able to estimate the Morse index of any critical point of a Morse function using finitely many local evaluations.

[05010] Analysis of solids regarded as compositions of discrete entities

Format : Online Talk on Zoom
Author(s) : Andrey Jivkov (The University of Manchester)
Abstract : In contrast with the idealisation of materials as continua, their internal structures are regarded here as polyhedral complexes. One approach to formulate conservation laws of scalar (mass, energy, charge) and vector (linear and angular momentum) quantities on such complexes is presented. It uses combi-natorial differential forms, representing physical quantities, and operations with such forms (exterior derivatives, exterior products, and codifferentials), describing processes and conservations. The derived conservation laws are background independent.

[00598] Hyperplane arrangements and enumerative problems

Session Time & Room : 2C (Aug.22, 13:20-15:00) @A617

Type : Proposal of Minisymposium
Abstract : Hyperplane arrangements appear in many areas of mathematics, including topology, combinatorics, algebraic geometry. One of the important aspects is that hyperplane arrangements have several discrete structures e.g., poset of intersections, chambers, lattice points. Enumerations of these objects play crucial roles in many problems, e.g., enumerative problems, coding theory. In this minisymposium, we focus on enumerative aspects of these objects.
Organizer(s) : Masahiko Yoshinaga, Norihiro Nakashima
Classification : 52C35, 05C31
Minisymposium Program :

00598 (1/1) : 2C @A617 [Chair: Takuro Abe]

[01887] Coboundary polynomial and related polynomial invariants

Format : Talk at Waseda University
Author(s) : Norihiro Nakashima (Nagoya Institute of Technology)
Abstract : The coboundary polynomial is a polynomial computed by all characteristic polynomials for restriction arrangements to all flats in the intersection poset. It is known that the coboundary polynomial is essentially the same as the weight enumerator and Tutte polynomial. In this talk, we introduce some known results about these relationship and future issues.

[01889] Generalizations of Tutte-Grothendieck polynomials

Format : Talk at Waseda University
Author(s) : Tsuyoshi Miezaki (Waseda University)HIMADRI SHEKHAR CHAKRABORTY (Shahjalal University of Science and Technology)CHONG ZHENG (Waseda University)
Abstract : A Tutte-Grothendieck polynomial is a graph invariant that satisfies a generalized deletion-contraction formula. In this talk, we introduce the notion of weighted Tutte-Grothendieck polynomial and weighted Tutte-Grothendieck invariant for matroid and discuss some of its properties. Moreover, we show that the weighted Tutte-Grothendieck invariant is stronger than the Tutte-Grothendieck invariant. This is joint work with Himadri Chakraborty (SUST) and Chong Zheng (Waseda University).

[01791] Characteristic quasi-polynomials of arrangements over algebraic integers

Format : Talk at Waseda University
Author(s) : Shuhei Tsujie (Hokkaido University of Education)
Abstract : Kamiya, Takemura, and Terao initiated the theory of the characteristic quasi-polynomial of an integral arrangement, which is a function counting the elements in the complement of the arrangement modulo positive integers.
In this talk, we will discuss arrangements over the rings of integers of algebraic number fields.

[01780] Counting the regions of hyperplane arrangements related to Coxeter arrangements.

Format : Online Talk on Zoom
Author(s) : Yasuhide Numata (Hokkaido University)
Abstract : We consider the Shi and Ish arrangement of type B_n. Both are hyperplane arrangements in the real vector space of dimension n containing the Coxeter arrangement of type B_n. We discuss combinatorial objects which parametrize the regions, i.e. connected components of complement of the arrangement, of these arrangement.

[00603] Mean field stochastic control problems and related topics

Session Time & Room : 1C (Aug.21, 13:20-15:00) @E502

Type : Proposal of Minisymposium
Abstract : Mean-field (or, McKean-Vlasov) SDEs have been studied for a long time and have found lots of applications in different domains. Recently, with their pioneering seminal papers (2006-2007) on mean-field games and their applications in economics, finance and game theory, Lasry and Lions have given new impulses to this research topic, opened the way to new applications and attracted lots of researchers to this topic. One of these applications is the study of mean-field stochastic optimal control problems. In our symposium we will study the viability property for controlled mean-field flows, the mass-conserving SPDE coming from spatial mean-field term, etc.
Organizer(s) : Juan Li
Classification : 60H10, 60K35, 93E03
Minisymposium Program :

00603 (1/1) : 1C @E502

[01320] Stochastic maximum principle for weighted mean-field system

Format : Talk at Waseda University
Author(s) : Jie Xiong (Southern University of Science and Technology)
Abstract : We study the optimal control problem for a weighted mean-field system. A new feature of the control problem is that the coefficients depend on the state process as well as its weighted measure and the control variable. By applying variational technique, we establish a stochastic maximum principle. Also, we establish a sufficient condition of optimality. As an application, we investigate the optimal premium policy of an insurance firm for asset–liability management problem. This talk is based on a joint paper with Yanyan Tang.

[00653] The mass-conserving stochastic partial differential equaton coming from spatial mean-field term

Format : Talk at Waseda University
Author(s) : Qi Zhang (Fudan University)
Abstract : In this talk, I will introduce our study about the mass-conserving stochastic partial differential equaiton. It is a kind of equation with spacial mean-field term such that its solution satisfies a mass-conservative property. We prove the existence and uniqueness of solution, and then construct a stationary solution by the nonlinear Feynman-Kac formula under Lipschitz assumption. Moreover, the existence of solution in the non-Lipschitz case is considered.

[01321] A quadratic mean-field BSDE with its applications

Format : Talk at Waseda University
Author(s) : Huilin Zhang (Shandong University)
Abstract : In this talk I will introduce the well-posedness of a quadratic mean-field BSDE.
Moreover we show its several applications, in particular in the utility theory.

[01324] Mean field stochastic control under sublinear expectation

Format : Talk at Waseda University
Author(s) : Juan Li (Shandong University)
Abstract : In this talk we study Pontryagin's stochastic maximum principle for a mean-field optimal control problem under Peng's G-expectation. The dynamics of the controlled state process is given by a SDE driven by a G-Brownian motion, whose coefficients depend not only on the control, the controlled state process but also on its law under the G-expectation. Also the associated cost functional is of mean-field type. We give a necessary optimality condition for control processes, and also a sufficient one. The main difficulty which we have to overcome in our work consists in the differentiation of the G-expectation of parameterized random variables.
Based on joint work with Rainer Buckdahn (UBO, France), Bowen He (SDU, China).

[00604] Frontiers of Collaboration with Industry: Towards International Mathematical Commons

Session Time & Room :

00604 (1/2) : 3C (Aug.23, 13:20-15:00) @G301

00604 (2/2) : 3D (Aug.23, 15:30-17:10) @G301

Type : Proposal of Industrial Minisymposium
Abstract : This mini-symposium introduces the forefront of various organizational initiatives aimed at mathematical research and educational institutions around the world using the power of mathematics for solving industrial problems, including activities to provide a basic environment and to promote the building of relationships with industry. By sharing not only the outputs but also various issues and solutions conducted through these activities with participants, we expect to contribute to the formation of an international platform, a mathematical common, where mathematicians, together with industry, can overcome the myriad of difficulties our society must confront.
Organizer(s) : Kenji Kajiwara, Takashi Sakajo, Hiroshi Suito
Classification : 00A05, 00A06, 00A69, 00A71, 00A72
Minisymposium Program :

00604 (1/2) : 3C @G301 [Chair: Takashi Sakajo]

[01978] The UniSA Mathematics Clinic: How to build a work-integrated-learning ecosystem

Format : Talk at Waseda University
Author(s) : Lesley Ann Ward (University of South Australia)
Abstract : The University of South Australia Mathematics Clinic runs yearlong authentic industry-sponsored research projects for small teams of final-year undergraduate mathematics students. I will outline how to build the necessary commitment and structure for such a programme, touching on curriculum; articulation with other mathematics courses;

coaching students in professional skills and leadership roles; pitching and recruitment of industry sponsors; engaging students and academic staff; intellectual property, confidentiality, and contracts; and scoping and development of suitable projects.

[02932] Industrial Student Research Programs and Industry Connections at IPAM

Format : Talk at Waseda University
Author(s) : Christian Ratsch (UCLA)
Abstract : The goal of the Institute for Pure and Applied Mathematics (IPAM) is to foster the interaction of mathematics with a broad range of science and technology. In this talk I will review and discuss some of the IPAM activities that are used to fulfill this goal. I will discuss the Research in Industrial Projects for Students (RIPS) program, where undergraduate students work in teams on projects that have been sponsored by an industrial partner.

[01963] Development of Mathematics for Industry in Japan: New Research Area, Education and Platform

Format : Talk at Waseda University
Author(s) : Kenji Kajiwara (Institute of Mathematics for Industry, Kyushu University)
Abstract : In this talk, we exhibit activities of "Mathematics for Industry" (MfI) in Japan, initiated by the Institute of Mathematics for Industry(IMI), Kyushu University founded in 2011. MfI intends to develop a new research area of mathematics formed by responding to the needs of industries associated with various relevant activities such as education and network/platform formed by mathematicians and mathematical institutes. We present various challenges to realizing the idea of MfI in Japan.

[01984] APCMfI and International Mathematical Commons for Asia Pacific region

Format : Online Talk on Zoom
Author(s) : Zainal Abdul Aziz (Universiti Teknologi Malaysia)
Abstract : In order to facilitate Mathematics for Industry-MfI within the platform of International Mathematical Commons for Asia Pacific region i.e., encompassing academia, industrial, government and communal sectors; then APCMfI have to implement more effective mechanisms. These include fostering Asia Pacific Study Groups with Industry, proposing Centres of MfI-based in Universities, establishing Asia Pacific Networks, promoting National Networks, supporting Conferences and Workshops on Industrial Problems, Student Programmes and Modelling Camps, Internships and Industry/Academia Exchanges and Consultancy.

00604 (2/2) : 3D @G301 [Chair: Kenji Kajiwara]

[01944] European Consortium for Mathematics in Industry - research and education

Format : Talk at Waseda University
Author(s) : Alessandra Micheletti (Università degli Studi di Milano)
Abstract : The European Consortium for Mathematics in Industry (ECMI) is a consortium of academic institutions and industrial companies that acts co-operatively to promote and support the use of mathematical modelling, simulation, and optimization in any activity of social or economic importance. ECMI is devoted to research motivated by industrial problems and education of Industrial Mathematicians to meet the growing demand for such experts. In this talk we will present an overview of ECMI activities in research, education and international cooperation.

[01965] EU-MATHS-IN OpenDesk. Un infrastructure to boost industry's competitiveness.

Format : Online Talk on Zoom
Author(s) : Manuel Cruz (EU-MATHS-IN OpenDesk; LEMA-ISEP | Instituto Superior de Engenharia do Porto)Véronique Maume-Deschamps (EU-MATHS-IN OpenDesk; Université Claude Bernard Lyon 1 | Institut Camille Jordan)Peregrina Quintela Estévez (EU-MATHS-IN OpenDesk; CITMAga)Alexander Scherrer (EU-MATHS-IN OpenDesk; Fraunhofer Institute for Industrial Mathematics ITWM)Antonino Sgalambro (EU-MATHS-IN OpenDesk; Sheffield University Management School; National Research Centre of Italy)Janusz Szwabinski (EU-MATHS-IN OpenDesk; Wrocław University of Science and Technology)
Abstract : The EU-MATHS-IN OpenDesk is a one-stop-shop aimed to make companies more competitive through mathematical technologies (MSODE). It facilitates the access to the best European technology transfer centres and

coordinates the looking for the most appropriate partners to solve the current challenges.
In this talk, the main points of interest of the OpenDesk will be introduced as well as its main services and procedures.

[02986] mathematics in the society: rethinking its role, one graduate student at a time.

Format : Online Talk on Zoom
Author(s) : yuliy baryshnikov (UIUC)
Abstract : Each year, a wave of new PhD in mathematics graduate. Statistically just about half of them will find a position in academia. How are we preparing the rest to the increasingly important role the mathematicians play in the modern society?

In this talk I will present some observations and experiences from perspectives of both academic and industrial research departments.

[05594] A Knowledge Exchange Hub for the Mathematical Sciences

Format : Online Talk on Zoom
Author(s) : Ulrike Tillmann (Isaac Newton Institute)
Abstract : An influential 2018 review of knowledge exchange (KE) in the mathematical sciences in the UK called for an improved infrastructure at national level. Five years later, we report on the journey towards a KE-Hub, its vision and ambitions. An important part of the journey was the award winning Virtual Forum for KE in the Mathematical Sciences (V-KEMS) set-up during the pandemic.

[00605] Recent advances in theory and application of quantum computing technology

Session Time & Room :

00605 (1/3) : 4C (Aug.24, 13:20-15:00) @D405

00605 (2/3) : 4D (Aug.24, 15:30-17:10) @D405

00605 (3/3) : 4E (Aug.24, 17:40-19:20) @D405

Type : Proposal of Minisymposium
Abstract : There are great expectations for quantum computing, and various efforts are being made to develop its hardware and software.
However, its scale is currently inferior, and the discrepancy is enormous compared to the high-performance computing (HPC) field.
Quantum annealing also still has many challenges in its application to practical problems.
Basic research on quantum computers is expected to develop further in the future.
In this minisymposium, we present research on quantum computing technology, especially the theory and practice of quantum annealing.
The implementations of quantum annealing will be covered both quantum annealers and quantum-inspired annealers.
Organizer(s) : Tomohiro Suzuki
Classification : 81-10, 81P68, Quantim annealing
Minisymposium Program :

00605 (1/3) : 4C @D405 [Chair: Kazuhiko Komatsu]

[03620] QUBO encoding of inequality constraints in Quantum Minimum Fill-in algorithm

Format : Talk at Waseda University
Author(s) : Tomoko Komiyama (University of Yamanashi)Tomohiro Suzuki (University of Yamanashi)
Abstract : Expressing constraints with complex conditions in terms of inequalities in solving optimization problems is common. When solving problems with quantum annealing, inequality constraints must be transformed into an unconstrained quadratic form that does not contain inequalities. There are various methods for this transformation,

which vary in the number of auxiliary variables to be added and the total number of solutions that will be optimal. We compare these transformation methods and discuss which is suitable for quantum annealing.

[02807] Approximate block diagonalization of symmetric matrices using a quantum annealing

Format : Talk at Waseda University
Author(s) : Koshi Teramoto (The University of Electro-Communications)Masaki Kugaya (The University of Electro-Communications)Shuhei Kudo (The University of Electro-Communications)Yusaku Yamamoto (The University of Electro-Communications)
Abstract : Approximate block diagonalization is an efficient preprocessing technique for accelerating the block Jacobi method to solve the symmetric eigenvalue problem.
The aim of this study is to speed up this process using quantum annealing.
To achieve this, we formulated it as a combinatorial optimization problem and expressed it in Quadratic Unconstrained Binary Optimization (QUBO) that can be dealt with by D-Wave's quantum annealing system.
Numerical experiments on small matrices using D-Wave Advantage show that optimal approximate block diagonalization that minimizes the off-diagonal norm can be obtained with high probability.

[03304] Performance evaluation of quantum-inspired machine and quantum simulator

Format : Talk at Waseda University
Author(s) : Makoto Morishita (Nagoya University)Takahiro Katagiri (Nagoya University)Satoshi Ohshima (Kyusyu University)Tetsuya Hoshino (Nagoya University)Toru Nagai (Nagoya University)
Abstract : The purpose of this research is to construct a heterogeneous environment in which next-generation computers that quantum computers are equipped as an accelerator specialized for specific calculations (e.g., solving QUBO).
The performance of annealing-base and gate-base by benchmarks is evaluated as a preliminary result. In particular, we evaluated the performance of solving QUBO by the annealing-base such as digital annealers, and by the gate-base of quantum circuits implementing QAOA.
Hyperparameters such as coefficients of constraint terms appearing in the QUBO formula, and the number of unitary gates in QAOA, are tuned by utilizing Optuna in our experiment.

[03892] Use of digital annealer for HPC applications

Format : Talk at Waseda University
Author(s) : Masatoshi kawai (Nagoya University)
Abstract : In some high-performance applications, combinatorial optimization problems (COPs) are solved in unique methods. However, solving these COPs with more constraint conditions and complex evaluation functions may improve the performance of the applications. In this study, we discuss the performance improvement obtained by using Digital Annealing to solve the complex COPs derived from lattice H-matrices with dynamic load balancing and the parallelized incomplete Cholesky conjugate gradient method using a multi-coloring technique.

00605 (2/3) : 4D @D405 [Chair: Tomohiro Suzuki]

[04414] Performance Evaluation of Ising Machines using Constraint Combinatorial Optimization Problems

Format : Talk at Waseda University
Author(s) : Kazuhiko Komatsu (Tohoku University)Makoto Onoda (Tohoku University)Masahito Kumagai (Tohoku University)Hiroaki Kobayashi (Tohoku University)
Abstract : Ising machines have been developed rapidly by various implementations. However, the characteristics of Ising machines have not been clarified yet because a unified evaluation method and commonly used benchmark program for Ising machines have not been established.
This research evaluates various Ising machines using constraint combinatorial optimization problems. Through the evaluation, the characteristics of Ising machines are clarified.

[04218] Nonnegative binary matrix factorization by continuous relaxation and reverse annealing

Format : Talk at Waseda University
Author(s) : Renichiro Haba (Tohoku University)Masayuki Ohzeki (Tohoku University)Kazuyuki Tanaka (Tohoku University)
Abstract : In this talk, we introduce a reverse annealing framework with relaxation strategies for nonnegative/binary matrix factorization, a feature extraction technique. Reverse annealing is one of the quantum annealing techniques and its specific usage has not been well explored. Experimental results reveal performance comparable to exact optimization methods, indicating the potential for expanding the applicability of reverse annealing.

[03976] Kernel learning by quantum annealer

Format : Talk at Waseda University
Author(s) : Yasushi Hasegawa (Tohoku University)Hiroki Oshiyama (Tohoku University)Masayuki Ohzeki (Tohoku University)
Abstract : Kernel methods are powerful in machine learning. It is known that shift-invariant kernels can be represented by Fourier transformation of a probability distribution of frequencies. Recently the method called Implicit Kernel Learning is proposed, which learns the probability distribution according to the given data by generative model.
We developed a new method that uses quantum annealing as a sampler to train Boltzmann machines for the probability distribution. We demonstrate our method by using D-Wave quantum annealer.

00605 (3/3) : 4E @D405 [Chair: Takahiro Katagiri]

[03609] mpiQulacs: A Distributed Quantum Computer Simulator for A64FX-based Cluster Systems

Format : Talk at Waseda University
Author(s) : Masafumi Yamazaki (Fujitsu LTD.)Satoshi Imamura (Fujitsu LTD.)Takumi Honda (Fujitsu LTD.)Akihiko Kasagi (Fujitsu LTD.)Akihiro Tabuchi (Fujitsu LTD.)Hiroshi Nakao (Fujitsu LTD.)Naoto Fukumoto (Fujitsu LTD.)Kohta Nakashima (Fujitsu LTD.)
Abstract : Quantum computer simulators running on classical computers are essential for understanding real quantum states and developing emerging quantum applications. In particular, state-vector simulators, which store the complete state vector in memory can be used to analyze the behavior of all types of quantum applications.
Here, we briefly introduce a distributed state-vector simulator and describe its distributed implementation and optimization. Finally, we present the scaling performance of the large-scale simulation using an A64FX-based cluster system.

[04257] Examples of application of CMOS annealing

Format : Talk at Waseda University
Author(s) : Akiko Masaki (Hitachi, Ltd.)Kaho Takahashi (Hitachi, Ltd.)Kazuo Ono (Hitachi, Ltd.)Taro Aratani (National Institute of Maritime, Port and Aviation Technology)Takahiro Majima (National Institute of Maritime, Port and Aviation Technology)
Abstract : Hitachi has developed CMOS annealing technology as a next-generation computing technology that can solve large-scale, complex optimization problems at high speed.
In this talk, we will introduce some examples of practical applications of CMOS annealing technology. In particular, we will present examples of applications that are proving effective in the field of public infrastructure, where there are large-scale problems that cannot be solved by conventional computing technologies.

[04116] Outline and present development status of CMOS annealing

Format : Talk at Waseda University
Author(s) : Masanao Yamaoka (Hitachi, Ltd.)
Abstract : Today, optimization processing is important for various fields. The CMOS annealing technology, which is a new-paradigm computing technology inspired by quantum computers, was developed to accelerate the optimization processing for the new value creation. By utilizing semiconductor technology, CMOS annealing can achieve large-scale integration and can be easily implemented for the practical usage. In this talk, the outline of CMOS annealing will be introduced with some examples of actual applications as a present development status.

[00607] Analysis and computation of interface evolution equation and related topics

Session Time & Room : 5C (Aug.25, 13:20-15:00) @F411

Type : Proposal of Minisymposium

Abstract : Analyzing and computational methods for interfacial motion including some singularities or topological changes has been continued to develop and applied to various fields. Recently, these methods are extended to the problems with strong singularity and constraint, nonlocal evolution law, or coupling system and other phenomena. In these developments, there has been high demand for fast and accurate computing, and rigorous mathematical analysis of parametric or non-parametric interface motion. This minisymposium will feature the recent developments on modelling, computation and analysis for interface evolution equation involving the above motivation and related topics.

Organizer(s) : Takeshi Ohtsuka, Yoshihito Kohsaka

Classification : 53E10, 53E40, 65M22, 35K65, 35K67

00607 (1/1) : 5C @F411 [Chair: Yoshihito Kohsaka]

[03814] A minimizing movement approach to surface constrained interfacial motions

Format : Talk at Waseda University

Author(s) : Elliott Ginder (Meiji University)

Abstract : By extending the applicability of minimizing movements to the surface PDE setting, we will develop threshold dynamics for surface-constrained interfacial motions. In particular, we will show how our approach enables one to approximate multiphase, volume-preserving, curvature flows on surfaces via generalized MBO and HMBO algorithms.

[02801] Geometric Sobolev gradient flows on spaces of curves

Format : Talk at Waseda University

Author(s) : Philip Schrader (Murdoch University)

Abstract : The curve-shortening flow, which deforms a closed planar curve by moving its points perpendicular to the curve with velocity proportional to curvature, was proposed by Mullins as a model for the motion of grain boundaries in the process of annealing. It can be characterised as the gradient descent of the length functional on curves, when the gradient is taken with respect to a parametrisation invariant L^2 inner product. In this talk I will describe some of the gradient flows which result when taking instead the gradient with respect to some Sobolev parametrisation invariant inner products. I will discuss the different kinds of asymptotic behaviour that are possible and also the numerical advantages of H^1 products.

[03938] A Simple Algorithm for the Monge-Ampere Equation on a Sphere

Format : Talk at Waseda University

Author(s) : Richard Tsai (The University of Texas at Austin)Axel Turnquist (University of Texas at Austin)

Abstract : In this talk, we present a novel approach for solving the Monge-Ampere (MA) equation defined on a sphere. Specifically, we extend the MA equation on a sphere to a narrowband around the sphere by formulating an equivalent optimal transport problem. We demonstrate that the extended MA equation can be solved using existing algorithms developed for the MA equation on Euclidean space, making the resulting algorithm simple and easy to implement. Our approach provides a useful tool for solving problems that involve the MA equation defined on or near a sphere, which has a wide range of applications in fields such as computer graphics, image processing, and fluid dynamics.

[02029] Waiting time effects for the wearing process of a non-convex stone

Format : Talk at Waseda University

Author(s) : Nao Hamamuki (Hokkaido University)Ryosuke Takahashi (Hokkaido University)

Abstract : We investigate evolution of a non-convex stone by the wearing process. Following the formulation introduced by Ishii and Mikami 2001, 2004, we study the unique viscosity solution of a nonlocal Gauss curvature flow equation describing the wearing process and prove that waiting time effects occur on an appropriate subset in a cavity of the stone, that is, any point on the set does not move at all for some positive time.

[00608] Limit behavior and asymptotic properties in fluid mechanics

Session Time & Room :

00608 (1/3) : 3E (Aug.23, 17:40-19:20) @G703

00608 (2/3) : 4C (Aug.24, 13:20-15:00) @G703

00608 (3/3) : 4D (Aug.24, 15:30-17:10) @G703

Type : Proposal of Minisymposium
Abstract : The mathematical analysis of problems from fluid mechanics under the passage to certain limits can lead to new insights into the underlying physics and can help to improve numerical implementations. This minisymposium brings together scientists studying such kinds of asymptotic behaviors in different settings. The speakers present their research on homogenization problems and singular limits for fluid models, as well as on long-time and far-field behavior of fluid flows. Bringing together scientists working on these very different kinds of limit problems might create synergies between their approaches that usually differ significantly.
Organizer(s) : Thomas Eiter, Florian Oschmann
Classification : 35Q35, 76M45, 76M50
Minisymposium Program :

[01787] Homogenization of nonstationary incompressible viscous non-Newtonian flows

Format : Talk at Waseda University
Author(s) : Yong Lu (NANJING UNIVERSITY)Zhengmao Qian (NANJING UNIVERSITY)
Abstract : We consider the homogenization of the nonstationary incompressible viscous non-Newtonian fluid flows in a domain perforated with a large number of tiny holes, where the size of the holes is proportional to the mutual distance of the holes, and the stress tensor satisfies the Carreau-Yasuda law. Darcy's law is derived in the limit as the size of holes goes to zero and the number of holes goes to infinity simultaneously.

[05572] Homogenization of compressible Navier-Stokes in critically perforated domains in Limit behavior and asymptotic properties in fluid mechanics

Format : Talk at Waseda University
Author(s) : Peter Bella (TU Dortmund)Friederike Lemming (TU Dortmund)Roberta Marziani (TU Dortmund)Florian Oschmann (Czech Academy of Sciences)
Abstract : We consider homogenization of the time-dependent compressible Navier-Stokes equations in the low Mach number regime in critically periodically perforated domains. In analogy to a classical result of Allaire (ARMA 90) for the incompressible fluids, we obtain in the limit the incompressible Navier-Stokes system with an additional Brinkman friction form.

[05422] Existence of weak solutions and hard-congestion limit in the dissipative Aw-Rascle system

Format : Online Talk on Zoom
Author(s) : Ewelina Zatorska (Imperial College London)Nilasis Chaudhuri (Imperial College London)
Abstract : In this talk I am going to present the dissipative Aw-Rascle model of evolution of congestions. I will first explain its connection with other models in fluid mechanics (compressible Euler and Navier-Stokes) and present our progress on the existence theory. In the second part of my talk I will focus on discussing a singular limit passage leading to the so-called "hard-congestion" system.

[01575] Γ-convergence of nearly incompressible fluids

Format : Talk at Waseda University
Author(s) : Peter Bella (TU Dortmund)Eduard Feireisl (Czech Academy of Sciences)Florian Oschmann (Czech Academy of Sciences)
Abstract : We consider the time-dependent compressible Navier–Stokes equations in the low Mach number regime in a family of domains $\Omega_\varepsilon \subset \mathbb{R}^d$ converging in the sense of Mosco to a domain $\Omega \subset \mathbb{R}^d,\ d \in \{2, 3\}$. We show the limit is the

incompressible Navier–Stokes system in Ω. This is joint work with Peter Bella (TU Dortmund) and Eduard Feireisl (CAS).

00608 (2/3) : 4C @G703 [Chair: Thomas Eiter]

[04842] Invariant manifolds for the thin film equation

Format : Talk at Waseda University
Author(s) : Christian Seis (University of Munster)Dominik Winkler (University of Munster)
Abstract : The large-time behavior of solutions to the thin film equation with linear mobility in the complete wetting regime on R^N is examined: We investigate the higher order asymptotics of solutions converging towards self-similar Smyth--Hill solutions under certain symmetry assumptions on the initial data. The analysis is based on a construction of finite-dimensional invariant manifolds that solutions approximate to an arbitrarily prescribed order.

[03881] The Navier-Stokes flow in the exterior Lipschitz domain

Format : Talk at Waseda University
Author(s) : Keiichi Watanabe (Suwa University of Science)
Abstract : Consider the three-dimensional Navier-Stokes equations in an exterior Lipschitz domain Ω. In this talk, we show the unique existence of a global strong solution u to the Navier-Stokes equations and investigate the large time behavior of the solution u. Although the boundary is not smooth, we show that the large time behavior of the Navier-Stokes flow is completely recovered in the exterior Lipschitz domain Ω along exactly the same argument as usual.

[04533] Anisotropically spatial-temporal behavior of the Navier-Stokes flow past an obstacle

Format : Talk at Waseda University
Author(s) : Tomoki Takahashi (Tokyo Institute of Technology)
Abstract : We consider the spatial-temporal behavior of the Navier-Stokes flow past a three dimensional rigid body and deduce
the temporal decay rate with the spatial weight caused by translation. The key tool is the L^q-L^r estimate of the Oseen semigroup in exterior domains and we develop the weighted L^q theory of the Oseen semigroup. New results on the Stokes semigroup in isotropic L^q spaces are also discussed.

[01603] Stokes and Oseen fundamental solutions: asymptotic properties of fluid flows and applications in computational fluid dynamics

Format : Talk at Waseda University
Author(s) : Ana Leonor Silvestre (Instituto Superior Técnico, Universidade de Lisboa)
Abstract : Starting from the Stokes and Oseen steady and unsteady fundamental solutions, we discuss asymptotic properties of fluid flow around a translating and rotating rigid body. This part of the talk includes joint work with Toshiaki Hishida, from Nagoya University, Japan, and Takéo Takahashi, from INRIA Nancy - Grand Est, France. In the second part of the talk, based on joint work with Carlos Alves, Rodrigo Serrão, from Instituto Superior Técnico, Portugal, and Svilen Valtchev, from Instituto Politécnico de Leiria, Portugal, we present a numerical study of the Method of Fundamental Solutions for Stokes and Oseen boundary value problems. The accuracy of the method is illustrated through a series of numerical tests, which include a comparison between analytic and numerical solutions and the application of the method to classical benchmark problems.

00608 (3/3) : 4D @G703 [Chair: Florian Oschmann]

[04660] Multiscale analysis - from compressible to incompressible system

Format : Talk at Waseda University
Author(s) : Aneta Wróblewska-Kamińska (Institute of Mathematics, Polish Academy of Sciences)
Abstract : We will show asymptotic analysis for hydrodynamic systems as a tool in in the situation when certain parameters
vanish or become infinite. We will concentrate on rigorous mathematical analysis of low Mach number limits with so called ill-prepared dat. I will present some results which concerns passage from compressible to incompressible models including Navier-Stokes-Fourier system on varying domains, a multi-scale problem for viscous heat-conducting fluids in fast rotation and FENE model for dilute polymeric fluids.

[04114] Mixing and enhanced dissipation for fluid suspensions

Format : Talk at Waseda University
Author(s) : David Gerard-Varet (Universite Paris Cite et IMJ-PRG)
Abstract : We consider a model introduced by D. Saintillan and M. Shelley to describe active suspensions of elongated particles. This model couples a Stokes equation for the fluid substrate and a transport equation for the density distribution of
particles in space and orientation. We investigate mixing properties of this model (damping and enhanced dissipation). The main new feature of the analysis is that the usual velocity variable of the euclidean space is replaced by an orientation variable on the sphere, which is responsible for strong qualitative changes and new mathematical difficulties. This is joint work with M. Coti Zelati and H. Dietert.

[05036] Resolvent estimate for the Stokes equations in the Besov spaces

Format : Talk at Waseda University
Author(s) : Jou chun Kuo (Graduate School of Fundamental Science and Engineering, Waseda University)
Abstract : This talk is devoted to proving the resolvent estimates of the linearized system of the compressible Navier-Stokes equations with homogeneous boundary conditions in the half-space. We construct the solution in $B^s_{q,1}$ for $1

[05215] Conditions for energy balance in 2D incompressible ideal fluid flow

Format : Online Talk on Zoom
Author(s) : Milton da Costa Lopes Filho (Universidade Federal do Rio de Janeiro)Samuel Lanthaler (California Institute of Technology)Fabian Jin (ETH-Zurich)Helena Judith Nussenzveig Lopes (Universidade Federal do Rio de Janeiro)
Abstract : In this talk I will discuss necessary and sufficient conditions on the regularity of the external force for energy balance to hold for weak solutions of the 2D incompressible Euler equations. This is motivated by turbulence modeling and the result is in contrast with the situation in 3D and the existence of wild solutions.

[00612] New models and methods for capacity planning and scheduling

Session Time & Room :

00612 (1/3) : 1C (Aug.21, 13:20-15:00) @D505

00612 (2/3) : 1D (Aug.21, 15:30-17:10) @D505

00612 (3/3) : 1E (Aug.21, 17:40-19:20) @D505

Type : Proposal of Minisymposium
Abstract : Scheduling theory has received a wide coverage in the literature on operations research and discrete optimization over the last five decades or so, but the literature seems to have reached a “sink” equilibrium with respect to the standard assumptions and parameters to be included in the models. In this symposium we aim to present recent new scheduling models that extend the classic ones, and where the extensions have a direct link with practical operations scheduling in a variety of industries. We focus especially also on computational methods for solving the new models.
Organizer(s) : Roel Leus, Norbert Trautmann
Classification : 90B35, 90B36, 90C27, 90C11
Minisymposium Program :

00612 (1/3) : 1C @D505 [Chair: Roel Leus]

[01483] Joint replenishment combined with machine scheduling: offline and online algorithms

Format : Talk at Waseda University
Author(s) : Tamás Kis (SZTAKI)Peter Gyorgyi (SZTAKI)Timea Tamasi (SZTAKI)Jozsef Bekesi (University of Szeged)
Abstract : In this scheduling problem, each job requires a subset of resource types that have to be purchased after the release date of the job and prior to starting the job. The goal is to determine a schedule along with the purchasing dates and quantities for each resource type to minimize the sum of purchasing costs plus a scheduling criterion.
Complexity results and online algorithms will be presented for different special cases of the problem.

[01552] Sequential testing in batches with resource constraints

Format : Talk at Waseda University
Author(s) : Fan Yang (Shanghai Normal University)Ben Hermans (ORTEC)Nicolas ZUFFEREY (University of Geneva)Roel Leus (KU Leuven)
Abstract : We consider the problem of determining the state of a system through costly tests of its components, where components can be tested simultaneously in batches to exploit economies of scale. This problem is a generalization of the classical sequential testing problem and it has applications in various settings, including machine maintenance, disease diagnosis, and new product development. We prove that the problem is strongly NP-hard, and several models and algorithms are proposed for it.

[00764] A flow-based formulation for parallel machine scheduling using decision diagrams

Format : Talk at Waseda University
Author(s) : Daniel Kowalczyk (KU Leuven)Roel Leus (KU Leuven)Christopher Hojny (Eindhoven University of Technology)Stefan Ropke (Technical University of Denmark)
Abstract : We present a new flow-based formulation for identical parallel machine scheduling, which is constructed with the help of a decision diagram that represents all job sequences that respect specific ordering rules. These rules rely on a partition of the planning horizon into, generally non-uniform, periods. We develop a branch-and-price framework that solves several instances from the literature for the first time. We compare the new formulation with the time-indexed and arc-time-indexed formulation.

[00808] Parallel Machine Scheduling Under Uncertainty: Models and Exact Algorithms

Format : Online Talk on Zoom
Author(s) : Guopeng Song (National University of Defense Technology)Roel Leus (KU Leuven)
Abstract : We study parallel machine scheduling for makespan minimization with uncertain job processing times. To incorporate uncertainty and generate solutions that are insensitive to unfolding information, three different modeling paradigms are adopted: a robust model, a chance-constrained model, and a distributionally robust chance-constrained model. We focus on devising generic solution methods that can efficiently handle these different models. We compare the solutions from the different models for scheduling under uncertainty and report the general lessons learned.

00612 (2/3) : 1D @D505 [Chair: Shunji Tanaka]

[02307] Energy-aware flow shop scheduling with uncertain renewable energy

Format : Talk at Waseda University
Author(s) : Morteza DAVARI (SKEMA Business School)Masoumeh Ghorbanzadeh (Ferdowsi University)Mohammad Ranjbar (Ferdowsi University)
Abstract : This paper investigates an energy-aware flow shop scheduling problem with on-site renewable and grid energy resources. To deal with the uncertainty of renewable energy resources, we first develop two two-stage stochastic programming formulations to minimize the total energy cost purchased from the grid and then, we develop two robust models. Computational results reveal that Benders decomposition algorithms outperform compact models for robust problems and not for stochastic problem.

[02657] An effective model-driven heuristic algorithm for the collaborative operating room scheduling problem

Format : Talk at Waseda University
Author(s) : Yang Wang (School of Management, Northwestern Polytechnical University)Haichao Liu (School of Management, Northwestern Polytechnical University)Abraham Punnen (Simon Fraser University)
Abstract : In this work, we study a collaborative operating room scheduling problem subject to shared surgeons and downstream wards. We propose an effective model-driven heuristic algorithm to make both weekly surgery assignment and daily sequencing decisions for multiple heterogeneous hospitals. Extensive experimental
results disclose the merit of the integrated optimization modelling and the usefulness of coordinating the
allocation of key resources within collaborative hospitals.

[01493] Valid inequalities for the parallel stack loading problem of minimizing the number of badly-placed items

Format : Talk at Waseda University

Author(s) : Shunji Tanaka (Kyoto University)Sven Boge (Osnabrück University)

Abstract : This study addresses the parallel stack loading problem to find an optimal loading plan of incoming items into parallel stacks so that the workload for retrieving them later is minimized. We propose valid inequalities for an integer programming formulation of the problem to minimize the number of badly-placed items as an index of the workload. We examine their effectiveness by computational experiment.

[01466] Branch-and-Price-and-Cut for the Team Orientation Problem with Interval-Time-Varying Profit

Format : Online Talk on Zoom

Author(s) : jiaojiao li (National University of Defense Technology)

Abstract : This paper studies the team orienteering problem, where the profit depends on whether two visits are completed and the interval time of the two visits. The result of this interaction can be expressed as a discrete profit function. In the practical application of Earth observation satellites, it is often necessary to make two consecutive observations of some important targets at reasonable intervals to improve the observation effect. To solve the problem, we effectively describe the time interval requirement by the number of days between two visits and the combination of time windows, then formulate mixed-integer programming (MIP) models and propose a branch-and-price-cut algorithm, along with valid inequalities for tightening the upper bound. Computational results show the effectiveness of our algorithm. Furthermore, we analyze the impact of the following four aspects on computing time, including basic and modified graph, unidirectional and bidirectional label-setting, ng-path relaxation and dynamic ng-path relaxation, algorithms with and without the valid inequality. Then we present the impact of the third level of branching and non-branching on computing time and profit.

00612 (3/3) : 1E @D505 [Chair: Norbert Trautmann]

[03681] A hybrid algorithm of integrated container truck scheduling problem

Format : Talk at Waseda University

Author(s) : Wenchao Wei Yanrong Zhang (Beijing Jiaotong University)

Abstract : This article establishes an inland container transportation network that includes inland container depots (ICDs) and studies the dispatching problem of container empty containers and trucks in the network. A mixed integer programming model is proposed to tackle the scheduling problem together with ICD locations. To solve the proposed problem, we develop a hybrid algorithm combining large neighborhood search in a fix-and-optimize framework and a tabu search algorithm.

[05024] Compact formulations for parallel machine scheduling with conflicts

Format : Talk at Waseda University

Author(s) : Phablo Moura (KU Leuven)Roel Leus (KU Leuven)Hande Yaman (KU Leuven)

Abstract : Parallel machine scheduling with conflicts consists in, given a set of jobs V with known processing times, a set of identical machines M, and an undirected graph (V, E), finding a mapping from V to M such that pairs of jobs in E are assigned to different machines, and the maximum completion time (makespan) is minimized. We present compact MILP formulations, introduce classes of valid inequalities, and report on preliminary computational experiments

[01311] Project scheduling under various resource constraints

Format : Talk at Waseda University

Author(s) : Nicklas Klein (University of Bern)Mario Gnägi (University of Bern)Norbert Trautmann (University of Bern)

Abstract : The execution of a project often requires two types of resources: renewable resources representing, e.g., staff members or equipment; and production and consumption resources representing, e.g., the project budget. We present a mixed-integer linear programming formulation for scheduling such a project which significantly outperforms state-of-the-art models from the literature.

[00615] Nonlinear PDEs & Probability

Session Time & Room :

00615 (1/2) : 5B (Aug.25, 10:40-12:20) @G710

00615 (2/2) : 5C (Aug.25, 13:20-15:00) @G710

Type : Proposal of Minisymposium

Abstract : The aim of this mini-symposium is to present recent results in analysis and probability with applications to the study of nonlinear PDEs relating to mathematical physics, kinetic theory, and fluid mechanics. This includes questions of regularity and irregularity, stability, and geometric properties of solutions. We want to bring together young researchers and specialists to foster scientific exchange and explore new exciting developments in the fields.

00615 (1/2) : 5B @G710 [Chair: Tobias Ried]

[04215] A mixed-norm estimate of two-particle reduced density matrix of many-body Schrödinger dynamics for deriving Vlasov equation

Format : Talk at Waseda University

Author(s) : Li Chen (Universität Mannheim)

Abstract : We re-examine the combined semi-classical and mean-field limit in the N-body fermionic Schrödinger equation with pure state initial data using the Husimi measure framework. The Husimi measure equation involves three residue types: kinetic, semiclassical, and mean-field. The main result of this paper is to provide better estimates for the kinetic and mean-field residue than those in the authors' previous work. Especially, the estimate for the mean-field residue is shown to be smaller than the semiclassical residue by a mixed-norm estimate of the two-particle reduced density matrix factorization. Based on this estimate, we find that the mean-field residue is of higher order than the semiclassical residue. The talk is based on the joint work with Jinyeop Lee, Matthew Liew, and Yue Li.

[03911] Hydrodynamic limit equations derived from microscopic interacting particle systems

Format : Talk at Waseda University

Author(s) : Makiko Sasada (University of Tokyo)

Abstract : Hydrodynamic limit provides a rigorous mathematical method to derive the deterministic partial differential equations describing the time evolution of macroscopic parameters, from the stochastic dynamics of a microscopic large scale interacting system. In this talk, by introducing the notion of a class of valid interacting particle systems, and we discuss what kind of equations can be derived from such interacting particle systems.

[01645] The Vicsek-BGK equation in collective dynamics

Format : Talk at Waseda University

Author(s) : Raphael Winter (University of Vienna)

Abstract : The Vicsek-BGK equation describes the collective motion of agents with local alignment. It is known that the spatially homogeneous model undergoes a phase transition from disoriented motion to collective motion. In this contribution we give a prove the onset of a phase transition in the spatially inhomogeneous case. Joint work with Sara Merino Aceituno and Christian Schmeiser.

[03240] Quasilinear SPDEs with rough paths

Format : Talk at Waseda University

Author(s) : Alexandra Neamtu (University of Konstanz)Antoine Hocquet (Technical University of Berlin)

Abstract : We investigate quasilinear parabolic evolution equations driven by a γ-Hölder rough path, where $\gamma \in (1/3, 1/2]$. This includes the Brownian motion and a fractional Brownian motion with Hurst index $H \in (1/3, 1/2]$. We explore the mild formulation combining functional analytic techniques with the controlled rough paths approach. We apply our results to the stochastic Landau-Lifshitz-Gilbert equation for which we additionally prove the existence of stochastic flows. This talk is based on a joint work with Antoine Hocquet.

00615 (2/2) : 5C @G710 [Chair: Jonas Sauer]

[03798] A regularity structure for the quasilinear generalized KPZ equation

Format : Talk at Waseda University
Author(s) : Masato Hoshino (Osaka University)Ismael Bailleul (Universite Rennes 1)Seiichiro Kusuoka (Kyoto University)
Abstract : We prove the local well-posedness of a regularity structure formulation of the quasilinear generalized KPZ equation and give an explicit form of the renormalized equation in the full subcritical regime.

