Abstract : The Crank-Nicolson (CN) method is a fashionable time integrator for evolutionary partial differential equations (PDEs) arisen in many areas of applied mathematics, however since the solution at any time depends on the solution at previous time steps, thus the CN method will be inherently difficult to parallelize. In this talk, we consider a parallel approach for the solution of evolutionary PDEs with the CN scheme. Using an all?at-once approach, we can solve for all time steps simultaneously using a parallelizable over time preconditioner within a standard iterative method. Due to the diagonalization of the proposed preconditioner, we can minutely prove that most eigenvalues of preconditioned matrices are equal to 1 and the others $z \in \mathbb{C}$ have the model with $1/(1 + \alpha) < |z| < 1/(1 - \alpha)$, where $0 < \alpha < 1$ is a free parameter. Meanwhile, the efficient and parallel implementation of this proposed preconditioner is described in details. Finally, we will verify our theoretical findings via numerical experiments.

[05468] A preconditioned MINRES method for optimal control of wave equations

Format : Talk at Waseda University
Author(s) : Sean Hon (Hong Kong Baptist University)
Abstract : In this work, we propose a novel preconditioned Krylov subspace method for solving an optimal control problem of wave equations, after explicitly identifying the asymptotic spectral distribution of the involved sequence of linear coefficient matrices from the optimal control problem. Namely, we first show that the all-at-once system stemming from the wave control problem is associated to a structured coefficient matrix-sequence possessing an eigenvalue distribution. Then, based on such a spectral distribution of which the symbol is explicitly identified, we develop an ideal preconditioner and two parallel-in-time preconditioners for the saddle point system composed of two block Toeplitz matrices. For the ideal preconditioner, we show that the eigenvalues of the preconditioned matrix-sequence all belong to the set $\left(-\frac{3}{2},-\frac{1}{2}\right)\bigcup\left(\frac{1}{2},\frac{3}{2}\right)$ well separated from zero, leading to mesh-independent convergence when the minimal residual method is employed. The proposed parallel-in-time preconditioners can be implemented efficiently using fast Fourier transforms or discrete sine transforms, and their effectiveness is theoretically shown in the sense that the eigenvalues of the preconditioned matrix-sequences are clustered around ± 1, which leads to rapid convergence. When these parallel-in-time preconditioners are not fastly diagonalizable, we further propose modified versions which can be efficiently inverted. Several numerical examples are reported to verify our derived localization and spectral distribution result and to support the effectiveness of our proposed preconditioners.

[03484] A block α-circulant based preconditioned MINRES method for evolutionary PDEs

Author(s) : Sean Hon (Hong Kong Baptist University)
Abstract : In this work, we propose a novel parallel-in-time preconditioner for an all-at-once system arising from the numerical solution of evolutionary partial differential equations (PDEs). Namely, considering the wave equation as a model problem, our main result concerns a block α-circulant matrix based preconditioner that can be fast diagonalized via fast Fourier transforms, whose effectiveness is theoretically supported for the modified block Toeplitz system arising from discretizing the concerned wave equation. Namely, after first transforming the original all-at-once linear system into a symmetric one, we develop the desired preconditioner based on the spectral information of the modified matrix. Then, we show that the eigenvalues of the preconditioned matrix are clustered around 1 without any extreme outlier far away from the clusters. In other words, mesh-independent convergence is theoretically guaranteed when the minimal residual method is employed. Moreover, our proposed solver is further generalized to a full block triangular Toeplitz system which arises when a high order discretization scheme is used. Numerical experiments are given to support the effectiveness of our preconditioner, showing that the expected optimal convergence can be achieved.

This is joint work with Xuelei Lin (Harbin Institute of Technology).

[00731] Optimal control: methods and applications

Session Time & Room :

00731 (1/2) : 5C (Aug.25, 13:20-15:00) @F401

00731 (2/2) : 5D (Aug.25, 15:30-17:10) @F401

Type : Proposal of Minisymposium
Abstract : This two part mini-symposium addresses theoretical aspects of optimisation of systems governed by ODEs and applications. Optimal control and the associated analysis indeed provides a framework general enough to cover the Riemannian case, and gradient flows on such manifolds, as well as the Finslerian one - in particular Zermelo type problems. It is also instrumental to deal with more singular situations involving for instance Fuller and turnpike phenomena. Two privileged domains of applications are considered: space mechanics, in connection with dynamical system analysis for mission design, and biology with a focus on micro-swimmers and bacterial growth.

[04845] A variational approach for modelling and optimal control of electrodynamic tether motion

Format : Talk at Waseda University
Author(s) : Yana Valentinova Lishkova (University of Oxfordrsity of Oxford)Mai Bando (Kyushu University)Sina Ober-Blöbaum (Paderborn University)
Abstract : We present a novel variational model for 6DOF spacecraft dynamics equipped with an electrodynamic tether in circular restricted three-body environment and use it to perform an optimal orbit transfer with simultaneous orbit and attitude control. We discuss the advantages of the suggested variational approach and develop an alternative multirate formulation of the model and OCP, investigating the extent to which such reformulations can reduce the computational cost of simulating and optimally controlling spacecraft in CR3BP.