[03415] Gradient continuity of weak solutions for perturbed one-Laplace problems

Format : Talk at Waseda University
Author(s) : Shuntaro Tsubouchi (Graduate School of Mathematical Sciences, University of Tokyo)
Abstract : This talk is concerned with continuity of a spatial derivative of weak solutions to very singular problems that involve both one-Laplace and p-Laplace operators. The main difficulty is that one-Laplacian has both singular and degenerate ellipticity, which makes it difficult to prove Hölder continuity of a spatial gradient across a facet, the degenerate region of a gradient. In this talk, the speaker would like to talk about recent results on gradient continuity across the facet.

[02739] Asymptotic behavior of geometric flows with contact angle conditions

Format : Talk at Waseda University
Author(s) : Takashi Kagaya (Muroran Institute of Technology)
Abstract : Several geometric flows were derived from interface phenomena. In this talk, contact angle conditions for the geometric flows are dealt with, motivated by surface tension problems. The asymptotic behavior of the geometric flows depends on the contact angle conditions. In particular, traveling waves have the asymptotic stability if we assume specific contact angle conditions. I will introduce my results related to the asymptotic behavior.

[05334] Weak-strong uniqueness for volume-preserving mean curvature flow

Format : Online Talk on Zoom
Author(s) : Tim Laux (University of Bonn)
Abstract : I will discuss a stability and weak-strong uniqueness principle for volume-preserving mean curvature flow. The proof is based on a new notion of volume-preserving gradient flow calibrations, which is a natural extension of the concept in the case without volume preservation recently introduced by Fischer et al. [arXiv:2003.05478]. The first main result shows that any strong solution with certain regularity is calibrated. The second main result consists of a stability estimate in terms of a relative entropy, which is valid in the class of distributional solutions to volume-preserving mean curvature flow.

[00616] Continuous optimization: theoretical and algorithmic trends

Session Time & Room :

00616 (1/3) : 1E (Aug.21, 17:40-19:20) @A207

00616 (2/3) : 2C (Aug.22, 13:20-15:00) @A207

00616 (3/3) : 2D (Aug.22, 15:30-17:10) @A207

Type : Proposal of Minisymposium
Abstract : Continuous optimization is one of the main areas in Applied Mathematics. It has plentiful applications and rich theory and algorithms. This mini-symposium presents recent advances in the area, starting from important theoretical aspects of optimality conditions that guide the development of different algorithms based on higher order information, like Newton-type and third-order algorithms. Many of the methods also exploit the specific structure of the underlying application to achieve high performance. Finally, the mini-symposium also pays tribute to José Mario Martínez's influence in the field. The contributions can be somewhat linked to his insightful ideas in different periods of his career.
Organizer(s) : Paulo J. S. Silva, Roberto Andreani

[03840] Constant rank constraint qualification for nonlinear second-order cone programming

Format : Talk at Waseda University
Author(s) : Gabriel Haeser (University of Sao Paulo)
Abstract : We revisit the classical notions of nondegeneracy and Robinson's condition in the context of nonlinear second-order cone programming. For an m-dimensional second-order cone, instead of stating nondegeneracy at the vertex as the linear independence of m derivative vectors, we do it in terms of several statements of linear independence of two derivative vectors. This allows embedding the structure of the second-order cone into the formulation of the conditions, providing weaker variants and applications.

[03851] Strong global convergence properties of an Augmented Lagrangian method for symmetric cones

Format : Talk at Waseda University
Author(s) : Daiana Oliveira dos Santos (UNIFESP)
Abstract : Sequential optimality conditions have played a major role in proving stronger global convergence results for numerical algorithms used in nonlinear programming. Several extensions have been described in conic contexts, leading to many open questions. In this talk, we will present new sequential optimality conditions for nonlinear symmetric cone programming. Stronger results are obtained by exploiting the rich algebraic structure of the problem.

[02990] On enhanced KKT optimality conditions for smooth nonlinear optimization

Format : Talk at Waseda University
Author(s) : Roberto Andreani (State University of Campinas/ UNICAMP)
Abstract : The Fritz-John and Karush-Kuhn-Tucker (KKT) conditions are crucial for finding minimizers in constrained optimization. They have been augmented with extra necessary conditions since the 1970s, with the enhanced KKT stationarity being one of them. This work focuses on enhanced KKT stationarity for smooth nonlinear programming and analyzes improved multipliers with quasi-normality. The results have implications for sequential optimality conditions and complementarity constraints in multi-objective problems.

00616 (2/3) : 2C @A207 [Chair: Stefania Bellavia]

[03586] Adaptive Third-Order Methods for Composite Convex Optimization

Format : Talk at Waseda University
Author(s) : Geovani Grapiglia (UCLouvain)Yurii Nesterov (UCLouvain)
Abstract : In this talk we present adaptive third-order methods for composite convex optimization problems in which the smooth part has Lipschitz continuous third-order derivatives. In our new schemes the regularization parameters are tunned by checking the progress of the inner solver used to compute trial points. In particular, this technique allows us to design an adaptive accelerated method that can find an ϵ-approximate solution using at most $\mathcal{O}\left(|\log(\epsilon)|\epsilon^{-\frac{1}{4}}\right)$ iterations of the inner solver.

[03706] On the globalization of nonlinear programming methods.

Format : Talk at Waseda University
Author(s) : L. Felipe Bueno (Universidade Federal de São Paulo)
Abstract : In this work we identify some very general conditions that guarantee the global convergence of numerical methods to solve constrained nonlinear optimization problems. With that in mind, we show that a range of Inexact Restoration methods fit the presented framework. Furthermore, we propose a particular algorithm in this line, combined with an acceleration process supported by the general theory of convergence. Computational tests attest to the efficiency of the proposed strategy.

[04137] Proportionality based algorithms for quadratic programming

Format : Talk at Waseda University

Author(s) : Gerardo Toraldo (Università della Campania "L.Vanvitelli")William W. Hager (University of Florida)Marco Viola (University College Dublin)

Abstract : We present a decomposition of the negative gradient on the tangent cone at a feasible point for optimization problems with polyhedral constraints. This decomposition, based on the idea of proportioning, extends the definition of the free and chopped gradient in bound constrained optimization. Such decomposition allows us to generalize the definition of binding variables and to measure complementary aspects of stationarity that can be exploited to design effective switching rules in Gradient Projection two-phase algorithms.

00616 (3/3) : 2D @A207 [Chair: Roberto Andreani]

[03943] On the Inexact Restoration approach for adaptive sample size in finite sum minimization

Format : Talk at Waseda University

Author(s) : Stefania Bellavia (University of Florence)Natasa Krejic (University of Novi Sad)Benedetta Morini (University of Florence)Simone Rebegoldi (University of Florence)

Abstract : In this talk we discuss recent advances in the inexact restoration approach combined with stochastic trust-region methods for finite-sum minimization problems. At each iteration, the proposed methods approximate the function and the derivatives by subsampling. The choice of the function sample size is ruled by the Inexact Restoration approach, whereas the derivatives approximations are computed averaging in smaller sets.
We report worst-case complexity results in expectation and numerical results showing the advantages of adaptive approaches.

[03290] Block coordinate descent and the close enough traveling salesman problem

Format : Talk at Waseda University

Author(s) : Ernesto G. Birgin (University of São Paulo)

Abstract : At each iteration of a Block Coordinate Descent method one minimizes a constrained approximation of the objective function with respect to a generally small set of variables. In this work we address the problem in which block constraints are not defined by global sets of equations and inequations. An algorithm is defined and convergence and complexity are proved. The proposed method is used to solve a generalization of the close enough traveling salesman problem.

[02948] Sequential optimality conditions: how to stop optimization algorithms

Format : Talk at Waseda University

Author(s) : Paulo J. S. Silva (University of Campinas)

Abstract : Optimality conditions, like KKT, play essential roles in modern optimization. They may be used as a starting point to develop algorithms or as a condition to accept an approximate solution. This dynamic aspect, led to the development of sequential optimality conditions that try to capture the iterative approximation nature of computed sequences. In this talk, we will present how this development enlightened the convergence requirements and termination criteria of algorithms in nonlinear optimization.

[01945] Distributed Inexact Newton Method with Adaptive Step Sizes

Format : Talk at Waseda University

Author(s) : Natasa Krejic (University of Novi Sad)Dusan Jakovetic (University of Novi Sad)Greta Malaspina (University of Novi Sad)

Abstract : We consider distributed personalized optimization and consensus optimization and propose DINAS - Distributed Inexact Newton method with Adaptive Stepsize. DINAS employs large adaptive step-sizes, requires a reduced global parameters knowledge with respect to existing alternatives and does not need any local Hessian inversion nor Hessian communications. The method achieves quadratic convergence with respect to computational cost and linear convergence with respect to communication cost for personalized optimization and global convergence for consensus optimization.

[00621] Frontiers of Collaboration with Industry: Succeeding through Failure

Session Time & Room :

00621 (1/2) : 3D (Aug.23, 15:30-17:10) @G406

00621 (2/2) : 3E (Aug.23, 17:40-19:20) @G406

Type : Proposal of Industrial Minisymposium

Abstract : Corresponding to the organizational efforts introduced in the mini-symposium "Frontiers of Collaboration with Industry: Towards International Mathematical Commons," this mini-symposium introduces diverse efforts at practical research activities that engage mathematicians, together with companies, to solve specific problems. With a spirit of collaboration, we aim at sharing with participants some issues and challenges at the forefront of mathematical science research, a collaborative system with companies, and various mathematical ideas for application to problem-solving. Through collaboration between industry and mathematical science, all are intended for the successful resolution of the many issues which must be addressed by our society.

Organizer(s) : Takashi Sakajo, Kenji Kajiwara, Hiroshi Suito

Classification : 74-10, 76-10, 78-10, Applications to industrial problems

Minisymposium Program :

00621 (1/2) : 3D @G406 [Chair: Takashi Sakajo]

[01441] Mobility Optimization Engine and its Real-world Applications

Format : Talk at Waseda University

Author(s) : Katsuki Fujisawa (Kyushu University)

Abstract : Various efforts have been made to realize a so-called super-smart society recently. Our project team builds services to create new industries and other services through corporate collaboration. We have utilized large-scale computing infrastructures and developed the Cyber-Physical System Mobility Optimization Engine (CPS-MOE) that provides various functions, including creating new industries. It can reduce cost and industrial waste and constructing services to calculate the optimum control schedule of transportation agencies. The latest research results and industry-academia collaborative projects using CPS-MOE will be presented in this talk.

[02078] Mathematical modeling with industry in the water sector: what makes good practice

Format : Talk at Waseda University

Author(s) : Anthony John Jakeman (Australian National University)

Abstract : We emphasize the role of good practices in conducting an integrated assessment exercise in water availability settings, underlining attention throughout the framing, assessment and engagement steps. We stress the notion of reflexivity on pathway decisions at each decision fork in the exercise and a holistic attention to uncertainty sources throughout the process, not just in the formulated models. These aspects will be illustrated with a case study in a catchment of the Murray-Darling Basin.

[01474] An international research program on industrial problems for math students.

Format : Talk at Waseda University

Author(s) : Hiroshi Suito (Tohoku University)

Abstract : In this talk, a student research program with industrial projects in mathematics, called "g-RIPS-Sendai", which has been held in Japan since 2018 is introduced. This program offers graduate students in mathematics stimulating opportunities to work on realistic research projects provided by industries. For industrial partners, this program provides chances to try new mathematical approaches with fresh ideas from young students. Our experiences including several difficulties will be shared and discussed.

[02098] Collaboration with early graduate researchers, and improvements on simulated annealing

Format : Talk at Waseda University
Author(s) : Joseph David (University of Washington)Kemal Aziez Rachmansyah (Tohoku University)Rikuto Shigemi (University of Tsukuba)Zachary Brennan (Iowa State University)
Abstract : Students with a pure mathematics background can struggle to find early opportunities in industry without the correct guidance. As opposed to traditional graduate internships which may expect certain familiarity with industry-related problems, a hybrid academic-industry approach with both academic and industry mentors can provide a bridge for early graduate students wishing to transition to industry. This talk discusses the pros and cons of one such program from the perspective of a mid-career graduate student.

00621 (2/2) : 3E @G406 [Chair: Hiroshi Suito]

[02914] Development of a CNN-Based Model for Car Classification and Damage Detection from car accidents

Format : Talk at Waseda University
Author(s) : Busayamas pimpunchat (King Mongkut's Institute of Technology Ladkrabang)
Abstract : This study aimed to develop a convolutional neural network (CNN)-based model for car classification and damage detection from car accidents. The research found that the model was highly accurate in classifying the position of a single car and detecting damage and the model's performance in detecting multiple cars, a modified version of the Hough Transform algorithm was used to improve. The study's findings can help insurance companies analyze car damage and introduce relevant sections in vehicle regulations.

[03805] Failure and Success for Bauxite Moisture Measurement with Microwaves

Format : Talk at Waseda University
Author(s) : Mark Joseph McGuinness (Victoria University of Wellington)Lata I Paea (University of the South Pacific)Sione Paea (University of the South Pacific)
Abstract : The weight of bauxite ore is strongly dependent on moisture content. A microwave analyser measures phase and attenuation in real time, to infer moisture content, which directly impacts the price paid per tonne. Simple linear models fail to explain the highly nonlinear dependence on bauxite depth that is seen in attenuation data. Motivated by this failure, we develop a successful four-layer model that allows multiple reflections at interfaces between ore and air.

[02161] The UniSA Mathematics Clinic: Renewables, defence, mining, drones, and justice

Format : Talk at Waseda University
Author(s) : Lesley Ann Ward (University of South Australia)
Abstract : The University of South Australia Mathematics Clinic runs yearlong authentic industry-sponsored research projects for small teams of final-year undergraduate mathematics students. Clinic projects give students professional skills, experience, accomplishments, and employability, and generate research progress and publications. But things can go wrong – with sponsors, students, staff, projects, workload, and logistics. How can we minimise things going wrong, and fix them when they do? I'll offer some case studies, suggestions, and principles, drawn from Clinic experience.

[01470] Interdisciplinary research using Topological Flow Data Analysis through Math Clinic

Format : Talk at Waseda University
Author(s) : Takashi Sakajo (Kyoto University)
Abstract : Topological Flow Data Analysis "TFDA" is a new way of data analysis based on the classification theory of 2D vector fields. It extracts and quantifies topological features of complex flows from various datasets efficiently. We are organizing a research platform, called Math Clinic, at Kyoto University, where interdisciplinary research with other disciplines including industry has been conducted based on TFDA. In this talk, we will report on the activity and results of the Math Clinic.

[00622] Inverse Problems and Imaging

Session Time & Room :

00622 (1/3) : 1C (Aug.21, 13:20-15:00) @E605

00622 (2/3) : 1D (Aug.21, 15:30-17:10) @E605

00622 (3/3) : 1E (Aug.21, 17:40-19:20) @E605

Type : Proposal of Minisymposium
Abstract : Inverse problems are concerned with determining unknown parameters of interest from indirect, partial, and noisy measurements with the aid of a mathematical model. Such problems are fundamental in biomedical imaging, non-destructive testing, and modern astronomy. Often, these parameters take the form of images rather than scalar or vector-valued parameters, requiring special methods adapted to the distributed structure. The aim of this minisymposium is to gather an active group of researchers working on variational methods for solving inverse and imaging problems, in order to foster increased interaction between these fields and those of applications in science, technology, and industry.
Organizer(s) : Christian Clason
Classification : 65J22, 92C55, inverse problems; mathematical imaging; medical imaging; non-destructive testing
Minisymposium Program :

00622 (1/3) : 1C @E605 [Chair: Clason]

[01259] Testing statistical hypothesis in Inverse Problems

Format : Talk at Waseda University
Author(s) : Frank Werner (Universität Würzburg)Remo Kretschmann (Universität Würzburg)Daniel Wachsmuth (Universität Würzburg)
Abstract : In this talk, we propose a regularized approach to hypothesis testing in Inverse Problems in the sense that the underlying estimators or test statistics are allowed to be biased. As one major result we prove that regularized testing is always at least as good as classical unregularized testing. We furthermore provide an adaptive test by maximizing the power functional, which outperforms unregularized tests in numerical simulations by several orders of magnitude.

[01346] Disentangling domain bias in medical images for meaningful embeddings

Format : Talk at Waseda University
Author(s) : Samuel Tull (University of Cambridge)
Abstract : Machine learning models using imaging have been promising to revolutionise healthcare for many years but are rarely deployed in the clinic due to underlying dataset biases and distribution shifts. In medical images, several sources of bias cause a distribution shift: image acquisition protocols, the instrument used and any image processing. We discuss a method giving meaningful image embeddings, useful for downstream tasks, that have been disentangled from sources of bias, achieving improved generalisability and interpretability.

[01553] A Bregman-Kaczmarz method for nonlinear systems of equations

Format : Talk at Waseda University
Author(s) : Maximilian Winkler (TU Braunschweig)
Abstract : We propose a new randomized method for solving systems of nonlinear equations for sparse solutions or solutions which are subject to simple additional constraints. The method uses only gradients of component functions and is based on Bregman projections. Convergence is established for convex nonnegative functions and for functions that fulfill the local tangential cone condition. We demonstrate in examples that the method can find sparse or simplex-constrained solutions of inverse problems.

[01556] A complementary ℓ^1-TV reconstruction algorithm for limited data CT

Format : Talk at Waseda University
Author(s) : Simon Goeppel (University of Innsbruck)Jürgen Frikel (OTH Regensburg)Markus Haltmeier (University of Innsbruck)
Abstract : In this talk, we introduce a new variational reconstruction framework for inverse problems, suffering from incomplete data. As it is known that a single regularizer does not work flawlessly for noise reduction and artifact removal simultaneously, we instead adress both problems by subsequent reconstructions. These reconstructions are connected by a data-consistency term, which enables us to uitilize both properties of ℓ_1-curvelet and total variation regularization in the example of limited angle tomography.

00622 (2/3) : 1D @E605 [Chair: Frank Werner]

[01577] 3D image reconstruction for cone beam computed tomography using sparsity

Format : Talk at Waseda University
Author(s) : Alexander Meaney (University of Helsinki)Samuli Siltanen (University of Helsinki)
Abstract : Cone beam computed tomography is an increasingly popular three-dimensional medical imaging technique. However, in many settings it suffers from suboptimal image quality. In this work, we will present a new approach to regularized iterative image reconstruction. Our technique has an in-built automatic choice of the regularization parameter, based on a priori knowledge on gradient sparsity. Combined with a novel primal-dual optimization algorithm, this results in an efficient technique for large-scale reconstruction of improved quality.

[01591] High Dynamic Range Tomography via Modulo Radon Transform

Format : Talk at Waseda University
Author(s) : Matthias Beckmann (University of Bremen)
Abstract : Recently, practitioners in tomography proposed high dynamic range solutions that are inspired by multi-exposure fusion strategies in computational photography. In this talk, we propose a single-shot alternative based on the novel Modulo Radon Transform, which folds Radon projections via modulo non-linearity into the dynamic range of the sensor to avoid information loss due to saturation. We propose a sequential reconstruction algorithm, which is backed by mathematical guarantees, and illustrate our theoretical results by numerical simulations.

[01593] A new inversion scheme for elastic diffraction tomography

Author(s) : Bochra Mejri (RICAM, Austria Johann Radon Institute for Computational and Applied Mathematics)Otmar Scherzer (University of Vienna)
Abstract : We consider the problem of elastic diffraction tomography, which consists in reconstructing elastic properties, i.e. mass density and elastic Lamé parameters, of a weakly scattering medium from full-field data of scattered waves outside the medium. Elastic diffraction tomography refers to the elastic inverse scattering problem after linearization using a first-order Born approximation. In this paper, we prove the Fourier diffraction theorem, which relates the 2D Fourier transform of scattered waves with the Fourier transform of the scatterer in the 3D spatial Fourier domain. Elastic wave mode separation is performed, which decomposes a wave into four modes. A new two-step inversion process is developed, providing information on the modes first and secondly on the elastic parameters. Finally, we discuss reconstructions with plane wave excitation experiments for different tomographic setups and with different plane wave excitation frequencies, respectively.

[01606] inverse electromagnetic scattering problems with internal dipoles

Format : Talk at Waseda University
Author(s) : Yakun Dong (University of Vienna)Otmar Scherzer (University of Vienna)Kamran Sadiq (Radon Institute for Computational and Applied Mathematics)
Abstract : We propose a method to reconstruct the optical properties of inverse scattering problems with internal sources. The method is based on macroscopic Maxwell's equations and achieves super-resolution reconstruction. Applications in single-molecule localization microscopy are shown.

00622 (3/3) : 1E @E605 [Chair: Clason]

[03917] A paraxial approach for the inverse problem of vibroacoustic imaging

Format : Talk at Waseda University
Author(s) : Teresa Rauscher (University of Klagenfurt)
Abstract : Vibroacoustography by means of ultrasound is an imaging method that was developed to achieve higher resolutions while avoiding the drawbacks of scattering and stronger attenuation. High frequency waves that show a strongly preferred direction of propagation are sent into the medium. Therefore, we make use of a paraxial approach to arrive at a system of PDEs that involve space dependent parameters. In this talk, we will deal with the modeling and inverse problem for vibroacoustography.

[05513] Primal-dual proximal splitting and generalized conjugation in non-smooth non-convex optimization

Format : Talk at Waseda University
Author(s) : Christian Clason (University of Graz)Stanislav Mazurenko (Masaryk University)Tuomo Valkonen (EPN, Quito and University of Helsinki)
Abstract : We demonstrate that non-convex non-smooth optimization problems like the Potts segmentation model can be written in terms of generalized conjugates of convex functionals, which can be solved by a conceptually straightforward extension of the primal–dual proximal splitting method of Chambolle and Pock. We show convergence and illustrate these theoretical results numerically on the aforementioned example problem.

[00624] At the interface between neural networks and differential equations

Session Time & Room :

00624 (1/2) : 3C (Aug.23, 13:20-15:00) @E702

00624 (2/2) : 3D (Aug.23, 15:30-17:10) @E702

Type : Proposal of Minisymposium
Abstract : Deep neural networks have recently been used to design innovative, and arguably revolutionary, methods for solving a large number of challenging problems from science and engineering which are modeled by differential equations. Conversely, differential equations provide an important set of tools for understanding methods based upon neural networks. This minisymposium is dedicated to recent progress at the interface between neural networks and differential equations, including topics such as the theoretical convergence analysis and computation of neural networks for solving high dimensional PDEs in addition to the analysis, training, and design of neural networks using perspectives from the study of differential equations.
Organizer(s) : Yulong Lu, Jonathan Siegel, Stephan Wojtowytsch
Classification : 65M22, 68W25, Machine Learning
Minisymposium Program :

00624 (1/2) : 3C @E702 [Chair: Yulong Lu]

[01481] Operator learning and nonlinear model reduction by deep neural networks

Format : Talk at Waseda University
Author(s) : Wenjing Liao (Georgia Institute of Technology)
Abstract : This talk focuses on the problem of operator learning to learn an operator between function spaces from data. Model reduction plays a significant role, to reduce the data dimension and the problem size. We consider a neural network architecture to utilize low-dimensional nonlinear structures in model reduction, and prove an upper bound of the generalization error. Our theory shows that, the sample complexity depends on the intrinsic dimension of the model.

[01838] A deep learning framework for geodesics under spherical Wasserstein-Fisher-Rao metric

Format : Talk at Waseda University
Author(s) : Yang Jing (Shanghai Jiao Tong University)
Abstract : Wasserstein-Fisher-Rao (WFR) distance is a family of metrics to gauge the discrepancy of two measures. Compared to the case for Wasserstein distance, the understanding of geodesics under spherical WFR is less clear . We develop a deep learning framework to compute geodesics under spherical WFR metric, and the learned geodesics can be adopted to generate weighted samples. Our framework can be beneficial for applications with given weighted samples, especially in Bayesian inference.

[01927] Mean-field Analysis of Piecewise Linear Solutions for Wide ReLU Networks

Format : Talk at Waseda University
Author(s) : Marco Mondelli (Institute of Science and Technology Austria (ISTA))
Abstract : We consider a two-layer ReLU network trained via SGD for univariate regression. By connecting the SGD dynamics to the solution of a gradient flow, we show that SGD is biased towards a simple solution: at convergence, the ReLU network implements a piecewise linear map of the inputs, and the number of "knot" points - i.e., points where the tangent of the ReLU network estimator changes - between two consecutive training inputs is at most three.

[02274] On the Mean-field Theory of Neural Network Training

Format : Talk at Waseda University
Author(s) : Zhengdao Chen (Google)
Abstract : To understand the training of wide neural networks, prior studies have considered the infinite-width mean-field limit of two-layer neural networks, whose training dynamics is characterized as the Wasserstein gradient flow of a probability distribution. In this talk, we will present a mean-field theory for a type of three-layer neural networks whose first-layer weights are random and fixed, through which we prove a linear-rate convergence guarantee and generalization bounds.

00624 (2/2) : 3D @E702 [Chair: Yulong Lu]

[01535] Machine learning for/with Differential Equation Modeling: Statistics and Computation

Format : Online Talk on Zoom
Author(s) : Yiping Lu (Stanford University)
Abstract : Massive data collection and computational capabilities have enabled data-driven scientific discoveries and control of engineering systems. However, there are still several questions that should be answered to understand the fundamental limits of just how much can be discovered with data and what is the value of additional information. For example, 1) How can we learn a physics law or economic principle purely from data? 2) How hard is this task, both computationally and statistically? 3) What’s the impact on hardness when we add further information (e.g., adding data, model information)? I’ll answer these three questions in this talk in two learning tasks. A key insight in both two cases is that using direct plug-in estimators can result in statistically suboptimal inference.

The first learning task I’ll discuss is linear operator learning/functional data analysis, which has wide applications in causal inference, time series modeling, and conditional probability learning. We build the first min-max lower bound for this problem. The min-max rate has a particular structure where the more challenging parts of the input and output spaces determine the hardness of learning a linear operator. Our analysis also shows that an intuitive discretization of the infinite-dimensional operator could lead to a sub-optimal statistical learning rate. Then, I’ll discuss how, by suitably trading-off bias and variance, we can construct an estimator with an optimal learning rate for learning a linear operator between infinite dimension spaces. We also illustrate how this theory can inspire a multilevel machine-learning algorithm of potential practical use.

For the second learning task, we focus on variational formulations for differential equation models. We discuss a prototypical Poisson equation. We provide a minimax lower bound for this problem. Based on the lower bounds, we discover that the variance in the direct plug-in estimator makes sample complexity suboptimal. We also consider the optimization dynamic for different variational forms. Finally, based on our theory, we explain an implicit acceleration of using a Sobolev norm as the objective function for training

[02223] Momentum Based Acceleration for Stochastic Gradient Descent

Format : Talk at Waseda University
Author(s) : Kanan Gupta (Texas A&M University)Stephan Wojtowytsch (Texas A&M University)Jonathan Wolfram Siegel (Texas A&M University)
Abstract : We will discuss first order optimization algorithms based on discretizations of the heavy ball ODE. Particularly, we introduce a discretization that leads to an accelerated gradient descent algorithm, which provably achieves an accelerated rate of convergence for convex objective functions, even if the stochastic noise in the gradient estimates is significantly larger than the gradient. We compare the optimizer’s performance with other popular optimizers on the non-convex problem of training neural networks on some standard datasets.

[03468] The Effects of Activation Functions on the Over-smoothing of GCNs

Format : Online Talk on Zoom
Author(s) : Bao Wang (University of Utah)
Abstract : Smoothness has been shown to be crucial for the success of graph convolutional networks (GCNs); however, over-smoothing has become inevitable. In this talk, I will present a geometric characterization of how activation functions of a graph convolution layer affect the smoothness of their input leveraging the distance of graph node features to the eigenspace of the largest eigenvalue of the (augmented) normalized adjacency matrix, denoted as M. In particular, we show that 1) the input and output of ReLU or leaky ReLU activation function are related by a high-dimensional ball, 2) activation functions can increase, decrease, or preserve the smoothness of node features, and 3) adjusting the component of the input in the eigenspace M can control the smoothness of the output of activation functions. Informed by our theory, we propose a universal smooth control term to modulate the smoothness of learned node features and improve the performance of existing graph neural networks.

[03523] On the generalization and training of Deep Operator Networks

Format : Online Talk on Zoom
Author(s) : Yeonjong Shin (North Carolina State University)Sanghyun Lee (Florida State University)
Abstract : We propose a novel training method for Deep Operator Networks (DeepONets). DeepONets are constructed by a sum of products of two sub-networks, namely, branch and trunk networks. The goal is to effectively learn DeepONets that accurately approximate nonlinear operators from data. The standard approaches train the two sub-networks simultaneously via first-order optimization methods. The proposed method, however, trains trunk networks first based on norm-minimization, and then trains branch networks in sequence. Furthermore, we estimate a generalization error of DeepONets in terms of the numbers of training data, sensors in inputs and outputs, and DeepONet size. Several numerical examples including Darcy flow in heterogeneous porous media are presented to illustrate the effectiveness of the proposed training method.

[00625] Mathematical Modeling and Combinatorial Optimization

Session Time & Room :

00625 (1/2) : 4C (Aug.24, 13:20-15:00) @D501

00625 (2/2) : 4D (Aug.24, 15:30-17:10) @D501

Type : Proposal of Minisymposium
Abstract : Combinatorial optimization problems aim to compute optimal solutions under a series of constraints, where the set of feasible solutions is discrete, such as scheduling and routing problems. It involves thousands of real-world problems. This minisymposium will focus on mathematical modeling and combinatorial optimization. We have eight junior and senior researchers giving their latest research results on algorithm design, modeling of real-world problems and simulation. The purpose of this minisymposium is to discuss new ideas and challenging problems, as well as to explore new research topics.

[02230] Sports Scheduling: Number of Trips in the Traveling Tournament Problem

Format : Talk at Waseda University
Author(s) : Takaki Ono (Chuo University)Shinji Imahori (Chuo University)
Abstract : This talk deals with the traveling tournament problem, which is a well-known benchmark problem in the field of sports scheduling. We propose a new technique to improve the efficiency of an existing algorithm for the problem. We also design a new method to improve the quality of solutions. Our method first solves an integer programming problem to compute a round-robin tournament, and constructs a double round-robin tournament with smaller number of trips.

[04421] Efficient allocation of demand to facilities on road networks

Format : Talk at Waseda University
Author(s) : Ken-ichi Tanaka (Keio University)Mutsunori Yagiura (Nagoya University)
Abstract : We focus on road networks in which some facilities exist and demand for deliveries arises along the edges of the network. We consider the problem of assigning a subset of edges to each facility so that the total facility-demand delivery distances are minimized with the constraint that each facility addresses almost the same amount of demand. We propose an approach to obtain simple and geographically compact service areas by iteratively solving integer optimization problems.

[01600] Optimal UAV Flight Path Planning for Herding Sheep

Format : Talk at Waseda University
Author(s) : I-Lin Wang (Professor)Ying-Ting Lin (Ph.D. student)
Abstract : We will first introduce how literature solves the shepherding problem by autonomous agents. All the previous research designed heuristic algorithms to collect the sheep when they are too dispersed and then drive them to the destination after aggregating them. We, on the other hand, propose an innovative framework based on graph theory and integer programming models. Our approaches have a significant performance improvement and provide a new viewpoint on how this problem can be solved.

[02992] Formulations and algorithms for a square independent packing problem

Format : Talk at Waseda University
Author(s) : Wei Wu (Shizuoka University)Hiroki Numaguchi (Tokyo University of Science)Jotaro Kuno (Nagoya University)Yannan Hu (Tokyo University of Science)Vitor Mitsuo Fukushige Hama (Nagoya University)Mutsunori Yagiura (Nagoya University)
Abstract : Given a set of squares and a strip with a fixed width, we consider a square independent packing problem (SIPP) that minimizes the strip height such that all squares are packed into cells by setting vertical and horizontal dividers that pass through the entire strip. We show that the SIPP is NP-hard. To solve the SIPP, we design three mathematical formulations based on different solution representations, and then we propose a fully polynomial-time approximation scheme.

00625 (2/2) : 4D @D501 [Chair: Kazuki Hasegawa]

[02859] A core selection method for the robust traveling salesman problem

Format : Talk at Waseda University
Author(s) : Kazuki Hasegawa (Shizuoka University)Wei Wu (Shizuoka University)Mutsunori Yagiura (Nagoya University)
Abstract : We consider the robust traveling salesman problem with interval costs under a min–max regret criterion. We first show that the iterated dual substitution method is applicable for solving this problem, and we examine 18 implementations based on different cut generation rules and mathematical models of the classical traveling salesman problem. Then, we propose a new heuristic approach: core selection method. The core selection method achieved state-of-the-art results on all benchmark instances.

[02909] Algorithms for two-machine job-shop scheduling problem with one joint job

Format : Talk at Waseda University
Author(s) : Hiroki Numaguchi (Tokyo University of Science)Wei Wu (Shizuoka University)Yannan Hu (Tokyo University of Science)
Abstract : We introduce a two-machine job-shop scheduling problem with one joint job where a joint job is defined as a job whose operations are to be processed by different machines. We prove that this problem is strongly NP-hard and propose a polynomial-time algorithm based on dynamic programming when the number of jobs is given as a fixed number. We further improve time complexity using various techniques, including the two-pointers method.

[04538] A New Multivariate Decision Tree Based on Mixed Integer Linear Programming

Format : Talk at Waseda University
Author(s) : Ryo Kurosu (University of Kyoto)Kazuya Haraguchi (University of Kyoto)
Abstract : We study a novel framework of inferring molecule structures that are expected to have desired properties (e.g., high boiling point, low solubility), exploiting machine learning and operations research, where accurate prediction tools are indispensable. In this paper, we propose a new classification decision tree algorithm that builds a multivariate decision tree (i.e., node split is done by hyperplane) based on mixed integer linear programming. Our algorithm is a generalization of conventional ones in the sense that their decision trees are univariate. We describe experimental results on how accurate decision trees are built by our algorithm and by conventional ones, using data sets from cheminformatics.

[04561] A Linear Delay Algorithm for Enumeration of 2-Edge/Vertex-connected Induced Subgraphs

Format : Talk at Waseda University
Author(s) : Takumi Tada (Graduate School of Informatics, Kyoto University, Japan)Kazuya Haraguchi (Graduate School of Informatics, Kyoto University, Japan)
Abstract : In this paper, we present the first linear delay algorithms to enumerate all 2-edge-connected induced subgraphs and to enumerate all 2-vertex-connected induced subgraphs for a given simple undirected graph. We treat these subgraph enumeration problems in a more general framework based on set systems. For an element set V, $(V,\mathcal{C}\subseteq 2^V)$ is called a {\em set system}, where we call $C\in\mathcal{C}$ a {\em component}. A nonempty subset $Y\subseteq C$ is a {\em removable set of C} if $C\setminus Y$ is a component and Y is a {\em minimal removable set} ({\em MRS}) {\em of C} if it is a removable set and no proper nonempty subset $Z\subsetneq Y$ is a removable set of C. We say that a set system has {\em subset-disjoint} ({\em SD}) property if, for every two components $C,C'\in\mathcal{C}$ with $C'\subsetneq C$, every MRS Y of C satisfies either $Y\subseteq C'$ or $Y\cap C'=\emptyset$. We assume that a set system with SD property is implicitly given by an oracle that returns an MRS of a component which is given as a query. We provide an algorithm that, given a component C, enumerates all components that are subsets of C in linear time/space with respect to $|V|$ and oracle running time/space. We then show that, given a simple undirected graph G, the pair of the vertex set $V=V(G)$ and the family of vertex subsets that induce 2-connected (or 2-vertex-connected) subgraphs of G has SD property, where an MRS in a 2-edge-connected (or 2-vertex-connected) induced subgraph corresponds to either an ear or a single vertex with degree greater than two.

[00626] Finite element complexes for structure-preservation in continuum mechanics

Session Time & Room :

00626 (1/3) : 2E (Aug.22, 17:40-19:20) @E710

00626 (2/3) : 3C (Aug.23, 13:20-15:00) @E710

00626 (3/3) : 3D (Aug.23, 15:30-17:10) @E710

Type : Proposal of Minisymposium
Abstract : Exact sequences of function spaces, called complexes, have played a central role in developing structure-preserving numerical methods in the framework of the finite element exterior calculus. Discrete preservation of the underlying complex structure between function spaces often preserves physical quantities and conservation laws of interest; examples include pressure-robust schemes for Navier–Stokes flows, conservation of angular momentum in linear elasticity, and propagation of the constraint equations of general relativity. In this minisymposium, we seek to investigate how far this approach can be taken by bringing together numerical analysts from across the broad spectrum of continuum mechanics problems arising in applications.

[02976] Finite element gradgrad and divdiv complexes in three dimensions

Format : Talk at Waseda University
Author(s) : Jun Hu (Peking University)Yizhou Liang (University of Augsburg)Rui Ma (Beijing Institute of Technology)
Abstract : We introduce the first family of conforming discrete gradgrad complexes and divdiv complexes in three dimensions. In gradgrad complexes, the first construction of finite element spaces of $H(\mathrm{curl}, \mathbb{S})$ and $H(\mathrm{div}, \mathbb{T})$ was proposed, and in divdiv complexes , finite element spaces of $H(\mathrm{sym\,curl}, \mathbb{T})$ are newly constructed. We prove that these finite element complexes are exact. We also present a special family of degrees of freedom of these complexes.

[05087] Structure-preserving discretization for wave equations

Format : Talk at Waseda University
Author(s) : Sanna Mönkölä (University of Jyväskylä)Jonni Lohi (University of Jyväskylä)Markus Kivioja (University of Jyväskylä)Tytti Saksa (University of Jyväskylä)Lauri Kettunen (University of Jyväskylä)Tuomo Rossi (University of Jyväskylä)
Abstract : We present a comprehensive framework for linear wave equations to consider hyperbolic problems in both classical and quantum mechanics. The framework is based on differential geometry in $(d+1)$-dimensional spacetime. To discretize the equations, we use a spacetime extension of the discrete exterior calculus including a leapfrog-style evolution in the time direction. To demonstrate the efficacy of this approach, we carry out numerical simulations using a C++ software library developed at the University of Jyväskylä.

[03866] Regge finite elements and the linearized Einstein tensor

Format : Talk at Waseda University
Author(s) : Evan Gawlik (University of Hawaii)Michael Neunteufel (TU Wien)
Abstract : In general relativity, the linearization of the Einstein tensor plays an important role in studies of gravitational waves. We study the action of this differential operator on elements of the Regge finite element space: piecewise polynomial symmetric (0,2)-tensor fields with tangential-tangential continuity across simplex interfaces. We show that the Regge finite elements and the linearized Einstein operator fit into a commutative diagram of differential complexes that generalizes one studied by Christiansen in the lowest-order setting.

[03058] Variational structures in cochain projection based discretization of classical field theories

Format : Talk at Waseda University
Author(s) : Brian Tran (UC San Diego)Melvin Leok (UC San Diego)
Abstract : Compatible discretizations, such as finite element exterior calculus, provide a discretization framework that respect the cohomological structure of the de Rham complex, which can be used to systematically construct stable mixed finite element methods. Multisymplectic variational integrators are a class of geometric numerical integrators for Lagrangian and Hamiltonian field theories, and they yield methods that preserve the multisymplectic structure and momentum-conservation properties of the continuous system. In this talk, we discuss the synthesis of these two approaches, by constructing discretization of the variational principle for Lagrangian field theories utilizing structure-preserving finite element projections. In our investigation, compatible discretization by cochain projections plays a pivotal role in the preservation of the variational structure at the discrete level, allowing the discrete variational structure to essentially be the restriction of the continuum variational structure to a finite-dimensional subspace. The preservation of the variational structure at the discrete level will allow us to construct a discrete Cartan form, which encodes the variational structure of the discrete theory, and subsequently, we utilize the discrete Cartan form to naturally state discrete analogues of Noether's theorem and multisymplecticity. Time permitting, we will relate the covariant spacetime discretization to the tensor product discretization approach using variational integration in space and symplectic integration in time.

00626 (2/3) : 3C @E710 [Chair: Francis Aznaran]

[02047] Local Exactness of de Rham Conforming Hierarchical B-spline Differential Forms

Format : Talk at Waseda University
Author(s) : Kendrick M Shepherd (Brigham Young University)Deepesh Toshniwal (TU Delft)
Abstract : Conservation laws present in partial differential equations arising in fluid mechanics and electromagnetics are frequently described using the de Rham sequence of differential forms. Stability of numerical methods solving these equations requires discrete preservation of these conservation laws. This talk will present sufficient local exactness criteria for a set of smooth, high-order, isogeometric, locally-refinable spline spaces in Euclidean space of arbitrary dimension in order to enable stable high-order, geometrically-precise finite element analyses.

[02065] Multigrid solvers for the de Rham complex with optimal complexity in polynomial degree

Format : Talk at Waseda University
Author(s) : Pablo D. Brubeck (University of Oxford)Patrick Emmet Farrell (University of Oxford)
Abstract : We present multigrid solvers for the high-order FEM de Rham complex with the same time and space complexity as sum-factorized operator application. Our approach relies on new finite elements with orthogonality properties on the reference hexahedron. The resulting sparsity enables the fast solution of the patch problems arising in the Pavarino, Arnold–Falk–Winther, and Hiptmair space decompositions, in the separable case. In the non-separable case, the method can be applied to a sparse auxiliary operator.

[04622] On partially continuous finite element spaces in variational problems of continuum mechanics

Format : Talk at Waseda University
Author(s) : Adam Sky (University of Luxembourg)
Abstract : The use of partially continuous finite element spaces in continuum mechanics is well-established. Common applications are mixed formulations, for example in linear elasticity. While strongly symmetric finite elements for the discretisation of the stresses have been introduced, their mapping from a reference element is non-trivial. As such, in the first part of this talk we will introduce simple mappings for base functions of the Hu-Zhang element, which are applicable to hp-FEM, and discuss related problems in linear elasticity.

Linear elasticity represents one limited model of continuum mechanics. With the goal of describing more complex phenomena, generalised continua have been introduced. In the context of the linear relaxed micromorphic model, the strain field is augmented via a microdistortion field. In recent works, it was proven that the field can be defined in H(symCurl), such that well-posedness is maintained. With that in mind, the second part of this talk will discuss novel finite elements for the discretisation of the H(symCurl)-space and their application to the relaxed micromorphic sequence.

[05396] New Class of Stabilized Mixed FEM for Compressible and Incompressible Nonlinear Elasticity

Format : Talk at Waseda University
Author(s) : Ali Gerami Matin (The George Washington University)
Abstract : In this paper, we introduce two stabilized class of mixed finite element methods with bubble functions and a perturbation method for 2D and 3D compressible and incompressible nonlinear elasticity. Two approaches, namely, the L^2-projection and projections of partly sobolev classes, have been employed to obtain weak formulations. Both structured and unstructured simplicial meshes have been considered to investigate effects of different meshes on our formulation. Finally, by solving some benchmark problems, we investigate performance of the stabilized elements in different circumstances. Benchmark results demonstrate that our stabilized formulation provide a robust and computationally efficient way of simulating compressible, near-incompressible, and incompressible materials. These formulations also show good performance in approximating stress and pressure in bending problems, 2D and 3D solids with complex geometries, and heterogeneous bodies.