[04761] The Role of Stable Manifolds in Optimal Control under Stochastic Noise

Format : Talk at Waseda University
Author(s) : Mai Bando (Kyushu University)Shohei Morimitsu (Kyushu University)Takuro Nishimura (Kyushu University)Shinji Hokamoto (Kyushu University)
Abstract : This study investigates the optimal control around a hyperbolic fixed point under stochastic noise. For a deterministic system without noise, it is known that the stable manifold of a hyperbolic fixed point is the solution to the minimum-energy problem with infinite horizon. We analyze the structure of the optimal control under a stochastic noise based on path integral approach and investigate the role of the stable manifold of the hyperbolic fixed point.

[04228] Second-order averaging of time-optimal low-thrust orbital transfers

Format : Talk at Waseda University
Author(s) : Lamberto Dell'Elce (Inria & Université Côte Azur)
Abstract : This work offers a numerical methodology to solve low-thrust orbital transfer problems. After detailing necessary conditions for optimality stemming from the Pontryagin maximim principle, a numerical methodology based on the averaging of the extremal flow of the optimal control hamiltonian is proposed. First, a one-parameter family of averaged solutions is obtained. Second, perturbations of these solutions associated to both short-periodic variations and second-order terms are computed. Finally, the magnitude of the thrust-to-mass ratio is identified by reconstructing a first-order approximation of the fast variables from the averaged solution.

[03208] Optimization on manifolds by Riemannian gradient methods

Format : Talk at Waseda University
Author(s) : Hiroyuki Sato (Kyoto University)
Abstract : In this talk, we will discuss optimization on Riemannian manifolds. After introducing examples of manifold optimization problems, some recent results by the speaker will be presented. In particular, the Riemannian conjugate gradient method is a simple first-order method, which does not use the Hessian but only the gradient of the objective function, and it shows much faster convergence performance than the Riemannian steepest descent method. Reference: H. Sato, Riemannian Optimization and Its Applications, Springer, 2021.

00731 (2/2) : 5D @F401 [Chair: Lamberto Dell'Elce]

[04787] Curvature related properties of Finsler manifolds and applications

Format : Talk at Waseda University
Author(s) : Sorin Sabau (Tokai University)
Abstract : Finsler manifolds are important generalizations of Euclidean and Riemannian ones with applications in different domains of mathematics, physics and engineering. In the present talk we are going to present some recent results concerning Finsler connections, curvature and relation with statistical models in the real world. We suggest possible development of information geometry on Finsler manifolds that would allow a wide range of applications.

[03504] Optimal microswimmer control and a microfluidic control example

Format : Talk at Waseda University
Author(s) : Clement Moreau (RIMS, Kyoto University)
Abstract : Microscale swimmers are becoming increasingly prevalent. A natural question that arises from such swimmers, particularly those synthetic swimmers with targeted applications, is that of guidance and control.
The purpose of this presentation is to give an overview of the results of optimal control theory in the study of micro-

swimming organisms and devices. As an illustrative example, I will present time-optimal trajectories for a model of microfluidic control representing a swimmer guided through the external flow generated by a neighboring wall.

[04894] Control Problems inspired by Biological Phenomena

Format : Talk at Waseda University
Author(s) : Tetsuya J. Kobayashi (Institute of Industrial Science, UTokyo)Takehiro Tottori (The University of Tokyo)Shuhei A Horiguchi (The University of Tokyo)
Abstract : In order to understand the design principles of biological systems, which sometimes demonstrate more efficient and sophisticated behaviors than engineering systems, the notion of control is indispensable. However, the control theories developed in the engineering domain under their standard assumptions can not necessarily be appropriately applied to biological phenomena, resulting in limited applicability to biological systems. In this presentation, we will discuss several extended control theories inspired by biological phenomena and their potential applications.

[04045] Control in biology: topics in bacterial growth

Format : Talk at Waseda University
Author(s) : Jean-Baptiste Caillau (Université Côte d'Azur, CNRS, Inria, LJAD)
Abstract : We consider bacteria whose internal dynamics is modelled by the so-called self-replicator equations. This low dimensional ODE system accounts for the behaviour of the cell. The control mimics the allocation process of the cell that decides to use substrate either for gene expression or for its metabolism. Another control can be added to model an external action on a the bio-engineered cell; thanks to optogenetics, one can for instance use light to trigger the production by the cell of a metabolite of interest. Several criteria are of interest here, particularly growth maximisation, or metabolite production. Pontrjagin maximum principle allows to analyse these problems, revealing two characteristic features of these optimal control problems: Fuller phenomenon and turnpike behaviour. Some symbolic-numeric results are given to illustrate these.

Joint work with colleagues from Biocore, McTAO and MICROCOSM Inria teams. Support from the ANR is acknowledged (Maximic project).

[00733] Compressible fluid dynamics and related PDE topics

Session Time & Room :

00733 (1/4) : 3C (Aug.23, 13:20-15:00) @G606

[01289] Time-asymptotic stability of Riemann solutions to the compressible Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Yi Wang (AMSS, Chinese Academy of Sciences)
Abstract : The talk is concerned with our recent developments on the time-asymptotic stability of generic Riemann solutions to the one-dimensional compressible Navier-Stokes equations including both isentropic and full cases.

[01339] Stability analysis of Prandtl expansions for two dimensional MHD equations in Sobolev spaces

Format : Talk at Waseda University
Author(s) : Feng Xie (Shanghai Jiao Tong University)
Abstract : In this talk, I will review briefly the classical Prandtl boundary layer expansions method to analyze the structure of viscous flow under the high Reynolds number. And then I will discuss the vanishing viscosity limit of solution to initial boundary value problem for both incompressible and compressible magneto-hydrodynamics (MHD) equations in Sobolev spaces, where the velocity is always imposed the no-slip boundary condition. The effects of the normal component of magnetic field, tangential component of magnetic field, magnetic diffusion and the change of density on the mathematical analysis for stability of MHD boundary layer and vanishing viscosity limit of solution to MHD equations will be addressed.

[01378] Global Strong and Weak Solutions to Compressible MHD System

Format : Talk at Waseda University
Author(s) : Xiaoding Shi (Beijing University of Chemical Technology)
Abstract : The barotropic compressible magnetohydrodynamic equations in a general two-dimensional bounded simply connected domain is considered here. For initial density allowed to vanish, we prove that the initial-boundary-value problem of 2D compressible MHD system admits the global strong and weak solutions without any restrictions on the size of initial data.

[01436] Inviscid Limit Problem of radially symmetric stationary solutions for compressible Navier-Stokes equation

Format : Talk at Waseda University
Author(s) : itsuko hashimoto (kanazawa university)Akitaka Matsumura (Osaka university)
Abstract : The present paper is concerned with an inviscid limit problem of radially symmetric stationary solutions for an exterior problem in R^n (n≧2) to compressible Navier-Stokes equation, describing the motion of viscous barotropic gas without external forces, where boundary and far field data are prescribed. For both inflow and outflow problems, the inviscid limit is considered in a suitably small neighborhood of the far field state. For the outflow problem, we prove the uniform convergence of the Navier-Stokes flows to the Euler flows in the inviscid limit. On the other hand, for the inflow problem, we show that the Navier-Stokes flows uniformly converge to a superposition of boundary layer solution and Euler flows in the inviscid limit. The estimates of algebraic rate toward the inviscid limit are also obtained.

00733 (2/4) : 3D @G606 [Chair: Itsuko Hashimoto]

[01614] Convergence Rate Estimates for the Low Mach and Alfven Number Three-Scale Singular Limit of Compressible Ideal Magnetohydrodynamics

Format : Talk at Waseda University
Author(s) : Qiangchang JU (Institute of Applied Physics and Computational Mathematics, Beijing)
Abstract : Convergence rate estimates are obtained for singular limits of the compressible ideal magnetohydrodynamics equations, in which the Mach and Alfven numbers tend to zero at different rates. The proofs use a detailed analysis of exact and approximate fast, intermediate, and slow modes together with improved estimates for the solutions and their time derivatives, and the time-integration method. This is a joint work with Bin Cheng and Steve Schochet

[01617] Nonlinear asymptotic stability of vortex sheets with viscosity effects

Format : Talk at Waseda University
Author(s) : Qian Yuan (Chinese Academy of Sciences)
Abstract : In this talk, we can see that although a vortex sheet is not an asymptotic attractor for the compressible Navier-Stokes equations, a viscous profile that approximates the vortex sheet can be computed explicitly. It is shown that if the strength of vortex sheet is weak, then its associated viscous profile is asymptotically stable in the L^∞-norm with small initial perturbations for the compressible Navier-Stokes equations.

[01660] Time-asymptotic expansion with pointwise remainder estimates for 1D viscous compressible flow

Format : Talk at Waseda University
Author(s) : Kai Koike (Tokyo Institute of Technology)
Abstract : We consider solutions to 1D compressible Naiver–Stokes equations around a constant steady state. We construct a time-asymptotic expansion with pointwise remainder estimates. The leading-order term of the expansion is the well-known diffusion wave and the higher-order terms are newly introduced family of waves which we call higher-order diffusion waves. Thanks to the pointwise remainder estimates, we can show that the expansion is valid for a fixed point x and also in any $L^p(\mathbb{R})$-norm including the case of $1 \leq p < 2$. The proof is based on pointwise estimates of Green's function.

[01694] Asymptotic stability for the two-phase Navier-Stokes equations with surface tension and gravity

Format : Talk at Waseda University
Author(s) : Hirokazu Saito (The University of Electro-Communications)
Abstract : We consider the motion of two immiscible, viscous, incompressible capillary fluids, fluid$_+$ and fluid$_-$, in the presence of a uniform gravitational field acting vertically downward in $\mathbf{R}^N$ for $N \geq 3$. At the initial time, fluid$_-$ occupies a half-space-like domain such as oceans of infinite depth, while the complement of its closure is filled with fluid$_+$. The asymptotic stability of the trivial steady state is proved if fluid$_-$ is heavier than fluid$_+$.