00626 (3/3) : 3D @E710 [Chair: Francis Aznaran]

[05491] Machine-Learned Whitney Forms for Structure Preservation

Format : Talk at Waseda University
Author(s) : Jonas Albert Actor (Sandia National Laboratories)Nathaniel Trask (Sandia National Laboratories)Andy Huang (Sandia National Laboratories)
Abstract : For many applications, scientific machine learning techniques provide few guarantees on structure preservation or convergence rates. Towards this limitation, we introduce a partition of unity architecture to parameterize data-driven Whitney forms, allowing discovery of mixed finite element spaces. The resulting geometric parameterization extracts reduced models from full-field data while exactly preserving physics and matching expected convergence rates. We provide examples for H(div) problems in two dimensions, highlighting the capabilities of the learned Whitney form architecture.

[04438] Study of a structure preserving discretization framework for Maxwell-Klein-Gordon equations.

Format : Online Talk on Zoom
Author(s) : Snorre Christiansen (University of Oslo)Tore Halvorsen (University of Oslo)Claire Scheid (Côte d'Azur University)
Abstract : We propose a numerical discretization framework for a general family of gauge invariant mechanical Lagrangian. Through the definition of a discrete gauge invariant Lagrangian, we study a fully discrete leap-frog time integration scheme based on conforming space discretizations. We prove the stability and convergence of the scheme without the a priori knowledge of the solution. We will then show how our general framework apply to the Maxwell-Klein-Gordon system.

[05131] Compatible finite elements for terrain following meshes

Format : Talk at Waseda University
Author(s) : Karina Kowalczyk (Imperial College London)Colin J Cotter (Imperial College London)
Abstract : In this talk we are presenting a new approach for compatible finite element discretisations for atmospheric flows on a terrain following mesh. In classical compatible finite element discretisations, the H(div)-velocity space involves the application of Piola transforms when mapping from a reference element to the physical element in order to guarantee normal continuity. In the case of a terrain following mesh, this causes an undesired coupling of the horizontal and vertical velocity components. We are proposing a new finite element space, that drops the Piola transform. For solving the equations we introduce a hybridisable formulation with trace variables supported on horizontal cell faces in order to enforce the normal continuity of the velocity in the solution. Alongside the discrete formulation for various fluid equations we discuss solver and time-stepping approaches that are compatible with them and present our latest numerical results. In the case of the Helmholtz equations we give a proof of well-posedness of the arising discrete system.

[04775] Structure-preserving discretization of momentum-based formulations of fluids using discrete exterior calculus

Format : Talk at Waseda University
Author(s) : Christopher Eldred (Sandia National Laboratories)
Abstract : Representation of physical quantities as differential forms (using exterior calculus) has proved to be a powerful approach to formulating continuum mechanics. However, most prior work has focused on scalar-valued differential forms, and therefore electrodynamics and velocity-based formulations of fluids. This talk will present progress towards a discrete exterior calculus for (vector) bundle-valued differential forms, such as those needed to describe momentum, and illustrate its applicability for discretization of momentum-based formulations of (charged) fluid models.

[00632] From model-blind to model-aware learning of inverse problems in imaging

Session Time & Room :

00632 (1/2) : 3C (Aug.23, 13:20-15:00) @E812

00632 (2/2) : 3D (Aug.23, 15:30-17:10) @E812

Type : Proposal of Minisymposium
Abstract : In recent years, there has been an increasing interest in exploring how to combine the practical advantages of learning-based methods with the theoretical understanding and the convergence guarantees coming from model-based approaches for the regularisation of ill-posed inverse problems. This mini-symposium will bring together researchers working on data-driven methods and deep learning for inverse problems in the attempt to providing an overview of the mathematical insights able to shed light on how learned image reconstruction approaches can be reliable tools for real-world applications.
Organizer(s) : Tatiana A. Bubba, Luca Calatroni, Luca Ratti
Classification : 68T07, 65R32, 45Q05, artificial neural networks, deep learning, inverse problems
Minisymposium Program :

00632 (1/2) : 3C @E812 [Chair: Luca Calatroni]

[03849] Untrained networks with latent-space disentanglement for motion separation in videos

Format : Talk at Waseda University
Author(s) : Malena Sabaté Landman (Department of Applied Mathematics and Theoretical Physics, University of Cambridge)Abudllah Abudllah (Department of Mathematics, The Chinese University of Hong Kong)Martin Holler (Institute of Mathematics and Scientific Computing, University of Graz)Karl Kunisch (Institute of Mathematics and Scientific Computing, University of Graz)
Abstract : In this talk I will present an algorithm that allows to efficiently isolate different, highly non-linear motion types in video data, using untrained generator networks together with a specific technique for latent space disentanglement that uses minimal, one-dimensional information on some of the underlying dynamics.

[01569] Continuous Generative Neural Networks for Inverse Problems

Format : Talk at Waseda University
Author(s) : Giovanni Alberti (University of Genoa)Matteo Santacesaria (University of Genoa)Silvia Sciutto (University of Genoa)
Abstract : We study Continuous Generative Neural Networks CGNNs, namely, generative models in the continuous setting. The architecture is inspired by DCGAN, with one fully connected layer, several convolutional layers and nonlinear activation functions. In the continuous L^2 setting, the dimensions of the spaces of each layer are replaced by the scales of a multiresolution analysis of a compactly supported wavelet. We present conditions on the convolutional filters and on the nonlinearity that guarantee that a CGNN is injective. This theory finds applications to inverse problems, and allows for deriving Lipschitz stability estimates for possibly nonlinear infinite-dimensional inverse problems with unknowns belonging to the manifold generated by a CGNN.

[02780] Learned proximal operators in accelerated unfolded methods with pseudodifferential operators

Format : Online Talk on Zoom
Author(s) : Andrea Sebastiani (University of Bologna)Tatiana Alessandra Bubba (University of Bath)Luca Ratti (University of Genoa)Subhadip Mukherjee (University of Bath)
Abstract : In recent years, hybrid reconstruction frameworks has been proposed by unfolding iterative methods and learning a suitable pseudodifferential correction on the part that can provably not be handled by model-based methods. In this talk, I will present a variant of this approach, where an accelerated iterative algorithm is unfolded and the proximal operator is replaced by a learned operators, as in the PnP framework. The numerical experiments on limited-angle CT achieve promising results.

[02946] Electrical impedance tomography, virtual X-rays, and stroke

Format : Talk at Waseda University
Author(s) : Samuli Siltanen (University of Helsinki)
Abstract : A connection between Electrical Impedance Tomography (EIT) and X-ray tomography was found in (Greenleaf et al. 2018) using microlocal analysis. Fourier transform applied to the spectral parameter of Complex Geometric Optics solutions produces virtual X-ray projections, enabling a novel filtered back-projection type nonlinear reconstruction algorithm for EIT. This approach is called Virtual Hybrid Edge Detection. Machine learning can be used for classifying stroke (into ischemic and hemorrhagic) based on virtual X-ray profiles of the conductivity.

00632 (2/2) : 3D @E812 [Chair: Luca Ratti]

[03308] Beyond supervised learning in imaging: measurement-driven computational imaging

Format : Talk at Waseda University
Author(s) : Julian Tachella (CNRS, ENSL)
Abstract : Most computational imaging algorithms rely either on hand-crafted prior models (total variation, wavelets) or on supervised learning with a ground truth dataset of references. The first approach generally obtains suboptimal reconstructions, whereas the latter is impractical in many scientific and medical imaging applications where ground-truth data is expensive or even impossible to obtain. In this talk, I will present recent algorithmic and theoretical advances in unsupervised learning for imaging inverse problems that overcome these limitations, by learning from noisy and incomplete measurement data alone and leveraging weak prior knowledge on the reconstructed image distribution, such as invariance to groups of transformations (rotations, translations, etc.) and low-dimensionality.

[03519] Deep Learning for Reconstruction in Nano CT

Format : Talk at Waseda University
Author(s) : Alice Oberacker (Saarland University)Anne Wald (Georg-August-Universität Göttingen)Bernadette Hahn-Rigaud (Universität Stuttgart)Tobias Kluth (Universität Bremen)Johannes Leuschner (Universität Bremen)Maximilian Schmidt (Universität Bremen)Thomas Schuster (Saarland University)
Abstract : Tomographic X-ray imaging at the nano-scale helps reveal the structures of materials like alloys and biological tissue. However, environmental perturbances during data acquisition can cause motion between the object and scanner. To reduce noise in the back-projection, a learned version of the RESESOP-Kaczmarz method was investigated. The deep network was trained with simulated imaging data to unroll the iterative reconstruction process, allowing the network to learn the back-projected image after a fixed number of iterations.

[04062] Learning intrinsic shape representations via LBO spectra

Format : Talk at Waseda University
Author(s) : serena morigi (University of Bologna)
Abstract : Neural fields are emerging as a new function representation paradigm for image processing, computer vision, computer graphics, and more. The intrinsic neural fields rely on a feature embedding based on the Laplace Beltrami Operator. We derive the embedding functions from the solution of graph Laplacian-based variational regularization problems. This allows to impose property which directly derived from the associated variational formulation. An efficient model-aware method as well as a model-blind neural network will be presented.

[04272] Inexact Algorithms for Bilevel Learning

Format : Talk at Waseda University
Author(s) : Mohammad Sadegh Salehi (University of Bath)
Abstract : We consider hyperparameter estimation for variational methods formulated as a bilevel learning problem. Due to the use of numerical solvers, one can only compute an inexact gradient with respect to the hyperparameters. We introduce and analyse a new framework that dynamically updates the accuracy in inexact algorithms and selects stepsizes based on linesearch. We compare the performance of our method with existing methods through numerical experiments.

[00633] Unconventional numerical methods for advection-diffusion PDEs

Session Time & Room :

00633 (1/2) : 4E (Aug.24, 17:40-19:20) @E705

00633 (2/2) : 5B (Aug.25, 10:40-12:20) @E705

Type : Proposal of Minisymposium
Abstract : Advection-diffusion PDEs represent a broad range of mathematical models in different fields of science and engineering, involving physical processes such as fluid flow, heat and mass transfer, diffusion, etc. Discretizations of advection-diffusion PDEs must be physically consistent, accurate and efficient on emerging computing architectures. The purpose of this minisymposium is to showcase recent developments in numerical methods that explore unconventional approaches to address these challenges. Methods such as residual distribution, flux-corrected transport, hybridized DG and FEM, SBP-SAT, machine learning enhanced methods, as well as methods for non-local extensions of classical advection-diffusion PDEs are of particular interest to this miniymposium.

[03915] Dissipation-based WENO stabilization of high-order finite element methods for hyperbolic problems

Format : Online Talk on Zoom

Author(s) : Dmitri Kuzmin (TU Dortmund University)Joshua Vedral (TU Dortmund University)

Abstract : We propose a new kind of weighted essentially nonoscillatory (WENO) schemes to high-order finite element discretizations of hyperbolic conservation laws. In contrast to WENO-based limiters for DG approximations, our approach uses a reconstruction-based smoothness sensor to blend the numerical viscosity operators of high- and low-order stabilization terms. The so-defined hybrid approximation introduces low-order nonlinear diffusion in the vicinity of shocks, while preserving the high-order accuracy of the baseline discretization in regions where the exact solution is smooth. The underlying reconstruction procedure performs Hermite interpolation on stencils consisting of a mesh cell and its neighbors. The amount of numerical dissipation depends on the relative differences between partial derivatives of reconstructed candidate polynomials and those of the consistent finite element approximation. All derivatives are taken into account by the employed smoothness sensor. To assess the accuracy of our WENO scheme, we derive error estimates and perform numerical experiments. In particular, we prove that the consistency error of the nonlinear stabilization is of the order p+1/2, where p is the polynomial degree. For uniform meshes and smooth exact solutions, the experimentally observed rate of convergence is as high as p+1.

[04012] A Residual Distribution Approach to Isotropic Wave Kinetic Equations

Format : Talk at Waseda University

Author(s) : Steven Walton (Los Alamos National Laboratory)

Abstract : We present a Petrov-Galerkin Residual Distribution (PG-RD) approach to solve isotropic wave kinetic equations (WKEs). The RD method is well-known for its ability to accurately solve advection dominated flow problems due to its intrinsic multi-dimensional upwinding property. While WKEs are nonlinear and non-local integro-differential equations, very different from the historical applications of RD methods, the energy flux of the equations we consider is local. We show that the PG-RD method derived generalizes a finite volume scheme given in a previous work. Analysis of the convergence properties of the method is also provided. The method is verified against established theoretical work for isotropic WKEs.

[04019] High order Flux Reconstruction schemes for turbulent flows and spectral analysis

Format : Talk at Waseda University

Author(s) : ROMARIC SIMO TAMOU (IFPEN)JULIEN BOHBOT (IFPEN)JULIEN COATLÉVEN (IFPEN)VINCENT PERRIER (INRIA)QUANG HUY TRAN (IFPEN)

Abstract : This study focuses on evaluating Flux Reconstruction schemes for turbulent flows. For these schemes, we perform new analyses of their dissipation and dispersion properties, and we find consistent results with the classical analysis. Ultimately, we evaluate the effect of the high order and correction functions on the DNS of Taylor-Green vortex. This work provides valuable insights into the performance of FR schemes for turbulent flows and presents a promising new approach for analyzing their stability.

[04429] The Cartesian Grid Active Flux Method with Adaptive Mesh Refinement

Format : Talk at Waseda University

Author(s) : Erik Chudzik Christiane Helzel (Heinrich-Heine Universität)

Abstract : We present the first implementation of the Active Flux method on Cartesian grids with adaptive mesh refinement: A new finite volume method for hyperbolic conservation laws, that was introduced by Eymann and Roe, which uses a continuous, piecewise quadratic reconstruction and Simpson's rule to compute numerical fluxes. Point values at grid cell interfaces together with cell averages are used to compute the reconstruction. The resulting method is third order accurate and has a compact stencil in space and time.

00633 (2/2) : 5B @E705 [Chair: Eric Tovar]

[04883] Optimization-based, property-preserving algorithm for passive tracer transport

Format : Talk at Waseda University

Author(s) : Pavel Bochev (Sandia National Laboratories)Kara Peterson (Sandia National Laboratories)Denis Ridzal (Sanda National Laboratories)

Abstract : We present a new optimization-based property-preserving algorithm for passive tracer transport. The algorithm utilizes a semi-Lagrangian approach based on incremental remapping of the mass and the total tracer.

However, unlike traditional semi-Lagrangian schemes, which remap the density and the tracer mixing ratio through monotone reconstruction or flux correction, we utilize an optimization-based remapping that enforces conservation and local bounds as optimization constraints.

In so doing we separate accuracy considerations from preservation of physical properties to obtain a conservative, second-order accurate transport scheme that also has a notion of optimality. Moreover, we prove that the optimization-based algorithm preserves linear relationships between tracer mixing ratios. We illustrate the properties of the new algorithm using a series of standard tracer transport test problems in a plane and on a sphere.

[04980] Multi-material ALE remap: interface sharpening in a matrix-free computation

Format : Talk at Waseda University
Author(s) : Vladimir Z Tomov (Lawrence Livermore National Lab)Tzanio Kolev (Lawrence Livermore National Laboratory)Robert Rieben (Lawrence Livermore National Lab)Arturo Vargas (Lawrence Livermore National Lab)
Abstract : We propose a new method for remap of material volume fractions, densities, and specific internal energies in the context of compressible ALE hydrodynamics. The remap is based on advection in pseudotime. As the volume fraction method can diffuse materials over many mesh elements, we introduce a sharpening modification on PDE level. We explain the effects of the modification and how it produces results that are still conservative and bounded. The latter involves FCT-type methods. The second major contribution, next to sharpening, is that all remap methods avoid assembly of global matrices. This avoids data motion and provides higher computational efficiency.

Performed under the auspices of the U.S. Department of Energy under Contract DE-AC52-07NA27344 (LLNL-ABS-847808)

[05104] Robust second-order approximation of the compressible Euler Equations with an arbitrary equation of state

Format : Talk at Waseda University
Author(s) : Eric Joseph Tovar (Los Alamos National Laboratory)Bennett Clayton (Texas A&M University)Jean-Luc Guermond (Texas A&M University)Matthias Maier (Texas A&M University)Bojan Popov (Texas A&M University)
Abstract : This work is concerned with constructing a robust, high-order approximation of the compressible Euler equations for gas dynamics supplemented with an arbitrary or tabulated equation of state. In particular, we show how to construct a high-order graph-viscosity coefficient using an interpolated entropy pair useful when the equation of state is given by tabulated experimental data. Similarly, we construct an entropy surrogate functional that is used in a convex limiting technique that preserves the invariant domain of the system. Finally, the numerical method is then verified with analytical solutions and then validated with several benchmarks seen in the literature and laboratory experiments.

[05153] Heuristic Topological Estimation of Reduced Order Model Basis Functions from PDE Solution Snapshots

Format : Talk at Waseda University
Author(s) : Candace Pauline Diaz (Sandia National Laboratories)Pavel Bochev (Sandia National Laboratories)Denis Ridzal (Sandia National Laboratories)
Abstract : Proper Orthogonal Decomposition (POD) is a common approach to obtain reduced basis sets for projection-based model reduction. For some classes of problems, such as hyperbolic Partial Differential Equations (PDEs), POD does not always achieve reasonable order reduction due to the lack of exponential decay of the leading singular values. In this work we investigate persistent homology as an alternative approach for deriving reduced order basis functions that may be particularly parsimonious for such PDEs.

[00635] Mean field games and optimal transport with applications in data science and biology

Session Time & Room :

00635 (1/2) : 1C (Aug.21, 13:20-15:00) @F403

00635 (2/2) : 1D (Aug.21, 15:30-17:10) @F403

Type : Proposal of Minisymposium

Abstract : Mean field games (MFG) study the behavior of individual players in large populations, where each player controls their own state, while some collective behavior is considered for decision-making. Specific MFG models can be formulated as generalized measure transportation problems, exemplifying one of the tight connections to optimal transport (OT).

This mini-symposium highlights the close relationship between MFG and OT, advancing research directions in modeling and numerical algorithms, and expanding fields of applications. Particular emphasis will lie on new applications in data science, such as point-cloud analysis on networks, and in biology, such as single-cell data integration.

[05205] Manifold Interpolating Optimal-Transport Flows for Trajectory Inference

Format : Online Talk on Zoom

Author(s) : Smita Krishnaswamy (Yale University)Guillaume Huguet (University of Montreal)Alexander Tong (University of Montreal)Oluwadamilola Fasina (Yale University)Daniel Sumner Magruder (Yale University)Manik Kuchroo (Yale University)Guy Wolf (University of Montreal)

Abstract : We present a method called Manifold Interpolating Optimal-Transport Flow (MIOFlow) that learns stochastic, continuous population dynamics from static snapshot samples taken at sporadic timepoints. MIOFlow combines dynamic models, manifold learning, and optimal transport by training neural ordinary differential equations (Neural ODE) to interpolate between static population snapshots as penalized by optimal transport with manifold ground distance. Further, we ensure that the flow follows the geometry by operating in the latent space of an autoencoder that we call a geodesic autoencoder (GAE). In GAE the latent space distance between points is regularized to match a novel multiscale geodesic distance on the data manifold that we define. We show that this method is superior to normalizing flows, Schrödinger bridges and other generative models that are designed to flow from noise to data in terms of interpolating between populations. Theoretically, we link these trajectories with dynamic optimal transport. We evaluate our method on simulated data with bifurcations and merges, as well as scRNA-seq data from embryoid body differentiation, and acute myeloid leukemia treatment.

[01462] A Distributed Algorithm for Wasserstein Proximal Operator Splitting

Format : Online Talk on Zoom

Author(s) : Iman Nodozi (University of California Santa Cruz)Abhishek Halder (University of California Santa Cruz)

Abstract : Many time-stepping algorithms are available to numerically realize the Wasserstein proximal updates, which generalize the concept of gradient steps to the manifold of probability measures. This talk will present a distributed algorithm to perform the Wasserstein proximal updates. The proposed algorithm generalizes the finite dimensional Euclidean consensus ADMM to the measure-valued Wasserstein, and to its entropy-regularized version. We will explain how the proposed algorithm differs compared to the Euclidean case, and will provide numerical case-studies.

[05216] Wasserstein gradient flows and Hamiltonian flows on the generative model

Format : Online Talk on Zoom

Author(s) : Shu Liu (Math department, UCLA)Wuchen Li (University of South Carolina)Hao Wu (Georgia Institute of Technology)Xiaojing Ye (Georgia State University)Haomin Zhou (Georgia Institute of Technology)

Abstract : In this talk, we introduce a series of sampling-friendly, optimization-free methods for computing high-dimensional gradient flows and Hamiltonian flows on the Wasserstein probability manifold by leveraging generative models from deep learning. Such methods project the corresponding probability flows to parameter space and obtain finite-dimensional ordinary differential equations (ODEs) which can be directly solved by using classical numerical methods. Furthermore, the computed generative models can efficiently generate samples from the probability flows via pushforward maps.

[05393] Linear Optimal Transport (LOT) Framework for Graph-Based Semi-Supervised Learning using Point Cloud Data

Format : Talk at Waseda University
Author(s) : Mary Chriselda Antony Oliver (University of Cambridge)Michael Roberts (University of Cambridge)Matthew Thorpe (University of Manchester)
Abstract : In this study, we introduce a novel application of the linear optimal transport (LOT) framework, leveraging the geometrical structure of its linear embeddings. We incorporate these embeddings in the form of projections (velocity fields) post dimensionality reduction using graph-based semi-supervised algorithms. Additionally, we compute the shortest path between two prominent nodes (geodesic) for the feature vector within the graphical setting. Finally, we demonstrate the performance through numerical experiments conducted on benchmark 3-D point cloud data.

00635 (2/2) : 1D @F403 [Chair: Wuchen Li]

[05294] Towards a mathematical theory of development

Format : Talk at Waseda University
Author(s) : Geoffrey Schiebinger (University of British Columbia)
Abstract : This talk introduces a mathematical theory of developmental biology, based on optimal transport. While, in principle, organisms are made of molecules whose motions are described by the Schödinger equation, there are simply too many molecules for this to be useful. Optimal transport provides a set of equations that describe development at the level of cells. We propose that this optimal transport hypothesis is a fundamental mathematical principle of developmental biology.

[03712] Applications of Gromov-Wasserstein Distance to Graph and Hypergraph Analysis

Format : Talk at Waseda University
Author(s) : Tom Needham (Florida State University)
Abstract : Gromov-Wasserstein distances are metrics, inspired by the usual Wasserstein distances of optimal transport, which are designed to handle comparisons between distributions that lie on different spaces. I will overview some recent applications of these metrics to the analysis of graph and hypergraph datasets.

[03382] Single-cell data integration using optimal transport

Format : Talk at Waseda University
Author(s) : Ritambhara Singh (Brown University)Pinar Demetci (Brown University)Rebecca Santorella (Brown University)Bjorn Sandstede (Brown University)William Stafford Noble (University of Washington)Ievgen Redko (Jean Monet University, Saint Etienne)Quang Huy Tran (Université Bretagne-Sud, CNRS, IRISA, Vannes)
Abstract : Integration of single-cell multi-omic measurements is crucial to understand the underlying biology. However, this is particularly challenging due to the lack of sample-wise or feature-wise correspondence information across single-cell datasets generated from different samples. In this talk, I will present our optimal transport-based integration methods that perform the alignment of different single-cell measurements with minimal supervision. We demonstrate their state-of-the-art performance on simulations and real-world datasets.

[03962] Multi-agent reinforcement learning for collaborative games: a mean-field perspective

Format : Online Talk on Zoom
Author(s) : Haotian Gu (UC Berkeley)Xin Guo (UC Berkeley)Renyuan Xu (University of Southern California)Xiaoli Wei (Tsinghua-Berkeley Institute)
Abstract : Multi-agent reinforcement learning (MARL) has enjoyed substantial successes in many applications including real-time resource allocation, order matching for ride-hailing, and autonomous driving. Despite the empirical success of MARL, general theories behind MARL algorithms are less developed due to the intractability of interactions, complex information structure, and the curse of dimensionality. Instead of directly analyzing the multi-agent systems, the mean-field theory provides a powerful approach to approximate the games under various notions of equilibria. Moreover, the analytically feasible framework of mean-field theory leads to efficient and tractable learning algorithms with theoretical guarantees.

In this talk, we will demonstrate how mean-field theory can contribute to analyzing a class of simultaneous-learning-and-decision-making problems under cooperation, with unknown rewards and dynamics. Moreover, we will show that the learning procedure can be further decentralized and scaled up if a network structure is specified. Our result lays the first theoretical foundation for the so-called "centralized training and decentralized execution" scheme, a widely used training scheme in the empirical works of cooperative MARL problems.

[00638] Minisymposium on Interaction between Harmonic Analysis and Data Science

Session Time & Room :

00638 (1/3) : 3E (Aug.23, 17:40-19:20) @E812

00638 (2/3) : 4C (Aug.24, 13:20-15:00) @E812

00638 (3/3) : 4D (Aug.24, 15:30-17:10) @E812

Type : Proposal of Minisymposium
Abstract : Over the last twenty years, data science, machine learning, and deep learning in particular, has begun transforming the global economy and modern life. While much attention is focused on purely empirical data mining results, there are considerable mathematical structures and a growing body of theory about how the structures relate to observable properties of real-world systems. Discovering such structures may lead to important mathematical insights and implications for practitioners. The minisymposium will facilitate interactions between harmonic analysts and experts on the theory of data science, machine learning, and deep learning to foster further research in this fast developing area.
Organizer(s) : Hrushikesh Mhaskar, Nicole Muecke, Ding-Xuan Zhou
Classification : 68T07, 41A63, 42C40, 68Q32
Minisymposium Program :

00638 (1/3) : 3E @E812 [Chair: Dingxuan Zhou]

[01801] Algorithms for quantizing neural networks with guaranteed accuracy

Format : Talk at Waseda University
Author(s) : Rayan Saab (University of California San Diego)
Abstract : We present both deterministic and stochastic algorithms for quantizing neural networks, which can achieve significant savings in cost, computation time, memory, and power consumption while preserving the network's performance. Our methods are data-driven, computationally efficient, and have provable error guarantees. We showcase our results through numerical experiments on large multi-layer networks. Time permitting, we also discuss open problems and connections to other areas of research. This is joint work, in parts, with Jinjie Zhang, Yixuan Zhou, and Johannes Maly.

[01538] Learning nonlinear functionals using deep ReLU networks

Format : Talk at Waseda University
Author(s) : Linhao Song (City University of Hong Kong)Jun Fan (Hong Kong Baptist University)Dingxuan Zhou (University of Sydney)
Abstract : Functional neural networks have been proposed and studied in order to approximate nonlinear continuous functionals defined on $L^p([-1,1]^s)$ for integers $s \geq 1$ and $1 \leq p < \infty$. However, their theoretical properties are largely unknown beyond universality of approximation or the existing analysis does not apply to the rectified linear unit (ReLU) activation function. In this talk we investigate the approximation power of functional deep ReLU networks and establish their rates of approximation under mild regularity conditions.

[01578] Compressed sensing for the sparse Radon transform

Format : Talk at Waseda University
Author(s) : Giovanni S. Alberti (University of Genoa)Matteo Santacesaria (University of Genoa)S. Ivan Trapasso (Polytechnic University of Turin)Alessandro Felisi (University of Genoa)
Abstract : Compressed sensing allows for the recovery of signals from a number of measurements that is proportional, up to logarithmic factors, to their sparsity. The classical theory considers random linear measurements or subsampled isometries, with applications to, e.g., MRI. I will show how compressed sensing can be applied to the sparse Radon transform, where a finite number of angles are considered. The result follows from a new theory of compressed sensing for infinite-dimensional ill-posed problems.

[01808] Super-resolution of sparse measures: recent advances

Format : Online Talk on Zoom
Author(s) : Dmitry Batenkov (Tel Aviv University)
Abstract : The problem of sparse super-resolution asks to recover a linear combination of Dirac point measures from low-frequency and inaccurate measurements. This is a popular model for applications including spectral estimation, direction of arrival, imaging of point sources, and sampling of signals below the Nyquist limit.

In this talk I will describe recent results on deriving optimal recovery bounds and corresponding algorithms for this model and its generalizations to sparse distributions defined on homogeneous Riemannian manifolds.

00638 (2/3) : 4C @E812 [Chair: Hrushikesh Mhaskar]

[04107] Proximal neural networks and Plug-and-Play methods

Format : Talk at Waseda University
Author(s) : Gabriele Steidl (TU Berlin Berlin)Johannes Hertrich (TU Berlin)Sebastian Jonas Neumayer (EPFL)
Abstract : We introduce stable tight frame proximal neural networks (PNNs)
which are by construction averaged operators.
For the training of PNNs, we propose a stochastic gradient descent on (a submanifold of) the Stiefel manifold.
First, we apply cPNN based denoisers within a Plug-and-Play framework and provide convergence results
for the corresponding PnP forward-backward splitting algorithm based on an oracle construction.
Second, we use the averagedness property of PNNs to construct a new architecture within
residual flows.

[03587] The Bayesian Learning Rule

Format : Talk at Waseda University
Author(s) : Mohammad Emtiyaz Khan (RIKEN Center for AIP)
Abstract : Humans and animals have a natural ability to autonomously learn and quickly adapt to their surroundings. How can we design machines that do the same? In this talk, I will present Bayesian principles to bridge such gaps between humans and machines. I will show that a wide-variety of machine-learning algorithms are instances of a single learning-rule derived from Bayesian principles. The rule unravels a dual perspective yielding new mechanisms for knowledge transfer in learning machines. My hope is to convince the audience that Bayesian principles are indispensable for an AI that learns as efficiently as we do.

[02888] Learning linear operators: Infinite-dimensional regression as a well-behaved non-compact inverse problem

Format : Talk at Waseda University
Author(s) : Nicole Mücke (TU Brunswick)
Abstract : We consider the problem of learning a linear operator between two Hilbert
spaces from empirical observations, which we interpret as least squares regression in infinite
dimensions. We show that this goal can be reformulated as an inverse problem with the
feature that its forward operator is generally non-compact.
We prove that this inverse problem is equivalent to the known compact inverse
problem associated with scalar response regression.
Our framework allows for obtaining dimension-free rates for generic learning
algorithms. They hold for a variety of practically-
relevant scenarios in functional regression as well as nonlinear regression with operator-
valued kernels and match those of classical kernel regression with scalar response.

[02915] A Non-Asymptotic Analysis of Dropout in the Linear Model

Format : Talk at Waseda University
Author(s) : Gabriel Clara (University of Twente)Sophie Langer (University of Twente)Johannes Schmidt-Hieber (University of Twente)
Abstract : We investigate the statistical behavior of iterates generated by gradient descent with dropout in a linear model. Non-asymptotic convergence rates for expectations and covariance matrices of the iterates are presented. Difficulties arising from the interaction between gradient descent dynamics and the variance added by dropout are examined. The results motivate and support discussion of statistical aspects of dropout, focusing on optimality of the variance.

00638 (3/3) : 4D @E812 [Chair: Nicole Mücke]

[04309] Direct method for function approximation on data defined manifolds, II

Format : Talk at Waseda University
Author(s) : Hrushikesh Mhaskar (Claremont Graduate University)Ryan Michael O'Dowd (Claremont Graduate University)
Abstract : In theoretical analysis of function approximation in the context of machine learning, a standard approach is to assume that given data lies on an unknown manifold. We view the unknown manifold as a sub-manifold of an ambient hypersphere and construct a one-shot approximation using spherical polynomials. Our approach does not require pre-processing of the data to obtain information about the manifold other than its dimension. We give optimal rates of approximation for relatively ``rough'' functions.

[04364] Distribution learning for count data

Format : Talk at Waseda University
Author(s) : Xin Guo (The University of Queensland)Qiang Fu (The University of British Columbia)Tian-Yi Zhou (Georgia InstitGeorgia Institute of Technologyute of Technology)Hien Nguyen (The University of Queensland)
Abstract : Parameter and density estimation for count models are classical problems in statistics, and are widely used in many branches of physical and social sciences. Grouped and right-censored (GRC) counts are widely used in criminology, demography, epidemiology, marketing, sociology, psychology and other related disciplines to study behavioural and event frequencies, especially when sensitive research topics or individuals with possibly lower cognitive capacities are at stake. Yet, the co-existence of grouping and right-censoring poses major difficulties in regression analysis. To implement generalised linear regression of GRC counts, we derive modified Poisson estimators and their asymptotic properties, develop a hybrid line search algorithm for parameter inference, demonstrate the finite-sample performance of these estimators via simulation, and evaluate its empirical applicability based on survey data of drug use in America. This method has a clear methodological advantage over the ordered logistic model for analysing GRC counts. We will also present our recent works on mixing density estimation through kernel methods and deep neural networks.

[05188] Hierarchical systems of exponential bases for partitions of intervals

Format : Online Talk on Zoom
Author(s) : Goetz Pfander (Catholic University Eichstätt Ingolstadt, Mathematical Institute for Machine Learning and Data Science)David Walnut (George Mason University)
Abstract : Fourier series form a cornerstone of analysis; it allows the expansion of a complex valued 1-periodic function in
the basis of integer frequency exponentials. A simple rescaling argument shows that by splitting the integers into evens and odds, we obtain orthogonal bases for functions defined on the first, respectively the second half of the unit interval. We develop generalizations of this curiosity and show that, for example, for any finite partition of the unit interval into subintervals exists a partition of integers into subsets, each of which forms a basis for functions supported on the respective subinterval.

[00639] Analytical and computational aspects of topological photonics

Session Time & Room :

00639 (1/2) : 4E (Aug.24, 17:40-19:20) @E710

00639 (2/2) : 5B (Aug.25, 10:40-12:20) @E710

Type : Proposal of Minisymposium
Abstract : Topological photonics is an emerging area in material sciences that explores and utilizes the topological invariants of photonic materials, which take integer values and are robust against system disorder. The area has attracted significant interest in recent years due to the ability of topological photonic materials to transport photon energy in a very robust manner, yet its mathematical development is in its infancy. This minisymposium aims to bring together mathematicians and scientists interested in this interdisciplinary area to share recent results and exchange ideas.
Organizer(s) : Chiu-Yen Kao, Junshan Lin, Braxton Osting
Classification : 35P05, 35B10, 35Q93, 49R05, 65K10
Minisymposium Program :

00639 (1/2) : 4E @E710 [Chair: Braxton Osting]

[03761] TE band structure of high contrast honeycomb photonic crystals

Format : Talk at Waseda University
Author(s) : Maxence Cassier (Aix Marseille Univ, CNRS, Centrale Marseille, Institut Fresnel, Marseille, France)Michael Weinstein (Dept of Applied Physics & Applied Mathematics, and Dept. of Mathematics, Columbia University, New-York, United States)
Abstract : We analyse the propagation of transverse electric (TE) waves in a two dimensional honeycomb photonic medium.
This medium consists of a homogeneous bulk of fixed permittivity and an array of high permittivity dielectric inclusions centered at the vertices of a honeycomb lattice. Our mathematical results, supported by numerical simulations, give detailed local information about the conical crossings of dispersion surfaces (Dirac points) as well as global information about the high contrast behavior of dispersion surfaces.

[03902] Super band gaps and interface modes in one-dimensional quasicrystals

Format : Talk at Waseda University
Author(s) : Bryn Davies (Imperial College London)Lorenzo Morini (Cardiff University)Richard Craster (Imperial College London)
Abstract : Quasicrystalline photonic crystals show significant potential (large spectral gaps and robustness) but are underutilised in applications due to the lack of efficient modelling techniques. In this work, we show that periodic (supercell) approximations give accurate predictions of the main spectral gaps of Fibonacci quasicrystals. This is based on characterising the growth of the underlying recursion relation and corroborates the existence of previously observed “super band gaps”. We also present a strategy for creating interface modes.

[03872] Mathematical theory for the interface mode in a waveguide bifurcated from a Dirac point

Format : Talk at Waseda University
Author(s) : Jiayu QIU (Hong Kong University of Science and Technology)Junshan LIN (Auburn University)Peng XIE (Hong Kong University of Science and Technology)Hai ZHANG (Hong Kong University of Science and Technology)
Abstract : In this talk, we present our new results on the existence of a bound state in a waveguide consisting of two semi-infinite periodic structures separated by an interface. The two periodic structures are perturbed from the same periodic medium with a Dirac point, and possess a common band gap enclosing the Dirac point. Using the layer potential technique and asymptotic analysis, we are able to overcome the difficulty imposed by the sharp interface.

[05154] Bloch Waves for Maxwell's Equations in High-Contrast Photonic Crystals

Format : Talk at Waseda University
Author(s) : Robert Paul Viator (Swarthmore College)Robert Lipton (Louisiana State University)Silvia Jimenez Bolanos (Colgate University)Abiti Adili (University of Massachusetts - Lowell)
Abstract : We investigate the Bloch spectrum of a 3-dimensional high-contrast photonic crystal. The Bloch eigen-values, for fixed quasi-momentum, are expanded in a power series in the material contrast parameter in the high-contrast limit, together with a convergence radius, obtained by decomposing an appropriate
vectorial Sobolev space into three mutually orthogonal curl-free subspaces. We also identify the limit spectrum in the periodic case. Time permitting, we will describe some geometries which admit this spectral structure.

00639 (2/2) : 5B @E710 [Chair: Chiu-Yen Kao]

[05207] Pseudo-magnetism and Landau Levels in strained 2-dimensional photonic crystals

Format : Online Talk on Zoom
Author(s) : Michael I Weinstein (Columbia University)
Abstract : The principal use of photonic crystals is to engineer the photonic density of states, which controls light-matter coupling. We show theoretically that a strained 2D honeycomb photonic crystal can generate artificial electromagnetic fields and highly degenerate Landau
levels, having high density of states. Since the tight-binding approximation is generally
not applicable to photonics, we employ a multiscale analysis

of the full continuum 2D Helmholtz wave equation and derive effective Dirac equations
with pseudo-magnetic and pseudo-electric potentials for the dynamics of wave-packets. The deformation can be chosen to induce a constant pseudo-magnetic field, for which the effective Hamiltonian has Landau level spectrum.
Our numerical simulations of the full continuum wave equations show mildly dispersive Landau levels, which we show can be “flattened" by adjusting the pseudo-electric potential.
This theory is joint work with J. Guglielmon and M.C. Rechtsman.
The predictions have recently been corroborated in optical experiments, in joint work with M. Barsukova, Z. Zhang, B. Zhen, L. He, F. Grisé, R. McEntaffer, S. Vaidya, J. Guglielmon and M.C. Rechstman

[05298] Quantized Fractional Thouless Pumping of Solitons

Format : Online Talk on Zoom
Author(s) : Mikael Rechtsman (Penn State Univ)
Abstract : I will present my group’s recent work on the fractional pumping of solitons in photonic Thouless pumps. Specifically, I will show that the displacement (in unit cells) of solitons in Thouless pumps is strictly quantized to the Chern number of the band from which the soliton bifurcates in the low power regime; whereas in the intermediate power regime, nonlinear bifurcations lead to fractional quantization of soliton motion. This fractional quantization can be predicted from multi-band Wannier functions associated with the states of the pump.

[04812] Topological insulators in semiclassical regime

Format : Online Talk on Zoom
Author(s) : Alexis Drouot (University of Washington)
Abstract : I will study a semiclassical Dirac equation that originates in the field of topological insulators. The semiclassical regime allows to make sense of propagating and counter-propagating companion states. We'll derive speed and profile for wavepackets corresponding to topological edge states, and show that the counter-propagating state disperses strongly -- an unusual phenomena in the analysis of coherent states.

[05311] Topological-cavity surface-emitting laser

Format : Online Talk on Zoom
Author(s) : Ling Lu (Institute of Physics, CAS)
Abstract : Contrary to the perception that the Nobel-winning topological physics has not found useful applications, we show that the textbook design of daily-life semiconductor lasers are equivalent to standard topological models in 1D. By upgrading to the 2D vortex zero mode, we invent the topological-cavity surface-emitting lasers (TCSEL) whose performance far exceeds that of the commercial counterparts. Finally, we demonstrate the monopole cavity in 3D with the optimal single-mode behavior, completing the kink-vortex-monopole trilogy of topological defect modes.

[00640] Variational Analysis: Theory and Applications

Session Time & Room :

00640 (1/2) : 2C (Aug.22, 13:20-15:00) @F401

00640 (2/2) : 2D (Aug.22, 15:30-17:10) @F401

Type : Proposal of Minisymposium
Abstract : Variational Analysis lies at the heart of modern optimization and underlies the convergence analysis of many algorithms. The purpose of this session is to bring together selected experts from the worldwide optimization and analysis communities to exchange ideas and present new results. We will strike a balance between early-career researchers and experts.
Organizer(s) : Heinz Bauschke, Xianfu Wang
Classification : 49J53, 65K10, 90C25, Variational Analysis, Convex Analysis and Optimization Methods
Minisymposium Program :

00640 (1/2) : 2C @F401 [Chair: Shawn Xianfu Wang]

[01802] Fixed point strategies for sparsity aware inverse problems and hierarchical convex optimization

Format : Talk at Waseda University

Author(s) : Isao Yamada (Tokyo Institute of Technology)Masao Yamagishi (Tokyo Institute of Technology)

Abstract : We present central ideas behind the recently developed fixed point strategies for a nonconvexly regularized sparse least squares model and a hierarchical convex optimization problem. Related advancements for nonconvex optimization and signal processing will also be introduced briefly.

[02724] The splitting algorithms by Ryu, by Malitsky-Tam, and by Campoy applied to normal cones of linear subspaces converge strongly to the projection onto the intersection

Format : Talk at Waseda University

Author(s) : Heinz H Bauschke (University of British Columbia Okanagan)Shambhavi Singh (University of British Columbia Okanagan)shawn xianfu wang (University of British Columbia Okanagan)

Abstract : Finding a zero of a sum of maximally monotone operators is a fundamental problem in modern optimization and nonsmooth analysis. Assuming that the resolvents of the operators are available, this problem can be tackled with the Douglas-Rachford algorithm. However, when dealing with three or more operators, one must work in a product space with as many factors as there are operators. In groundbreaking recent work by Ryu and by Malitsky and Tam, it was shown that the number of factors can be reduced by one. A similar reduction was achieved recently by Campoy through a clever reformulation originally proposed by Kruger. All three splitting methods guarantee weak convergence to some solution of the underlying sum problem; strong convergence holds in the presence of uniform monotonicity.
In this paper, we provide a case study when the operators involved are normal cone operators of subspaces and the solution set is thus the intersection of the subspaces. Even though these operators lack strict convexity, we show that striking conclusions are available in this case: strong (instead of weak) convergence and the solution obtained is (not arbitrary but) the projection onto the intersection. Numerical experiments to illustrate our results are also provided.

[02977] Fixed Point Algorithms: Convergence, stability and data dependence results

Format : Talk at Waseda University

Author(s) : Javid Ali (Aligarh Muslim University, Aligarh)

Abstract : {\bf Abstract.} In this talk, we discuss a newly introduced two step fixed point iterative algorithm. We prove a strong convergence result for weak contractions. We also prove stability and data dependency of a proposed iterative algorithm. Furthermore, we utilize our main result to approximate the solution of a nonlinear functional Volterra integral equation. Some numerical examples are also furnished. If time permits, then we will discuss Image recovery problem as well.

00640 (2/2) : 2D @F401 [Chair: Shawn Xianfu Wang]

[01896] Adaptive proximal algorithms for convex optimization under local Lipschitz continuity of the gradient

Format : Talk at Waseda University

Author(s) : Puya Latafat (KU Leuven)Andreas Themelis (Kyushu University)Lorenzo Stella (Amazon Berlin)Panagiotis Patrinos (KU Leuven)

Abstract : Gradient-based proximal algorithms have traditionally being bound to global Lipschitz differentiability requirements. Attempts to widen their applicabilty or reduce conservatism typically involve wasteful trial-and-error backtracking routines. Extending recent advancements in the smooth setting, we show how for convex problems it is possible to avoid backtrackings altogether and retrieve stepsizes adaptively without function evaluations. We demonstrate this with an adaptive primal-dual three-term splitting method that includes proximal gradient as special case.

[02427] Level proximal subdifferential and its resolvent

Format : Talk at Waseda University

Author(s) : Ziyuan Wang (University of British Columbia)shawn xianfu wang (University of British Columbia)

Abstract : In this talk, we introduce a new subdifferential whose resolvent completely represents the associated proximal operator. After illustrating that the usual limiting subdifferential representation is only valid when the given function is weakly convex, we propose level proximal subdifferential, which is a careful refinement of the well-known proximal subdifferential. As such, its resolvent always coincides with the associated proximal operator regardless of weak

convexity. Besides this pleasant identity, we also investigate several useful properties of level proximal subdifferential. Finally, numerous examples are given to further illustrate our results.

[02993] On quasidifferentiability and optimization problems

Format : Talk at Waseda University
Author(s) : VIVEK LAHA (Banaras Hindu University)
Abstract : The talk presents suitable optimality conditions based on some recent works in fractional programming and variational inequaliites in terms of quasidifferentials. The presentation deals with Fritz-John and Karush-Kuhn-Tucker type necessary optimality conditions at an optimal point in the framework of the quasidifferentiable analysis. Further, several other applications of the results are investigated in different fields of optimization like mathematical programs with equilibrium constraints and/or vanishing constraints.

[00641] Emerging Collaborations: Mathematical Views of Modelling Biological Scales

Session Time & Room :

00641 (1/2) : 1C (Aug.21, 13:20-15:00) @A512

00641 (2/2) : 1D (Aug.21, 15:30-17:10) @A512

Type : Proposal of Minisymposium
Abstract : In this session, we highlight interdisciplinary efforts of mathematicians whose work integrates biological processes and mathematical tools. Often researchers focus on modeling or simulating with a particular biological scale in mind while neglecting the dynamical connections across scales. The aims of the work showcased in this symposium are to develop and use efficient algorithms, data structures, visualization, and communication tools with the goal of computer modeling of biological systems from the cellular to the population scale. This minisymposium features speakers who are currently working in this area and have an interest in establishing new collaborations.

Organizer(s) : Amy Buchmann, Candice Price, Arietta Fleming-Davies

Minisymposium Program :

00641 (1/2) : 1C @A512 [Chair: Amy Buchmann]

[01865] A Multiscale, Interdisciplinary Approach to Blood Clot Degradation

Format : Talk at Waseda University
Author(s) : Brittany Bannish (University of Central Oklahoma)Nathan Hudson (East Carolina University)Valerie Tutwiler (Rutgers University)
Abstract : Blood clots are critical to prevent bleeding, but complications arise when clots are not degraded effectively. We present a stochastic model of clot degradation that includes structural and biochemical details from the single fiber to full clot scales. We show that modeling in tandem with laboratory experimentation yields physiological insights that were impossible with models or experiments alone. We also discuss the need for future models that include mechanical forces.

[01970] Explorations of DNA Knot Shadows

Format : Talk at Waseda University
Author(s) : Candice Price (Smith College)
Abstract : A core question in knot theory is: How do we identify whether two knots are equivalent under a specific set of operations? Knot theory deals not only with the curious variations in the underlying topological structure, e.g. strands, loops, choice of operations of knots, but also with invariants, e.g. Alexander, Jones, link homologies. Knot theory has been used in various fields of mathematics and has become an essential resource for understanding the topology and the geometry of DNA. In this presentation, we will describe and explore our work to interpret 2-dimensional projections of knots, called knot shadows.

[02104] A mathematical approach to understanding reproductive health disparities at the intersection of ovulatory and metabolic dysfunction

Format : Talk at Waseda University
Author(s) : Erica J Graham (Bryn Mawr College)
Abstract : Endocrine physiology is a complex system of crosstalk between hormones in various tissues. Reproductive hormone dysregulation may disrupt ovulation and may be exacerbated by metabolic abnormalities. Racial and ethnic disparities are also prevalent at the intersection of metabolic and ovarian dysfunction. Here we introduce a mathematical model of the human ovulatory cycle and consider mechanisms of disruption to characterize ovulatory phenotypes. We then examine how health disparities might influence--or be influenced by--model-based phenotypes.

[02133] Harmonic Analysis on Simplicial Simplexes: How far could we take it?

Format : Talk at Waseda University
Author(s) : Karamatou Yacoubou Djima (Wellesley College)
Abstract : Networks' emergence as an ideal setting for studying complex systems brought enormous interest in extending powerful harmonic analysis (HA) tools from Euclidean spaces to graphs. Most efforts focused on the graph Laplacian's eigendecomposition, producing results such as the graph Fourier transform. Recently, the same endeavor moved to higher-order network structures—simplicial simplexes. We survey classical Fourier analysis and its graph extensions before presenting new developments and challenges of HA on simplicial complexes based on the Hodge Laplacian.

00641 (2/2) : 1D @A512 [Chair: Candice Price]

[02145] Ecological consequences of heterogeneity in host-pathogen population dynamics

Format : Talk at Waseda University
Author(s) : Arietta Fleming-Davies (University of San Diego)
Abstract : Variation within-species is key in evolutionary processes. We asked how quantitative variation changes along with mean differences in pathogen performance across populations of the hosts they infect. We fit statistical models incorporating a Gamma distribution of host disease susceptibility to experimental dose response data from an insect baculovirus system, to ask how variation in infectivity might change with genotype by genotype (G x G) combinations of pathogen and host populations.

[02146] Modeling microscale biofluids

Format : Talk at Waseda University
Author(s) : Amy Lyn Buchmann (University of San Diego)
Abstract : Mathematical models can be used to study the role of hydrodynamic interactions in the coordination and self-organization of microorganisms. For example, cilia self-organize to form a metachronal wave that propels the surrounding fluid, yet how this organization occurs is not well understood. Additionally, the coordination of bacterial flagella may be studied to inspire the development of motors in microfluidic devices that can effectively mix and pump a viscous fluid. Here we present a mathematical model to study the interactions between elastic structures in a viscous fluid and investigate their coordination.

[02152] We are what we eat: a mathematical model of the gut-brain axis.

Format : Talk at Waseda University
Author(s) : Ami Radunskaya (Pomona College)
Abstract : The ``gut-brain axis" is the communication between the enteric nervous system (in the gut) and the central nervous system (in the brain). Over the past few decades, scientists have collected data that confirms a bidirectional communication channel between these two nervous systems that is closely tied to the bacterial ecology of the gut, the production of serotonin in both the gut and the brain, and the interaction of serotonin with other hormones. We propose a mathematical model that illuminates both the dynamics of this communication channel and the effect of perturbations due to treatment strategies.

[02213] Modeling the long term effects of thermoregulation on human sleep

Format : Talk at Waseda University
Author(s) : Alicia Prieto Langarica (Youngstown State University)
Abstract : The connection between human sleep and energy exertion has long been regarded as part of the reasoning for the need to sleep. We used to think that we sleep in order to rest. However, a recent theory proposes a different

explanation, one that unifies sleep among all species. This talk presents a mathematical model of human sleep/wake regulation with thermoregulatory functions. The model is used to gain quantitative insight into the effects of ambient temperature on sleep quality and how this relates to the unifying theory for sleep.

[00642] Traveling Waves in Mathematical Epidemiology

Session Time & Room : 1C (Aug.21, 13:20-15:00) @G601

Type : Proposal of Minisymposium
Abstract : Wave propagation in epidemic models is known as one of the interesting issues in the field of mathematical epidemiology. Mathematical theory of traveling wave solutions in epidemic models has been developed in recent years. In many cases, the basic reproduction number or a corresponding threshold value plays an important role in determining the existence of the traveling wave. The purpose of this minisymposium is to share and discuss recent developments and results on this topic among interested researchers.

00642 (1/1) : 1C @G601 [Chair: Toshikazu Kuniya]

[05106] Traveling wave solutions for an epidemic model with free boundary

Format : Talk at Waseda University
Author(s) : Yoichi Enatsu (Tokyo University of Science)Emiko Ishiwata (Tokyo University of Science)Takeo Ushijima (Tokyo University of Science)
Abstract : Free boundary problems are recently used to model phenomena of biological invasion for species such as migration into a new habitat. In this talk, we consider a diffusive epidemic model with free boundary. We prove the existence and nonexistence of a traveling wave solution of the model. We numerically observe the traveling wave and the front motion of the model. This is a joint work with Takeo Ushijima and Emiko Ishiwata.

[01447] Traveling Wave Solutions for Discrete Diffusive SIR Epidemic Model

Format : Talk at Waseda University
Author(s) : Ran Zhang (Heilongjiang University)Jinliang Wang (Heilongjiang University)Shengqiang Liu (Tiangong University)
Abstract : In this talk, we deal with the conditions of existence and nonexistence of traveling wave solutions for a class of discrete diffusive epidemic model. In addition, the boundary asymptotic behavior of traveling wave solutions is obtained by constructing a suitable Lyapunov functional and employing Lebesgue dominated convergence theorem. Our result could answer some unsolved problems in the previous studies on discrete diffusive epidemic model.

[04496] Traveling waves of a differential-difference diffusive Kermack-McKendrick epidemic model with age-structured protection phase

Format : Talk at Waseda University
Author(s) : Mostafa Adimy (Inria and UCBL 1, Lyon)Abdennasser Chekroun (University of Tlemcen)Toshikazu Kuniya (Kobe University)
Abstract : We consider a general class of diffusive Kermack-McKendrick SIR epidemic models with an age-structured protection phase with limited duration, for example due to vaccination or drugs with temporary immunity. A saturated incidence rate is also considered which is more realistic than the bilinear rate. The characteristics method reduces the model to a coupled system of a reaction-diffusion equation and a continuous difference equation with a time-delay and a nonlocal spatial term caused by individuals moving during their protection phase. We study the existence and non-existence of non-trivial traveling wave solutions. We get almost complete information on the threshold and the minimal wave speed that describes the transition between the existence and non-existence of non-trivial traveling waves that indicate whether the epidemic can spread or not. We discuss how model parameters, such as protection rates, affect the minimal wave speed. The difficulty of our model is to combine a reaction-diffusion system with a continuous difference equation. We deal with our problem mainly by using Schauder's fixed point theorem. More precisely, we reduce the problem of the existence of non-trivial traveling wave solutions to the existence of an admissible pair of upper and lower solutions.

[00643] Stochastic modeling in cell biology

Session Time & Room :

00643 (1/3) : 1E (Aug.21, 17:40-19:20) @A512

00643 (2/3) : 2C (Aug.22, 13:20-15:00) @A512

00643 (3/3) : 2D (Aug.22, 15:30-17:10) @A512

Type : Proposal of Minisymposium
Abstract : Emerging forms of experimental data in cellular and molecular biology have driven new modeling frameworks, many of which are stochastic due to noisy characteristics at these scales. This session features stochastic model construction and analysis of microbiological systems ranging in scale from the movement of genetic material (e.g., DNA) to multi-cell tissues, including mathematical advances motivated by the challenges to explain observed phenomena. Mathematical themes will include stochastic differential equations, Monte Carlo techniques for stochastic simulation, and stochastic PDEs. Several talks will also incorporate novel approaches to effectively representing and incorporating experimental data into the modeling process.
Organizer(s) : Peter Kramer, Christopher Miles
Classification : 92-10, 60G07, 35Q92, 62M30
Minisymposium Program :

00643 (1/3) : 1E @A512 [Chair: Peter Kramer]

[04558] Intracellular Transport Across Scales

Format : Talk at Waseda University
Author(s) : Keisha Cook (Clemson University)Scott A. McKinley (Tulane University)
Abstract : Biological systems are traditionally studied as isolated processes (e.g. regulatory pathways, motor protein dynamics, transport of organelles, etc.). Although more recent approaches have been developed to study whole cell dynamics, integrating knowledge across biological levels remains largely unexplored. In experimental processes, we assume that the state of the system is unknown until we sample it. Many scales are necessary to quantify the dynamics of different processes. These may include a magnitude of measurements, multiple detection intensities, or variation in the magnitude of observations. The interconnection between scales, where events happening at one scale are directly influencing events occurring at other scales, can be accomplished using mathematical tools for integration to connect and predict complex biological outcomes. In this work we focus on building inference methods to study the complexity of the cytoskeleton from one scale to another.

[02757] Inferring RNA Dynamic Rates from Spatial Stochastic Snapshots

Format : Talk at Waseda University
Author(s) : Christopher Edward Miles (University of California, Irvine)
Abstract : There are unresolved mysteries about the dynamics of RNA splicing, an important molecular process in the genetic machinery. These mysteries remain because the obtainable data for this process are not time series, but rather static spatial images of cells with stochastic particles. From a modeling perspective, this creates a challenge of finding the right mathematical description that respects the stochasticity of individual particles but remains computationally tractable. I'll share our approach to constructing a spatial Cox process with intensity governed by a reaction-diffusion PDE. We can do inference on this process with experimental images by employing variational Bayesian inference. Several outstanding issues remain about how to combine classical and modern statistical/data-science approaches with more exotic mechanistic models in biology. This work is in collaboration with the Ding lab of Biomedical Engineering at UCI.

[02952] Centrosome Movement and Clustering During Mitosis

Format : Online Talk on Zoom
Author(s) : Sarah Olson (Worcester Polytechnic Institute)Amity Manning (Worcester Polytechnic Institute)
Abstract : While much work has been done to understand the roles of the key molecular components of the mitotic spindle
during cell division, identifying the consequences of force perturbations in the spindle remains a challenge. In particular, cells with extra centrosomes may undergo a bipolar or multipolar division. We combine experimental approaches with computational modeling to define a role for cortical dynein in centrosome clustering, allowing for a bipolar division in cells with extra centrosomes.

[01821] Stochastic model of nuclear size control in S. pombe

Format : Online Talk on Zoom

Author(s) : Xuesong Bai (Brandeis University)Thomas Fai (Brandeis University)

Abstract : The size of the nucleus scales robustly with cell size so that the nuclear-to-cell size—the N/C ratio—is maintained during growth in many cell types. To address the fundamental question of how cells maintain the size of their organelles despite the constant turnover of proteins and biomolecules, we consider a model based on osmotic force balance predicts a stable nuclear-to-cell size ratio, in good agreement with experiments on the fission yeast Schizosaccharomyces pombe. We model the synthesis of macromolecules during growth using chemical kinetics and demonstrate how the N/C ratio is maintained in homeostasis. We compare the variance in the N/C ratio predicted by the model to that observed experimentally.

00643 (2/3) : 2C @A512 [Chair: Christopher Miles]

[05399] Stochastic models of DNA methylation, plasticity and drug resistance

Format : Online Talk on Zoom

Author(s) : Jasmine Foo (University of Minnesota)

Abstract : In this talk I will discuss some recent work on modeling stochastic intracellular DNA methylation processes and examine their consequences on population dynamics within a growing tumor.

[04460] Stochastic modeling of ovarian aging

Format : Online Talk on Zoom

Author(s) : Sean Lawley (University of Utah)

Abstract : Why are women born with up to a million primordial follicles when only a few hundred will ever ovulate a mature egg? What physiological mechanisms trigger menopause? Can the age of natural menopause be predicted? Can menopause be delayed? In this talk, we will describe recent stochastic models of ovarian aging which are aimed at answering these questions.

00643 (3/3) : 2D @A512 [Chair: Christopher Miles]

[02211] Optimal curvature and directional sensing in long-range cell-cell communication

Format : Talk at Waseda University

Author(s) : Jun Allard (University of California Irvine)Sohyeon Park (University of California Irvine)Dae Seok Eom (University of California Irvine)Hyunjoong Kim (University of Pennsylvania)

Abstract : Cells in tissue can communicate long-range via diffusive signals. In addition, another class of cell-cell communication is by long, thin cellular protrusions that are ~ 100 microns in length, i.e., many cell-lengths, and ~ 100 nanometers in width, i.e., below traditional microscope resolution. These protrusions have been recently discovered in many organisms, including nanotubes humans and airinemes in zebrafish. But, before establishing communication, these protrusions must find their target cell. Here we demonstrate airinemes in zebrafish are consistent with a finite persistent random walk model. We study this model by stochastic simulation, and by numerically solving the survival probability equation using Strang splitting. The probability of contacting the target cell is maximized for a balance between ballistic search and diffusive highly curved, random search. We find that the curvature of airinemes in zebrafish, extracted from live cell microscopy, is approximately the same value as the optimum in the simple persistent random walk model. We also explore the ability of the target cell to infer direction of the airineme's source, finding the experimentally observed parameters to be at a Pareto optimum balancing directional sensing with contact initiation.

[04467] Centrosome asymmetry in the early C. elegans embryo

Format : Talk at Waseda University

Author(s) : Adriana Dawes (Ohio State University)Shayne Plourde (The Ohio State University)David Ignacio (The Ohio State University)Andrew Cohen (The Ohio State University)

Abstract : Centrosome positioning, which determines where a cell divides, is mediated by microtubules, biopolymers nucleated at the centrosomes, and the motor protein dynein. Using stochastic and continuum models along with a measure of centrosome movement, we identify key proteins involved in regulating centrosome movement in early embryos of the nematode worm C. elegans, and demonstrate the parallel role of cell geometry in proper positioning of the centrosomes.

[04462] Modeling and tracking random motion in micrometer-scale living systems

Format : Talk at Waseda University
Author(s) : Jay Mack Newby (University of Alberta)
Abstract : We study stochastic motion of objects in micrometer-scale living systems: tracer particles in living cells, pathogens in mucus, and single cells foraging for food. We use stochastic models and state space models to track objects through time and infer properties of objects and their surroundings. For example, we can calculate the distribution of first passage times for a pathogen to cross a mucus barrier, or we can spatially resolve the fluid properties of the cytoplasm in a living cell. Recently developed computational tools, particularly in the area of Markov Chain Monte Carlo, are creating new opportunities to improve multiple object tracking. The primary remaining challenge, called the data association problem, involves mapping measurement data (e.g., positions of objects in a video) to objects through time. I will discuss new developments in the field and ongoing efforts in my lab to implement them. I will motivate these techniques with specific examples that include tracking salmonella in GI mucus, genetically expressed proteins in the cell cytoplasm, active transport of nuclei in multinucleate fungal cells, and raphid diatoms in seawater surface interfaces.

[04071] Stochastic effects in molecular motor teams under detachment and reattachment

Format : Talk at Waseda University
Author(s) : Peter Kramer (Rensselaer Polytechnic Institute)Joseph Klobusicky (The University of Scranton)John Fricks (Arizona State University)
Abstract : We revisit two paradigms of cooperative action by kinesin molecular motors involving a coupling of the detachment and reattachment processes with the stochastic spatial dynamics. First, for two dissimilar types of kinesin transporting a common cargo, we provide approximate analytical characterizations for how incorporating slack in the tether model affects the cooperative dynamics. Secondly, we extend consideration of gliding assays to a situation where microtubules are crosslinked while being crowdsurfed by immobilized kinesin.

[00652] Recent Advances in Quasi-Monte Carlo Methods and Related Topics

Session Time & Room :

00652 (1/3) : 5B (Aug.25, 10:40-12:20) @G304

00652 (2/3) : 5C (Aug.25, 13:20-15:00) @G304

00652 (3/3) : 5D (Aug.25, 15:30-17:10) @G304

Type : Proposal of Minisymposium
Abstract : Many applications, such as computational finance, uncertainty quantification involving PDEs with random inputs, and training of deep neural networks, require tackling computational problems with high dimensions. This minisymposium will bring together people working in Quasi-Monte Carlo (QMC) methods, a powerful class of methods for such problems with high dimensionality. More specifically, QMC methods have been proved efficient for integration over the multi-dimensional unit cube, over other domains, function approximation, and density estimation. In this minisymposium, we aim to showcase recent advances in QMC methods and foster interaction between researchers working in these areas.

[04989] The fast reduced QMC matrix-vector product

Format : Talk at Waseda University
Author(s) : Josef Dick (UNSW)Adrian Ebert (JKU Linz)Lukas Herrmann (RICAM Linz)Peter Kritzer (RICAM Linz)Marcello Longo (ETH Zurich)
Abstract : We study the approximation of integrals of the form $\int_D f(\boldsymbol{x}^\top A)\, d\mu(\boldsymbol{x})$, where A is a matrix, by quasi-Monte Carlo (QMC) rules $N^{-1}\sum_{k=0}^{N-1} f(\boldsymbol{x}_k^\top A)$. We are interested in cases where the main computational cost in computing the

approximation arises from the computation of $\boldsymbol{x}_k^\top A$. We design QMC rules for which the computation of $\boldsymbol{x}_k^\top A$, $k = 0, 1, \dots, N-1$ can be done in a fast way.

[05066] Recent Advances on discrepancy and WCE of constructible point sets on spheres

Format : Talk at Waseda University
Author(s) : Johann S. Brauchart (Graz University of Technology)
Abstract : We discuss bounds for the L_2-discrepancy and worst-case error for equal-weight quasi Monte Carlo rules (and compare them with optimal bounds) for constructible N-point sets that arise from mapping rational lattice points in the plane to the sphere using an area preserving Lambert transformation. Our standard examples are spherical Fibonacci point configurations defined by a Fibonacci lattice in the unit square.

This is joint work with Josef Dick (UNSW) and Yuan Xu (University of Oregon).

[03448] Quasi-Monte Carlo approach to Bayesian optimal experimental design

Format : Talk at Waseda University
Author(s) : Vesa Kaarnioja (Free University of Berlin)
Abstract : The goal in Bayesian optimal experimental design (OED) is to maximize the expected information gain for the reconstruction of unknown quantities given a limited budget for collecting measurement data. Quasi-Monte Carlo (QMC) methods have been demonstrated to be effective for numerical treatment of partial differential equations (PDEs) involving input uncertainties in recent years. In this talk, we derive tailored QMC cubature rules to reduce the computational burden in Bayesian OED problems governed by PDEs.

[04877] Density estimation by Monte Carlo and quasi-Monte Carlo

Format : Talk at Waseda University
Author(s) : Pierre L'Ecuyer (University of Montreal)
Abstract : Estimating the density of a continuous random variable X has been studied extensively in settings where n independent observations of X are given a priori. Popular methods include histograms and kernel density estimators. These methods have bias and their mean square error converges at a slower rate than the usual O(1/n) rate. In this talk, we consider the situation where the observations are generated by Monte Carlo simulation from a model. Unbiased estimators and better convergence rates can then be obtained, sometimes much better than O(1/n). We show how this can be achieved, using techniques such as conditional Monte Carlo, likelihood ratio methods for derivative estimation, and randomized quasi-Monte Carlo. Theoretical and empirical results will be given. This is based on joint work with Amal Ben Abdellah and Florian Puchhammer.

00652 (2/3) : 5C @G304 [Chair: Yoshihito Kazashi]

[03343] High dimensional approximation and the curse of dimensionality

Format : Talk at Waseda University
Author(s) : Ian Hugh Sloan (UNSW Sydney)
Abstract : This talk, joint work with Kuo and Kaarnioja, extends a 2022 result with Kazashi and Nobile. It uses periodic kernels located at lattice points. The lattice points and the kernels depend on parameters called “weights”. Using new “serendipitous” weights, the cost grows linearly with both dimension and number of lattice points, allowing practical computations in 1,000 dimensions, and no curse of dimensionality.

[01697] QMC and sparse grids beyond uniform distributions on cubes

Format : Talk at Waseda University
Author(s) : Ilja Klebanov (Free University of Berlin)Tim Sullivan (University of Warwick)
Abstract : While Monte Carlo and MCMC methods are generally applicable and have a dimension-independent convergence rate, this rate is rather slow and unfeasible for many applications. Sparse grids and Quasi Monte Carlo methods provide better convergence rates under certain assumptions, but have only been constructed for uniform distributions on cubes and several other very specific distributions such as Gaussians. In this talk, I will show how these methods can be generalized to mixtures of such specific distributions, e.g. Gaussian mixtures, by means of a properly constructed transport map, which is a crucial step towards combining QMC and sparse grids methods with state of the art importance sampling algorithms, that are often based on such mixtures. I will avoid technical details and present lots of illustrations and videos instead.

[02052] Can hyperinterpolation part with quadrature exactness?

Format : Online Talk on Zoom

Author(s) : Congpei An (Southwestern University of Finance and Economics)Hao-Ning Wu (The Hong Kong University)

Abstract : We discuss the approximation of continuous functions on the unit sphere by spherical polynomials of degree n via hyperinterpolation. Hyperinterpolation of degree n is a discrete approximation of the L2-orthogonal projection of degree n with its Fourier coefficients evaluated by a positive-weight quadrature rule that exactly integrates all spherical polynomials of degree at most 2n. This talk aims to bypass this quadrature exactness assumption by replacing it with the Marcinkiewicz--Zygmund property. Consequently, hyperinterpolation can be constructed by a positive-weight quadrature rule--not necessarily with quadrature exactness. This scheme is called unfettered hyperinterpolation. We provide a reasonable error estimate for unfettered hyperinterpolation. The error estimate generally consists of two terms: a term representing the error estimate of the original hyperinterpolation of full quadrature exactness and another introduced as compensation for the loss of exactness degrees. A guide to controlling the newly introduced term in practice is provided. In particular, if the quadrature points form a quasi-Monte Carlo design, then there is a refined error estimate. Numerical experiments verify the error estimates and the practical guide.

[04553] Quasi-Monte Carlo-Based Algorithms for Deep Learning with Applications

Format : Online Talk on Zoom

Author(s) : Xiaoqun Wang (Tsinghua University)

Abstract : Deep learning methods are now used to solve (stochastic) partial differential equations in high dimensions, where the loss functions are defined as mathematical expectations. Traditional method to approximate the expectation is Monte Carlo (MC) method. We propose novel deep learning algorithms based on quasi-Monte Carlo (QMC) method, which is a deterministic version of MC method. We prove that the theoretical convergence order of QMC-based deep learning algorithms is asymptotically higher than that of MC-based algorithms. Numerical experiments demonstrate the substantial superiority of QMC-based algorithms in various applications.

00652 (3/3) : 5D @G304 [Chair: Takashi Goda]

[04614] Lattice rules for integration on $\mathbb{R}^d$

Format : Talk at Waseda University

Author(s) : Dirk Nuyens (KU Leuven)

Abstract : For integration of periodic functions of mixed smoothness on the unit cube lattice rules are a very good choice. Their group theoretical structure allows for a convenient error analysis.

When integrating functions on $\mathbb{R}^d$ there are multiple ways of still making use of lattice rules. We could truncate the integration region, and take into account the truncation error and the projection distance to the periodic subspace; or we could do a substitution and map the integrand to the unit cube. Depending on how we proceed it is possible to retain the smoothness and obtain higher order convergence with a lattice rule.

[04320] SNPE-B Revisited: Rethinking of Data Efficiency and Variance Reduction

Format : Talk at Waseda University

Author(s) : Zhijian He (South China University of Technology)

Abstract : Sequential neural posterior estimation (SNPE) techniques have recently proposed for dealing with simulation-based models with intractable likelihoods. Unlike approximate Bayesian computation, SNPE techniques learn the posterior from sequential simulation using neural network-based conditional density estimators. This paper reclaims the efficiency of SNPE-B proposed by Lueckmann et al. (2017) through sophisticated sampling strategies. We firstly introduce a concentrated loss function based on an adaptive calibration kernel that reweights the simulated data appropriately to improve the data efficiency. We also provide a theoretical analysis of the variance of importance sampling-based estimators. We then propose several variance reduction techniques including quasi-Monte Carlo sampling to further accelerate the process of learning. Numerical experiments demonstrate that our method outperforms the original SNPE-B method together with other existing competitors on certain tasks.

[04916] Variable importance measures in high dimensional data sets

Format : Talk at Waseda University
Author(s) : Art B Owen (Stanford University)
Abstract : This talk connects some ideas from QMC sampling to new problems in explainable AI. Variable importance measures in global sensitivity analysis are commonly derived from the ANOVA decomposition. The ANOVA is problematic with dependent variables. Then Shapley values and related quantities are used to measure importance, and those can be studied through the anchored decomposition, also common in quasi-Monte Carlo sampling.

Based on work with Ben Seiler, Christopher Hoyt, Masayoshi Mase and Naofumi Hama.

[03703] Tuning QMC point sets using WAFOM-like value

Format : Talk at Waseda University
Author(s) : Makoto Matsumoto (Hiroshima University)
Abstract : There are many figures of merit for QMC point set P. The star discrepancy D^*(P) is a famous one. We restrict ourself to the case of 2-adic digital nets. Then, P can be considered as an F2-vector space, where F2 is the two-element field. Let P' be the perpendicular space of P. Then, P' is considered as the space of linear relations satisfied by P. As a rough sketch, P is more uniform if any non-zero element A in P' is sufficiently complicated. One way to measure the complexity of A is Niederreiter-Rosenbloom-Tsfasman (NRT) weight; the smallest NRT weight among all possible non-zero weights gives the t-value. As other figures of merits, we may consider Dick weight mu_alpha(A) of A in P'. Summation of 2^{-mu_alpha(A)} over nonzero A in P' gives figures of merit studied by Dick, and by considering the limit where alpha goes to infinity, we obtain WAFOM. It is used by Harase that NRT weight is invariant by lower triangular trransformation, but WAFOM differs, and so one can obtain better performance for smooth integrand when WAFOM is optimized while t-value is fixed. We study a justification of this method, and variation where Dick weight is replaced with NRT weight.

[00654] Poset Combinatorics

Session Time & Room : 2D (Aug.22, 15:30-17:10) @G302

Type : Proposal of Minisymposium
Abstract :
To a finite poset P we associate two algebraic objects: the order polynomial $\Omega(P,n)$, which counts the number of order preserving labeling maps of posets from P to $1<2<\ldots<n$; and the generating series $\sum \Omega(P,n)x^n$, called order series.
This algebraic setting leads to interactions with operad theory, metric spaces, cellular automata, and combinatorial species. In this mini-symposium, the experts will introduce those tools and expose their contributions as well as open questions. The talks will include theoretical results as well as applications to nonlinear signal-flow graphs.
Organizer(s) : Eric Rubiel Dolores-Cuenca
Classification : 05a15, 06a11, 18m80
Minisymposium Program :

[02151] The operad of finite posets acts on zeta values

Format : Talk at Waseda University
Author(s) : Eric Dolores Cuenca (Yonsei University)
Abstract : Consider Riemann zeta function $\zeta(k)=\sum_{n=1}^{\infty}\frac{1}{n^k}$. We develop a theory in which the zeta values and the order polytopes share the same combinatorial information. More precisely, we show that the operad of finite posets acts on Stanley order polynomials, and the aforementioned operad acts on a set of numbers generated by zeta values.
To demonstrate that the action of the operad on zeta values is not trivial, we explicitly compute a quaternary associative non commutative operation.

[01777] What is -Q for a poset Q?

Format : Talk at Waseda University
Author(s) : Masahiko Yoshinaga (Osaka University)
Abstract : In the context of combinatorial reciprocity, it is a natural question to ask what "−Q" is for a poset Q. In a previous work, the definition "−Q:=Q×R with lexicographic order" was proposed based on the notion of Euler characteristic of semialgebraic sets. In fact, by using this definition, Stanley's reciprocity for order polynomials was generalized to an equality for the Euler characteristics of certain spaces of increasing maps between posets. The purpose

of this paper is to refine this result, that is, to show that these spaces are homeomorphic if the topology of Q is metrizable.

[04172] A new expression for the order polynomial

Format : Online Talk on Zoom
Author(s) : Fengming Dong (Nanyang Technological University)
Abstract : In 1970s, Stanley introduced the order polynomial of a poset P. For a poset P, a mapping $\sigma : P \to [m]$ is said to be order-preserving if $u \preceq v$ implies that $\sigma(u) \leq \sigma(v)$. The order polynomial $\Omega(P, x)$ is defined to be the function which counts the number of order-preserving mappings $\sigma : P \to [m]$ whenever $x = m$ is a positive integer. In this talk, I will introduce an expression for $\Omega(P, x)$, and an expression for the chromatic polynomial of a graph by applying this new result on order polynomial.

[02099] Polychrony as chinampas

Format : Online Talk on Zoom
Author(s) : José Antonio Arciniega-Nevárez (Universidad de Guanajuato)
Abstract : In this talk, we will discuss the effect of stimulating some nodes at certain time (initial condition) in a signal flow path with auto-edges. The stimuli are applied at different times. The effect of these stimuli propagates through the vertices of the path, causing other nodes, which we will call secondary nodes, to cascade. We are interested in cascades in which the initial stimuli are less than or equal to the number of secondary vertices. This can be transferred to the study of a graph with weights, these weights being the times at which a signal travels from the output vertex to the arrival vertex. We are interested in knowing the time at which a node will be activated under a certain initial condition. The problem is nonlinear, so to deal with time, we propose to study a latiz, where, vertically, the time is described and horizontally, the vertices of the path are repeated. In this way, a vertex of the latiz will be connected to another one to which it was already connected in the path but at a different height, depending on the time.

If the time is always t=1, the problem becomes to study an automaton, where a cell at time t lives depending on the cells alive at time t-1, in particular we are interested in the rule 192 with the difference that the automaton is reactivated at different times (with the initial condition). The generated automata,that we call chinampas, have topological and combinatorial properties that allow us to solve the initial problem. Moreover, we can characterize automata in which the number of cells outside the initial condition are equal to or one more than those of the initial condition.

For the case in which we have more than one of these cells, we have translated the problem to one of triangular series with order conditions. These series can be obtained from partially ordered sets (posets). We have noted that the series obtained are known as generalizations of Stanley polynomials whose coefficients count the different ways of labeling a poset preserving the order.

The problem was inspired by the behavior of a neural network so this work is related to those who study such neural networks as polychrony groups, in fact, this is a particular case of polychrony.

[00656] Multiscale Pattern Formation

Session Time & Room :

00656 (1/3) : 1D (Aug.21, 15:30-17:10) @G501

00656 (2/3) : 1E (Aug.21, 17:40-19:20) @G501

00656 (3/3) : 2C (Aug.22, 13:20-15:00) @G501

Type : Proposal of Minisymposium
Abstract : One way to understand the complex dynamics in dissipative systems is to decompose the object into subsystems with different spatiotemporal scales. The resulting subsystems could be unified by singular perturbation, fast-slow method, unfolding of singularities, bifurcation, and data-driven approaches. We collect 12 talks to present the state-of-the-art multi-scale pattern formation arising in biology, chemical reaction, fluid dynamics, and materials science in homogeneous and heterogeneous media. One of our goals is to find a promising direction in the newly emerging field of multiscale pattern formation problems.

[01951] Multiscale pattern formation in space and time

Format : Talk at Waseda University
Author(s) : Yasumasa Nishiura (Hokkaido University/Chubu University)
Abstract : One way to understand the complex dynamics in dissipative systems is to decompose the object into subsystems with different spatiotemporal scales. The resulting subsystems could be unified by singular perturbation, fast-slow method, unfolding of singularities, bifurcation, averaging, and data-driven approaches. I will try to present the state-of-the-art multi-scale pattern formation arising in biology, chemical reaction, fluid dynamics, and materials science in homogeneous and heterogeneous media.

[01983] Localized spot dynamics: curvature and instability

Format : Talk at Waseda University
Author(s) : Justin Tzou (Macquarie University)
Abstract : For localized spots solutions of singularly perturbed reaction-diffusion systems, we discuss two aspects of slow drift dynamics: the oscillatory instabilities, and effects of domain curvature. The problem with curvature is analyzed within the context of a model of vegetation patterns on a curved terrain, which incorporates advection effects due to flow of water downhill. The stability analysis on flat domains centers on understanding how domain geometry selects dominant modes of oscillation.

[01901] Spiky patterns in a three-component consumer chain model

Format : Talk at Waseda University
Author(s) : Shuangquan Xie (Hunan University)
Abstract : We study a cooperative consumer chain model with one producer and two consumers, which is a three-component extension of the Schankenberg model. We show that consumers can survive and have a profile of a spike for sufficiently high consumption. We then study the stability of spike solutions. When the consumption constant is further increased to a certain threshold, the system undergoes a Hopf bifurcation and the spiky pattern begins to oscillate.

[01941] Emergence of locomotion by autonomous parameter tuning

Format : Talk at Waseda University
Author(s) : Keiichi Ueda (University of Toyama)Takumi Horita (University of Toyama)
Abstract : A peristaltic locomotion model with parameter tuning is presented. The parameter tuning system is described by the dynamical system with selection algorithm. The model autonomously generates stable elongation-contraction wave and finds appropriate anchor timing. We model the parameter tuning system as distributed system in order that the system achieves adaptability to various environmental changes.

00656 (2/3) : 1E @G501 [Chair: Edgar Knobloch]

[01917] Symmetry-Breaking for a Compartmental-Reaction Diffusion System

Format : Talk at Waseda University
Author(s) : Michael Ward (University of British Columbia)
Abstract : We investigate pattern formation for a 2D PDE-ODE bulk-cell model, where two bulk diffusing species are coupled to nonlinear intracellular reactions that are confined within a disjoint collection of small circular compartments within the domain. The bulk species are coupled to the spatially segregated intracellular reactions through Robin conditions across the cell boundaries. For this compartmental-reaction diffusion system, symmetry-breaking bifurcations, regulated by a membrane binding rate ratio, occur even when the bulk species have equal diffusivities.

[01765] Bayesian Model Selection of PDEs for Pattern Formation

Format : Talk at Waseda University
Author(s) : Natsuhiko Yoshinaga (Tohoku University)Satoru Tokuda (Kyushu University)
Abstract : Partial differential equations (PDEs) have been widely used to reproduce patterns in nature and to give insight into the mechanism underlying their formation. PDE models often rely on the pre-request knowledge of physical laws and developing a model to reproduce a desired pattern remains difficult. We propose a method to estimate the best PDE from one snapshot of an objective pattern under the stationary state. We apply our method to complex patterns, such as quasi-crystals.

[02979] Spectral Stability of Far-from-Equilibrium Planar Periodic Patterns

Format : Online Talk on Zoom
Author(s) : Björn de Rijk (Karlsruhe Institute of Technology)
Abstract : We consider the existence and spectral stability of far-from-equilibrium planar periodic patterns in reaction-diffusion-advection systems. The planar periodic traveling waves are constructed by bifurcating from one-dimensional wave trains undergoing a transverse short-wave destabilization. The selected wavenumber matrix and velocity vector at bifurcation are fully determined by the wavenumber, velocity and critical Bloch modes of the underlying wave train. Our spectral analysis of the planar periodic pattern yields an expansion of the critical spectral surface touching the origin due to translational invariance in both spatial directions. In particular, such an expansion allows for an explicit verification of the spectral stability conditions implying nonlinear stability of the planar periodic pattern against spatially localized perturbations. This is joint work with Miguel Rodrigues (Université de Rennes 1, France).

[01867] Fronts in the wake of a slow parameter ramp

Format : Online Talk on Zoom
Author(s) : Ryan Goh (Boston University)Tasso Kaper (Boston University)Arnd Scheel (University of Minnesota)Theodore Vo (Monash University)
Abstract : We discuss front solutions in the presence of a parameter ramp which slowly varies in space, rigidly propagates in time, and moderates the (in)stability of a spatially-homogeneous equilibrium, nucleating a traveling wave in its wake. For moving ramps, the front location is governed by a slow passage between convective and absolute instability; a projectivized fold. For stationary ramps, fronts are governed by slow-passage through a pitchfork and a connecting solution of the Painléve-II equation.

[02507] Front propagation in a multi-variable morphogenetic model of branching

Format : Talk at Waseda University
Author(s) : Edgar Knobloch (University of California at Berkeley)Arik Yochelis (Ben-Gurion University of the Negev)
Abstract : We study the existence and stability of propagating fronts in the Meinhardt model of branching in 1D. We identify a sniper bifurcation of fronts that leads to episodic front propagation in the parameter region below propagation failure and show that this state is stable. We show that propagation failure is a consequence of a T-point in a spatial dynamics description and identify additional T-points responsible for a large multiplicity of different traveling front-peak states.

[02105] CONTROL OF ENGULFMENT FOR BINARY POLYMER PARTICLES

Format : Talk at Waseda University
Author(s) : Takashi Teramoto (Asahikawa Medical University)
Abstract : Engulfment configurations with separated phases occur in the nanoparticles of a binary polymer mixture. Numerical investigations of the Cahn-Hilliard model with the boundary contact energy show the relationships between the free energies and two types of configurations within confined spheres in three-dimensions. These results are consistent with experimental observations. A Janus-type configuration forms a spherical-cap-shaped interface inside a particle. In the core-shell configuration, one of polymer phases completely engulfs another phase to form concentric interfaces with inner and outer phases. We consider the sharp interface limit of equilibrium configurations and derive the stability condition that each configuration becomes the only minimizer when the contact angle changes between the three phases.

[03494] Instability of Planar Interfaces in Reaction-Diffusion-Advection Equations

Format : Talk at Waseda University
Author(s) : Paul Carter (University of California, Irvine)
Abstract : We consider planar interfaces between stable homogeneous rest states in singularly perturbed 2-component reaction diffusion advection equations, motivated by the appearance of fronts between bare soil and vegetation in dryland ecosystems, as well as multi-interface solutions, such as vegetation stripes. On sloped terrain, one can find stable traveling interfaces, while on flat ground, one finds that sideband instabilities along the interface can lead to labyrinthine Turing-like patterns. To explore this behavior, using geometric singular perturbation methods, we analyze instability criteria for planar interfaces in reaction diffusion advection systems, focussing on a specific Klausmeier-type model, and examine the effect of terrain slope on the stability of the interfaces.

[04510] Patterns on patterns

Format : Online Talk on Zoom
Author(s) : Martina Chirilus-Bruckner (Leiden University)Jolien Kamphuis (Leiden University)
Abstract : The formation of patterns on top of spatially varying background states in the context of reaction-diffusion systems with spatially varying coefficients (such as the extended Klausmeier model) is motivated by the study of vegetation patterns on changing topographies. We present two regimes: (i) At onset when the background state loses stability and small amplitude modulations occur and (ii) in the long wavelength limit where the patterned state is composed of highly localized individual pulses.

[00657] Tomographic inverse problems and deep learning techniques

Session Time & Room : 3E (Aug.23, 17:40-19:20) @F401

Type : Proposal of Minisymposium
Abstract : Tomographic inverse problems involve the recovery of physical quantity (shown as image) from indirect observations. These inverse problems are typically ill-posed and there have been numerous attempts to obtain the proper solution based on mathematical modeling. Deep learning has recently emerged as a powerful tool for solving the inverse problem, as it demonstrates the potential to handle uncertainty of the solution with large amounts of training data. In this mini-symposium, we will discuss mathematical and deep learning strategies for solving inverse problems related to imaging modalities such as computed tomography (CT), magnetic resonance imaging (MRI), and electrical impedance tomography (EIT).

[05264] Ill-posed Inverse problems in Low-dose Dental Cone-beam Computed Tomography

Format : Talk at Waseda University
Author(s) : Hyoung Suk Park (National Institute for Mathematical Sciences)Chang Min Hyun (Yonsei University)Jin Keun Seo (Yonsei University)
Abstract : Dental cone-beam computed tomography (CBCT) has been increasingly being used in various dental fields such as implant/prosthetics, oral and maxillofacial surgery, and orthodontic treatment. It aims to provide high-resolution images with the lowest possible radiation dose at a low cost for equipment. However, this cost-competitive goal makes the inverse problem of dental CBCT more nonlinear and ill-posed. In this presentation, we describe the mathematical structure of an ill-posed nonlinear inverse problem of low-dose dental CBCT and explain the advantages and limitations of the deep learning-based approach for CBCT image reconstruction compared to conventional regularization methods.