[01716] Global solutions on compressible Euler and Euler-Poisson equations

Format : Online Talk on Zoom
Author(s) : Yong Wang (Academy of Mathematics and System Sciences, CAS, China)
Abstract : I will talk some results on the global existence of solutions to compressible Euler and Euler-Poisson of large intial data with spherical symmetry.

[01715] Global solutions on compressible Euler and Euler-Poisson equations

Format : Online Talk on Zoom
Author(s) : Yong Wang (Academy of Mathematics and System Sciences, CAS, China)
Abstract : I will talk some results on the global existence of solutions to compressible Euler and Euler-Poisson of large intial data with spherical symmetry.

[01776] Some recent results on compressible Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Jing Li (AMSS, Chinese Academy of Sciences)
Abstract : We investigate the barotropic compressible Navier-Stokes equations with slip boundary conditions in a three-dimensional (3D) simply connected bounded domain, whose smooth boundary has a finite number of two-dimensional connected components. For any adiabatic exponent bigger than one, after obtaining some new estimates on boundary integrals related to the slip boundary conditions, we prove that both the weak and classical solutions to the initial-boundary-value problem of this system exist globally in time provided the initial energy is suitably small. Moreover, the density has large oscillations and contains vacuum states. Finally, it is also shown that for the classical solutions, the oscillation of the density will grow unboundedly in the long run with an exponential rate provided vacuum appears (even at a point) initially.

[03229] Hidden structures behinds the compressible Navier-Stokes equations and its applications to the corresponding models

Format : Online Talk on Zoom
Author(s) : Xiangdi Huang (Academy of Mathematics and Systems Science)
Abstract : In this talk, we will review the past developments on the solutions of the compressible Navier-Stokes equations and reveal the three hidden structures which linked the weak solution to the strong one. Based on these observations, we proved the Nash's conjecture in 1958s and establish global exsitence theory for both isentropic and heat-conductive compressible Navier-Stokes equations.

Moreover, for the 3D compressible Navier-Stokes equations, we will show the existence of local weak solutions with higher regularity and local strong solutions with lower regularity. Also, we will mention the recent results on the blowup of the local strong solutions to the MHD equations in finite time and global existence of weak solutions of the compressible Navier-Stokes equations in bounded domains under Dirichlet boundary conditions.

[00736] Modeling and Computation for Interface Dynamics in Fluids and Solids

Session Time & Room :

00736 (1/2) : 2C (Aug.22, 13:20-15:00) @E708

00736 (2/2) : 2D (Aug.22, 15:30-17:10) @E708

Type : Proposal of Minisymposium
Abstract : Interfacial phenomena are widely observed in nature and play important roles in materials science and fluid mechanics. The dynamics of the interfaces between different phases is of great interest not only because of the associated scientific questions but also due to its various applications. The different phases separated by the interfaces can be both liquids, or liquid-gas phases, or solid-gas phases, etc. Modelling and simulation of such systems is rather challenging, especially in the presence of moving contact lines. This mini-symposium will mainly focus on the mathematical modeling of interface dynamics and the development of efficient numerical methods.

[02231] Competition between viscous flow and diffusion in pinch-off dynamics

Format : Talk at Waseda University
Author(s) : Tiezheng Qian (Hong Kong University of Science and Technology)
Abstract : We employ the Cahn-Hilliard-Navier-Stokes model to investigate the pinch-off dynamics of a liquid thread surrounded by a viscous fluid. A characteristic length scale is introduced to measure the competition between diffusion and viscous flow. This length scale is adjustable in the model and can approach micrometer scale for aqueous two-phase systems close to the critical point. Numerical examples are presented to show the pinch-off processes in the Stokes regime and the diffusion-dominated regime respectively.

[02273] A phase field model of vesicle growth or shrinkage

Format : Talk at Waseda University
Author(s) : Shuwang Li (Illinois Institute of Technology)Xiaoxia Tang (Illinois Institute of Technology)Steven Wise (University of Tennessee)
Abstract : We present a diffuse interface model for vesicle growth or shrinkage induced by an osmotic pressure. The model consists of an Allen-Cahn equation describing the evolution of phase field and a Cahn-Hilliard equation describing the evolution of concentration field. We establish control conditions for expanding or shrinking vesicles via a common tangent construction. Numerical experiments reveal that the model can capture the main feature of dynamics: formation of circle-like (expanding) and finger-like (shrinking) vesicles.

[03394] A symmetrized parametric finite element method for anisotropic surface diffusion

Format : Talk at Waseda University
Author(s) : YIFEI LI (National University of Singapore)
Abstract : In this talk, we introduce an energy-stable numerical scheme for 2D closed curve motion under anisotropic surface diffusion using a general anisotropic surface energy γ(n). We propose a symmetric surface energy matrix Z_k(n), derive a symmetrized variational formulation, and discretize it using an structure-preserving parametric finite element method (SP-PFEM). The SP-PFEM is proven unconditionally energy-stable under mild conditions on γ(n). Finally, we report the high performance through numerical results.