[05265] Machine learning for automatic signal quality assessment in multi-channel electrical impedance-based hemodynamic monitoring

Format : Talk at Waseda University
Author(s) : Chang Min Hyun (Yonsei University)
Abstract : Owing to recent advances in thoracic electrical impedance tomography, a patient's hemodynamic function can be noninvasively and continuously estimated in real-time by surveilling a cardiac volume signal associated with stroke volume and cardiac output. In clinical applications, however, a cardiac volume signal is often of low quality, mainly because of the patient's deliberate movements or inevitable motions during clinical interventions. This talk deals with developing a signal quality indexing method that assesses the influence of motion artifacts on transient cardiac volume signals. We apply divergent machine-learning methods from discriminative-model to manifold learning. The use of machine-learning could be suitable for our real-time monitoring application that requires fast inference and automation as well as high accuracy. In the clinical environment, the proposed method can be utilized to provide immediate warnings so that clinicians can minimize confusion regarding patients' conditions, reduce clinical resource utilization, and improve the confidence level of the monitoring system. Numerous experiments using actual EIT data validate the capability of cardiac volume signals degraded by motion artifacts to be accurately and automatically assessed in real-time by machine learning.

[05332] Application of AI-based Medical Diagnosis: focusing on tomography

Format : Talk at Waseda University
Author(s) : Soomin Jeon (Dong-A University)
Abstract : In this talk, we will see the various applications of artificial intelligence (AI) based medical diagnosis, focusing on tomography. From data set configuration for AI medical image research using tomography such as PET, X-ray, and X-ray CT, we look at the results of research on training algorithms. We also cover research related to the latest diagnostic technologies such as Alzheimer's disease.

[05324] Data-driven reconstruction in X-ray CT with provable convergence guarantees

Author(s) : Jürgen Frikel (OTH Regensburg)Simon Göppel (University of Innsbruck)Markus Haltmeier (University of Innsbruck)
Abstract : Computed tomography (CT) is a widely used imaging technique in various fields including medicine, engineering, and materials science. CT image reconstruction is an ill-posed problem, which means that small errors in the measurements can lead to significant errors in the reconstruction. In order to stabilize the image reconstruction, the use of regularization techniques is crucial. Classical regularization methods (e.g., variational regularization) are known to provide convergent methods, but the resulting reconstructions may not be optimal. On the other hand, regularization strategies based on machine learning methods have been shown to produce better reconstructions, but often lack theoretical convergence guarantees. To address these challenges, we propose a convergent data-driven reconstruction method for x-ray tomography. Our framework consists of two steps, where in a classical regularization is used in the first step and a deep learning approach is used in the second step. Both steps are coupled by integrating data proximity into a network architecture. This integration allows us to leverage the strengths of both approaches while addressing their limitations. Our experimental results demonstrate the effectiveness of our approach in improving the accuracy of CT image reconstruction, while providing convergence guarantees.

[00666] Simulations and Algorithms for Materials Sciences

Session Time & Room :

00666 (1/3) : 1C (Aug.21, 13:20-15:00) @D101

00666 (2/3) : 1D (Aug.21, 15:30-17:10) @D101

00666 (3/3) : 1E (Aug.21, 17:40-19:20) @D101

Type : Proposal of Minisymposium
Abstract : Simulation and computational methodologies are the third pillar alongside theory and experiment in materials science and engineering. Multiphysics and multiscale modeling and simulations incorporating proper numerical techniques and algorithms are key to understand the fundamental mechanisms in controlling the macroscopic material behaviors and make predictions. The development requires interdisciplinary collaborations and efforts, including applied physics, materials science, solid mechanics and applied mathematics. We propose a minisymposium in three sessions, with the aim of bringing together experts from diverse communities to share recent advances and research highlights in the understanding of this topic from their respective perspectives.

[02135] ESES, a Eulerian and Lagrangian molecular surface generator

Format : Talk at Waseda University
Author(s) : Weihua Geng (Southern Methodist University)
Abstract : The Poisson-Boltzmann (PB) model is numerically solved either on grid based meshes using finite difference/element methods or on body-fitted meshes using boundary element methods. In this talk, we investigate the distinguished features of the Eulerian Solvent Excluded Surface (ESES) software with which both Eulerian and Lagrangian surfaces are produced. We investigate the performance with these two types of surface discretization usingthe grid based MIBPB solver and body-fitted TABI-PB solvers.

[02756] From nanocrystals to glasses: a strengthening mechanism analysis for amorphization.

Format : Talk at Waseda University
Author(s) : Chuqi CHEN (Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)
Abstract : Recently, many studies investigated the correlation between the strength of the polycrystals, and the grain size and grain boundary width through both experimental and molecular dynamics simulation approaches. Results reveal that as grain boundary width increases, the crystalline structure of the grain boundary region transforms into an amorphous state. We propose mechanism analysis to elucidate the underlying mechanisms that govern the aforementioned relationships.

[02794] Sum-of-Gaussians method with applications to molecular dynamics simulations

Format : Talk at Waseda University
Author(s) : Jiuyang Liang (Shanghai Jiao Tong University)
Abstract : Sum-of-Gaussians (SOG) method has attracted attention in many applications. In this talk, we will review some recently-developed SOG methods. Based on a sum-of-Gaussians decomposition of the Coulomb kernel, we develop an accurate, highly efficient, and scalable random batch sum-of-Gaussians (RBSOG) method for molecular dynamics simulations of systems with long-range interactions. Numerical results, including SPC/E bulk water and phase-separated electrolytes, are presented to show the attractive performance of the algorithm, including the superscalability in parallel computing.

[03201] Random-batch Ewald method for molecular dynamics

Format : Talk at Waseda University
Author(s) : Zhenli Xu (Shanghai Jiao Tong University)
Abstract : We present a random-batch Ewald method for molecular dynamics of particle systems with long-range interactions. It takes advantage of the random minibatch strategy for particles, leading to an order N algorithm. It is based on the Ewald splitting of the Coulomb kernel and the random importance sampling is employed in the Fourier part such that the force variance can be reduced. Numerical results are presented to show the attractive performance of the algorithm.

00666 (2/3) : 1D @D101 [Chair: Zecheng Gan]

[04335] Molecular Dynamics Simulation of Concentrated Entangled Polymers in Athermal Solvents

Format : Talk at Waseda University
Author(s) : Jiayi wang (HKUST)
Abstract : We have developed a coarse-grained model to simulate the geometric and dynamical properties of entangled polymer chains dissolved in athermal solvents. Our model successfully verifies the concentration scaling relationships of the geometric characteristics. In terms of the dynamical aspect, we have discovered that the swelling of the entangled polymer chains in athermal solvents leads to enhanced local chain stiffness or effective system elastic modulus.

[04386] Multiscale modeling and Simulations of Interfacial Defects in based on PN model

Author(s) : Shuyang Dai (Wuhan University)
Abstract : A multiscale continuum model is developed to describe the defect structures in crystalline material such as FCC metals. The interface structure for twist, tilt and misfit grain boundaries are described by the dislocation network. The model incorporates both the anisotropy elasticity of each grain in crystalline materials and the molecular dynamics calculation informed interaction between two bulks, i.e., the nonlinear generalized stacking-fault energy. The equilibrium structures are obtained from the numerical simulations of the force balance differential equations. We apply this approach to determine the structure and energetics of twist, tilt and general grain boundaries. We also investigated the dislocation structure in heterogeneous crystalline material. Our model agrees well with the atomistic results. An analytical description is developed based on the obtained structural features.

[04817] Solving integral equations on non-smooth boundaries

Format : Talk at Waseda University
Author(s) : Shidong Jiang (Center for Computational Mathematics, Flatiron Institute, Simons Foundation)Johan Helsing (Lund University)
Abstract : A numerical scheme is presented for the solution of Fredholm second-kind boundary integral equations on non-smooth boundaries. The scheme, which builds on recursively compressed inverse preconditioning (RCIP), is universal as it is independent of the nature of the singularities. The performance of the scheme is illustrated via several numerical examples.

[05284] A fast algorithm for Dirichlet partition problems

Format : Talk at Waseda University
Author(s) : Dong Wang (The Chinese University of Hong Kong, Shenzhen)
Abstract : A Dirichlet k-partition of a domain is a collection of k pairwise disjoint open subsets such that the sum of their first Laplace--Dirichlet eigenvalues is minimal. In this talk, we propose a new relaxation of the problem by introducing auxiliary indicator functions of domains and develop a simple and efficient diffusion generated method to compute Dirichlet k-partitions for arbitrary domains. The method only alternates three steps: 1. convolution, 2. thresholding, and 3. projection. The method is simple, easy to implement, insensitive to initial guesses and can be effectively applied to arbitrary domains without any special discretization. At each iteration, the computational complexity is linear in the discretization of the computational domain. Moreover, we theoretically prove the energy decaying property of the method. Experiments are performed to show the accuracy of approximation, efficiency and unconditional stability of the algorithm. We apply the proposed algorithms on both 2- and 3-dimensional flat tori, triangle, square, pentagon, hexagon, disk, three-fold star, five-fold star, cube, ball, and tetrahedron domains to compute Dirichlet k-partitions for different k to show the effectiveness of the proposed method. Compared to previous work with reported computational time, the proposed method achieves hundreds of times acceleration.

[00669] Mathematical Solutions of Industrial Applications

Session Time & Room : 3C (Aug.23, 13:20-15:00) @G404

Type : Proposal of Industrial Minisymposium
Abstract : Mathematics plays an important role in modern industry, for instance, as a tool for research & development and as algorithmic parts of products. This session presents success stories of industrial mathematics as a solution to various business challenges. Several domains of industry are considered: automotive, optics, manufacturing, medical imaging and agriculture. The following specific topics are included: 1. Data-driven development in industry, 2. Industrial applications of machine learning, 3. Inverse problems in medical X-ray imaging, 4. Machine learning in industry. Each talk will discuss the motivation, approaches and implementations based on mathematics.

[02716] Prediction of Leaf Area Index of Tomato Plants by Image Processing and Deep Learning

Format : Talk at Waseda University
Author(s) : Mario Tsukassa Sato (University of Tsukuba)Aiga Goto (University of Tsukuba)Nanami Isoda (University of Tsukuba)Ayu Kaise (University of Tsukuba)Claus Aranha (University of Tsukuba)Akira Imakura (University of Tsukuba)Tetsuya Sakurai (University of Tsukuba)Naomichi Fujiuchi (Ehime University)Naoya Fukuda (University of Tsukuba)
Abstract : In this work, we study how to improve image recognition in greenhouse tomato plants using Machine Learning. We propose a method for non-destructively estimating the Leaf Area Index (LAI), as well as a method to improve the segmentation of different parts of the plant. Moreover, we discuss our investigation of three ways to estimate the relevant parts of the segmented image. Additionally, we investigated new methods to improve the task of semantic segmentation of the whole plant.

[02893] Frequency based graph estimation for multivariate time-series

Format : Talk at Waseda University
Author(s) : Yuuya Takayama (Nikon Corporation)
Abstract : We propose a method to estimate an underlying graph structure from multivariate time-series data. This method is derived from the Dynamic Mode Decomposition (DMD) method so as to recover an exact graph from a solution of the graph wave equation. In our talk, we introduce its applications and discuss uncertainty of an estimated graph based on the mathematical equation.

[02900] Passive Gamma Emission Tomography for Spent Nuclear Fuel

Format : Talk at Waseda University
Author(s) : Riina Virta (Radiation and Nuclear Safety Authority (STUK), and Helsinki Institute of Physics, University of Helsinki)Tatiana Alessandra Bubba (University of Bath)Mikael Moring (Radiation and Nuclear Safety Authority (STUK))Samuli Siltanen (Department of Mathematics and Statistics of the University of Helsinki)Tapani Honkamaa (Radiation and Nuclear Safety Authority (STUK))Peter Dendooven (Helsinki Institute of Physics, University of Helsinki)
Abstract : Spent nuclear fuel needs to be verified prior to geological disposal in a deep underground repository. In Passive Gamma Emission Tomography (PGET), the gamma radiation emitted by the fuel is recorded with highly collimated semiconductor detectors and 2D slice images of activity and attenuation are simultaneously reconstructed to account for the high self-attenuation of the material. General information about the object geometry is used as a prior to regularize the ill-posed inverse problem.

[02901] Boundary estimation of the X-ray tomographic reconstruction using persistent homology

Format : Talk at Waseda University
Author(s) : Elli Karvonen (University of Helsinki)
Abstract : In some applications, one can only use limited-angle X-ray tomography, which results in a much more difficult reconstruction problem than a full-angle case. Despite an algorithm, all parts of the smooth boundaries of the target object cannot be detected stably. In this talk the new boundary estimation method, which utilizes complex wavelets and persistent homology, is presented. The latest results are shown and discussed.

[00670] Financial Risk Management and Related Topics

Session Time & Room :

00670 (1/2) : 1C (Aug.21, 13:20-15:00) @D502

00670 (2/2) : 1D (Aug.21, 15:30-17:10) @D502

Type : Proposal of Minisymposium
Abstract : The development of mathematical models used in financial risk management over the past few decades has been remarkable, and it is certainly an area of applied mathematics where many important research topics remain to be explored. This mini-symposium will focus on discussing recent topics related to mathematical methods for quantitative financial risk management. Specifically, topics such as credit risk modeling, applications of stochastic analysis to risk management, risk measures, multivariate statistical modelings, and so on will be presented.
Organizer(s) : Hidetoshi Nakagawa, Suguru Yamanaka
Classification : 91-10
Minisymposium Program :

00670 (1/2) : 1C @D502 [Chair: Hidetoshi Nakagawa]

[03276] Discrepancy between Regulations and Practice in Initial Margin Calculation

Format : Talk at Waseda University
Author(s) : Ryosuke Kitani (Hitotsubashi University)Hidetoshi Nakagawa (Hitotsubashi University)
Abstract : Counterparty risk remains at issue in OTC derivative transactions. Since it is difficult to calculate the initial margin according to the regulations, it has been calculated in practice using a simplified method "ISDA SIMM". In this study, we derive an approximate formula for some indicators of counterparty risk for a stochastic volatility model and

illustrate some numerical analyses to examine the effect of discrepancy between regulations and practice in margin calculation.

[02781] Last Passage Time and its Applications in Risk Management

Format : Talk at Waseda University
Author(s) : Masahiko Egami (Kyoto University)Rusudan Kevkhishvili (Kyoto University)
Abstract : We decompose the Laplace transform of a regular transient diffusion's last passage time into a simple formula based on Green functions. This result allows us to bypass often hard calculations related to diffusions with switching parameters by reducing the problem to two processes without switching. The last passage time is not a stopping time because it looks into the future path of the process. We demonstrate its application in credit risk and loss-given-default distribution modeling.

[04631] Construction and sample path properties of Brownian house-moving

Format : Talk at Waseda University
Author(s) : Kensuke Ishitani (Tokyo Metropolitan University)
Abstract : We are currently investigating higher-order chain rules for computing higher-order Greeks of barrier options, and we expect a stochastic process called ``Brownian house-moving'' to play an important role in their computation. Brownian house-moving is a Brownian bridge conditioned to stays between two curves. The purpose of this talk is to construct Brownian house-moving. Also studied are the sample path properties of Brownian house-moving.

[02599] Stability of High Order Moments: a Risk Management Approach

Format : Talk at Waseda University
Author(s) : Olivier Arnaud Le Courtois (emlyon business school)Silvia Faroni (emlyon business school)
Abstract : Little research has been produced on the statistical reliability of high order moments. This work studies the stability of higher order moments in equity markets. We extend our study to conditional annual higher order moment using different quantiles. Our aim is to identify which moment is more stable over time, which leads to a more reliable assessment of the future market risk and thus to more robust investment and risk management practices.

00670 (2/2) : 1D @D502 [Chair: Suguru Yamanaka]

[03952] Gross-revenue-based structural credit risk model

Format : Talk at Waseda University
Author(s) : Suguru Yamanaka (Aoyama Gakuin University)Hidetoshi Nakagawa (Hitotsubashi University)
Abstract : For calculation of firms' default probability, structural models are often used to formulate the stochastic variation of stock variables such as total assets and firm value. In contrast, we propose a new type of structural model based on gross revenue, a flow variable that reflects the income and expenditure of firms. We test the validity of the default probabilities calculated from our proposed model using data on Japanese firms.

[03406] Insider vs. Outsider: Information and Enlargement of Filtrations

Format : Talk at Waseda University
Author(s) : Kiichi Kitajima (Mitsubishi UFJ Trust Investment Technology Institute Co., Ltd. & Graduate School of Economics, Hitotsubashi University)
Abstract : In this presentation, we introduce a stock price process where a large insider can control the price movement through trading. Under the condition that additional insider information is binary, the study establishes that the information drift is a martingale and that the model has a unique equivalent martingale measure when the insider optimizes their trading. We also characterize the stock's expected return by the insider and an outsider with limited information.

[02711] Sparse factor model of high dimension

Format : Talk at Waseda University
Author(s) : Benjamin POIGNARD (Osaka University)Yoshikazu TERADA (Osaka University)
Abstract : We consider the estimation of factor model-based covariance matrix when the factor loading matrix is sparse. We develop a penalized estimating function framework to account for the identifiability of the factor loading matrix while fostering sparsity. We prove the oracle property of the penalized estimator for factor model, that is the penalization can recover the true sparse support and the estimator is asymptotically normal. These theoretical results are supported by simulations and real data experiments.

[03676] On a measure of tail asymmetry for the bivariate skew-normal copula

Format : Talk at Waseda University
Author(s) : Toshinao Yoshiba (Tokyo Metropolitan University)Takaaki Koike (Hitotsubashi University)Shogo Kato (Institute of Statistical Mathematics)
Abstract : Asymmetry in the upper and lower tails is an important feature in modeling financial risk factors. We analyze asymptotic behavior of a measure of tail asymmetry at extremely large and small thresholds of the bivariate skew-normal copula. We numerically show, when the correlation or skewness parameters are around at the boundary values, some proposed asymptotic approximations are not suitable to compute the measure of tail asymmetry.

[00672] Efficient inference for large and high-frequency data

Session Time & Room :

00672 (1/3) : 5B (Aug.25, 10:40-12:20) @E502

00672 (2/3) : 5C (Aug.25, 13:20-15:00) @E502

00672 (3/3) : 5D (Aug.25, 15:30-17:10) @E502

Type : Proposal of Minisymposium
Abstract : In this minisymposium, the notion of asymptotically efficient estimation and asymptotically efficient statistical decision is discussed for various models appearing in finance and econometrics.
For some applications, the data are acquired at high-frequency and in-fill observation scheme is considered. Here, asymptotical properties of the estimators for the parameters of the rough volatility models in quantitative finance and for the solutions of stochastic differential equations with jumps or with singular coefficients will be presented.
In other applications, the large sample observation scheme is used. Asymptotical efficient statistical decisions and estimations are introduced for time series in econometrics (FARIMA, Threshold AR).

[05600] Fast and asymptotically efficient inference for large and high-frequency data

Format : Talk at Waseda University
Author(s) : Alexandre Brouste (Le Mans Université)
Abstract : In this minisymposium, the notion of asymptotically statistical decision is discussed for various models appearing in finance and econometrics. In some applications, the large sample observation scheme is used. Asymptotical efficient statistical decisions and estimations are introduced for time series in econometrics (FARIMA, Threshold AR). For other applications, the data are acquired at high-frequency and in-fill observation scheme is considered. Asymptotical properties for the estimators of the parameters in the solutions of stochastic differential equations with jumps or with singular coefficients or in the rough volatility models in quantitative finance will be presented.

[05624] On Adaptive Kalman Filtration

Format : Talk at Waseda University
Author(s) : Yury Kutoyants (Le Mans University)
Abstract : We consider a linear partially observed system. The coefficients of this system depend on some unknown parameter. We study the problems of the construction of adaptive Kalman-Bucy filtration equations in the asymptotic of large samples. The properties of the MLE and BE are described. The adaptive filter is constructed in two steps. First we propose a method of moments preliminary estimator. Then this estimator is used for construction of One-step MLE-process. Finally we construct an adaptive recurrent filter.

[05359] Fast calibration of weak FARIMA models

Format : Talk at Waseda University
Author(s) : Youssef Esstafa (Le Mans Université)
Abstract : In this work, we investigate the asymptotic properties of Le Cam's one-step estimator for weak FARIMA models. For these models, noises are uncorrelated but neither necessarily independent nor martingale differences errors. We show under some regularity assumptions that the one-step estimator is strongly consistent and asymptotically normal with the same asymptotic variance as the least squares estimator. We show through simulations that the proposed estimator reduces computational time compared with the least squares estimator.

[05613] Fast Inference for Stationary Time Series

Format : Talk at Waseda University
Author(s) : Samir BEN HARIZ (Le Mans Université)Marius Soltane (Université de Compiègne)Alexandre Brouste (Le Mans Université)Youssef Esstafa (Le Mans Université)
Abstract : Stationary processes are widely used to model temporal dependence in various random phenomena including Economy, Finance, Hydrology,... In the Gaussian case, statistical inference for such processes, which is well-known, often relies on the maximum likelihood estimation or its approximation using the Whittle method. The asymptotic variance is then optimal in both cases. However, these methods are generally computationally expensive or even extremely difficult to apply to large samples.

We propose an alternative which is computationally fast while keeping the same asymptotic properties both in terms of speed and asymptotic variance. The procedure consists of applying a so-called one-step method to an initial estimator that is easy to implement and satisfies a certain condition on its convergence rate.
The process begins by initializing the parameter estimate by a simple and eventually poor estimator. Once the initial estimates are determined, the iteration step begins. Using the score vector and the Fisher Information Matrix, the parameter estimates are updated. The updated estimates are obtained by taking a step proportional to the inverse of the Fisher Information Matrix multiplied by the score vector. The one-step estimation method is called so because it updates the parameter estimates only once per iteration. This makes it computationally efficient and relatively simple to implement compared to other more complex estimation methods.

We will start with the simplest case where the process is Gaussian and then generalize this procedure to non-Gaussian processes. We also illustrate the numerical performance of this method through simulations and compare it to classical methods.

00672 (2/3) : 5C @E502 [Chair: Laurent Denis]

[03747] Local asymptotic property for the Euler approximation of SDE driven by a stable Lévy process

Format : Talk at Waseda University
Author(s) : Emmanuelle Clément (University Gustave Eiffel)Alexandre Brouste (Le Mans University)Thi Bao Trâm Ngô (Le Mans University)Laurent DENIS (Le Mans University)
Abstract : We study the stochastic differential equations driven by a symmetric stable Lévy process, in which the joint parametric estimation of the drift coefficient, the scale coefficient and the jump activity of the process based on high frequency observations on a fixed time interval is considered. For these experiments, due to the non-explicit form of the likelihood function, our methodology will be to identify a simpler experiment, where the likelihood function has a traceable form, which is asymptotically equivalent in the Le Cam distance at the process observed at high frequency. To cover all values of jumping activity, the most appropriate experiment is to consider a numerical scheme that combines Euler's approximation of the scale coefficient with the solution of the ordinary equation given by the coefficient of derivative. We therefore prove the LAMN property for this corresponding Euler scheme with the ordinary differential equation. Thanks to the obtained LAMN property, we show that the one-step estimator is efficient. With an easy-to-compute initial estimator with good asymptotic behavior, it can exhibit a performance quite similar to that of the maximum likelihood estimator and reduce a lot of computation time. We illustrate our results by numerical simulations with the one-step procedure.

[03713] Asymptotics for Student-Lévy regression

Format : Talk at Waseda University
Author(s) : Hiroki Masuda (University of Tokyo)
Abstract : We consider the quasi-likelihood analysis for a linear regression model driven by a Student Lévy process with constant scale and arbitrary degrees of freedom. We consider joint estimation of trend, scale, and degrees of freedom when the model is observed at a high frequency over an extending period. The bottleneck in this problem is that the Student distribution is not closed under convolution, making it difficult to estimate all the parameters fully based on the high-frequency time scale. To efficiently deal with that intricate nature, we propose a two-step quasi-likelihood analysis:

first, we make use of the Cauchy quasi-likelihood for estimating the regression-coefficient vector and the scale parameter; then, we construct the sequence of the unit-period cumulative residuals to estimate the remaining degrees of freedom. We will present the hopefully asymptotically efficient theoretical behavior of the proposed estimator, which quantitatively clarifies the need for data thinning.

[01903] High-frequency estimation of pure jump alpha-CIR process

Format : Talk at Waseda University

Author(s) : Elise Bayraktar (Université Gustave Eiffel)

Abstract : We consider a pure-jump stable Cox-Ingersoll-Ross (α-stable CIR) process defined by
$X_t = x_0 + \int_0^t (a - bX_s)ds + \int_0^s \delta X_{s-}^{1/\alpha} dL_s^\alpha$ where $(L_t^\alpha)_{t\geq 0}$ is a compensated α-stable Lévy process with non-negative jumps and $\alpha \in (1,2)$.
We study the joint estimation of drift, scaling and jump activity parameters (a, b, δ, α) from high-frequency observations of the process on a fixed time period. We prove the existence of a consistent and asymptotic mixed normal estimator based on an approximation of the likelihood function.

[02309] Local asymptotic properties for the growth rate of a jump-type CIR process

Format : Online Talk on Zoom

Author(s) : Mohamed Ben Alaya (University of Rouen)Ahmed Kebaier (University of Evry)Gyula Pap (University of Szeged)Ngoc Khue Tran (Hanoi University of Science and Technology)

Abstract : In this paper, we consider a one-dimensional jump-type Cox-Ingersoll-Ross pro- cess driven by a Brownian motion
and a subordinator, whose growth rate is an unknown parameter. The Lévy measure of the subordinator is finite or infinite. Considering the process observed continuously or discretely at high frequency, we derive the local asymptotic properties for the growth rate in both ergodic and non-ergodic cases.
Three cases are distinguished: subcritical, critical and supercritical. Local asymptotic normality (LAN) is proved in the subcritical case, local asymptotic quadraticity (LAQ) is derived in the critical case, and local asymptotic mixed normality (LAMN) is shown in the supercritical case. To do so, techniques of Malliavin calculus and a subtle analysis on the jump structure of the subordinator involving the amplitude of jumps and number of jumps are essentially used.

[01940] Statistical inference for rough volatility: minimax theory

Format : Talk at Waseda University

Author(s) : Grégoire Szymanski (Ecole Polytechnique, CMAP)Carsten Chong (Columbia University, 1Department of Statistics)Marc Hoffmann (Université Paris Dauphine-PSL, Ceremade)Yanghui Liu (Baruch College CUNY, 3Department of Mathematics)Mathieu Rosenbaum (Ecole Polytechnique, CMAP)

Abstract : Rough volatility models have gained considerable interest in the quantitative finance community in recent years. In this paradigm, the volatility of the asset price is driven by a fractional Brownian motion with a small value for the Hurst parameter H. In this work, we provide a rigorous statistical analysis of these models. To do so, we establish minimax lower bounds for parameter estimation and design procedures based on wavelets attaining them. We notably obtain an optimal speed of convergence of $n^{-1/(4H+2)}$ for estimating H based on n sampled data, extending results known only for the easier case $H > 1/2$ so far. We therefore establish that the parameters of rough volatility models can be inferred with optimal accuracy in all regimes.

[01388] Statistical inference for rough volatility: Central limit theorems

Format : Online Talk on Zoom

Author(s) : Carsten H. Chong (HKUST)Marc Hoffmann (Université Paris Dauphine-PSL)Yanghui Liu (Baruch College CUNY)Mathieu Rosenbaum (Ecole Polytechnique)Grégoire Szymanski (Ecole Polytechnique)

Abstract : In recent years, there has been substantive empirical evidence that stochastic volatility is rough. In other words, the local behavior of stochastic volatility is much more irregular than semimartingales and resembles that of a fractional Brownian motion with Hurst parameter $H < 0.5$. In this paper, we derive a consistent and asymptotically mixed normal estimator of H based on high-frequency price observations. In contrast to previous works, we work in a semiparametric setting and do not assume any a priori relationship between volatility estimators and true volatility. Furthermore, our estimator attains a rate of convergence that is known to be optimal in a minimax sense in parametric rough volatility models.

[02004] A GMM approach to estimate the roughness of stochastic volatility

Format : Talk at Waseda University
Author(s) : Anine Bolko (Aarhus University)Kim Christensen (Aarhus University)Mikko Pakkanen (University of Waterloo)Bezirgen Veliyev (Aarhus University)
Abstract : I will present an approach to estimate log normal stochastic volatility models, including rough volatility models, using the generalised method of moments, GMM. In this GMM approach, estimation is done directly using realised measures, e.g., realised variance, avoiding the biases that arise from using a proxy of spot volatility. I will also present asymptotic theory for the GMM estimator, lending itself to inference, and apply the methodology to Oxford-Man realised volatility data.

[01999] Asymptotically Efficient Estimation for Fractional Brownian Motion with Additive Noise

Format : Talk at Waseda University
Author(s) : Tetsuya Takabatake (Hiroshima University)Grégoire Szymanski (Ecole Polytechnique, CMAP)
Abstract : We will talk about an asymptotically efficient estimation of the Hurst index and the volatility parameter for a fractional Brownian motion with additive noise based on discrete observations. We will propose an asymptotically efficient estimator combining the ideas of the one-step method and a quadratic variation-type estimator using pre-averaged data.

[00673] Recent advances in discontinuous Galerkin methods and the related applications

Session Time & Room :

00673 (1/2) : 2C (Aug.22, 13:20-15:00) @E703

00673 (2/2) : 2D (Aug.22, 15:30-17:10) @E703

Type : Proposal of Minisymposium
Abstract : Discontinuous Galerkin methods are widely employed in computational science and engineering fields, as they offer accurate and efficient simulations. In particular, discontinuous Galerkin methods offer appealing features including high-order approximation, hp adaptivity, and local mass conservations, which are particularly important for practical applications. The development, analysis, and applications of discontinuous Galerkin methods have stimulated significant research. The aim of this mini-symposium is to gather experts as well as junior researchers in the field to introduce recent achievements on discontinuous Galerkin methods and the related applications, as well as promote exchanges.

[03246] Bound preserving DG methods for multi-species flow with chemical reactions

Format : Talk at Waseda University
Author(s) : Jie Du (Tsinghua University)
Abstract : For multispecies chemical reactive flows, the solutions have some physical bounds. The mass fraction does not satisfy a maximum principle and hence it is not easy to preserve the upper bound. Also, most of the bound-preserving techniques available are based on Euler forward method. For problems with stiff source, the time step will be significantly limited. In this work, we will construct third order conservative bound-preserving DG methods to overcome all these difficulties.

[03960] Staggered discontinuous Galerkin methods for the Stokes problem on rectangular grids

Format : Talk at Waseda University
Author(s) : Hyea Hyun Kim (Kyung Hee University)Thien Binh Nguyen (Vietnamese-German University)Gung-Min Gie (University of Louisville)Chang-Yeol Jung (UNIST)
Abstract : A staggered DG (Discontinous Galerkin) method, that was originally developed on triangular meshes, is extended to rectangular grids for the second order elliptic problems in the first, second, and fourth authors' previous work. On the rectangular grids, the higher order polynomials in higher dimensions can be easily formed without the need for meshing the physical domain. In this talk, we present the extension of our previous staggered DG method to the Stokes system and provide the optimal error estimate for the given polynomial order. Compared to the triangle based DG methods, we also obtain a better inf-sup stability result for the rectangular based DG methods. Numerical results are presented to confirm our optimal error estimate results.

[02857] A mass conservative scheme for the coupled flow and transport

Format : Talk at Waseda University
Author(s) : Lina Zhao (City University of Hong Kong)Shuyu Sun (KAUST)
Abstract : In this talk, I will present a mass conservative scheme for the coupled Brinkman flow and transport, where the flow equations are discretized using staggered DG method and mixed FEM. As such, the interface conditions are naturally incorporated into the formulation. Then the transport equation is discretized using unwinding staggered DG methods. The optimal convergence error estimates for all the variables are carried out. Several numerical experiments are carried out to demonstrate the performance.

[03078] hp-Multigrid preconditioner for a divergence-conforming HDG scheme for the incompressible flow problems

Format : Online Talk on Zoom
Author(s) : Guosheng Fu (University of Notre Dame)Wenzheng Kuang (University of Notre Dame)
Abstract : In this study, we present an hp-multigrid preconditioner for a divergence-conforming HDG scheme for the generalized Stokes and the Navier-Stokes equations using an augmented Lagrangian formulation. Our method relies on conforming simplicial meshes in two- and three-dimensions. The hp-multigrid algorithm is a multiplicative auxiliary space preconditioner that employs the lowest-order space as the auxiliary space, and we developed a geometric multigrid method as the auxiliary space solver. For the generalized Stokes problem, the crucial ingredient of the geometric multigrid method is the equivalence between the condensed lowest-order divergence-conforming HDG scheme and a Crouzeix-Raviart discretization with a pressure-robust treatment as introduced in Linke and Merdon (Comput. Methods Appl. Mech. Engrg., 311 (2016)), which allows for the direct application of geometric multigrid theory on the Crouzeix-Raviart discretization. The numerical experiments demonstrate the robustness of the proposed hp-multigrid preconditioner with respect to mesh size and augmented Lagrangian parameter, with iteration counts insensitivity to polynomial order increase. Inspired by the works by Benzi & Olshanskii (SIAM J. Sci. Comput., 28(6) (2006)) and Farrell et al. (SIAM J. Sci. Comput., 41(5) (2019)), we further test the proposed preconditioner on the divergence-conforming HDG scheme for the Navier-Stokes equations. Numerical experiments show a mild increase in the iteration counts of the preconditioned GMRes solver with the rise in Reynolds number up to 10^3.

00673 (2/2) : 2D @E703 [Chair: Lina Zhao]

[04124] Numerical Modelling of the Brain Poromechanics by High-Order Discontinuous Galerkin Methods

Format : Online Talk on Zoom
Author(s) : Paola Francesca Antonietti (Politecnico di Milano)Mattia Corti (Politecnico di Milano)Luca Dede' (Politecnico di Milano)Alfio Quarteroni (Politecnico di Milano)
Abstract : In this talk we introduce and analyze a discontinuous Galerkin method for the numerical modelling of the equations of Multiple-Network Poroelastic Theory (MPET) in the dynamic formulation. The MPET model can comprehensively describe functional changes in the brain considering multiple scales of fluids. Concerning the spatial discretization, we employ a high-order discontinuous Galerkin method on polygonal and polyhedral grids and we derive stability and a priori error estimates. The temporal discretization is based on a coupling between a Newmark β-method for the momentum equation and a θ-method for the pressure equations. We present verification numerical results and perform a convergence analysis using an agglomerated mesh of a geometry of a brain slice. We also present a simulation in a three-dimensional patient-specific brain reconstructed from magnetic resonance images. The model presented in this paper can be regarded as a preliminary attempt to model perfusion in the brain.

[03151] Cell-average based Neural Network method for time dependent PDEs

Format : Talk at Waseda University
Author(s) : Changxin Qiu (Ningbo University)Jue Yan (Iowa State University)
Abstract : Motivated by finite volume scheme, a cell-average based neural network method is proposed. The method is based on the integral or weak formulation of partial differential equations. Offline supervised training is carried out to obtain the optimal network parameter set, which uniquely identifies one finite volume like neural network method. Once well trained, the network method is implemented as a finite volume scheme and can adapt large time step size for solution evolution.

[04606] A non-overlapping Schwarz algorithm for the HDG method

Format : Talk at Waseda University
Author(s) : Issei Oikawa (University of Tsukuba)
Abstract : This talk is concerned with a non-overlapping Schwarz algorithm for the hybridizable discontinuous Galerkin (HDG) method for the steady-state diffusion problem. We present several iterative algorithms based on the non-overlapping Schwarz domain decomposition method and their numerical results.

[03898] Adaptive methods for fully nonlinear PDE

Format : Online Talk on Zoom
Author(s) : Iain Smears (University College London)
Abstract : Hamilton--Jacobi--Bellman and Isaacs equations are important classes of fully nonlinear PDE with applications from stochastic optimal control and two player stochastic differential games. In this talk, we present our recent proof of the convergence of a broad family of adaptive nonconforming DG and C^0-interior penalty methods for the class of these equations that satisfy the Cordes condition in two or three space dimensions. The adaptive mesh refinement is driven by reliable and efficient a posteriori error estimators, and convergence is proven in H^2-type norms without higher regularity assumptions of the solution. A foundational ingredient in the proof of convergence is the concept of the limit space used to describe the limiting behaviour of the finite element spaces under the adaptive mesh refinement algorithm. We develop a novel approach to the construction and analysis of these nonstandard function spaces via intrinsic characterizations in terms of the distributional derivatives of functions of bounded variation. We provide a detailed theory for the limit spaces, and also some original auxiliary function spaces, that resolves some foundational challenges and that is of independent interest to adaptive nonconforming methods for more general problems. These include Poincare and trace inequalities, a proof of the density of functions with nonvanishing jumps on only finitely many faces of the limit skeleton, symmetry of the Hessians, approximation results by finite element functions and weak convergence results.

[00674] Modern numerical methods for PDE-constrained optimization and control

Session Time & Room :

00674 (1/2) : 5B (Aug.25, 10:40-12:20) @G704

00674 (2/2) : 5C (Aug.25, 13:20-15:00) @G704

Type : Proposal of Minisymposium
Abstract : Control problems, including optimization problems with PDE constraints, have numerous applications across science and engineering, including chemical processes, mathematical biology, fluid flow control, imaging problems, and mean-field games. Of crucial importance is to develop efficient and robust numerical schemes which can solve mathematical models for such problems and the large-scale optimality systems. This can involve accurate and stable discretization schemes, modern linear algebra to solve systems of equations resulting from such problems, and, increasingly, technologies from parallel computing. This session will cover the state-of-the-art in the design of numerical methods for such problems, arising from a range of scientific applications.

[03637] Recent Developments in Preconditioning for PDE-Constrained Optimization

Format : Talk at Waseda University
Author(s) : John Pearson (University of Edinburgh)
Abstract : In this talk, we survey some recent research into numerical linear algebra for PDE-constrained optimization problems. In particular, we consider preconditioned iterative methods for the robust solution of resulting linear(ized) systems. Having provided some motivation for the construction of effective preconditioners, we briefly summarise some solution strategies devised by the speaker along with collaborators, for time-dependent problems, fluid flow control systems, and multiple saddle-point systems arising from PDE-constrained optimization.

[01670] GKBO method for global optimization of non-convex high dimensional functions.

Format : Talk at Waseda University
Author(s) : Federica Ferrarese (University of Verona and Trento)
Abstract : The study of numerical methods for global optimization of non-convex high dimensional functions has attracted a lot of attention in recent years. In this talk, a new efficient numerical method for global optimization inspired to classical
algorithms will be presented. Different theoretical and numerical results will be shown comparing this algorithm to the classical ones. Finally, further extensions to localized versions of this algorithm, useful to minimize functions with multiple global minima, will be introduced.

[01649] Online identification and control of PDEs via RL methods

Format : Talk at Waseda University
Author(s) : Alessandro Alla Michele Palladino (Università degli studi dell'Aquila)Agnese Pacifico (Sapienza, Università di Roma)Andrea Pesare (Bending Spoons)
Abstract : In this talk we focus on the control of unknown Partial Differential Equations. Our approach is based on the idea to control and identify on the fly. The control, in this work, is computed using the State Dependent Riccati approach whereas the identification of the model on bayesian linear regression. At each iteration we obtain an estimation of the a-priori unknown coefficients of the PDEs based on the observed data and then we compute the control of the correspondent model. We show by numerical evidence the convergence of the method for infinite horizon problems.

[03371] A statistical POD approach for feedback boundary optimal control in fluid dynamics

Format : Online Talk on Zoom
Author(s) : Luca Saluzzi (Scuola Normale Superiore di Pisa)Sergey Dolgov (University of Bath)Dante Kalise (Imperial College London)
Abstract : I consider feedback boundary optimal control problems and their reduction by the means of a Statistical Proper Orthogonal Decomposition, method characterized by the introduction of stochastic terms in the model to enrich the knowledge of the Full Order Model and in the collection of optimal trajectories as snapshots. The HJB equation is then solved by a data-driven Tensor Train Cross and applied to the control of the incompressible Navier-Stokes equation in a backward-step domain.

00674 (2/2) : 5C @G704 [Chair: John Pearson]

[04310] Optimal Control of Some Nonlocal PDEs

Format : Talk at Waseda University
Author(s) : Roland Herzog (Heidelberg University)Masoumeh Hashemi (Heidelberg University)
Abstract : Partial differential equations (PDEs) with nonlocal effects pose various challenges in the analysis as well as the numerical solution. This is all the more true for optimal control problems involving nonlocal PDEs. In this presentation, we will discuss examples of optimal control problems for nonlocal PDEs and exhibit the numerical challenges posed by the associated blocks in the optimality systems.

[01642] Decentralized strategies for coupled shape and parameter inverse problems

Format : Talk at Waseda University
Author(s) : Abderrahmane HABBAL (University Cote d'Azur Inria)
Abstract : We present a novel family of algorithms framed within game theory setting and dedicated to solve ill-posed inverse problems, where unknown shapes -obstacles or inclusions- or sources are to be reconstructed
as well as missing boundary conditions, for steady Stokes fluids.
Some theoretical results and several numerical experiments are provided that corroborate the ability
of the approch to tackle harsh problems.

[04057] Stability-exploiting adaptive finite elements for optimal control

Format : Talk at Waseda University
Author(s) : Manuel Schaller (Technische Universität Ilmenau)
Abstract : Optimal control problems often exhibit a particular stability property which, for time-dependent problems, manifests itself, e.g., by means of a turnpike property. The latter states that optimal solutions to dynamic problems reside close to a particular steady state for the majority of the time. Such a stable behavior can be shown under stabilizability and detectability-like assumptions and in particular also can be shown to hold when the uncontrolled equations are unstable. In this talk, we will show how this stability leads to locality of discretization errors which can be exploited by means of adaptive finite-element methods, leading to a significant reduction in computational expenses, e.g., in a Model Predictive Controller.

[00675] New trends in (optimal) control theory

Session Time & Room :

00675 (1/2) : 4E (Aug.24, 17:40-19:20) @F401

00675 (2/2) : 5B (Aug.25, 10:40-12:20) @F401

Type : Proposal of Minisymposium
Abstract : The goal of this mini-symposium is to bring together experts in several fields of interest in control and optimal control theory, including controllability, stabilization, and large-time behavior of optimal controls, in order to foster scientific interactions. This mini-symposium also aims to be at the intersection between theoretical issues and applications, notably to machine learning, traffic flow and microswimmers.

[01796] Surveillance-evasion games with visibility constraints

Format : Talk at Waseda University
Author(s) : Carlos Esteve-Yague (University of Cambridge)
Abstract : In this talk, I consider a two-player zero-sum game in which the payoff involves the visibility of the players. First, I will present a new analysis of the boundary conditions for the associated Hamilton-Jacobi-Isaacs HJI equation. As we shall see, these boundary conditions turn out to be non-trivial, and the regularity is related to the curvature of the obstacles. Then, using a new notion of visibility, I will introduce suboptimal feedback strategies for the players which can be proven to approximate the optimal feedback given by the solution of the HJI equation. The main advantage of using these suboptimal feedback controls is that they are computationally efficient and are scalable to the case of multiple players.

[01823] Steering undulatory micro-swimmers in a fluid flow through reinforcement learning

Format : Online Talk on Zoom
Author(s) : Zakarya El-Khiyati (Université Côte d'Azur, Inria, CNRS, Sophia-Antipolis)Raphaël Chesneaux (Université Côte d'Azur, Inria, CNRS, Sophia-Antipolis)Laetitia Giraldi (Université Côte d'Azur, Inria, CNRS, Sophia-Antipolis)Jérémie Bec (Université Côte d'Azur, Inria, CNRS, Sophia-Antipolis)
Abstract : The talk deals with optimal navigation policies for thin, deformable microswimmers, which progress in a viscous fluid flow by propagating a sinusoidal undulation along their slender body. The swimmer has to compete with the drifts, strains, and deformations inflicted by the external flow. Such an intricate situation, where swimming and navigation are tightly bonded, is addressed using various methods of reinforcement learning. A study of the swimming strategies selected set will be provided.

[02637] Optimization problems under uncertainty

Format : Online Talk on Zoom
Author(s) : teresa scarinci (Università di Cassino e del Lazio Meridionale)
Abstract : The study of models with uncertainty plays an important role in scientific numerical simulations. This class of problems is strongly utilized in engineering, biology, and finance. In this talk, we discuss the importance of including uncertainty in optimal control. Randomness can be utilised to model applications where the data of the problem -- such as the dynamic, the coefficients, or the time delay -- are not known a priori and one knows only statistical information.

00675 (2/2) : 5B @F401 [Chair: Idriss Mazari]

[01828] Stability of open quantum systems designed by reservoir engineering.

Format : Talk at Waseda University
Author(s) : Rémi Robin (Laboratoire de Physique de l'école Normale Supérieure, Mines Paris, Inria, CNRS, ENS-PSL, Sorbonne Université, PSL Research University)Pierre Rouchon (Laboratoire de Physique de l'école Normale Supérieure, Mines Paris, Inria, CNRS, ENS-PSL, Sorbonne Université, PSL Research University)Lev-Arcady Sellem (Laboratoire de Physique de l'Ecole Normale Supérieure, Mines Paris, CNRS, ENS-PSL, Inria, Sorbonne Université, PSL Research University, Paris, France)
Abstract : Dynamically protected cat-qubits are an open quantum system that stabilizes a finite dimensional subspace of a quantum harmonic oscillator. Such a process is achieved through reservoir engineering, a method of coupling a high-quality cavity with a dissipative one. In this talk, we will present a new generalized LaSalle's invariance principle to prove the long time convergence of this system towards the finite dimensional subspace of interest.

[01818] Turnpike phenomena in optimal control

Format : Talk at Waseda University
Author(s) : Roberto Guglielmi (University of Waterloo)
Abstract : We provide a characterization of the exponential turnpike property for infinite dimensional generalized linear-quadratic optimal control problems in terms of structural properties of the control system, such as exponential stabilizability and detectability. The proof relies on the analysis of the exponential convergence of solutions to the differential Riccati equations to the algebraic counterpart, and on a necessary condition for exponential stabilizability in terms of a closed range test.

[02571] Stabilization of traffic flow using fixed bottlenecks

Format : Talk at Waseda University
Author(s) : Thibault Liard (University of Limoges)
Abstract : We study the asymptotic behavior of scalar conservation laws with local side constraints. Our aim is to construct a boundary feedback law, based on a sliding mode procedure, which globally stabilizes G-solutions of scalar conservation laws around a given stationary solutions. To that end, we will extend the notion of generalized characteristics to G-solutions. In the context of vehicular traffic, this leads to control the flow of cars at the tolls of a highway to reach a given target function. Thus, some bottlenecks could be created. Simulations using particle methods will be given to illustrate our results.

[02530] Optimal Boundary Control for the semilinear Transport Equation under Uncertainty: A Turnpike Result

Format : Talk at Waseda University
Author(s) : Michael Schuster (FAU Erlangen-Nuremberg)Noboru Sakamoto (Nanzan University Nagoya)
Abstract : We show an integral turnpike result for an optimal Dirichlet boundary control problem with a semilinear transport equation in the sense that if the time horizon goes to infinity, then the dynamic optimal control converges to the corresponding steady state optimal control. Further we show that the integral turnpike result also holds if the initial data and/or the source term is uncertain with respect to a random variable

[00685] Mathematical modeling, simulation and optimization in stroke risk assessment

Session Time & Room : 2C (Aug.22, 13:20-15:00) @E820

Type : Proposal of Minisymposium
Abstract : The aim of the minisymposium is to bring together scientists working on computational and mathematical analysis tools to improve clinical pathways in the exploration, analysis and treatment of stenosis to reduce the risk of ischemic stroke. Topics covered include novel methods for patient specific hemodynamic modeling and simulation, mathematical shape optimization for fluid-structure-interaction, and machine learning approaches. Combining these mathematical approaches with clinical data then allows to complement and improve existing tools for the exploration of risk sites of the corresponding arteries.
Organizer(s) : Michael Hinze, Anna Hundertmark

[03136] Hemodynamic modeling of directional shear risk metrics in the carotid artery

Format : Talk at Waseda University
Author(s) : Anna Hundertmark (RPTU Kaiserslautern-Landau)Kevin Richter (RPTU Kaiserslautern-Landau)Tristan Probst (RPTU Kaiserslautern-Landau)
Abstract : We present a numerical evaluation of hemodynamic risk metrics and their multi-directional behavior in human
stenosed carotid artery. In the FSI model considered, the elastic modulus is strain-dependent in agreement with laboratory compliance measurements. We investigate the multidirectional behavior of wall shear stress (WSS) based on specially constructed longitudinal tangent vectors using centerline projection approach. We present the utility of longitudinal WSS evaluation for the detection of opposing or transverse (injurious) WSS in slow flow.

[03760] Physiological flow simulations for stroke assessement and importance of distensiblity

Format : Talk at Waseda University
Author(s) : Kevin Richter (RPTU Landau)
Abstract : In the process of bringing hemodynamic simulations to the clinical forefront we present the creation of a database that can offer guidance in the assessement of stroke risks in the carotid bifurcation area. We established a working pipeline for creating CFD simulations for over 100 patient-specific
geometries. The importance of realistic boundary conditions are highlighted. To incorporate realistic distensibility of the arterial wall, we compared simulations to in vivo experiments.

[03568] Predicting Stroke Risk with Graph Neural Networks and CFD Simulations

Format : Talk at Waseda University
Author(s) : Rohit Pochampalli (RPTU Kaiserslautern)Nicolas R. Gauger (RPTU Kaiserslautern)
Abstract : We propose a novel approach for predicting stroke risk using graph neural networks (GNNs) and computational fluid dynamics (CFD) simulations. GNNs enable us to capture the complex, nonlinear relationships

between the geometry of the blood vessel and features such as the distribution of shear stresses on the vessel walls, which are known to influence the development of atherosclerosis. Our approach provides new insights into the relationship between blood flow patterns and stroke risk, potentially enabling more personalized prevention and treatment strategies.

[03834] Shape optimization in applications of blood flows under uncertainties

Format : Online Talk on Zoom
Author(s) : Georgios Bletsos (Hamburg University of Technology (TUHH))Michael Hinze (Universität Koblenz)Winnifried Wollner (University of Hamburg)Thomas Rung (Hamburg University of Technology (TUHH))
Abstract : The goal of this study is to minimize the expected value and standard deviation of blood damaging metrics of biomedical geometries, by updating their shape while considering uncertainties of the flow or the blood modeling.

The robust shape optimization procedure is realized by means of a gradient-descent method. Gradient information is obtained by a hybrid stochastic-deterministic approach or by an adjoint-assisted method in which uncertainty quantification is realized based on the FOSM approach.

[00686] Higher-order networks for complex systems

Session Time & Room :

00686 (1/3) : 3C (Aug.23, 13:20-15:00) @F412

00686 (2/3) : 3D (Aug.23, 15:30-17:10) @F412

00686 (3/3) : 3E (Aug.23, 17:40-19:20) @F412

Type : Proposal of Minisymposium
Abstract : Complex systems often exhibit emergent phenomena that cannot be understood by studying mere pairwise interactions. Emblematic examples include chemical reaction and molecular biology, where interactions often involve more than just two elements. Nevertheless, most of the mathematical tools of network science have been developed using traditional graphs, which are an explicitly pairwise representation. This mini-symposium will focus on the mathematical objects which are better suited to modelling higher order interactions, such as simplicial complexes and hypergraphs, as well as on the tools that can be used to investigate them.
Organizer(s) : Gillian Grindstaff, Heather Harrington, Raffaella Mulas

[02953] Towards mixed volumes of binomial reaction networks

Format : Online Talk on Zoom
Author(s) : Jane Ivy Coons (University of Oxford)Mark Curiel (University of Hawai'i)Elizabeth Gross (University of Hawai'i)
Abstract : Mass action kinetics on a chemical reaction network give rise to a polynomial system of equations. The zeros of this system are the steady states of the network, and its mixed volume is an upper bound on the number of complex steady states. We show that when the steady state ideal is binomial and the conservation laws satisfy a "partitionability" property, the mixed volume can be easily computed as a determinant.

[02968] A Hypergraph Model of Opinion Dynamics

Format : Online Talk on Zoom
Author(s) : Abigail Hickok (UCLA)Yacoub Kureh (Industry)Heather Zinn Brooks (Harvey Mudd College)Michelle Feng (Caltech)Mason A. Porter (UCLA)
Abstract : Networks encode only pairwise interactions and cannot take into account polyadic interactions. I’ll discuss how the incorporation of polyadic interactions (encoded by a hypergraph) changes the qualitative behavior of an opinion dynamics model, which is a model of how people’s opinions change with time as they interact. We show that our hypergraph model converges to consensus under a wide range of initial conditions, whereas network models converge to polarization under the same initial conditions.

[02963] Topological techniques for classification of agent-based tumour-immune model

Format : Talk at Waseda University
Author(s) : Gillian Grindstaff (University of California, Los Angeles)Jingjie Yang (University of Oxford)Hai Fang (University of Oxford)Jagdeep Dhesi (University of Oxford)Hee Rhang Yoon (Wesleyan University)Joshua A. Bull (University of Oxford)Helen M. Byrne (University of Oxford)Heather A. Harrington (University of Oxford)
Abstract : We address the problem of classifying time series of synthetic 2-d spatial data from an agent-based model of tumour growth that includes tumour cells, macrophages, and blood vessels. We implement and compare the predictive power of four topological vectorizations specialized to such cell data: persistence images of Vietoris-Rips and radial filtrations at static time points, and persistence images for zigzag filtrations and persistence vineyards varying in time.

[02931] Topological methods for spatial data in molecular biology

Format : Talk at Waseda University
Author(s) : Katherine Benjamin (University of Oxford)
Abstract : Single-parameter persistent homology – the flagship tool in topological data analysis – has witnessed a wide range of successful applications in the biological sciences over the last decade. Multiparameter persistent homology is a natural generalisation allowing for higher-order analysis of more complex phenomena including time-varying data. In this talk, we demonstrate some applications of multiparameter persistent homology to spatial data in biology.

00686 (2/3) : 3D @F412 [Chair: Gillian Grindstaff]

[02955] Clustering and trajectory classification via the Hodge Laplacian

Format : Talk at Waseda University
Author(s) : Michael Schaub (RWTH Aachen University)
Abstract : We present methods to cluster point cloud data and trajectories based on spectral properties of the Hodge Laplacian. Our approach relies on similar ideas as found in spectral embeddings such as Laplacian eigenmaps. However, rather than constructing a single graph to cluster the data, we consider appropriately constructed simplicial complexes, and (a set of) associated Hodge-Laplacians which allow us to leverage a rich set of topological features for classification.

[02956] Kernel-based independence measures, hypergraphs, and higher-order interactions

Format : Talk at Waseda University
Author(s) : Mauricio Barahona (Imperial College London)
Abstract : This talk will cover the use of kernel-based methods for the detection of higher order interactions and the relationships with formalizations using hypergraphs.

[02966] Higher-Order Phase Oscillator Networks from Phase Reductions

Format : Talk at Waseda University
Author(s) : Christian Bick (Vrije Universiteit Amsterdam)
Abstract : Synchronization is a fascinating effect of the interaction between coupled oscillatory units and is ubiquitous in biological systems. If the coupling between units is sufficiently weak, phase reductions provide an adequate description of the dynamics. We discuss phase reductions beyond first order that yield phase oscillator networks with higher-order interactions. Specifically, we discuss how the nonpairwise higher-order phase interactions depend on the shape of the limit cycles and the underlying network structure.

[03193] When do two networks have the same steady state ideal?

Format : Talk at Waseda University
Author(s) : Mark Curiel (University of Hawaii at Manoa)Elizabeth Gross (University of Hawaii at Manoa)Carlos Munoz (San Jose State University)
Abstract : Chemical reaction networks are often used to model biological processes, e.g. cell signaling. Assuming mass action kinetics, a reaction network gives rise to a polynomial system. We consider the ideal generated by these polynomials, called steady-state ideals. Our main results describe three combinatorial operations on the reaction graph that preserve the steady-state ideal. Furthermore, we give combinatorial conditions to identify monomials in a steady-state ideal.

00686 (3/3) : 3E @F412 [Chair: Gillian Grindstaff]

[02960] Hypergraph representation of topological features in complex systems

Format : Talk at Waseda University
Author(s) : Agnese Barbensi (The University of Melbourne)
Abstract : Understanding how a system's behaviour emerges from its shape and structure is a critical question across modern science. Topological data analysis provides a powerful computational window on this problem. I will present some recent work in which we develop a framework to analyse the behaviour of complex systems via their structures. The proposed method is based on an interpretation of persistent homology summaries with network theoretical tools, combined with statistical and computational techniques.

[02964] Spectral theory of graphs and hypergraphs

Format : Online Talk on Zoom
Author(s) : Raffaella Mulas (Vrije Universiteit Amsterdam)
Abstract : Spectral graph theory studies the qualitative properties of a graph that can be inferred from the eigenvalues and the eigenvectors of an operator associated with it. It has a long history, and it is widely used in applications. In this talk, we recall the key properties of the graph normalized Laplacian and we generalize it to the case of hypergraphs.

[02989] Role analysis for higher-order social systems

Format : Talk at Waseda University
Author(s) : Nina Otter (Queen Mary University of London)
Abstract : Social scientists have been using networks to model social systems since at least the 1970s. A social network model is typically a collection of simple graphs, which can be thought of as a multi-relational graph. Studying the roles of actors in the network amounts to studying the semigroup structure of compound relations that arise from the multi-relational graph. These graph models assume a pairwise interaction between social actors. We study ways to extend the analysis of social roles to models that take into account not only pairwise but also higher-order relationships between social actors, such as social simplicial complexes and hypergraphs. A challenge in this process is to define compound higher-order relations with desirable algebraic and topological properties. In this talk I will discuss several ways to address this problem, drawing inspiration from various areas to find an appropriate generalization of composition, including q-analysis, PROPs, and chemical hypergraphs. I will then illustrate how different composition operations capture different types of information in real-world social systems.

The talk is based on joint work in progress, started at the AMS MRC 2022 on Applied Category Theory, jointly with Daniel Cicala, Rachel Hardeman Morrill, Abigail Hickok, Elise McMahon, Nikola Milicevic, Nima Motamed, Emily Roff.

[02951] Topological Information Retrieval with Dilation-Invariant Bottleneck Comparative Measures

Format : Online Talk on Zoom
Author(s) : Anthea Monod (Imperial College London)Yueqi Cao (Imperial College London)Athanasios Vlontzos (Advanced Causal Inference (ACI) Lab)Luca Schmidtke (Imperial College London)Bernhard Kainz (Imperial College London)
Abstract : Representing elements in a database so that queries may be accurately matched is a central task in information retrieval. This is achieved by embedding the graph of the database into a manifold using a variety of metrics. Persistent homology is able to characterize a database in terms of hierarchy and connectivity. We show that embeddings retaining the database topology coincide topologically with dilation-invariant comparisons, which we propose to address metric distortion on manifolds.

[00687] Recent advances in deep learning-based inverse and imaging problems

Session Time & Room :

00687 (1/3) : 2C (Aug.22, 13:20-15:00) @E605

00687 (2/3) : 2D (Aug.22, 15:30-17:10) @E605

00687 (3/3) : 2E (Aug.22, 17:40-19:20) @E605

Type : Proposal of Minisymposium
Abstract : The interplay of deep learning with inverse and imaging problems has seen a tremendous progress during the last years producing state-of-the-art results in most tasks. Apart from the availability of large data and the increased computing power, this progress has been mainly facilitated by the development of rigorous theoretical investigations. The purpose of this minisymposium is to bring together experts in data-driven inverse imaging problems who work both in theory and applications. The aim is to stimulate a fruitful knowledge exchange about how mathematical theories can contribute and further develop this field.
Organizer(s) : Guozhi Dong, Michael Hintermüller, Kostas Papafitsoros
Classification : 65J22, 65K10, 68T07
Minisymposium Program :

00687 (1/3) : 2C @E605 [Chair: Michael Hintermueller]

[05273] Data-driven parameter optimization for some inverse problems with sparsity-based priors

Format : Talk at Waseda University
Author(s) : Juan Carlos De los Reyes (MODEMAT)
Abstract : In recent years, novel ideas have been applied to several inverse problems in combination with machine learning approaches, to improve the inversion by optimally choosing different parameters of interest. A fruitful approach in this sense is bilevel optimization, where the inverse problems are considered as lower-level constraints, while on the upper-level a loss function based on a training set is used. When confronted with inverse problems with sparsity-based regularizers, however, the bilevel optimization problem structure becomes quite involved to be analyzed, as classical nonlinear or bilevel programming results cannot be directly utilized.
In this talk, I will discuss on a strategy to overcome these difficulties, leading to a reformulation of the bilevel problems as mathematical programs with complementarity constraints. This enables to obtain sharp first-order optimality conditions, but at the price of lifting the problems to a higher dimension. Some ideas on how to reduce the dimension of the problems back will also be presented, together with the different challenges that these problems pose, when dealing with large training sets.

[03185] Data-driven Joint Inversion for PDE Models

Format : Talk at Waseda University
Author(s) : Kui Ren (Columbia University)
Abstract : The task of simultaneously reconstructing multiple physical coefficients in partial differential equations from observed data is ubiquitous in applications. In this work, we propose an integrated data-driven and model-based iterative reconstruction framework for such joint inversion problems where additional data on the unknown coefficients are supplemented for better reconstructions. Our method couples the supplementary data with the PDE model to make the data-driven modeling process consistent with the model-based reconstruction procedure. We characterize the impact of learning uncertainty on the joint inversion results for two typical model inverse problems. This is based on a joint work with Lu ZHang.

[02972] A scalable deep learning approach for solving high-dimensional dynamic optimal transport

Format : Talk at Waseda University
Author(s) : Zuoqiang Shi (Tsinghua University)
Abstract : The dynamic formulation of optimal transport has attracted growing interests. In this talk, we propose a deep learning based method to solve the dynamic optimal transport in high dimensional space based on carefully designed representation of the velocity field, the discretization along the characteristics, and the computation of high dimensional integral by Monte Carlo method. Numerical experiments show that our method could give more accurate results in high dimensional cases and has very good scalability.

[04688] Learning nonlinearities in time-dependent PDEs from data

Format : Talk at Waseda University
Author(s) : Christian Aarset (University of Göttingen)Martin Holler (University of Graz)Tram Thi Ngoc Nguyen (Max-Planck Institute for Solar System Research, Göttingen)
Abstract : We introduce and analyze an all-at-once approach for learning parts of a partial-differential-equation-based model from data. More specifically, we consider the learning of a non-linearity in the model, which acts pointwise on the state, from indirect, noisy measurements. We provide a function-space analysis of the corresponding learning problem and of the resulting PDE with learned components in a general setting. Furthermore, we show numerical experiments that confirm the practical feasibility of the proposed method.

00687 (2/3) : 2D @E605 [Chair: Kostas Papafitsoros]

[04070] Conductivity imaging using deep neural networks

Format : Online Talk on Zoom
Author(s) : Bangti Jin (Chinese University of Hong Kong)
Abstract : Conductivity imaging from various observational data represents one fundamental task in medical imaging. In this talk, we discuss numerical methods for identifying the conductivity parameters in elliptic PDEs. Commonly, a regularized formulation consists of a data fidelity and a regularizer is employed, and then it is discretized using finite difference method, finite element methods or deep neural networks in practical computation. One key issue is to establish a priori error estimates for the recovered conductivity distribution. In this talk, we discuss our recent findings on using deep neural networks for this class of problems, by effectively utilizing relevant stability results.

[04396] Model-corrected learned primal-dual models for fast photoacoustic tomography

Format : Talk at Waseda University
Author(s) : Andreas Hauptmann (University of Oulu)
Abstract : Learned iterative reconstructions hold great promise to accelerate tomographic imaging with empirical robustness to model perturbations. Adoption for photoacoustic tomography is hindered by the computational expensive forward model. Computational feasibility can be obtained by the use of fast approximate models, but model errors need to be compensated.

In this talk we discuss conceptual difficulties and present methodological advances for model corrections in learned image reconstructions by embedding the model correction in a learned primal-dual framework.

[03165] Learning the Regularisation Parameter for Inverse Problems

Format : Online Talk on Zoom
Author(s) : Sebastian Scott (University of Bath)Matthias Ehrhardt (University of Bath)Silvia Gazzola (University of Bath)
Abstract : Solving linear inverse problems via variational regularisation involves the use of unknown regularisation parameters. In order to attain a meaningful reconstruction, these parameters must be carefully chosen. This work will cover bilevel learning, a framework in which one is able to learn appropriate parameter values via a machine learning approach.

[04247] Lipschitz Training for Adversarially Robust Neural Networks

Format : Talk at Waseda University
Author(s) : Tim Roith (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : Adversarial examples have revealed the vulnerability of neural networks, making stability and robustness key concerns. To address this, we explore the role of the Lipschitz constant in adversarial machine learning. I will present an algorithm that employs an approximate Lipschitz constant as a regularizer. In each training step, we compute points that aim to maximize a difference quotient. Finally, I will discuss the conceptual limits of methods enforcing a low Lipschitz constant of neural networks.

00687 (3/3) : 2E @E605 [Chair: Guozhi Dong]

[05448] The Unrolled Dynamics Modeling for Computed Tomography

Format : Talk at Waseda University
Author(s) : Haimiao Zhang (Beijing Information Science and Technology University)
Abstract : Deep learning revolutionized the research paradigm of medical imaging in the last decades. In this talk, I will show our works on combining classical mathematical models in computed tomography (CT) imaging with the modern deep neural network. These new computational imaging techniques give us a broader way of dealing with the medical imaging problem. Furthermore, numerical results demonstrated that the proposed deep models could be generalized to different datasets, scanning geometries, and noise levels.

[04836] Dictionary learning for an inverse problem in quantitative MRI

Format : Talk at Waseda University
Author(s) : Guozhi Dong (Central South University)Michael Hintermueller (Weierstrass Institute Berlin)Clemens Sirotenko (WIAS Berlin)
Abstract : The field of quantitative Magnetic Resonance Imaging aims at extracting physical tissue parameters from a

sequence of highly under sampled MR images. Mathematically, this can be achieved by estimating a set of unknown parameters in an ODE model. We employ dictionary learning based approaches to regularize the reconstruction process and investigate iterative schemes to solve the resulting non-convex and non-smooth problems for stationarity. Moreover numerical results and open questions are presented.

[05295] Deformable volumetric Image registration based on unsupervised learning

Author(s) : Ahsan Raza Siyal (University of Innsbruck)
Abstract : Deformable image registration has found its way into clinical routine, from image-guided adaptive radiotherapy to brain surgery. The traditional methods optimize an objective function independently for each pair of images, which is highly expensive in terms of time and computation. On the other hand, the deformable registration task can be defined as a parametric function and optimize its parameters on available image pairs and the function can be modeled as neural networks which learn the off-set displacement field through unsupervised loss function which contains data similarity term and a regularization term.

[00690] Computational methods for interfaces in physics an mechanics

Session Time & Room :

00690 (1/2) : 2D (Aug.22, 15:30-17:10) @F403

00690 (2/2) : 2E (Aug.22, 17:40-19:20) @F403

Type : Proposal of Minisymposium
Abstract : This minisymposium gathers analysts interested in the evolution of interfaces, singularities and lower dimensional objects, applied to fracture evolution, inverse problems, or shape optimization, and more.
Fracture can be computed by successive minimizations of "free discontinuity" energies, approached with phase-field methods. Evolving or static interfaces, or lower dimensional singularities, can be computed by discretizing geometric measure theoretical objects. Level sets methods can be used to identify defects in conductive media. The speakers address such issues from different point of views or apply similar methods to different problems. This will foster fruitful interaction between the participants and the audience.
Organizer(s) : Antonin Chambolle, Blaise Bourdin
Classification : 49NXX, 74PXX, 35QXX
Minisymposium Program :

00690 (1/2) : 2D @F403 [Chair: Blaise Bourdin]

[01367] Computation of free boundary minimal surfaces via extremal Steklov eigenvalue problems

Format : Talk at Waseda University
Author(s) : Braxton Osting (University of Utah)
Abstract : Recently Fraser and Schoen showed that the solution of a certain extremal Steklov eigenvalue problem on a compact surface with boundary can be used to generate a free boundary minimal surface, i.e., a surface contained in the ball that has (i) zero mean curvature and (ii) meets the boundary of the ball orthogonally. In this talk, I'll discuss numerical methods that use this connection to realize free boundary minimal surfaces. Namely, on a compact surface, Σ, with genus γ and b boundary components, we maximize $\sigma_j(\Sigma,g)\,L(\partial\Sigma,g)$ over a class of smooth metrics, g, where $\sigma_j(\Sigma,g)$ is the j-th nonzero Steklov eigenvalue and $L(\partial\Sigma,g)$ is the length of $\partial\Sigma$. Our numerical method involves (i) using conformal uniformization of multiply connected domains to avoid explicit parameterization for the class of metrics, (ii) accurately solving a boundary-weighted Steklov eigenvalue problem in multi-connected domains, and (iii) developing gradient-based optimization methods for this non-smooth eigenvalue optimization problem. Eigenfunctions corresponding to the extremal Steklov eigenvalues are used to generate a free boundary minimal surface. This is joint work wtih Chiu-Yen Kao and Èdouard Oudet.

[05329] Capturing surfaces using differential forms

Format : Talk at Waseda University
Author(s) : Stephanie Wang (University of California, San Diego)Albert Chern (University of California, San Diego)
Abstract : Exterior calculus has been an important tool in solving numerical PDEs by representing physical quantities as differential forms. In this talk we expand the usage of differential forms to a whole new way of representing curves and surfaces. By doing so we reformulate the classical nonconvex Plateau minimal surface problem into a convex optimization problem, and introduce a new implicit surface representation that permits nonempty boundaries.

[05617] Nonlocal approximations of anisotropic surface energies on partitions

Format : Talk at Waseda University
Author(s) : Selim Esedoglu (University of Michigan)
Abstract : Nonlocal energies approximating the perimeter of sets and, in the multiphase case, partitions, arise in many settings. In particular, they play an important role in the study of threshold dynamics, an algorithm for multiphase mean curvature motion. Ensuring the convergence of nonlocal energies in the multiphase, anisotropic setting turns out to be tricky but essential for the correct behavior of these numerical methods. I will discuss conditions that guarantee convergence of the anisotropic energies.

[05463] On some extensions and applications of thresholding schemes

Format : Talk at Waseda University
Author(s) : Karel Svadlenka (Kyoto University)
Abstract : In this talk, I will present two examples of application of suitably modified thresholding schemes, which were originally developed by Merriman, Bence and Osher, and later generalized by Esedoglu and Otto. First example concerns elucidating cell pattern formation in morphogenesis of sensory epithelia, and the other example concerns understanding evolution of anisotropic particles on solid substrate. I will also touch on the mathematical background of the schemes and their numerical implementation.

00690 (2/2) : 2E @F403 [Chair: Antonin Chambolle]

[05615] Advanced discretization schemes for phase-field fracture

Format : Talk at Waseda University
Author(s) : Blaise Bourdin (McMaster UniversityMcMaster University)Frédéric Marazzato (Louisiana State University)
Abstract : Variational phase-field models of fracture have established themselves as a powerful and efficient computational approach in fracture mechanics. They are based on a regularization of Francfort and Marigo variational energy, where the crack geometry and discontinuous displacements are represented by smooth functions The most common implementations are based on finite element discretization via continuous finite elements, and a staggered minimization scheme.
In this talk, we present a new discretization scheme where displacements are discretized using discontinuous Lagrange elements and the phase field variable by Crouzeix-Raviart elements. We compare this scheme to the classical continuous Galerkin scheme and highlight how it leads to a better approximation of the fracture energy.

[01899] Numerical approximation of a viscoelastic Cahn--Hilliard model for tumour growth

Format : Talk at Waseda University
Author(s) : Dennis Trautwein (University of Regensburg)Harald Garcke (University of Regensburg)
Abstract : In this talk, we present a phase-field model for tumour growth, where a diffuse interface is separating a tumour from the surrounding host tissue. In our model, we include biological effects like chemotaxis and transport processes by an internal velocity field. We include viscoelastic effects with a general Oldroyd-B type description with stress relaxation and stress generation by growth. We analyze a numerical approximation of the model with a fully-practical, stable and converging discrete scheme, which preserves the physical properties of the model. Finally, we illustrate properties of solutions with the help of numerical simulations.

[02809] A second order Cahn Hilliard model for wetting simulation

Format : Talk at Waseda University
Author(s) : elie bretin (ICJ & INSA Lyon)
Abstract : We focus in this talk to the approximation of surface diffusion flow using a Cahn–Hilliard-type model.
We introduce a new second order variational phase field model that associates the classical Cahn-Hilliard energy with two degenerate mobilities. We also propose some simple and efficient numerical schemes to approximate the solutions

and provide 3D numerical simulations of the wetting of a thin tube on various solid supports. This work was done in collaboration with R. Denis, S. Masnou, G. Terii and A. Sengers

[04707] Finite element minimization of line and surface energies arising in liquid crystals

Format : Talk at Waseda University
Author(s) : Dominik Stantejsky (McMaster University)
Abstract : Originating in the study of defect structures in nematic liquid crystals, we consider the numerical minimization of an energy posed for two-dimensional surfaces T involving the surface area of T outside an obstacle E, as well as the length of the boundary ∂T and a surface integral over the obstacle surface, generalizing both the obstacle- and Plateau problem. We propose a finite element representation of the energy and minimize using an ADMM algorithm.

[00696] Scientific Machine Learning for Inverse Problems

Session Time & Room :

00696 (1/3) : 4E (Aug.24, 17:40-19:20) @G808

00696 (2/3) : 5B (Aug.25, 10:40-12:20) @G808

00696 (3/3) : 5C (Aug.25, 13:20-15:00) @G808

Type : Proposal of Minisymposium
Abstract : Inverse problems address learning complex systems from data. They are ubiquitous in various computational science and engineering areas with grand social impacts, e.g., geophysics, climate change, space missions, and health. Solving an inverse problem requires many solves of the forward model and can be challenging for complex and large-scale problems, e.g., those governed by partial differential equations. Recently, the development of scientific machine learning (SciML) has made tremendous progress in overcoming those challenges. This minisymposium covers progress on (i) the methodology development of SciML-based techniques for inverse problems, and (ii) the applications of SciML methods in solving complex inverse problems.
Organizer(s) : Jinlong Wu, Peng Chen
Classification : 35R30, 68T07

00696 (1/3) : 4E @G808 [Chair: Jinlong Wu]

[03211] Learning Stochastic Closures Using Sparsity-Promoting Ensemble Kalman Inversion

Format : Talk at Waseda University
Author(s) : Jinlong Wu (University of Wisconsin-Madison)Tapio Schneider (California Institute of Technology)Andrew Stuart (California Institute of Technology)
Abstract : Closure models are widely used in simulating complex dynamical systems such as turbulence and climate change, for which direct numerical simulation is often too expensive. Although it is almost impossible to perfectly reproduce the true system with closure models, it is often sufficient to correctly reproduce time-averaged statistics. Here we present a sparsity-promoting, derivative-free optimization method to estimate model error from time-averaged statistics. Specifically, we show how sparsity can be imposed as a constraint in ensemble Kalman inversion (EKI), resulting in an iterative quadratic programming problem. We illustrate how this approach can be used to quantify the model error in the closures of dynamical systems. In addition, we demonstrate the merit of introducing stochastic processes to quantify model error for certain systems. We also present the potential of replacing existing closures with purely data-driven closures using the proposed methodology. The results show that the proposed methodology provides a systematic approach to estimating model error in the closures of dynamical systems.

[03315] Efficient Bayesian Physics Informed Neural Networks for Inverse Problems via Ensemble Kalman Inversion

Format : Talk at Waseda University
Author(s) : xueyu zhu (Department of Mathematics, University of Iowa)andrew pensoneault (Department of Mathematics, University of Iowa)
Abstract : Bayesian Physics Informed Neural Networks (B-PINNs) have gained significant attention for PDE-based inverse problems. Existing inference approaches are either computationally expensive for high-dimensional posterior inference or provide unsatisfactory uncertainty estimates. In this paper, we present a new efficient inference algorithm for B-PINNs that uses Ensemble Kalman Inversion (EKI). We find that our proposed method can achieve inference results with informative uncertainty estimates comparable to Hamiltonian Monte Carlo (HMC)-based B-PINNs with a much reduced computational cost.

[02563] Neural operator acceleration of PDE-constrained Bayesian inverse problems: Error estimation and correction

Format : Talk at Waseda University
Author(s) : Lianghao Cao (The University of Texas at Austin)Thomas O'Leary-Roseberry (The University of Texas at Austin)Prashant K. Jha (The University of Texas at Austin)J. Tinsley Oden (The University of Texas at Austin)Omar Ghattas (The University of Texas at Austin)
Abstract : In this talk, we explore using neural operators to accelerate infinite-dimensional Bayesian inverse problems (BIPs) governed by nonlinear parametric partial differential equations (PDEs). Neural operators have gained attention in recent years for their ability to approximate nonlinear mappings between function spaces, particularly the parameter-to-solution mappings of PDEs. On the one hand, the computational cost of BIPs can be drastically reduced if the large number of PDE solves required in posterior characterization are replaced with evaluations of trained neural operators. On the other hand, reducing error in the resulting BIP solutions via reducing approximation error of the neural operators in training can be challenging and unreliable.

We provide an a-priori error bound result that implies certain BIPs can be ill-conditioned to the approximation error of neural operators, thus leading to inaccessible accuracy requirements in training. To reliably reduce error of neural operator predictions to be used in BIPs, we consider correcting predictions of a trained neural operator by solving a linear variational problem based on the PDE residual. We show that a trained neural operator with error correction can possibly achieve a quadratic reduction of its approximation error. Finally, we provide a numerical example based on the deformation of hyperelastic materials. We demonstrate that the posterior representation produced using neural operators is greatly and consistently enhanced by the error correction, while still retaining substantial computational speed ups.

[01533] Ensemble Kalman inversion with dropout in Scientific Machine Learning for Inverse Problems

Format : Talk at Waseda University
Author(s) : Shuigen Liu (National University of Singapore)Sebastian Reich (Universität Potsdam)Xin Thomson Tong (National University of Singapore)
Abstract : Ensemble Kalman inversion (EKI) is an ensemble-based method to solve inverse problems. However, EKI can face difficulties when dealing with high-dimensional problems using a fixed-size ensemble, due to its subspace property where the ensemble always lives in the subspace spanned by the initial ensemble. To address this issue, we propose a novel approach using dropout technique to mitigate the subspace problem. Compared to the conventional localization approach, dropout avoids the complex designs in the localization process. We prove that EKI with dropout converges in the small ensemble settings, and the complexity of the algorithm scales linearly with dimension. Numerical examples demonstrate the effectiveness of our approach.

00696 (2/3) : 5B @G808 [Chair: Peng Chen]

[03213] Projected variational inference for high-dimensional Bayesian inverse problems

Format : Online Talk on Zoom
Author(s) : Peng Chen (Georgia Institute of Technology)
Abstract : In this talk, I will present a class of transport-based projected variational methods to tackle the computational challenges of the curse of dimensionality and unaffordable evaluation cost for high-dimensional Bayesian inverse problems governed by complex models. We project the high-dimensional parameters to intrinsically low-dimensional data-informed subspaces, and employ transport-based variational methods to push samples drawn from the prior to a projected posterior. Moreover, we employ fast surrogate models to approximate the parameter-to-observable map. I will present error bounds for the projected posterior distribution measured in Kullback--Leibler divergence. Numerical

experiments will be presented to demonstrate the properties of our methods, including improved accuracy, fast convergence with complexity independent of the parameter dimension and the number of samples, strong parallel scalability in processor cores, and weak data scalability in data dimension.

[03215] Multifidelity deep neural operators for efficient learning of partial differential equations with application to fast inverse design of nanoscale heat transport

Format : Online Talk on Zoom
Author(s) : Lu Lu (University of Pennsylvania)Min Zhu (University of Pennsylvania)
Abstract : Deep neural operators can learn operators mapping between infinite-dimensional function spaces via deep neural networks and have become an emerging paradigm of scientific machine learning. However, training neural operators usually requires a large amount of high-fidelity data, which is often difficult to obtain in real engineering problems. Here we address this challenge by using multifidelity learning, i.e., learning from multifidelity data sets. We develop a multifidelity neural operator based on a deep operator network (DeepONet). A multifidelity DeepONet includes two standard DeepONets coupled by residual learning and input augmentation. Multifidelity DeepONet significantly reduces the required amount of high-fidelity data and achieves one order of magnitude smaller error when using the same amount of high-fidelity data. We apply a multifidelity DeepONet to learn the phonon Boltzmann transport equation (BTE), a framework to compute nanoscale heat transport. By combining a trained multifidelity DeepONet with genetic algorithm or topology optimization, we demonstrate a fast solver for the inverse design of BTE problems.

[02629] Surrogate modeling for many-body hydrodynamic interactions via graph neural networks

Format : Online Talk on Zoom
Author(s) : Wenxiao Pan (University of Wisconsin-Madison)
Abstract : This talk presents a new framework, the hydrodynamic interaction graph neural network (HIGNN), for fast simulation of particulate suspensions. It generalizes the state-of-the-art GNN by 1) introducing higher-order structures in graph and 2) reducing the scaling of its prediction cost down to quasi-linear. The HIGNN, once constructed with low training cost, permits fast predictions of the particles' velocities and is transferable across suspensions of different numbers/concentrations of particles subject to any external forcing.

[04531] A practical use of neural density estimators for Bayesian experimental design

Format : Online Talk on Zoom
Author(s) : Rafael orozco (Georgia Institute of Technology)Mathias Louboutin (Georgia Institute of Technology)Felix Herrmann (Georgia Institute of Technology)
Abstract : Neural density estimation is a powerful approach for learning conditional distributions, including Bayesian posteriors in inverse problems. While Bayesian statisticians find these methods promising, some practitioners remain skeptical about their practicality compared to deterministic solutions. We present a practical use case that exploits the posterior entropy minimization properties of conditional neural density estimators to identify optimal experimental designs. By utilizing normalizing flows, we demonstrate our technique's scalability for tackling realistic 2D and 3D inverse problems.

00696 (3/3) : 5C @G808 [Chair: Jinlong Wu]

[03214] Solving High-dimensional Inverse Problems with Weak Adversarial Networks

Format : Online Talk on Zoom
Author(s) : yaohua zang Yaohua Zang (Zhejiang University)Gang Bao (Zhejiang University)Xiaojing Ye (Georgia State University)Haomin Zhou (Georgia Institute of Technology)
Abstract : We present a weak adversarial network approach to numerically solve a class of inverse problems. The weak formulation of PDE in the inverse problem is leveraged with DNNs and induces a minimax problem. Then, the solution can be solved by finding the saddle points in the network parameters. As the parameters are updated, the network gradually approximates the solution of the inverse problem. Numerical experiments demonstrate the promising accuracy and efficiency of this approach.

[01482] Automatic discovery of low-dimensional dynamics underpinning time-dependent PDEs for inverse problems resolution

Format : Online Talk on Zoom
Author(s) : Francesco Regazzoni (MOX, Dipartimento di Matematica, Politecnico di Milano)Matteo Salvador (MOX, Dipartimento di Matematica, Politecnico di Milano)Stefano Pagani (MOX, Dipartimento di Matematica, Politecnico di Milano)Luca Dede' (MOX, Dipartimento di Matematica, Politecnico di Milano)Alfio Quarteroni (MOX, Dipartimento di Matematica, Politecnico di Milano)
Abstract : We present a novel Machine Learning technique able to learn differential equations that surrogate the solution of space-time-dependent problems. Our method exploits a finite number of latent variables, providing a compact representation of the system state, automatically discovered during training. It allows building, in a fully non-intrusive manner, surrogate models accounting for the dependence on parameters and time-dependent inputs. As such, our method is suitable to accelerate the resolution of inverse problems.

[00699] Delay and stochastic differential equations in life sciences and engineering

Session Time & Room :

00699 (1/4) : 1C (Aug.21, 13:20-15:00) @G404

00699 (2/4) : 1D (Aug.21, 15:30-17:10) @G404

00699 (3/4) : 1E (Aug.21, 17:40-19:20) @G404

00699 (4/4) : 2C (Aug.22, 13:20-15:00) @G404

Type : Proposal of Minisymposium
Abstract : The purpose of this minisymposium is to bring experts in delay differential and stochastic differential equations
and to discuss recent advancement in the area, as well as applications of dynamical systems to emerging areas of mathematical biology, medicine and engineering. Qualitative behaviour, stability, oscillation will be the focus of theoretical investigations. In theoretical advancement, the focus is on asymptotic behaviour, in particular local and global stability, and its control. The areas of application include population dynamics, modeling brain activity, cancer treatment, and engineering.

Organizer(s) : Elena Braverman
Classification : 34Kxx, 92D25, 92D30, 92Cxx, 93Exx
Minisymposium Program :

00699 (1/4) : 1C @G404 [Chair: Elena Braverman]

[04596] Impacts of demographic and environmental stochasticity on population dynamics with cooperative effects

Format : Talk at Waseda University
Author(s) : Yun Kang (Arizona State University)Tao Feng (Yangzhou University,)Hongjuan Zhou (Arizona State University)Zhipeng Qiu (Nanjing University of Science and Technology)
Abstract : This work provides rigorous analysis on stochastic persistence and extinction, ergodicity, and the existence of a nontrivial periodic solution to study the impacts of demographic and environmental stochasticity on population dynamics with component Allee effects. We show that stochasticity may affect population dynamics differently for different strength of Allee effects. Moreover, in the extinction case, demographic and environmental stochasticity can not change the trend of population extinction, but they can delay or promote population extinction.

[03954] Recent advances in modeling tick-borne dynamics using delay differential equations

Format : Talk at Waseda University
Author(s) : Jianhong Wu (York University)
Abstract : We provide a short survey of recent advances in modeling tick-borne disease transmission dynamics using structured population dynamics models and delay differential equations. Focus will be on those studies relevant to diapause, that

introduces additional delays in the modeling system (and periodic variation of the environment), and on co-feeding transmission route that requires incorporation of individual infestation dynamics into the tramsmission dynamics at the population level.

[03402] Delay and Resonance: From Differential Equations to Random Walks

Format : Talk at Waseda University
Author(s) : Toru Ohira (Graduate School of Mathematics, Nagoya University)
Abstract : Various types of oscillatory dynamics are associated with systems with delayed feedback. We present two simple models that take advantage of these oscillations to induce resonating behaviors. The first model is a simple first-order delay differential equation with a time linear coefficient. The other model is a simple stochastic binary bit with delayed feedback. Both models produce transient oscillatory dynamics that can show resonance with the tuned value of the delay.