[02478] On a diffuse interface model for incompressible viscoelastic two-phase flows

Format : Talk at Waseda University
Author(s) : Yadong Liu (University of Regensburg)Dennis Trautwein (University of Regensburg)
Abstract : This talk concerns a diffuse interface model for the flow of two incompressible viscoelastic fluids in a bounded domain. More specifically, the fluids are assumed to be macroscopically immiscible, but with a small transition region, where the two components are partially mixed. Considering the elasticity of both components, one ends up with a coupled Oldroyd-B/Cahn--Hilliard type system, which describes the behavior of two-phase viscoelastic fluids. We prove the existence of weak solutions to the system in two dimensions for general (unmatched) mass densities, variable viscosities, different shear moduli, and a class of physically relevant and singular free energy densities that guarantee that the order parameter stays in the physically reasonable interval. The proof relies on a combination of a novel regularization of the original system and a new hybrid implicit time discretization for the regularized system together with the analysis of an Oldroyd-B type equation.

00736 (2/2) : 2D @E708

[03198] Simulating solid-state dewetting of thin films: a phase-field approach

Author(s) : Wei Jiang (Professor)
Abstract : TBA

[03625] Modeling and simulation for solid-state dewetting problems

Author(s) : Quan Zhao (University of Regensburg)
Abstract : Deposited thin films are unstable and could dewet to form isolated islands on the substrate in order to minimize the total surface energy. I will introduce a sharp-interface model and a diffuse-interface model for describing the dewetting of solid thin films with anisotropic surface energies. The relationship between the two models is established via the asymptotic analysis. Numerical results are presented to validate the asymptotic results and to demonstrate the anisotropic effects in the evolution.

[02975] Modeling and Energy Stable Numerical Schemes of Network Development in Biology Gels

Author(s) : BOYI WANG (TU Wien)
Abstract : In this paper, we focus on the modeling and simulation of the network development in biological gels. A thermodynamically consistent model with homogenous Neumann or periodic boundary condition is derived based on the Rayleighian method. Two fully discrete numerical schemes are proposed to solve the problem. Energy stability is achieved at the discrete level for both schemes. Positivity-preserving property can be shown for the model with the Flory—Huggins potential at continuous and discrete level.

[03582] The mixed finite element method applied to cavitation in incompressible nonlinear elasticity

Author(s) : Weijie Huang (Beijing Jiaotong University)
Abstract : In this talk, I will introduce a mixed finite element method for solving cavitation problem for 2D incompressible nonlinear elastic materials. The method is analytically proved to be locking-free and convergent, and it is also shown to be numerically accurate and efficient by numerical experiments. Furthermore, the newly developed accurate method enables us to find an interesting bifurcation phenomenon in multi-cavity growth.

[00737] Numerical methods for semiconductor devices simulation and the computational lithography

00737 (1/3) : 4D (Aug.24, 15:30-17:10) @E704

00737 (2/3) : 4E (Aug.24, 17:40-19:20) @E704

00737 (3/3) : 5B (Aug.25, 10:40-12:20) @E704

Type : Proposal of Minisymposium
Abstract : As the feature size of modern integrated circuits goes to nanometer-scale, the design and analysis of integrated circuits become complicated. Quantum mechanical phenomena become prominent in numerical simulations of semiconductor device. At the same time, rigorous computational lithography beyond Kirchhoff approximation becomes more important, but are too resource intensive to use for full chip applications. Efficient and accurate numerical simulation of device and lithography continues to be a challenge. We are concerned with the numerical modeling of semiconductor devices simulation and electromagnetic computation in lithography. Of particular interest to this minisymposium are recent advances on general numerical methods.

[01756] Arbitrarily high order finite element methods for arbitrarily shaped domains with automatic mesh generation

Format : Talk at Waseda University
Author(s) : Zhiming Chen (Chinese Academy of Sciences)
Abstract : We consider high-order unfitted finite element methods on Cartesian meshes with hanging nodes for elliptic interface problems. We construct a reliable algorithm to merge small interface elements with their surrounding elements to automatically generate the finite element mesh whose elements are large with respect to both domains. Numerical examples are presented to illustrate the competitive performance of the method. This talk is based on a joint work with Yong Liu.

[01921] An iterative method for inverse lithography problem with TV regularization

Format : Talk at Waseda University
Author(s) : Junqing Chen (Tsinghua University)
Abstract : I will introduce an alternating direction method of multipliers (ADMM) to solve an optimization problem stemming from inverse lithography. The objective functional of the optimization problem includes three terms. In the framework of ADMM method, the optimization problem is divided into several subproblems. Each of the subproblems can be solved efficiently. The convergence analysis is given. Some numerical examples are shown to illustrate the effectiveness of the method.

[03833] A SOURCE TRANFER DOMAIN DECOMPOSITION METHOD FOR MAXWELL'S EQUATIONS

Format : Talk at Waseda University
Author(s) : TAO CUI (NCMIS, LSEC, Academy of Mathematics and Systems Science, Chinese Academy of Sciences)ZIMING WANG (School of Mathematical Sciences, University of Chinese Academy of Sciences)XUESHUANG XIANG (Qian Xuesen Laboratory of Space Technology, China Academy of Space Technology)
Abstract : In this paper, we develop an efficient solver for the Maxwell's equations in unbounded domain by extending the source transfer domain decomposition method (STDDM) proposed by Chen et al. Through the analysis of the fundamental solution of the Maxwell's equations, the convergence of STDDM is proved for the case of constant wave number. Numerical experiments are included, demonstrating that the proposed method can be used as an efficient preconditioner in the preconditioned GMRES method for solving the PML equation of the Maxwell's equations with constant and heterogeneous wave numbers, including an example for lithography.