[03310] Evolutionary Games with Strategy-Dependent Time Delays

Format : Talk at Waseda University
Author(s) : Jacek Miękisz (University of Warsaw)
Abstract : We present a new behavior of systems with time delays. We show that in differential replicator equations with strategy-dependent time delays, interior stationary states, describing the level of cooperation in evolutionary games of social dilemmas, depend continuously on time delays, they may also disappear or additional states can emerge. A Prisoner's Dilemma model with an asymptotically stable population with just cooperators is presented. We will also discuss some results for finite populations.

00699 (2/4) : 1D @G404 [Chair: John A. D. Appleby]

[03461] Asymptotic behaviour for nonautonomous Nicholson equations with mixed monotonicities

Format : Talk at Waseda University
Author(s) : Teresa Faria (Professor/University of Lisbon)
Abstract : A general nonautonomous Nicholson equation with multiple pairs of distinct delays is studied. Sufficient conditions for permanence are given, with explicit lower and upper uniform bounds. Imposing an additional condition on the size of some delays, the global attractivity of positive solutions is established. Sharper results are obtained when there exists a positive equilibrium or periodic solution. These results improve on recent literature, due to the generality of the equation and less restrictive constraints.

[03291] Periodicity and stability in some biological delay models

Format : Talk at Waseda University
Author(s) : Anatoli F Ivanov (Pennsylvania State University)
Abstract : We consider mathematical models of several biological processes which are described by simple form scalar delay differential equations. They include autonomous nonlinear equations as well as equations with periodic coefficients. New criteria for the global asymptotic stability of equilibrium states are proposed. It is proved that the instability of equilibria implies the existence of periodic motions in the models. Explicit examples from applications demonstrating theoretical findings are given.

[03816] Exponential stability of linear discrete systems with multiple delays

Format : Talk at Waseda University
Author(s) : Josef Diblik (Brno University of Technology)Josed Diblik (Brno University of Technology)
Abstract : The problem of exponential stability of delayed linear discrete systems with multiple delays and with constant matrices is studied. A new degenerated Lyapunov-Krasovskii functional is used to derive sufficient conditions for exponential stability and derive an exponential estimate of the norm of solutions. Though often used in the study of stability, the assumption that the spectral radius of the matrix of linear terms is less than 1 is not applied here.

[03498] On asymptotic stability of equations and systems with distributed, unbounded and infinite delays

Format : Talk at Waseda University
Author(s) : Elena Braverman (university of Calgary)Leonid Berezansky (Ben-Gurion University of Negev)
Abstract : Many differential equations of mathematical biology assume delayed production process and instantaneous mortality. Introduction of delay can destabilize the unique positive equilibrium and even lead to chaos. However, for

some types of equations and systems, lags in the reproduction term do not change stability properties. Consideration of variable, unbounded and distributed delays emphasizes robustness of this `absolute stability' property. Influence of an infinite, not just unbounded, delay is also outlined.

00699 (3/4) : 1E @G404 [Chair: Elena Braverman]

[04635] Asymptotic classification of forced stochastic systems with memory

Format : Talk at Waseda University
Author(s) : John A Appleby (Dublin City University)Emmet Lawless (Dublin City University)
Abstract : Linear stochastic functional differential equations are among the simplest stochastic systems that possess path-dependence. In recent work, the authors have characterised the asymptotic behaviour, including rates of convergence to equilibria, of solutions of such systems which are not externally forced. In this work, we are able to characterise the asymptotic behaviour of state-independent forcing terms which guarantee specified types of asymptotic rates of decay, growth and fluctuation size, of solutions.

[04851] Asymptotic analysis of stochastic functional differential equations

Format : Talk at Waseda University
Author(s) : Emmet Lawless (Dublin City University)John Appleby (Dublin City University)
Abstract : In this talk we are concerned with the asymptotic behaviour of the mean square of scalar stochastic functional differential equations with finite delay. We are primarily interested in providing characterisations of various types of mean square stability and discussing the robustness of solutions under perturbations. Additionally, we highlight how our methods of proof can be utilised to make progress in understanding the mean square behaviour of equations of Volterra type.

[03977] An order-one adaptive scheme for the strong approximation of stochastic systems with jumps.

Format : Online Talk on Zoom
Author(s) : Conall Kelly (University College Cork)Gabriel Lord (Radboud University)Fandi Sun (Heriot-Watt University)
Abstract : Consider a system of SDEs with coefficients that are locally Lipschitz and together satisfy a montone condition. It is known that the explicit Milstein scheme on a uniform mesh fails to converge here.
We construct an adaptive mesh to ensure order-one convergence that reduces the stepsize as solutions approach the boundary of a sphere, and modify it for systems additionally perturbed by Poisson jumps.
We demonstrate our scheme in the modelling of telomere length dynamics.

[02373] Mathematical Model of Hepatitis B Virus Combination Treatment

Format : Online Talk on Zoom
Author(s) : Irina Volinsky (Ariel University, Israel)
Abstract : HBV has a high mortality rate with respect to other common known diseases. The commonly used cure for chronic HBV cases is the fusion of interferon and analogous nucleoside methods. The addition of IL-2 therapy proposed in this article. This method was validated to be highly effective. This model will take into account the response of the immune system of the patient and will use immune therapy as a support.

00699 (4/4) : 2C @G404 [Chair: Elena Braverman]

[04297] The Impact of Time Delays on Synchrony in a Neural Field Model

Format : Online Talk on Zoom
Author(s) : Sue Ann Campbell (University of Waterloo)Isam Al-Darabsah (Jordan University of Science and Technology)Bootan Rahman (University of Kurdistan Hewler (UKH))Wilten Nicola (University of Calgary)Liang Chen (University of Waterloo)
Abstract : We consider a network of Wilson-Cowan nodes with homeostatic adjustment of the inhibitory coupling strength and time delayed, excitatory coupling. Without delay, the system exhibits rich dynamics including oscillations, mixed-mode oscillations, and chaos. We show that Hopf bifurcations induced by the excitatory coupling, the connectivity structure and the delay lead to different phase-locked oscillations: both synchronized and desynchronized. We show that interaction between different Hopf bifurcations can lead to complex solutions, such as intermittent synchronization.

[03295] Stability analysis of coupled feedback in hematopoiesis

Format : Talk at Waseda University
Author(s) : Jacques Bélair (Université de Montréal)
Abstract : Hematopoiesis, the production of mammalian blood cells, involves an intertwined network of physiological processes, with nonlinear, delayed feedback control mechanisms. We consider a simplified model of the coupled regulation of erythrocytes (red blood cells) and thrombocytes (platelets).
Equilibrium solutions are determined, their stability established and the nature of the oscillations when instability occurs are investigated. The mathematical part of the analysis revolves around a transcendental characteristic equation of second order with two delays.

[00702] Sequential Decision Making for Optimization, Learning and Search

Session Time & Room : 4C (Aug.24, 13:20-15:00) @F412

Type : Proposal of Minisymposium
Abstract : Key problems such as hyperparameter optimization, model calibration, and inverse/optimal design often involve exploring design spaces to identify desirable designs for one or more objectives of great value and great cost. Intelligently experimenting in this design space is fundamental to gaining valuable, actionable insights in a viable amount of time. In this minisymposium, we will discuss some of the common methodologies for identifying high-performing and optimal designs, including Bayesian and genetic methods, and several exciting applications which motivate the research in this field.
Organizer(s) : Michael McCourt
Classification : 60G15, 90C26, 62C10
Minisymposium Program :

00702 (1/1) : 4C @F412 [Chair: Michael McCourt]

[04910] Combinatorial 3D Shape Assembly with Sequential Decision-Making Processes

Format : Online Talk on Zoom
Author(s) : Jungtaek Kim (University of Pittsburgh)
Abstract : We require unit primitives, e.g., voxels and points, to create a 3D shape. In particular, if we consider a way to construct a 3D shape with the connectivity of primitives, a problem of 3D shape creation is characterized by sequential and combinatorial properties. By dealing with the sequential and combinatorial properties, we present a method for 3D shape assembly using sequential decision-making processes, i.e., Bayesian optimization and reinforcement learning.

[05274] Constraint active search as an alternative to optimization

Format : Online Talk on Zoom
Author(s) : Michael McCourt (Unaffiliated)
Abstract : Bayesian optimization is a sample efficient method for identifying high performing configurations of a black box function. This strategy is extremely powerful, but it is often a misguided tool for many practical circumstances -- problems with heavy noise, input/output imprecision, many objectives, discrepancy in cost of objective evalution, or a human-in-the-loop defined objective/preference all are situations where optimization may be the wrong strategy. Here, we discuss the shortcomings of optimization and propose an alternate strategy: the search for a satisfactory set of outcomes, as guided by user-defined performance thresholds. We refer to this as Constraint Active Search, and we present our motivating application as well as some theoretical analysis.

[05604] Optuna: A Software to Solve Black-box Optimization

Format : Online Talk on Zoom
Author(s) : Hideaki Imamura (Preferred Networks, Inc)
Abstract : Optuna is a software tool for solving black-box optimization problems. It provides a Pythonic interface to describe the search space and objective functions. It supports various algorithms, extensive visualization capabilities, and easy distributed optimization. In this presentation, we will introduce some of the latest features of Optuna and discuss the problem awareness that arises in black-box optimization and its application field, specifically hyperparameter optimization in machine learning.

[05288] Evolution Strategies: Principles and Practical Issues

Format : Online Talk on Zoom
Author(s) : Masahiro Nomura (CyberAgent)
Abstract : Evolution strategies (ES) is one of the most powerful frameworks for black-box continuous optimization. This talk will describe the design principles behind the empirical success of ES and the representative methods that have often been employed in science and industry. In addition, key issues that may be encountered when using ES in practice will be discussed.

[00703] Combining machine learning with domain decomposition and multilevel methods

Session Time & Room :

00703 (1/2) : 4E (Aug.24, 17:40-19:20) @E812

00703 (2/2) : 5B (Aug.25, 10:40-12:20) @E812

Type : Proposal of Minisymposium
Abstract : In this minisymposium, recent advances in using machine learning in domain decomposition and multilevel methods will be discussed as well as applying domain decomposition and multilevel techniques to improve different aspects of machine learning algorithms.
Organizer(s) : Victorita Dolean, Alexander Heinlein, Axel Klawonn, Rolf Krause
Classification : 68T07, 65M55, 65N55, 65K10
Minisymposium Program :

00703 (1/2) : 4E @E812 [Chair: Axel Klawonn]

[03764] A Domain Decomposition-Based CNN-DNN Architecture for Model Parallel Training

Format : Talk at Waseda University
Author(s) : Axel Klawonn (University of Cologne)Martin Lanser (University of Cologne)Janine Weber (University of Cologne)
Abstract : In this talk, a novel domain decomposition-based CNN-DNN (convolutional/deep neural network) architecture is presented that naturally supports a model parallel training strategy and that is loosely inspired by two-level domain decomposition methods. Experimental results for different 2D image classification problems are shown as well as for the classification of 3D computer tomography (CT) scans. The results show that the proposed approach can significantly accelerate the required training time without losing accuracy in most cases.

[03312] DNN-MG: A Hybrid Neural Network/Finite Element Method

Format : Talk at Waseda University
Author(s) : Nils Margenberg (Helmut Schmidt University Hamburg)Robert Jendersie (Otto von Guericke University Magdeburg)Christian Lessig (Otto von Guericke University Magdeburg)Thomas Richter (Otto von Guericke University Magdeburg)
Abstract : The Deep Neural Network Multigrid Solver (DNN-MG) augments classical finite element simulations in fluid-dynamics by deep neural networks to improve the computational efficiency. To achieve this, it combines a geometric multigrid solver with a DNN that is used when a full resolution of the effects is not feasible or efficient. Our method's efficiency, generalizability, and scalability is demonstrated through applications to 3D benchmark simulations of the Navier-Stokes equations.

[05268] Combining physics-informed neural networks with multilevel domain decomposition

Format : Online Talk on Zoom
Author(s) : Alexander Heinlein (Delft University of Technology (TU Delft))Victorita Dolean Maini (University of Strathclyde)Siddhartha Mishra (ETH Zurich)Ben Moseley (ETH Zurich)
Abstract : Physics-informed neural networks (PINNs) are a powerful approach for solving problems related to differential equations. However, PINNs often struggle to solve differential equations when they have high frequency and/or multi-scale solutions. In this work, we improve the performance of PINNs in this regime by combining them with domain decomposition. We build on the existing finite basis physics-informed neural networks (FBPINNs) framework and show that adding multilevel modelling to FBPINNs improves their performance.

[04823] Enhancing training of scientific machine learning applications

Format : Talk at Waseda University
Author(s) : Alena Kopanicakova (Brown University)
Abstract : Scientific machine learning has shown potential in creating efficient surrogates for complex multiscale and multiphysics problems. However, the computational cost of training these surrogates is prohibitively high.We propose a training procedure that utilizes the layer-wise decomposition of a deep neural network in order to construct a nonlinear preconditioner for the standard L-BFGS optimizer.The convergence properties of the novel training method will be analyzed by means of numerical experiments.

00703 (2/2) : 5B @E812

[04378] A Splitting Approach of Multilevel Optimization with an Application to Physics Informed Neural Networks

Format : Talk at Waseda University
Author(s) : Valentin Mercier (Université de Toulouse, IRIT, CERFACS, BRLi)Serge Gratton (Université de Toulouse, INP-ENSEEIHT, IRIT,ANITI)Philippe Toint (Namur Center for Complex Systems (naXys), University of Namur)Elisa Riccietti (Université de Lyon, INRIA, EnsL, UCBL, CNRS)
Abstract : We propose a multilevel optimization algorithm, based on coordinate-block descent, to solve nonlinear problems while maintaining the advantages of multilevel methods. We demonstrate its effectiveness in solving complex Poisson problems using neural networks (NN) with PINN's method. We address the unique challenges posed by NNs, such as the F-principle, by employing frequency-aware network architectures. Overall, our approach offers a cost-effective solution for solving complex nonlinear optimization problems using neural networks.

[04367] Improved Accuracy of Physics-Informed Neural Networks Using a Two-Level Training Approach and Lagrange Multipliers

Format : Online Talk on Zoom
Author(s) : Deok-Kyu Jang (Kyung Hee University)Kyungsoo Kim (Kyung Hee University)Hyea Hyun Kim (Kyung Hee University)
Abstract : In this talk, we introduce efficient techniques to enhance accuracy of Physics-Informed Neural Networks (PINNs) for solving second-order elliptic problems. We first present a two-level training approach incorporating a scaling process to capture high-frequency solution components more effectively at the first training stage, and a post-processing residual training step to resolve the remaining low-frequency components. We also introduce a non-overlapping domain decomposition method for PINNs where we employ Lagrange multipliers to enforce suitable interface conditions and boundary conditions so as to improve the solution accuracy further. We demonstrate the effectiveness of our proposed methods through numerical test examples.

[00704] Numerical Software Libraries Enabling Benefits to Scientific Applications

Session Time & Room :

00704 (1/3) : 3D (Aug.23, 15:30-17:10) @E803

00704 (2/3) : 3E (Aug.23, 17:40-19:20) @E803

00704 (3/3) : 4C (Aug.24, 13:20-15:00) @E803

Type : Proposal of Industrial Minisymposium

Abstract : Numerous numerical software libraries have high quality implementations of efficient algorithms and thus facilitate transfer of new algorithms developed in academia into scientific applications, including those in labs and industry. Recently, use of these libraries by labs and industry has significantly increased, and the value of these libraries has been made clear. Several libraries have enabled applications to migrate their simulation codes to the newest exascale systems as well as improve performance and capabilities. We will overview library activities undertaken to ensure value to applications and give examples demonstrating use of new algorithms as well as capability and speed improvements.

Classification : 65Z05, 65Y15, 65Y05
Minisymposium Program :

00704 (1/3) : 3D @E803 [Chair: Dan Martin]

[01829] The Need of Ecosystems of Numerical Libraries for Applications

Format : Talk at Waseda University
Author(s) : Ulrike Meier Yang (Lawrence Livermore National Laboratory)
Abstract : The emergence of heterogeneous computers with increasingly complex architectures necessitates continuous adaptation of software to take advantage of increased performance potential. Thus, the use of multiple mathematical libraries designed by expert mathematicians and software developers is crucial for application codes. Often, there exist interoperabilities between these libraries. So, as each library is ported to a new computer architecture, it is also important that these libraries continue to work together. This requires a healthy well-designed ecosystem. This talk will discuss the importance of a well-adjusted ecosystem of math libraries and its impact on applications.

[01773] Factorization based sparse solvers and preconditioners for robust solutions

Format : Talk at Waseda University
Author(s) : Xiaoye Sherry Li (Lawrence Berkeley National Laboratory)
Abstract : Many high fidelity simulation and data analysis involve large-scale multiphysics and multiscale modeling problems that generate highly ill-conditioned and indefinite algebraic equations. The factorization based algorithms are indispensible building blocks in the solver stack to solve these numerically challenging problems. We will highlight how factorizations and low-rank approximate factorizations can be effectively used as standalone direct solvers or as preconditioners for iterative solvers. The focus will be on recent advances in SuperLU and STRUMPACK targeting at exascale machines and applications.

[01874] Exploring the HPC Frontier with Ginkgo

Format : Talk at Waseda University
Author(s) : Marcel Koch (KIT)Hartwig Anzt (UTK)Terry Cojean (KIT)
Abstract : This talk will give an overview of the Ginkgo library and highlight its features through several integrations. Ginkgo is a modern C++ library composed of numerical linear algebra algorithms which are optimized for multicore processors and Nvidia, AMD, and Intel GPUs. The use of sustainable software development principles allows the rapid development of cutting edge algorithms with high-quality interfaces. Among others, these are used in plasma simulation, cardiac electrophysiology, or CFD.

[01866] Scalability Study for Planewave DFT Solvers

Format : Talk at Waseda University
Author(s) : Doru Thom Popovici (LBNL)Mauro del Ben (LBNL)Andrew Canning (LBNL)Osni Marques (LBNL)
Abstract : Modern supercomputers vary in compute power and network capabilities. For example, Summit and Frontier make use of GPUs for accelerating computation, while relying on either a fat-tree or dragonfly topology for transferring data between the nodes. On the other hand, Fugaku has thousands of CPUs and uses a six-dimensional torus for communication. In this work, we want to study these differences in the context of scaling the eigenvalue solvers used in planewave DFT calculations. More specifically, we will focus on four algorithms meant to solve a nonlinear eigenvalue problem, namely Conjugate Gradient, RMM-DIIS, Jacobi Davidson and Unconstrained. We will show that for each algorithm different considerations must be taken when parallelizing the computation. We will provide proxy applications for each algorithm, and we will provide a thorough analysis of each code on some of the state-of-the-art supercomputers.

We will emphasize that systematic approaches can be derived to guide the parallelization such that the computation can effectively use the compute and network resources.

00704 (2/3) : 3E @E803 [Chair: Ulrike Yang]

[01830] Overview and Application Experiences with SUNDIALS

Format : Talk at Waseda University
Author(s) : Carol Woodward (Lawrence Livermore National Laboratory)Cody Balos (Lawrence Livermore National Lab)David Gardner (Lawrence Livermore National Laboratory)Daniel Reynolds (Southern Methodist University)
Abstract : The SUNDIALS library of time integrators and nonlinear solvers has recently increased its support for large-scale GPU-based systems through new data structures and solver package interfaces. This talk will overview the SUNDIALS packages and recently added capabilities then show results on newly deployed systems. Several applications have taken advantage of these capabilities to improve their time integration performance, and results from a selection of these, including combustion, phase field modeling, and cosmology, will be shown.
Prepared by LLNL under Contract DE-AC52-07NA27344. LLNL-ABS-844590.

[01626] Experience with Exascale Applications using PETSc/TAO

Format : Talk at Waseda University
Author(s) : Todd Munson (Argonne National Laboratory)
Abstract : In this presentation, we will discuss the extensions of the PETSc/TAO library to support the GPU-based Frontier and Aurora exascale systems and provide some available performance results. We will then provide some perspectives on using PETSc/TAO from an application point of view and conclude with thoughts on future needs to support next generation architectures.

[01703] On the Design and Performance of Exascale Applications using the Trilinos Solver Framework

Format : Talk at Waseda University
Author(s) : Roger Pawlowski (Sandia National Laboratories)
Abstract : The Trilinos project supplies algorithms and enabling technologies for the solution of large-scale, complex multi-physics engineering and scientific problems on new and emerging high-performance computing architectures. Capabilities include performance portability abstractions, linear solvers, preconditioners, nonlinear solvers, time integration and finite element discretization tools. This talk will focus on recent achievements in developing exascale applications using Trilinos. We will show results from plasma physics simulations for electromagnetic environments and aerodynamics simulations for hypersonic reentry.

[01837] Paving the road for efficient volume coupling with preCICE

Format : Talk at Waseda University
Author(s) : David Schneider (University of Stuttgart)Benjamin Uekermann (University of Stuttgart)
Abstract : preCICE is an open-source coupling library enabling partitioned multi-physics simulations of separated software packages. It offers methods for data communication, equation coupling, and data mapping. This talk presents new data mapping concepts in preCICE in terms of efficiency and accuracy, which enable users to apply preCICE for large-scale coupling scenarios. The relevance of these new data mapping concepts is demonstrated by showing user-provided example cases.

00704 (3/3) : 4C @E803 [Chair: Carol Woodward]

[01915] MFEM: Accelerating Efficient Solution of PDEs at Exascale

Format : Talk at Waseda University
Author(s) : Tzanio Kolev (Lawrence Livermore National Laboratory)Veselin Dobrev (Lawrence Livermore National Laboratory)John Camier (Lawrence Livermore National Laboratory)Vladimir Tomov (Lawrence Livermore National Laboratory)Julian Andrej (Lawrence Livermore National Laboratory)Will Pazner (Portland State University)
Abstract : Efficient exploitation of exascale architectures requires rethinking of the numerical algorithms used in PDE-based simulations to expose fine-grain parallelism and maximize arithmetic intensity. In this talk we present an overview of MFEM (mfem.org), a library for high-order finite element methods, which powers HPC applications in a wide variety of fields. We review recent advancements in MFEM's discretization solver, and GPU-accelerated algorithms, and demonstrate their impact in several large-scale applications from the US Department of Energy.

[01650] Exascale-Ready Adaptive Mesh Refinement Applications with AMReX

Format : Talk at Waseda University
Author(s) : Andrew Myers (LBNL)
Abstract : AMReX is a block-structured adaptive mesh refinement library that supports a variety of advanced GPU and CPU architectures. I will describe AMReX and its associated ecosystem of application codes, spanning scientific domains such as astrophysics, plasma physics, wind farm modeling, epidemiology, and more. I will demonstrate how AMReX enables these codes to implement novel modeling capabilities involving a range of computational motifs and to run efficiently on some of the largest supercomputers in the world.

[01911] Supporting Applications with the Chombo Framework

Format : Talk at Waseda University
Author(s) : Daniel Francis Martin (Lawrence Berkeley National Laboratory)
Abstract : Many scientific and industrial applications solve systems of partial differential equations, and can often benefit from algorithmic strategies like adaptive mesh refinement (AMR), higher-order mapped grids, and linear and nonlinear solvers. These are often difficult to implement accurately and efficiently; software frameworks leverage this effort across many applications. We present case studies demonstrating how the modular design of the Chombo software framework supports performant applications, which then feed improved capabilities back into Chombo.

[01456] Firedrake: Math to Supercomputer

Format : Talk at Waseda University
Author(s) : Koki Sagiyama (Imperial College London)David A. Ham (Imperial College London)
Abstract : Firedrake is an open-source Python package for solving PDEs using finite element methods.
Using the UFL language originally developed for the FEniCS project and other packages in the Firedrake's ecosystem, Firedrake generates efficient finite element codes automatically from the math expressions provided by the users, allowing them to move from one idea to another quickly.
It also provides a transparent access to the linear/nonlinear solvers in the PETSc library.
Here, we will show some recent developments in Firedrake.

[00707] Theoretical and Numerical Challenges in the Modelling of Fluid Motion

Session Time & Room :

00707 (1/3) : 2C (Aug.22, 13:20-15:00) @D102

00707 (2/3) : 2D (Aug.22, 15:30-17:10) @D102

00707 (3/3) : 2E (Aug.22, 17:40-19:20) @D102

Type : Proposal of Minisymposium
Abstract : The goal of this mini-symposium is to provide a forum for presenting and discussing recent advances in mathematical and numerical modelling of fluid motion. The phenomena under consideration range from small oscillations of fluid droplets to large ocean waves. Topics of interest cover nonlinear waves and solitons in fluids, surface and internal ocean waves, atmospheric flows, as well as fluid dynamics methods for fatigue fracture analysis. In this mini-symposium a holistic approach to fluid dynamics is sought where the problem is studied by modern mathematical methods requiring advanced tools in functional analysis, geometry, PDEs, soliton theory and numerical modeling.
Organizer(s) : Rossen Ivanov, Michail Todorov
Classification : 76B55, 35Q31, 35Q35, 35Q51, 76B25, 76B25-Solitary waves for incompressible inviscid fluids, 76B55-Internal waves for incompressible inviscid fluids, 35Q31-Euler equations, 35Q35-PDEs in connection with fluid mechanics, 35Q51-Soliton equations
Minisymposium Program :

00707 (1/3) : 2C @D102 [Chair: Rossen Ivanov]

[03903] Paradigm and Long-Time Evolution of Localized Solutions of Wave Systems: Consistency vs Integrability

Format : Talk at Waseda University
Author(s) : Michail Todorov (Technical University of Sofia)
Abstract : Boussinesq's equation was the first model for the propagation of surface waves over shallow inviscid fluid layer. He proved that the balance between the steepening effect of the nonlinearity and the flattening effect of the dispersion maintains the shape of the wave - so termed 'Boussinesq Paradigm.' Apart from the significance for the shallow water flows, this paradigm is very important for understanding the particle-like behavior of nonlinear localized waves. As it should have been expected, most of the physical systems are not fully integrable (even in one spatial dimension) and only a numerical approach can lead to unearthing the pertinent physical mechanisms of the interactions. A different approach to removing the incorrectness is by changing the spatial fourth derivative to a mixed fourth derivative, which resulted into an equation know nowadays as the Regularized Long Wave Equation or Benjamin–Bona–Mahony equation - known as the 'Linear Impedance Relation'. The latter has produced innumerable instances of unphysical results.

[05180] Modelling of tsunami generated by submarine volcanic eruptions in statified oceans.

Format : Talk at Waseda University
Author(s) : Manish kanojia (Trinity College Dublin)
Abstract :
We present a novel mathematical model for the generation of tsunamis by submarine volcanic eruptions in stratified oceans. Unlike current models, our model accounts for the complex stratification of the ocean, providing a more accurate representation of the tsunami generation process.

[05211] Physics-informed neural network for computating steady periodic water waves

Format : Talk at Waseda University
Author(s) : Lin Chen (Tongji University)Ben Li (Tongji University)Chenyi Luo (ETH Zurich)
Abstract : We investigate full-field recovery and computation of rotational flow under nonlinear periodic water waves using physics-informed neural networks (PINNs). Flow characteristics beneath water waves are of interest in various disciplines, e.g., for hydraulic loading analysis. In ocean or water tunnel tests, wave heights, flow velocity, and pressure data are often collected at specific points. It is not feasible to measure the flow with very high spatial resolution, particularly for water waves with a wavelength of over 100 m in practice. Therefore, we develop PINNs for flow recovery taking multiple types of measurement data into account and with the Euler equation governing rotational flow embedded. High-fidelity datasets are obtained using the numerical continuation method which is able to solve nonlinear waves with limiting wave height. Different PINN architectures are proposed and compared based on the numerically computed datasets. Influences of the wave height, vorticity, the volume of datasets, and hyperparameters are discussed in detail.

[01814] Pressure distribution on seawalls due to wave effects

Format : Talk at Waseda University
Author(s) : Paul Suman (Indian Institute of Engineering Science and Technology, Shibpur)Aparna Dey Ghosh (Indian Institute of Engineering Science and Technology, Shibpur)Biswajit Basu (Trnity College Dublin)
Abstract : A numerical approach to obtain wave forces on seawalls is proposed using Bernoulli's equation. The nonlinear formulation computes horizontal and vertical velocities, and pressure distribution along the depth, without any restriction on wave height. Forces are obtained on the seawall for nonbreaking travelling waves. The wave force increases for waves of longer time periods. The existing guidelines are found to overestimate the wave forces as compared to the forces obtained from the proposed nonlinear formulation.

00707 (2/3) : 2D @D102 [Chair: Michail Todorov]

[02962] Internal waves, Coriolis force and undercurrents

Format : Talk at Waseda University
Author(s) : Rossen I. Ivanov (Technological University Dublin)David J. Henry (University College Cork)
Abstract : We study the linear and nonlinear differential equations modelling the interacting surface and internal waves of two fluid layers with different densities over a flat bed. Other effects such as underlying currents and Coriolis force are also included. We use the Hamiltonian formulation for the nonlinear governing equations that is adequate for structure-preserving perturbations, at the linear and at the nonlinear level.

Specific weakly nonlinear long-wave regimes are structure-enhancing and the dynamics is described by integrable Hamiltonian equations. Consequently, integrable models and their soliton solutions will be presented.

[05173] On three dimensional models of equatorial ocean flows

Format : Talk at Waseda University
Author(s) : BISWAJIT BASU (Trinity College Dublin)
Abstract : A recently developed three dimensional model of equatorial ocean flow is presented in this paper. The model is
inspired by the work of Constantin and Johnson and provides some explicit solution of velocity fields. The effect of density variation is discussed alongwith the influence of undercurrent. Some additional insights are provided based on conservation of potential vorticity.

[03835] Eddy viscosities and ageostrophic wind-speed profiles

Format : Online Talk on Zoom
Author(s) : Tony Lyons (South East Technological University)
Abstract : Wind speed profiles in the Ekman layer are used to deduce corresponding variable eddy coefficients. These eddy coefficients are parameterized in terms of a deflection angle, the geostrophic wind speed, and the transfer rate of horizontal momentum in the vertical direction. The classical Ekman flow has deflection angle 45°, while incorporating variable eddy coefficients changes this deflection angle. This deviation of deflection angle is used to estimate the depth of the Ekman layer.

00707 (3/3) : 2E @D102

[00708] Computational medicine of the heart: towards cardiac digital twins

Session Time & Room :

00708 (1/3) : 1C (Aug.21, 13:20-15:00) @E708

00708 (2/3) : 1D (Aug.21, 15:30-17:10) @E708

00708 (3/3) : 1E (Aug.21, 17:40-19:20) @E708

Type : Proposal of Minisymposium
Abstract : Computational cardiology is an emerging field that exploits Mathematics, Engineering, and Computational Science to develop quantitative approaches for understanding the mechanisms of cardiac physiology, for enhancing the diagnosis of pathologies, and for improving their clinical treatment. This minisymposium aims at gathering mathematicians, engineers, and more generally researchers working on mathematical and numerical modelling of the human heart. Topics may include, but are not limited to, coupled cardiac modelling, numerical methods, translational medicine, Scientific Computing, Scientific Machine Learning, and large-scale computing. The overarching aim is the construction of Cardiac Digital Twins.
Organizer(s) : Luca Dede', Alfio Quarteroni
Classification : 65Mxx, 65Nxx, 68Txx
Minisymposium Program :

00708 (1/3) : 1C @E708 [Chair: Alfio Quarteroni]

[04495] Multiphysics, multiscale, and computational models for simulating the cardiac function

Format : Talk at Waseda University
Author(s) : Luca Dede' (Politecnico di Milano)
Abstract : We present our novel 4-chambers model of the human heart. We couple state-of-the art models of electrophysiology, mechanical activation, passive mechanical response, and blood circulation, leading to a coupled electromechanical problem. Our multiscale model accounts for miscroscopic active force generation that exploits Machine Learning algorithms. We numerically solve the model in the HPC framework. We also present a Machine Learning method for real-time numerical simulations that allows efficient construction of cardiac digital twins.

[03710] Virtual Populations of Heart Chimaeras: Generative Compositional Learning from Datasets of Datasets

Format : Talk at Waseda University
Author(s) : Alejandro Federico Frangi (University of Leeds)Haoran Dou (University of Leeds)Seppo Virtanen (University of Leeds)Nishant Ravikumar (University of Leeds)Zeike Taylor (University of Leeds)
Abstract : Virtual populations capturing sufficient anatomical variability while remaining plausible are central to conducting in-silico trials of medical devices. Unfortunately, not all anatomical information is available from a single data sample or modality given a population. Instead, data with missing/partially overlapping anatomical information is often available from independent data samples and/or modalities. We introduce a generative anatomical model capable of learning complex anatomical structures from datasets of unpaired datasets and synthesising anatomical assemblies coined virtual chimaeras.

[03238] The role of the Eikonal model in personalized cardiac modeling from parameter acquisition to arrhythmia simulations

Format : Talk at Waseda University
Author(s) : Cristian Alberto Barrios Espinosa (Karlsruhe Institute of Technology (KIT))Jorge Sanchez Arciniegas (Valencia Polytechnic University)Laura Unger (Karlsruhe Institute of Technology (KIT))Marie Houillon (Karlsruhe Institute of Technology (KIT))Armin Luik (Städtisches Klinikum Karlsruhe)Axel Loewe (Karlsruhe Institute of Technology (KIT))
Abstract : The Eikonal model is widely used to simulate wave propagation in different fields, including cardiac modeling. A modified version of the Eikonal model can help to customize model parameters, like conduction velocity accounting for anisotropic propagation. Moreover, the modified Eikonal model can be used to simulate arrhythmia by allowing for reactivation, overcoming challenges of the fast iterative method. Finally, we show applications of the enhanced Eikonal models as a valuable tool for cardiac research applications.

[03521] An anisotropic eikonal model for cardiac repolarization and arrhythmias

Format : Talk at Waseda University
Author(s) : Simone Pezzuto (Università di Trento)Lia Gander (Università della Svizzera italiana)Rolf Krause (Università della Svizzera italiana)Martin Weiser (Zuse Institute Berlin)Francisco Sahli Costabal (Pontificia Universidad Católica de Chile)
Abstract : State-of-the-art computational models of cardiac electrophysiology are computationally expensive. Their clinical applicability is, therefore, limited. In the talk, we will present a lightweight eikonal approximation for real-time simulation of cardiac arrhythmias on a desktop computer. We provide several numerical tests and comparisons, including atrial fibrillation, ventricular tachycardia, and with fibrosis. Finally, we consider the problem of estimating the inducibility of fibrillation with a multi-fidelity framework by combining the eikonal approach with the high-fidelity model.

00708 (2/3) : 1D @E708 [Chair: Alfio Quarteroni]

[05281] Computational Models of Cardiac Electro-mechanical Function – Closing the Gaps between Virtual and Physical Reality

Format : Talk at Waseda University
Author(s) : Gernot Plank (Medical University of Graz)
Abstract : A fundamental concern hampering a broader adoption of digital twins in cardiology application is the lack of correspondence between the physiology of a virtual heart and the physical reality. We report on our latest advances addressing these issues. Real-time enabled whole heart electrophysiology as well as computationally efficient whole

heart multi-physics models of cardiac electro-mechanics will be discussed, along with techniques for automated patient-specific model calibration.

[04706] Scaling cardiac digital twins for population-based studies

Format : Talk at Waseda University
Author(s) : Shuang Qian (King's College London)Devran Ugurlu (King's College London)Elliot Fairweather (King's College London)Marina Strocchi (King's College London)Laura dal toso (King's College London)Yu Deng (King's College London)Alistair Young (King's College London)Martin Bishop (King's College London)Pablo Lamata (King's College London)Steven Niederer (King's College London)
Abstract : Cardiac digital twins, provide a physics and physiology-constrained framework, enabling personalised diagnosis and tailored therapies for individual patients. However, building patient-specific digital twins at scale remains challenging. This talk presents an open-sourced automatic pipeline of generating finite element biventricular heart models from CMRs in the UK biobank. Using this pipeline, each digital twin can be created in only 8 mins on a standard desktop, compatible with clinical time scales and also enabling large scale virtual population-based studies.

[04251] A Local Space-Time Adaptive Scheme to Simulate Cardiac Electrophysiology

Format : Talk at Waseda University
Author(s) : Dennis Ogiermann (Ruhr University Bochum, Chair of Continuum Mechanics)Luigi E. Perotti (University of Central Florida, Mechanical and Aerospace Engineering Department, Computational Biomechanics Lab)Daniel Balzani (Ruhr University Bochum, Chair of Continuum Mechanics)
Abstract : Cardiac electrophysiology simulations are often based on the monodomain model, which is characterized by traveling waves with a steep localized wavefront and slow changes in the remaining domain. This aspect renders schemes based on uniform spatial and temporal discretization expensive.
We present a numerical scheme that exploits the localized nature of the rapidly changing wavefront by combining discontinuous Galerkin on an adaptive mesh for the spatial discretization with an elementwise explicit local time stepping.

[03847] Parallel Performance of Robust and Scalable Multilevel Preconditioners in Cardiac Electrophysiology

Format : Talk at Waseda University
Author(s) : Edoardo Centofanti (Università degli Studi di Pavia)
Abstract : The EMI (Extracellular space, cell Membrane and Intracellular space) model is among the first models for describing the electrical activity of the heart at a cellular level. The resulting system of equations allows discontinuities of potentials between boundaries as well as particular distributions of ion charges on the cellular membranes. In this talk, we will study the performances of different multigrid and multilevel solvers for the solution of such systems both on CPU and GPU architectures.

00708 (3/3) : 1E @E708 [Chair: Luca Dede']

[04140] Cardiac hemodynamics simulations with fluid-structure interaction and reduced valve modeling

Format : Talk at Waseda University
Author(s) : Miguel A. Fernández (Inria)Oscar Ruz (Inria)Jérôme Diaz (Inria)Marina Vidrascu (Inria)Philippe Moireau (Inria)Dominique Chapelle (Inria)
Abstract : The development of efficient physiological simulations of the complete FSI phenomena involved in the heart is a challenging problem. We investigate an hybrid approach which combines FSI in the myocardium with a reduced modeling of the valves. A loosely coupled treatment of the interface coupling facilitates the treatment of the isovolumetric phases. The benefits of the proposed approach are investigated and compared with kinematic uncoupling in simulations of the left heart hemodynamics.

[03773] Parametric Fluid-structure interaction solvers for haemodynamics

Format : Talk at Waseda University
Author(s) : Damiano Lombardi (Inria Paris)Sébastien Riffaud (Inria Paris)Miguel A. Fernández (Inria Paris)
Abstract : Data assimilation and uncertainty quantification are essential tasks in numerous realistic applications.
They involve a prohibitive computational burden. The goal of the present work is to propose and investigate efficient parametric solvers for Partial Differential Equations describing fluid-structure interaction. The solvers consider parameters as extra variables and enable applications such as parameter estimation and uncertainty quantification.

Several formulations will be discussed and numerical experiments will be presented to assess the properties of the methods.

[04521] Towards developing high-speed cardiac mechanics simulations using a neural network finite element approach

Format : Online Talk on Zoom
Author(s) : Michael S Sacks (University of Texas at Austin)Shruti Motiwale (University of Texas at Austin)
Abstract : We have developed a neural network finite element (NNFE) approach for cardiac simulations, which is a physics-based method using a neural network to solve the parametric map and finite elements to define the problem domain. Cardiac simulations were performed to predict the P-V responses of a simulated left ventricle, accounting for active contraction and transmural fiber distributions. Results demonstrate the first application of the NNFE approach at the organ level within clinically relevant timeframes.

[05099] Modeling Cardiac Fluid-Structure Interaction in the Human Heart

Format : Online Talk on Zoom
Author(s) : Marshall Davey (University of North Carolina at Chapel Hill)Charles Puelz (Baylor College of Medicine)Simone Rossi (University of North Carolina at Chapel Hill)Margaret Anne Smith (University of North Carolina at Chapel Hill)David R. Wells (University of North Carolina at Chapel Hill)Boyce E. Griffith (University of North Carolina at Chapel Hill)
Abstract : Cardiac fluid-structure fundamentally involves interactions between complex blood flows and the structural deformations of the muscular heart walls and the thin, flexible valve leaflets. This talk will detail methods and models for simulating cardiac fluid-structure interaction in a comprehensive, image-based model of the human heart. The talk will highlight key methodological approaches to developing the model along with simulation results demonstrating its ability to generate physiologic outputs, including realistic pressure-volume loops.

[00710] Gender Equality in Mathematics: A Global Perspective

Session Time & Room :

00710 (1/2) : 3C (Aug.23, 13:20-15:00) @G302

00710 (2/2) : 3D (Aug.23, 15:30-17:10) @G302

Type : Proposal of Industrial Minisymposium
Abstract : In the last decade, the fields of mathematics and applied mathematics have increasingly recognized the highly creative contributions by women. However, there still remains a significant gap in the percentage of women in these fields, and barriers to achievement by women persist, especially in developing countries. The Gender Gap in Science project was executed to accumulate data on this gap and to provide recommendations on how to reduce and remove barriers to women. Speakers will discuss the gender gap in mathematics globally and overview challenges and activities to address the gap. The sessions will conclude with a moderated panel discussion.

Organizer(s) : Carol S. Woodward, Maria Esteban, GuiYing Yan
Classification : 01A80
Minisymposium Program :

00710 (1/2) : 3C @G302 [Chair: Carol Woodward]

[01733] Lessons on the global mathematical community from the 'Gender Gap in Science' global survey.

Format : Talk at Waseda University
Author(s) : Maria J. Esteban (CNRS and University Paris-Dauphine)
Abstract : This talk will present the 'Gender Gap in Science' projet and more specifically the global survey that was carried out in order to better understand the gender gap in Academia, continent by continent, field by field.

This will be completed with the description of the main results concerning Mathematics and Applied Mathematics in contrast with other scientific fields.

[02137] The African perspective about the Gender Gap in Science

Format : Talk at Waseda University
Author(s) : Sophie Dabo (INRIA- University of Lille)Maria J. Esteban (CNRS and University Paris-Dauphine)Colette Guillopé (University Paris Est Creteil)Marie-Françoise Ouedraogo (University Joseph ki_zeRBO)Marie-Françoise Roy (University of Rennes 1)
Abstract : In this talk, we aim to understand the results of the "Gender Gap in Science survey (2017-2019)" for African continent. We analyze in detail the gender gap in Science among scientists who are working in Africa, but also compare those
results with the rest of the world, in particular to see how economical and cultural differences can affect the gender gap among scientists.
Note that that survey addresses several aspects that often are not measured on bibliographic metadata such as work-life balance, family support, access to resources and sexual harassment.
It is important to note also that even if the number of answers was important both in Africa as elsewhere, these numbers are small compared to the whole population of scientists. Also it is necessary to understand that the answers are often subjective because they do not correspond to questions for which the answers are quantifiable, but to how people feel about some particular topic. All this to say that what we are going to state in this talk, is just an image that probably reflects the reality, but that has to be taken with a grain of attention.

[02048] gender diversity in Japanese concept

Format : Talk at Waseda University
Author(s) : Motoko KOTANI (Tohoku University)
Abstract : Japan is quite behind in gender equality and inclusive perspective. The progress is slow but steady. I would like to present the current situation and actions in Japan, in science in general, and in mathematics.

[02437] What we can do with Asian-Oceanian Women in Mathematics

Format : Talk at Waseda University
Author(s) : Yukari Ito (The University of Tokyo)
Abstract : Asian-Oceanian Women in Mathematics (AOWM), the continental organization for women in mathematics in Asia and Oceania was established on August 1, 2022. There are more than 200 founding members from 18 Asian and Oceanian countries. We will have the first Inaugural meeting of AOWM in India and hybrid from 24th to 28th April 2023. I will talk about the report of the meeting and what we can do with AOWM.

00710 (2/2) : 3D @G302 [Chair: Maria Esteban]

[02658] Women in mathematics: an experience report and some facts about the European situation

Format : Online Talk on Zoom
Author(s) : Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : In this talk I will discuss some facts about the situation of female mathematicians in Europe, provide an introduction to the European Women in Mathematics (EWM) association, and give a personal account on women and mathematics in our society.

[03111] Challenges for US Women in Math and the Activities of the AWM

Format : Online Talk on Zoom
Author(s) : Talitha Washington (Association for Women in Mathematics)
Abstract : While there have been many strides in getting more women into the mathematical sciences, the percentage of women receiving doctorates in mathematics has been decreasing. The complexities of the intersectionality of gender, race, and ethnicity warrant more diverse approaches. The purpose of the Association for Women in Mathematics (AWM) is to create a community where women can thrive. This presentation will share how AWM’s activities promote equitable opportunity for women and others of marginalized genders.

[01795] The Standing Committee for Gender Equality in Science

Format : Talk at Waseda University
Author(s) : Carol Woodward (Lawrence Livermore National Laboratory)
Abstract : Several unions in the International Science Council formed the Standing Committee for Gender Equality in Science (SCGES) in 2020 with the goal of promoting gender equality across all science disciplines. This talk will introduce the SCGES and discuss its activities, including delivery of a webinar series, an annual reporting activity to help share activities among participants, participation in the Global Women’s Breakfast, and the release of a statement on

gender equality in times of COVID-19.
LLNL-ABS-844495.

[02912] Panel Discussion on Gender Equality

Format : Talk at Waseda University
Author(s) : Carol Woodward (Lawrence Livermore National Laboratory)Maria J. Esteban (CNRS and University Paris-Dauphine)GuiYing Yan (Shandong University)
Abstract : In this session, we will have a panel discussion with speakers from our minisymposium discussing the state of gender equality in science and mathematics specifically.

[00711] Recent Advances in Optimal control and optimization

Session Time & Room :

00711 (1/2) : 1C (Aug.21, 13:20-15:00) @F401

00711 (2/2) : 1D (Aug.21, 15:30-17:10) @F401

Type : Proposal of Minisymposium
Abstract : In this minisyposium we discuss the recent developments in control and optimization.
We analyze solutions to PDE in a general framework and develop a new control and optimization methods and theoretic analysis.
The control PDE analysis includes the constrained stochastic Nash game,
optimal control problems in metric spaces and
optimal control of poroelastic systems and frequency dependent Hautus tests for controllability.
We apply our methods to specific examples in biomedicine, population dynamics and Economics
Also, we develop a new theoretic framework for optimal control and optimization
based on Rockafellar's perturbation theory
to analyze and solve general nonsmooth convex minimization and
monotone inclusion problems.
Organizer(s) : Kazufumi Ito
Classification : 49J52, 49J55, 49J30, 49J20, 35A01
Minisymposium Program :

00711 (1/2) : 1C @F401

[02838] PDE Constrained Optimization with Non-smooth Learning Informed Structures

Author(s) : Michael Hintermueller (Weierstrass Institute Berlin)
Abstract : A class of optimization problems subject to PDEs with components resulting from ReLU-based neural network models is studied analytically and numerically. Concerning the analysis it is shown that direct classical smoothing of the non-smooth structures leads to issues concerning the existence of solutions. Further, for the non-smooth setting stationarity conditions are derived and used numerically. With respect to the numerical solution, a bundle-free minimization algorithm relying on possible smoothing on the level of directional derivatives is introduced and analyzed, and a brief report on computational tests is provided.

[03725] Some optimal control problems in metric spaces

Author(s) : Hasnaa Zidani (INSA Rouen Normandie)Othmane Jerhaoui (INSA Rouen Normandie)Averil Prost (INSA Rouen Normandie)
Abstract : In this talk, we will discuss some optimal control problems in metric spaces (e.g. stratified systems, centralized control problems in Wasserstein space). We are mainly interested in the characterisation of the value function as viscosity solution of an adequate Hamilton-Jacobi (HJ) equation. For this, we introduce a notion of viscosity solutions for HJ equations in some metric spaces. This notion is based on test functions that are directionally differentiable and can be represented as a difference of two semi-convex functions. Under mild assumptions on the Hamiltonian and on the metric space, we can derive the main properties of viscosity theory: the comparison principle and Perron's method.

[03787] Exact controllability for systems describing plate vibrations. A perturbation approach.

Author(s) : Marius Tucsnak (University of Bordeaux)
Abstract : The aim of this talk is to describe new exact controllability properties of systems described by perturbations of the classical Kirchhoff plate equation. We first consider systems described by an abstract plate equation with a bounded control operator. The generator of these systems is perturbed by bounded operators which are not necessarily compact, thus not falling in the range of application of compactness-uniqueness arguments. Our first main result is abstract and can be informally stated as follows: if the system described by the corresponding unperturbed abstract wave equation, with the same control operator, is exactly controllable (in some time), then the considered perturbed plate system is exactly controllable in arbitrarily small time. The employed methodology is based, in particular, on frequency-dependent Hautus type tests for systems with skew-adjoint operators.
When applied to systems described by the classical Kirchhoff equations, our abstract results, combined with some elliptic Carleman-type estimates, yield exact controllability in arbitrarily small time, provided that the system described by the wave equation in the same spatial domain and with the same control operator is exactly controllable. The same abstract results can be used to prove the exact controllability of the system obtained by linearizing the von K'arm'an plate equation around a real analytic stationary state. This leads, via a fixed-point method, to our second main result: the nonlinear system described by the von K'arm'an plate equations is locally exactly controllable around any stationary state defined by a real analytic function.

[03789] A Perturbation Framework for Convex Minimization with Nonlinear Compositions

Author(s) : Luis Briceño-Arias (Universidad Técnica Federico Santa María)Patrick L. Combettes (North Carolina State University)
Abstract : We introduce a framework based on Rockafellar's perturbation
theory to analyze and solve general nonsmooth convex minimization
and monotone inclusion problems involving nonlinearly composed
functions as well as linear compositions.

00711 (2/2) : 1D @F401

[03864] Analysis and Control in Poroelastic Systems

Author(s) : Lorena Bociu (NC State University)
Abstract : We answer questions related to tissue biomechanics via wellposedness, sensitivity analysis, and optimal control problems for fluid flows through deformable porous media. These results are relevant for many applications in biology, medicine and bio-engineering. We focus on the local description of the problem, which involves implicit, degenerate, nonlinear poroelastic systems, as well as scenarios where the global features of the problem are accounted for through a multi-scale coupling with a lumped hydraulic circuit.

[00715] Recent Trends in Market Design

Session Time & Room :

00715 (1/3) : 2C (Aug.22, 13:20-15:00) @D505

00715 (2/3) : 2D (Aug.22, 15:30-17:10) @D505

00715 (3/3) : 2E (Aug.22, 17:40-19:20) @D505

Type : Proposal of Minisymposium
Abstract : Market design, also known as mechanism design, is a practical application of game theory, whose purpose is to develop decision making rules under which each individual has an incentive to take a desirable action in an equilibrium. In recent years, the research of market design has attracted the attention of researchers in various research fields, including mathematics, economics, computer science, biology, politics, psychology, etc. We have nine prospective researches in this minisymposium as invited speakers, who give us state-of-the-art of the theory and applications of market design.
Organizer(s) : Ayumi Igarashi, Shunya Noda, Taiki Todo

00715 (1/3) : 2C @D505

[01261] Fair division algorithms for house chores

Author(s) : Ayumi Igarashi (The University of Tokyo)
Abstract : Couples often encounter the challenge of sharing house chores. This raises the fundamental question of how to divide chores. In this paper, we present a new application for a fair division of household chores. Our platform, called Kajibuntan, allows couples to specify the set of chores to be shared, their preferences over them, and the current allocation. Our tool visualizes the current allocation and makes proposals according to their preferences based on the theory of fair division. The goal of our tool is to provide a systematic and transparent system to divide household chores and help creating harmony in the home.

[01327] Mechanism Design with Uncertainty

Author(s) : Taiki Todo (Kyushu University)
Abstract : My research is summarized as mechanism design with uncertainty. Traditional mechanism design focuses on static environments where all the (possibly probabilistic) information about the agents are observable by the mechanism designer. In practice, however, it is possible that the set of participating agents and/or some of their actions are not observable a priori. We therefore focused on various kinds of uncertainty in mechanism design and developed/analyzed several market mechanisms that incentivize agents to behave in a sincere way.

[01399] Best of Both Worlds in Fair Division

Author(s) : Rohit Vaish (IIT Delhi)
Abstract : Traditional approaches for fair allocation of indivisible resources focus either on randomized allocations that are fair in expectation or deterministic allocations that are approximately fair. I will discuss an algorithmic framework that reconciles randomization and approximation. Specifically, I will present an algorithm for finding a randomized allocation of indivisible goods that is ex-ante fair, i.e., envy-free in expectation, and ex-post approximately fair, i.e., envy-free up to one good.

[01408] Strong Revenue (Non-)Monotonicity of Single-parameter Auctions

Author(s) : Ziyun Chen (Tsinghua University)Zhiyi Huang (The University of Hong Kong)Dorsa Majdi (Sharif University of Technology)Zipeng Yan (The University of Hong Kong)
Abstract : Consider Myerson's optimal auction with respect to an inaccurate prior, e.g., estimated from data, which is an underestimation of the true value distribution. Can the auctioneer expect getting at least the optimal revenue w.r.t. the inaccurate prior since the true value distribution is larger? This so-called strong revenue monotonicity is known to be true for single-parameter auctions when the feasible allocations form a matroid. We find that strong revenue monotonicity fails to generalize beyond the matroid setting, and further show that auctions in the matroid setting are the only downward-closed auctions that satisfy strong revenue monotonicity. On the flip side, we recover an approximate version of strong revenue monotonicity that holds for all single-parameter auctions, even without downward-closedness. As applications, we get sample complexity upper bounds for single-parameter auctions under matroid constraints, downward-closed constraints, and general constraints. They improve the state-of-the-art upper bounds and are tight up to logarithmic factors.

00715 (2/3) : 2D @D505

[01426] Tract housing, the core, and pendulum auctions

Author(s) : Andrew Mackenzie (*Department of Microeconomics and Public Economics, Maastricht University)Yu Zhou (Graduate School of Economics, Kyoto University)
Abstract : We consider a model of tract housing where buyers and sellers have (i) wealth constraints, and (ii) unit demand over identical indivisible objects represented by a valuation. First, we characterize the strong core. Second, we characterize the bilateral weak core, or the weak core allocations with no side-payments. Finally, when buyer wealth constraints and valuations are private information and when transfers are discrete, we introduce two families of pendulum auctions, both of which consist of obviously strategy-proof implementations of the bilateral weak core. The buyer-optimal pendulum auctions are preferred by the buyers but are inefficient when side-payments are possible, while the efficient pendulum auctions are efficient.

[01516] Are Simple Mechanisms Optimal when Agents are Unsophisticated?

Author(s) : Jiangtao Li (Singapore Management University)Piotr Dworczak (Northwestern University)
Abstract : We study the design of mechanisms involving agents that have limited strategic sophistication. We define a mechanism to be simple if—given the assumed level of strategic sophistication—agents can determine their optimal strategy. We examine whether it is optimal for the mechanism designer who faces strategically unsophisticated agents to offer a simple mechanism. We show that when the designer uses a mechanism that is not simple, while she loses the ability to predict play, she may nevertheless be better off no matter how agents resolve their strategic confusion.

[01530] Representation Theorems for Path-Independent Choice Rules

Author(s) : Koji Yokote (The University of Tokyo)Isa E. Hafalir (University of Technology Sydney)Fuhito Kojima (The University of Tokyo)M. Bumin Yenmez (Boston College)
Abstract : Path independence is arguably the most important property of choice rules in market design. For example, it guarantees the existence of a desirable matching in two-sided markets. We show that a choice rule is path independent if and only if it is rationalized by a valuation function satisfying ordinal concavity. We also provide a representation result for choice functions that satisfy path independence and the law of aggregate demand using valuation functions satisfying ordinal concavity.

[01616] Optimal Dynamic Matching

Author(s) : Junpei Komiyama (New York University)Akira Matsushita (The University of Tokyo)Shunya Noda (The University of Tokyo)
Abstract : We propose a machine-learning method to construct an approximately optimal algorithm for a general class of dynamic matching problems. We apply our method to several problems and compare an algorithm generated by our method with simplistic ones, such as a greedy algorithm, to illustrate the importance of optimizing allocations in dynamic environments.

00715 (3/3) : 2E @D505

[01620] Multi-Unit Bilateral Trade

Author(s) : Bart de Keijzer (King's College London)
Abstract : We characterise the set of dominant strategy incentive compatible (DSIC), strongly budget balanced (SBB), and ex-post individually rational (IR) mechanisms for the multi-unit bilateral trade setting. In such a setting there is a single buyer and a single seller who holds a finite number k of identical items. The mechanism has to decide how many units of the item are transferred from the seller to the buyer and how much money is transferred from the buyer to the seller. We consider two classes of valuation functions for the buyer and seller: Valuations that are increasing in the number of units in possession, and the more specific class of valuations that are increasing and submodular.

Furthermore, we present some approximation results about the performance of certain such mechanisms, in terms of social welfare: For increasing submodular valuation functions, we show the existence of a deterministic 2-approximation mechanism and a randomised $e/(1-e)$ approximation mechanism, matching the best known bounds for the single-item setting.

Joint work with Matthias Gerstgrasser, Paul Goldberg, Philip Lazos, and Alexander Skopalik. Based on a paper published in the Proceedings of AAAI 2019.

[01693] Mechanism Design Powered by Social Interactions

Author(s) : Dengji Zhao (ShanghaiTech University)
Abstract : Mechanism design has traditionally assumed that the participants are fixed and independent. However, in reality, the participants are well-connected (e.g., via their social networks) and we can utilize their connections to power the design. One interesting trend is to incentivize the existing participants to use their connections to invite new participants. This helps to form larger games in auctions, coalitional games, matching etc., which is not achievable with the traditional solutions. The challenge is that the participants are competitors and they would not invite each other by default. Solving this is well-coupled with the existing challenges. For example, in auctions, solving it may require revenue monotonicity and false-name-proofness, which were proved impossible to achieve under certain sensible conditions. In matching, this cannot get along with standard optimality and stability. Hence, we believe there is an important theoretical value to discover and the study will stimulate many interesting applications, especially under decentralized systems with blockchain.

[01738] Optimal allocation with costly verification and distributional constraint

Author(s) : Yunan Li (City University of Hong Kong)
Abstract : A planner allocates multiple slots (e.g., a spot in college) among a finite number of agents, each of whom wants one slot and privately knows the value to the planner of assigning one slot to him. The slots are allocated based on the agents' reports. The planner can choose to inspect an agent's report at a cost. The constrained efficient mechanism for a planner facing a distributional constraint adds a constant to the values of the agents in the targeted group (a "flat subsidy") and specifies a threshold. The slots are first allocated to the agents whose (adjusted) values are above the threshold. Any remaining slots are randomly allocated among the agents whose (adjusted) values are below the threshold. For a stringent distributional constraint, the randomization favors the targeted group (a "quota").

[05446] Strategyproof Mechanisms for Group-Fair Facility Location Problems

Author(s) : Minming Li (City University of Hong Kong)Houyu Zhou (City University of Hong Kong)Hau Chan (University of Nebraska–Lincoln)
Abstract : We study the facility location problems where agents are located on a real line and divided into groups based on criteria such as ethnicity or age. Our aim is to design mechanisms to locate a facility to approximately minimize the costs of groups of agents to the facility fairly while eliciting the agents' locations truthfully. We first explore various well-motivated group fairness cost objectives for the problems and show that many natural objectives have an unbounded approximation ratio. We then consider minimizing the maximum total group cost and minimizing the average group cost objectives. For these objectives, we show that existing classical mechanisms (e.g., median) and new group-based mechanisms provide bounded approximation ratios, where the group-based mechanisms can achieve better ratios. We also provide lower bounds for both objectives. To measure fairness between groups and within each group, we study a new notion of intergroup and intragroup fairness (IIF) . We consider two IIF objectives and provide mechanisms with tight approximation ratios.

[00718] Data-driven and physics-informed techniques in Data Assimilation

Session Time & Room :

00718 (1/3) : 1C (Aug.21, 13:20-15:00) @E817

00718 (2/3) : 1D (Aug.21, 15:30-17:10) @E817

00718 (3/3) : 1E (Aug.21, 17:40-19:20) @E817

Type : Proposal of Minisymposium
Abstract : In light of the great proliferation of data and increase in computational power, the importance of effectively combining observations with dynamical models for the purpose of prediction, parameter estimation, and modeling remains a fundamental challenge. Exciting recent works at the interface of machine learning, analysis of PDEs, and data assimilation have led to the development of new methods, analytic insights and unifying perspectives, as well as novel applications. This mini-symposium will bring together researchers that have made such contributions in analytical or computational capacities.

[02864] Consistency Results for some Bayesian PDE inverse problems

Format : Online Talk on Zoom
Author(s) : Nathan Glatt-Holtz (Tulane)
Abstract : Frequently one would like to estimate functional parameters u in a physical model defined by a partial differential equation from a collection of sparse and uncertain observations. Here a Bayesian methodology provides an attractive statistical approach for many such estimation problems, one which provides a comprehensive picture of uncertainties in the unknown. An important step in the validation of this Bayesian methodology is to establish conditions for posterior consistency. Specifically we would like to determine when $\mu_N \rightharpoonup \delta_{u_*}$ where μ_N is the Bayesian posterior conditioned on N observations of the solution and u_* is the true value of the unknown.

In this talk we describe some rigorous approaches that we have recently developed tailored to address consistency for PDE inverse problems involving the recovery of an infinite dimensional unknown. We describe how our approach applies to a gallery of model problems including the recovery of a divergence free velocity field from the measurement of a solute which is advecting and diffusing in the fluid medium. This is joint work with Jeff Borggaard, Christian Frederiksen and Justin Krometis.

[05063] Data-driven and model-driven techniques in DA: applications, numerics, rigorous results

Format : Online Talk on Zoom
Author(s) : Jochen Broecker (Department of Mathematics and Statistics, University of Reading)
Abstract : Data Assimilation permeates all contributions in at least three ways: Firstly, novel approaches to data assimilation use machine learning and Bayesian inference to identify the current state as well as components of the system, two inextricably linked aims. Secondly, data assimilation has become an interesting application of (stochastic) PDE~theory. Thirdly, ergodic theory of infinite dimensional dynamical systems (asymptotic coupling) calls for sophisticated nudging or error feedback schemes. Finally, new venues for research will be sketched.

[02753] Nonparametric Bayesian inference of discretely observed diffusions

Format : Talk at Waseda University
Author(s) : Jean-Charles Croix (Amazon)Masoumeh Dashti (University of Sussex)Stylianos Katsarakis (University of Sussex)Istvan Kiss (University of Sussex)Tanja Zerenner (University of Bristol)
Abstract : We consider the inverse problem of recovering the diffusion and drift functions of a stochastic differential equation from discrete measurements of its solution. We show the stability of the posterior measure with respect to appropriate approximations of the underlying forward model allowing for priors with unbounded support. We then look at the approximated posterior obtained by Gaussian approximation of transition densities in the case where the diffusion coefficient is small.

[02850] A general involution framework for Metropolis-Hastings algorithms and applications to Bayesian inverse problems

Format : Talk at Waseda University
Author(s) : Cecilia Mondaini (Drexel University)Nathan Glatt-Holtz (Tulane University)
Abstract : We consider a general framework for Metropolis-Hastings algorithms used to sample from a given target distribution on a general state space. Our framework has at its core an involution structure, and is shown to encompass several popular algorithms as special cases, both in the finite- and infinite-dimensional settings. In particular, it includes random walk, preconditioned Crank-Nicolson (pCN), schemes based on a suitable Langevin dynamics such as the Metropolis Adjusted Langevin algorithm (MALA), and also ones based on Hamiltonian dynamics including several variants of the Hamiltonian Monte Carlo (HMC) algorithm. In addition, our framework comprises algorithms that generate multiple proposals at each iteration, which allow for greater efficiency through the use of modern parallel computing resources. Aside from encompassing existing algorithms, we also derive new schemes from this framework, including some multiproposal versions of the pCN algorithm. To illustrate effectiveness of these sampling procedures, we present applications in the context of certain Bayesian inverse problems in fluid dynamics. In particular, we consider the problem of recovering an incompressible background fluid flow from sparse and noisy measurements of the concentration of a passive solute advected by the flow. This talk is based on joint works with N. Glatt-Holtz (Tulane U), A. Holbrook (UCLA), and J. Krometis (Virginia Tech).

00718 (2/3) : 1D @E817 [Chair: Jochen Broecker]

[02843] Insights from Nonlinear Continuous Data Assimilation for Turbulent Flows

Format : Talk at Waseda University
Author(s) : Elizabeth Carlson (University of Victoria)Adam Larios (University of Nebraska - Lincoln)Edriss S Titi (University of Cambridge)
Abstract : One of the challenges of the accurate simulation of turbulent flows is that initial data is often incomplete. Data assimilation circumvents this issue by continually incorporating the observed data into the model. An emerging approach to data assimilation known as the Azouani-Olson-Titi (AOT) algorithm introduced a feedback control term to the 2D incompressible Navier-Stokes equations (NSE) in order to incorporate sparse measurements. The solution to the AOT algorithm applied to the 2D NSE was proven to converge exponentially to the true solution of the 2D NSE with respect to the given initial data. In this talk, we will focus on the insights of a nonlinear version of the AOT algorithm and distinguish the clear connections to the physics of the existing systems.

[02852] Linear response for nonlinear dissipative SPDEs

Format : Talk at Waseda University

Author(s) : Giulia Carigi (University of L'Aquila)Jochen Bröcker (University of Reading)Tobias Kuna (University of L'Aquila)

Abstract : A framework suitable to establish response theory for a class of nonlinear stochastic partial differential equations is provided, exploiting coupling methods. The results are applied to the 2D stochastic Navier-Stokes equation and the stochastic two-layer quasi-geostrophic model. In particular, studying the response to perturbations in the forcings for models in geophysical fluid dynamics gives a mathematical insight into whether statistical properties derived under current conditions will be valid under different forcing scenarios.

[05078] Data assimilation of the 2D rotating NSE

Format : Talk at Waseda University

Author(s) : Aseel Farhat (Florida State University)

Abstract : With sufficiently fast rotation, the solution of the 2D rotating NSE on the β plane approaches a nearly zonal state. Additionally, the number of degrees of freedom of the system decrease with faster rotation. We validate this analytically and numerically in the context of a continuous data assimilation algorithm based on nudging.

[02847] Using machine learning in geophysical data assimilation (some of the issues and some ideas)

Format : Online Talk on Zoom

Author(s) : Alberto Carrassi (Dept of Physics, University of Bologna)

Abstract : We show how ML can be included in the prediction and DA workflow in different ways. First, in “non-intrusive” ML, we show how supervised ML estimates the local Lyapunov exponents. ML is then combined with DA in an integrated fashion to learn a surrogate model from noisy and sparse data, and a parametrization of a physical’s model unresolved scales. DA is pivotal to extract information from the sparse, noisy, data that ML cannot handle alone.

00718 (3/3) : 1E @E817 [Chair: Sahani Pathiraja]

[02853] Almost Sure Error Bounds for Data Assimilation in Dissipative Systems with Unbounded Observation Noise

Format : Online Talk on Zoom

Author(s) : Tobias Kuna (Universita dell'Aquila)Jochen Broecker (University of Reading)Lea Oljaca (sustainable investment research)

Abstract : Data assimilation is widely used technique, in particular, in the geophysical community. It aims at inferring information of a model by combining incomplete and noisy observations with imperfect models even for very large models and often on the fly in real time. This methods have been extensively studied for a plethora of models, assimilation methods and error terms. In this talk, I will concentrate on how one can treat unbounded noise in the observations not only in expectation, but actually I will present a technique to obtain an a.s. bound. More specifically, we prove that the error is bounded by a finite and stationary processes. We use the simple replacement data assimilation scheme by Hayden, Olson and Titi, see [1] with observations discrete in time, including but not limited to 2D Navier-Stokes equation. The method should extend to more general algorithms like described in [2], as its estimates are based on absorbing and squeezing properties generalizing [3]. The content of the talk was published in [4].

[04934] Challenges in high dimensional nonlinear filtering

Format : Talk at Waseda University

Author(s) : Jana de Wiljes (Uni Potsdam)

Abstract : The seamless integration of large data sets into computational models is one of the central challenges for the mathematical sciences of the 21st century.

Despite the fact that the underlying assumptions do not hold for many applications, Gaussian approximative filters are considered state of the art as they have been successfully implemented for highly nonlinear settings with large

dimensional state spaces. Moreover several recent studies have been devoted to showing accuracy of such filters in terms of tracking ability for nonlinear evolution models and we will present one of these results given in the form of distinct bounds for certain filter variants.
While the robustness of such Gaussian approximative filters is undeniable there has been considerable aspiration to design filters that can achieve even higher levels of accuracy while maintaining an appropriate level of robustness and stability.
Here we will discuss a family of such filters that do not require a parametrization of the posterior distribution and can be combined with traditional Gaussian filters via a likelihood split.

[02745] Particle Filters for Data Assimilation

Format : Online Talk on Zoom
Author(s) : Dan Crisan (Imperial College London)
Abstract : I will present the latest developments of on-going work on the application of particle filters to develop high dimensional
data assimilation methodologies.

[04884] A novel regularity criterion for the 3D Navier-Stokes equations based on finitely many observations.

Format : Online Talk on Zoom
Author(s) : Animikh Biswas (University of Maryland Baltimore County)Abhishek Balakrishna (University of Maryland Baltimore County)
Abstract : We present a novel regularity criterion for the 3D Navier-Stokes equations (NSE) based on finitely many modal, nodal or volume element observations of the velocity field. The proof is based on a data assimilation algorithm utilizing a Newtonian relaxation scheme (nudging) motivated by feedback-control. The observations, which may be either modal, nodal or volume elements, are obtained from a weak solution of the 3D NSE and are collected almost everywhere in time over a finite grid. The regularity criterion we propose follows from our data assimilation algorithm and is hence intimately connected to the notion of determining functionals (modes, nodes and volumeelements). To the best of our knowledge, all existing regularity criteria require knowing the solutionof the 3D NSE almost everywhere in space. Our regularity criterion is fundamentally different fromany preexisting regularity criterion as it is based on finitely many observations (modes, nodes andvolume elements). We further prove that the regularity criterion we propose is both a necessaryand sufficient condition for regularity. Thus our result can be viewed as a natural generalizationof the notion of determining modes, nodes and volume elements as well as the asymptotic trackingproperty of the nudging algorithm for the 2D NSE to the 3D setting.

[00719] Recent Advances in Numerical PDE and Scientific Machine Learning

Session Time & Room :

00719 (1/2) : 3E (Aug.23, 17:40-19:20) @E702

00719 (2/2) : 4C (Aug.24, 13:20-15:00) @E702

Type : Proposal of Minisymposium
Abstract : Artificial intelligence is constantly evolving and researchers are utilizing deep neural networks in increasingly complex problem sets. To address the difficulties posed by these new setups, deep learning research is exploring new modeling tools, including differential equations, to improve the predictive capabilities of neural networks. These technologies have demonstrated potential in speeding up scientific simulations and achieved state-of-the-art performance in various fields. This minisymposium will focus on recent developments in the intersection of scientific computing and deep learning, highlighting their impact and application across multiple disciplines.

[04237] Level set learning for nonlinear dimensionality reduction in function approximation

Format : Talk at Waseda University
Author(s) : Zhu Wang (University of South Carolina)
Abstract : Approximating high-dimensional functions is challenging due to the curse of dimensionality. Inspired by the Nonlinear Level set Learning method that uses the reversible residual network, we developed a new method, Dimension Reduction via Learning Level Sets, for function approximations. It contains two major components: one is the pseudo-reversible neural network module that effectively transforms high-dimensional input variables to low-dimensional active variables, and the other is the synthesized regression module for approximating function values based on the transformed data in the low-dimensional space. Numerical experiments will be presented to demonstrate the proposed method.

[03271] Semi-analytic PINN methods for boundary layer problems on rectangular domains

Format : Talk at Waseda University
Author(s) : Chang-Yeol Jung (UNIST)Gung-Min Gie (University of Louisville)Youngjoon Hong (Sungkyunkwan University)Tselmuun Munkhjin (UNIST)
Abstract : Singularly perturbed boundary value problems exhibit sharp boundary layers in their solutions, making their numerical approximation challenging due to the stiffness of these layers, resulting in significant computational errors. Traditional numerical methods require extensive mesh refinements near the boundary to obtain accurate solutions, which can be costly in terms of computation.
To address these challenges, we have employed physics-informed neural networks (PINNs) to solve singularly perturbed problems. However, PINNs can struggle with rapidly varying singularly perturbed solutions over a small domain region, resulting in insufficient resolution that can lead to inaccurate results. To overcome this limitation, we consider the semi-analytic methods which enrich the PINNs with so-called corrector functions. Our numerical experiments demonstrate significant improvements in accuracy and stability.

[04847] Solving Wave Equations with Fourier Neural Operator

Format : Talk at Waseda University
Author(s) : Bian Li (Lehigh University)Hanchen Wang (Los Alamos National Lab)Shihang Feng (Los Alamos National Lab)Xiu Yang (Lehigh University)Youzuo Lin (Los Alamos National Lab)
Abstract : In the study of subsurface seismic imaging, solving the acoustic wave equation is a pivotal component in existing models. Inspired by the idea of operator learning, this work leverages the Fourier neural operator (FNO) to effectively learn the frequency domain seismic wavefields under the context of variable velocity models. We also propose a new framework paralleled Fourier neural operator (PFNO) for efficiently training the FNO-based solver given multiple source locations and frequencies.

[04931] Physics-informed variational inference for stochastic differential equations

Format : Talk at Waseda University
Author(s) : Hyomin Shin (POSTECH)Minseok Choi (POSTECH)
Abstract : In this talk, we propose a physics-informed learning based on variational autoencoder (VAE) to solve data-driven stochastic differential equations. We adopt VAE to extract the random state of the governing equation, and train the model by maximizing the evidence lower bound that incorporates the given physical laws. We present numerical examples to demonstrate the effectiveness of the proposed method.

00719 (2/2) : 4C @E702 [Chair: Minseok Choi]

[03076] Deep neural operator for learning transient response of composites subject to dynamic loading

Format : Online Talk on Zoom
Author(s) : Zhen Li (Clemson University)Minglei Lu (Clemson University)Ali Mohammadi (Clemson University)Zhaoxu Meng (Clemson University)Gang Li (Clemson University)
Abstract : Deep neural operator (DNO) is used learn the transient response of composites as surrogate of physics-based finite element analysis (FEA). We consider a 3D composites beam formed by two metals with different Young's modulus subject to dynamic loads. DNO is trained using sequence-to-sequence learning with incremental learning methods based on 5000 FEA data, leading to a 100X speedup. Results show that DNO can predict the transient mechanical response of composites at an accuracy of 97%.

[05598] Analysis of the derivative-free method for solving PDEs using neural networks

Format : Talk at Waseda University
Author(s) : Jihun Han (Dartmouth College)Yoonsang Lee (Dartmouth College)
Abstract : The derivative-free loss method (DFLM) uses a stochastic (Feynman-Kac) formulation to solve a certain class of PDEs using neural networks. The method avoids the derivative calculation from neural networks, using statistical information of local walkers to represent the solution. This work analyzes the effect of the time step and the number of walkers in DFLM. The analysis shows a lower bound for the time step to guarantee a certain accuracy, which contrasts the standard numerical methods with an upper bound. We also show a linear dependence of the walker in the accuracy.

[03762] Convergence analysis of unsupervised Legendre-Galerkin neural networks for linear second-order elliptic PDEs

Format : Talk at Waseda University
Author(s) : Seungchan Ko (Inha University)Seok-Bae Yun (Sungkyunkwan University)Youngjoon Hong (Sungkyunkwan University)
Abstract : In this talk, I will discuss the convergence analysis of unsupervised Legendre-Galerkin neural networks (ULGNet), a deep-learning-based numerical method for solving partial differential equations (PDEs). Unlike existing deep learning-based numerical methods for PDEs, the ULGNet expresses the solution as a spectral expansion with respect to the Legendre basis and predicts the coefficients with deep neural networks by solving a variational residual minimization problem. Using the fact that the corresponding loss function is equivalent to the residual induced by the linear algebraic system depending on the choice of basis functions, we prove that the minimizer of the discrete loss function converges to the weak solution of the PDEs. Numerical evidence will also be provided to support the theoretical result. Key technical tools include the variant of the universal approximation theorem for bounded neural networks, the analysis of the stiffness and mass matrices, and the uniform law of large numbers in terms of the Rademacher complexity.

[04540] Bi-orthogonal fPINN: A physics-informed neural network method for solving time-dependent stochastic fractional PDEs

Format : Talk at Waseda University
Author(s) : Lei Ma (Shanghai normal university)
Abstract : Mathematical models considering nonlocal interactions with uncertainty quantification can be formulated as stochastic fractional partial differential equations (SFPDEs). There are many challenges in solving SFPDEs numerically, especially for long-time integration. Here, we combine the bi-orthogonal (BO) method for representing stochastic processes with physics-informed neural networks (PINNs) for solving partial differential equations to formulate the bi-orthogonal PINN method (BO-fPINN) for solving time-dependent SFPDEs. We demonstrate the effectiveness of the BO-fPINN method for different benchmark problem.

[00721] Data-driven and Model Reduction methods for Subsurface Applications

Session Time & Room :

00721 (1/2) : 2E (Aug.22, 17:40-19:20) @E703

00721 (2/2) : 3C (Aug.23, 13:20-15:00) @E703

Type : Proposal of Minisymposium
Abstract : There are recently a lot of exciting new computational approaches with the aim of solving practical and challenging subsurface applications such as multiphase flow in a fractured reservoir as well as geothermal modeling with heat conduction. The aim of this mini-symposium is to review recent progress in data-driven and model-reduction methods like multiscale methods, numerical upscaling techniques, and learning-based algorithms for related applications and motivate new research directions in solving challenging problems from the field of computational geosciences.

[04298] Deep Learning Methods for PDEs and Reduced Order Models

Format : Talk at Waseda University

Author(s) : Min Wang (University of Houston)

Abstract : In this talk, we will discuss the use of neural networks to solve high-dimensional partial differential equations (PDEs) without being affected by the curse of dimensionality. We will explore three key questions: (1) How to formulate PDE problems as optimization problems for deep learning techniques, (2) The accuracy of neural network approximations, and (3) Systematic training for global minimum convergence. In specific, We will present various optimization formulations for the high-dimensional quadratic porous medium equation, analyze generalization and approximation errors for Ritz methods, and propose an adaptive optimization strategy for training residual neural networks. Numerical results will be provided to demonstrate the effectiveness of the proposed methods.

[03429] Nonlocal multicontinua with representative volume elements

Format : Talk at Waseda University

Author(s) : Wing Tat Leung (City University of Hong Kong)

Abstract : In this talk, we present a general derivation of multicontinuum equations and discuss cell problems. We present constraint cell problem formulations in a representative volume element and oversampling techniques that allow reducing boundary effects. We discuss different choices of constraints for cell problems. We present numerical results that show how oversampling reduces boundary effects. Finally, we discuss the relation of the proposed methods to our previously developed methods, Nonlocal Multicontinuum Approaches.

[05249] Physics-informed neural networks for learning the homogenized coefficients of multiscale elliptic equations

Format : Online Talk on Zoom

Author(s) : Jun Sur Richard Park (KAIST)Xueyu Zhu (Department of Mathematics, University of Iowa)

Abstract : Multiscale elliptic equations with scale separation are often approximated by the corresponding homogenized equations with slowly varying homogenized coefficients (the G-limit). The traditional homogenization techniques typically rely on the periodicity of the multiscale coefficients, thus finding the G-limits often requires sophisticated techniques in more general settings even when the multiscale coefficient is known, if possible. Our approach adopts physics-informed neural networks (PINNs) algorithm to estimate the G-limits from the multiscale solution data by leveraging a priori knowledge of the underlying homogenized equations. Unlike the existing approaches, our approach does not rely on the periodicity assumption or the known multiscale coefficient during the learning stage. We demonstrate that the proposed approach can deliver reasonable and accurate approximations to the G-limits as well as homogenized solutions through several benchmark problems.

00721 (2/2) : 3C @E703 [Chair: Wing Tat Leung]

[02709] Optimality of statistical criterion in hyper-reduction

Format : Talk at Waseda University

Author(s) : Siu Wun Cheung (Lawrence Livermore National Laboratory)

Abstract : While projection-based reduced order models can reduce the dimension of solutions, there may still be nonlinear terms which scale with the full order dimension. Hyper-reduction techniques are sampling-based methods that further reduce computational complexity of nonlinear terms. In this talk, we will view the state-of-the-art Discrete Empirical Interpolation Method from the perspective of optimal design, and introduce a new hyper-reduction method based on optimality of another statistical criterion.

[04174] Least-squares Method for Recovering Multiple Medium Parameters

Format : Talk at Waseda University

Author(s) : Ying Liang (Purdue University)

Abstract : We present a two-stage least-squares method for inverse medium problems of reconstructing multiple unknown coefficients simultaneously from noisy data. A direct sampling method is applied to detect the location of the inhomogeneity in the first stage, while a total least-squares method with a mixed regularization is used to recover the medium profile in the second stage. The total least-squares method is designed to minimize the residual of the model equation and the data fitting, along with an appropriate regularization, in an attempt to significantly improve the accuracy of the approximation obtained from the first stage. We shall also present an analysis on the well-posedness and convergence of this algorithm. Numerical experiments are carried out to verify the accuracies and robustness of this novel two-stage least-squares algorithm, with high tolerance of noise in the data.

[03801] Adaptive partially explicit splitting scheme for multiscale flow problems

Format : Online Talk on Zoom
Author(s) : Yating Wang (Xi'an Jiaotong University)Wing Tat Leung (City University of Hong Kong)
Abstract : In this talk, we will introduce an adaptive framework for a partially explicit splitting scheme of flow problems in high-contrast multiscale media. Due to the heavy computational burden is for the multiscale coefficient with high-contrast, in this work, we utilize a stable multirate temporal splitting scheme, and construct multiscale subspaces to handle the fast flow and slow flow parts separately. The construction of multiscale spaces ensures that the time-step size is independent of the contrast. We then derive both temporal and spatial error estimators to identify local regions where enrichments are needed for two components of the solutions. An adaptive algorithm is then proposed to achieve higher computational efficiency with the desired accuracy.

[00727] Recent Advances in Fast Iterative Methods for PDE Problems

Session Time & Room :

00727 (1/3) : 4C (Aug.24, 13:20-15:00) @E701

00727 (2/3) : 4D (Aug.24, 15:30-17:10) @E701

00727 (3/3) : 4E (Aug.24, 17:40-19:20) @E701

Type : Proposal of Minisymposium
Abstract : Solving vast sparse or structured linear systems is one of the major tasks when solving partial differential equation (PDE) problems in many applications in science and engineering. Iterative solvers such as Krylov subspace methods and the multigrid methods, with effective preconditioners, are often used for solving these linear systems efficiently. This minisymposium brings various researchers and experts in these areas together to present the latest development of iterative methods, preconditioners, and linear algebra software.

[02883] Multigrid Methods for Saddle-Point Matrices with Structured Blocks

Format : Talk at Waseda University
Author(s) : Isabella Furci (University of Genoa)Matthias Bolten (University of Wuppertal)Marco Donatelli (University of Insubria)Paola Ferrari (University of Wuppertal)
Abstract : We consider efficient multigrid methods for large linear systems with particular saddle-point structures. Often, powerful smoothers are used to take into account the special coupling. Alternatively, Notay recently proposed an algebraic approach that analyzes properly preconditioned saddle-point problems.
We provide theoretical tools to analyze the latter procedure when applied to saddle-point systems whith (multilevel) block-Toeplitz blocks. As a test problem, we consider the linear system stemming from the Finite Element approximation of the Stokes equation.

[05299] New Linear Solvers Features and Improvements in Trilinos

Format : Online Talk on Zoom
Author(s) : Jennifer Ann Loe (Sandia National Laboratories)Ichitaro Yamazaki (SNL)Sivasankaran Rajamanickam (Sandia National Laboratories)Heidi Thornquist (Sandia National Laboratories)Christian Glusa (Sandia National Laboratories)
Abstract : Trilinos is a large open-source mathematical software library which includes algorithms for discretization, optimization, preconditioners, non-linear solvers, and linear solvers. Its Tpetra linear algebra backend allows it to run effectively on highly parallel computers and various GPU accelerators. In this talk, we discuss recent improvements and additions to the Trilinos linear solver capabilities. One addition allows mixed precision solver and preconditioner combinations. Another recent improvement provides an abstract interface for small dense matrices in the linear solvers, eliminating extra data movement for GPU-based computers. We will demonstrate potential performance gains with use of the new linear solvers features.

[04769] A rational preconditioner for multi-dimensional Riesz fractional diffusion equations

Format : Online Talk on Zoom
Author(s) : Mariarosa Mazza (University of Insubria)Lidia Aceto (University of Eastern Piedmont)
Abstract : Starting from a rational approximation of the Riesz operator expressed as the integral of the standard heat diffusion semigroup, we propose a rational preconditioner for solving linear systems arising from the finite difference/element discretization of multi-dimensional Riesz fractional diffusion equations. We show that, despite the lack of clustering just as for the Laplacian, for fractional orders close to 1 our preconditioner provides better results than the Laplacian itself, while sharing the same computational complexity.

[02906] Some step-size independent theoretical bounds for preconditioning techniques of discrete PDEs

Format : Talk at Waseda University
Author(s) : Xuelei Lin (Harbin Institute of Technology Shenzhen)
Abstract : It is well-known that the condition number of coefficient matrices arising from discretization of differential equations increases as the grid gets refined, because of which iterative solvers converge slowly for the linear systems when the grid is dense. In this talk, preconditioning techniques for discretization of some differential equations are introduced, with which some Krylov subspace solvers for the preconditioned systems are proven to have a linear convergence rate independent of the stepsizes. Numerical results are also reported.

[04605] A single-sided all-at-once preconditioning for linear system from a non-local evolutionary equation with weakly singular kernels

Format : Talk at Waseda University
Author(s) : Xuelei Lin (Harbin Institute of Technology Shenzhen)Jiamei Dong (Hong Kong Baptist University)Sean Hon (Hong Kong Baptist University)
Abstract : We propose a preconditioning technique for the multilevel Toeplitz all-at-once linearsystem arising from a time-space fractional diffusion equation. The preconditioning tech-nique is based on replacing the spatial discretization matrix with aτ-matrix, due to whichthe preconditioner can be fast inverted. Theoretically, we show that the condition numberof the intermediate two-sided preconditioned matrix is bounded by 3. And the norm of ourpreconditioner residual is bounded by the residual of intermediate preconditioner .

[04933] Fast algorithms for space fractional Cahn-Hilliard equations

Format : Online Talk on Zoom
Author(s) : Xin Huang (Huazhong University of Science and Technology)
Abstract : In this talk, the space fractional Cahn-Hilliard (CH) equation is considered. Combining the scale auxiliary variable (SAV) technique with the leapfrog scheme, an unconditional energy-stable, non-couple and linearly implicit numerical scheme is derived. The fully-discrete scheme gives rise to an ill-conditioned system. The Krylov subspace method combing with the preconditioning technique is adopted to solve the resulting system. Numerical results are given to show the efficiency of the proposed method.

[05262] A parallel preconditioner for the all-at-once linear system from evolutionary PDEs with Crank-Nicolson discretization in time

Format : Online Talk on Zoom