[01824] Numerical simulation for quantum transports in nano-semiconductor device

Format : Talk at Waseda University
Author(s) : Haiyan Jiang (Beijing Institute of Technology)tiao Lu (Peking University)Weitong Zhang (Peking University)
Abstract : We develop a new hybrid scheme for the coupled systems of quantum transport in nano-semiconductor device. Sinc-Galerkin method is used to solve the time-dependent Wigner equation numerically with the spectral convergence of the cardinal sine basis function solution of Wigner function in velocity space. A second-order semi-implicit time integration scheme is designed for the Wigner-Poisson equations (TWPEs). The numerical method is applied to study a double-barrier resonant tunneling diode (RTD), Error estimation, stability, and convergence are also

investigated concretely. Numerical experiments validate the theoretical results and present the reliability and efficiency of the proposed algorithm to simulate quantum effects.

00737 (2/3) : 4E @E704 [Chair: Tao Cui]

[01985] An efficient iterative scheme for the coupled Schrödinger-Poisson equations

Format : Talk at Waseda University
Author(s) : Wenhao Lu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : We propose an efficient iterative scheme for solving the coupled Schrödinger-Poisson equations in three-dimensions. In this scheme, the series of electron densities is truncated to a sum of finite terms, and only a finite number of eigenvalues are computed at each iteration step. The convergence analysis is also presented. We present numerical results that demonstrate the properties of the proposed scheme.

[01922] Dispersion Analysis of CIP-FEM for Helmholtz Equation

Format : Talk at Waseda University
Author(s) : Haijun Wu (Nanjing University)Yu Zhou (Nanjing University)
Abstract : When solving the Helmholtz equation numerically, the accuracy of numerical solution deteriorates as the wave number k increases, known as `pollution effect' which is directly related to the phase difference between the exact and numerical solutions, caused by the numerical dispersion. In this paper, we propose a dispersion analysis for the continuous interior penalty finite element method (CIP-FEM) and derive an explicit formula of the penalty parameter for the p^{th} order CIP-FEM on tensor product (Cartesian) meshes, with which the phase difference is reduced from $\mathcal{O}\big(k(kh)^{2p}\big)$ to $\mathcal{O}\big(k(kh)^{2p+2}\big)$. Extensive numerical tests show that the pollution error of the CIP-FE solution is also reduced by two orders in kh with the same penalty parameter.

[01779] Efficient Simulation Algorithm for FinFET and Gate-All-Around FET

Format : Talk at Waseda University
Author(s) : Lang Zeng (Beihang University)
Abstract : In this talk, our self-developed device simulator based on the framework of Mode space method will be introduced which can accurately and efficiently simulate the current characteristic of FinFET and GAA FET. In our hybrid framework, the 3D device is divided into 2D cross-sectional direction with closed boundary condition and 1D transport direction with open boundary condition. Our simulator is designed by modular concept that different physical models can be picked and combined freely.

[01757] A finite element method for the Schr"{o}dinger-Poisson model

Format : Talk at Waseda University
Author(s) : Weiying Zheng (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : We propose a finite element method for solving the coupled Schrödinger-Poisson equations in three-dimensions. The series of electron density is truncated into the sum of finite terms. Sharp estimates are proved for both the truncation error and the finite element discretization error. A robust iterative scheme is proposed to solve the nonlinearly coupled problem.

[00739] Inequalities and entropy with applications

Session Time & Room :

00739 (1/3) : 4C (Aug.24, 13:20-15:00) @A510

00739 (2/3) : 4D (Aug.24, 15:30-17:10) @A510

00739 (3/3) : 4E (Aug.24, 17:40-19:20) @A510

Type : Proposal of Minisymposium

Abstract : Mathematical inequalities are of fundamental interest due to their applications in different problems in industrial and applied mathematics. Developing a new inequality is a challenging and crucial task.
On the other hand, entropy plays a key role in theoretical physics and information theory. Investigations in entropy need new mathematical inequalities. In contrast, research in inequality provides novel characteristics of entropy and divergence. For instance, we need matrix inequalities in quantum information theory.
In this mini-symposium, our aim is to provide the recent advances, problems and ideas at the interface of mathematical inequalities and entropy with various applications.

[02362] Refined Hermite-Hadamard inequalities and their applications to some n variable means

Format : Talk at Waseda University
Author(s) : Kenjiro Yanagi (Josai University)
Abstract : It is well known that the Hermite-Hadamard inequality (called the HH inequality) refines the definition of convexity of function $f(x)$ defined on $[a,b]$ by using the integral of $f(x)$ from a to b. There are many generalizations or refinements of the HH inequality. Futhermore the HH inequality has many applications to several fields of mathematics, including numerical analysis, functional analysis and operator inequality. Recently we gave several types of refined HH inequalities and obtained inequalities which were satisfied by weighted logarithmic means. In this talk, we give n variable HH inequality and apply to some n variable means. Finally we compare these means.

[02747] Generalization of Hermite-Hadamard Mercer Inequalities for Certain Interval Valued Functions

Format : Talk at Waseda University
Author(s) : Asfand Fahad (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University Multan, Pakistan)
Abstract : Due to its significance in economics, optimization and different fields, convex analysis theory has experienced various advancements and extensions over time. A modern development is the use of cr-convex functions to construct equivalent optimality conditions for constrained and unconstrained nonlinear optimization problems using interval-valued objective functions. By keeping in mind the relationships between convex functions and mathematical inequalities involving the convex functions, we investigated generalizations of well-known Hermite-Hadamard Mercer Inequalities for new types of cr-convex functions. We include several well-known consequences as special cases.

[01760] Generalized spectral radius of operators and related inequalities

Format : Talk at Waseda University
Author(s) : Kais Feki (University of Monastir)
Abstract : In this talk, we aim to introduce the notion of the spectral radius of bounded linear operators acting on a complex Hilbert space $\mathcal{H}$, which are bounded with respect to the seminorm induced by a positive operator A on $\mathcal{H}$. We denote this new concept by $r_A(\cdot)$. In this presentation, several basic properties and inequalities involving $r_A(\cdot)$ are investigated. Moreover, we study the connection between the notions of A-spectral radius and A-spectrum for A-bounded operators.

[03970] q-deformation of Böttcher-Wenzel inequality

Format : Talk at Waseda University
Author(s) : Hiromichi Ohno (Shinshu University)
Abstract : The Böttcher-Wenzel inequality states that the 2-norm of the commutator of matrices A and B is less than or equal to $\sqrt{2}$ times the product of the 2-norms of A and B. In this talk, we discuss q-deformation of the Böttcher-Wenzel inequality in which the commutator is replaced by a q-commutator.

00739 (2/3) : 4D @A510 [Chair: Hiroyuki Osaka]

[01998] The reduced quantum relative entropy

Format : Talk at Waseda University
Author(s) : Frank Hansen (University of Copenhagen)
Abstract : We introduce the notion of reduced relative quantum entropy and prove that it is convex. The result is used to give a simplified proof of a theorem of Lieb and Seiringer. We then proceed to describe an interpolation inequality between Golden-Thompson's trace inequality and Jensen's trace inequality.

[02970] On the quantum Tsallis relative entropy of real order

Format : Talk at Waseda University
Author(s) : Yuki Seo (Osaka Kyoiku University)
Abstract : In 2005, Furuichi-Yanagi-Kuriyama showed 1-parameter extension of matrix trace inequalities due to Hiai-Petz, and it revealed relationships between two quantum Tsallis relative entropies. In this talk, we show matrix trace inequalities related to quantum Tsallis relative entropy of real order, and improve on Furuichi-Yanagi-Kuriyama's result by using Furuta inequality.

[02482] On log-sum inequalities

Format : Talk at Waseda University
Author(s) : Supriyo Dutta (National Institute of Technology Agartala)Shigeru Furuichi (Nihon University)
Abstract : I shall present our recently published article entitled "On log-sum inequalities" in Linear and Multilinear Algebra. The log-sum inequality is a fundamental tool which indicates the nonnegativity for the relative entropy. We establish a set of inequalities which are similar to the log-sum inequality. We extend these inequalities for the commutative matrices. In addition, utilizing the L¨owner partial order relation and the Hansen-Pedersen theory for non-commutative positive semi-definite matrices we demonstrate several matrix-inequalities.

[02313] On certain properties of Shannon's Entropy

Format : Talk at Waseda University
Author(s) : Eleutherius Symeonidis (Faculty of Mathematics and Geography, Catholic University of Eichstaett-Ingolstadt)
Abstract : Let $P := (p_1, \ldots, p_n)$ be a discrete probability distribution, $H(P) := -\sum_{j=1}^{n} p_j \log p_j$ its Shannon entropy. Motivated by studies on the permutation entropy of time series of temperatures in combustion experiments we fix an integer $k, 1 \leq k \leq n$,
and consider the largest set $\Delta \subset \mathbb{R}^k$ such that $H(p_1, \ldots, p_{n-k}, p_{n-k+1}, \ldots, p_n) \geq H\left(0, \ldots, 0, \frac{1}{k}, \ldots, \frac{1}{k}\right)$ $(= \log k)$ for all P such that $(p_{n-k+1}, \ldots, p_n) \in \Delta$. In particular, we are interested in the smallest value of p such that $(p, \ldots, p) \in \Delta$.

00739 (3/3) : 4E @A510 [Chair: Hiromichi Ohno]

[02721] The permutation entropy and its applications on full-scale compartment fire data

Format : Talk at Waseda University
Author(s) : Flavia-Corina Mitroi-Symeonidis (Department of Applied Mathematics Academy of Economic Studies Calea Dorobanti 15-17, Sector 1 010552 Bucharest)
Abstract : Given the sparse literature on the usefulness of the entropy in characterizing fire data, we investigate the order characteristics of the compartment fire based on experimental data. We compare known algorithms dedicated to the extraction of the underlying probabilities, checking their suitability to point out the abnormal values and structure of the time series. We claim that the permutation entropy is suitable to detect the occurrence of the flashover and unusual data in fire experiments.

[02772] A Spectral Analysis of The Correlated Random Walk

Format : Talk at Waseda University
Author(s) : Akihiro Narimatsu (The University of Fukuchiyama)Yusuke Ide (Nihon University)
Abstract : In this talk, we consider a spectral analysis of the Correlated Random Walk with the isospectral coin cases. In the Szegedy's quantum walk, our method gives the arcsine law as the lower bound of the time averaged distribution.

[05367] On a class of k-entanglement witnesses

Format : Talk at Waseda University
Author(s) : Hiroyuki Osaka (Ritsumeikan University)
Abstract : Recently, Yang et al.showed that each 2-positive map acting from $\mathcal{M}_3(\mathbb{C})$ into itself is decomposable. It is equivalent to the statement that each PPT state on $\mathbb{C}^3 \otimes \mathbb{C}^3$ has Schmidt number at most 2. It is a generalization of Perez-Horodecki criterion which states that each PPT state on $\mathbb{C}^2 \otimes \mathbb{C}^2$ or $\mathbb{C}^2 \otimes \mathbb{C}^3$ has Schmidt rank 1 i.e. is separable. Natural question arises whether the result of Yang at al. stays true for PPT states on $\mathbb{C}^3 \otimes \mathbb{C}^4$. This question can be considered also in higher dimensions. We construct a positive maps which is suspected for being a counterexample. More generally, we provide a class of positive maps Φ_a between matrix algebras whose k-positivity properties can be easily controlled.
The estimate bounds on the parameter a are better than those derived from the spectral conditions considered by Chru'{s}ci'{n}ski and Kossakowski.
We found that in case where dimensions are differ by one we can give explicit analytic formula for parameter a that guarantee k-positivity.
As an apllication we show that Φ_a detects k-entanglement.

This is mainly based on joint work with Tomasz Mlynik and Marcin Marciniak (arXiv:2104.14058v4, 2022).

[03537] Violation of Bell's Inequality by Classical Correlation via Adaptive Dynamics

Format : Talk at Waseda University
Author(s) : Satoshi Iriyama (Tokyo University of Science)
Abstract : Ohya introduced the adaptive dynamics as subclasses of information dynamics. The notion of adaptive dynamics is helpful to find out characteristic factors in complex systems. In 2001, the chameleon effect proposed by Accardi et al. is the classical dynamics adopting that the local acts of observation may disturb local measurement, and its experimental implementation which can violate Bell's inequality was shown. In this talk, mathematical foundations of the chameleon dynamics and its applications are explained.

[00746] Variational methods for singularities and concentration on low dimensional sets

Session Time & Room :

00746 (1/2) : 5B (Aug.25, 10:40-12:20) @F312

00746 (2/2) : 5C (Aug.25, 13:20-15:00) @F312

Type : Proposal of Minisymposium
Abstract : This mini-symposium focuses on recent developments in the calculus of variations with application to problems in nonlinear elasticity, plasticity, liquid crystals, and foams, with an emphasis on topological defects.

Defects play a prominent role, for example, in superfluidity, superconductivity, and plasticity. Low-energy configurations exhibit lower-dimensional concentration patterns; examples include dislocations, vortices, grain boundaries, interfaces, and phase transitions.

The aim of the mini-symposium is to bring together experts focusing on different aspects of this common big picture, to promote exchange of ideas, and identify new ways of tackling open problems.

[04293] Ginzburg-Landau with Oblique Anchoring and Boojums

Format : Talk at Waseda University
Author(s) : Lia Bronsard (McMaster University)Stan Alama (McMaster University)Dmitry Golovaty (The University of Akron)
Abstract : We study the Ginzburg-Landau functional with oblique angle condition via boundary penalization. We consider the singular limit and for strong anchoring strength, defects will occur in the interior, but for weaker anchoring strength all defects will occur on the boundary. These `boojums'' defects carry a fractional winding number and will occur in ordered pairs along the boundary.   For the ``light'' boojums, we prove an asymptotic convergence. S. Alama, D. Golovaty, P. Mironescu are collaborators.

[04158] Dipole removal for discrete energy minimizers

Format : Talk at Waseda University
Author(s) : Mircea Petrache (Pontificia Catolica Universidad de Chile)Adriana Garroni (University of Rome La Sapienza)Emanuele Spadaro (University of Rome La Sapienza)
Abstract : We consider a minimization problem for vector fields in the plane, allowing discrete vortex-like singularities, and we find conditions on the boundary datum on the boundary of a ball, under which the minimum-energy optimizer must have a single interior singularity. A consequence is that the screw dislocation energy minimizers with continuous boundary datum close enough to $u(\theta) = \theta$ will have exactly one charge.

The approach passes by a discretized version of the problem of independent interest, connected to the initial problem via the Smirnov decomposition of 1-currents, and proved by a discussion based on the MaxFlow - MinCut theorem. The same strategy may apply to a larger class of problems with integer-degree topological singularities.

Extension of the 1-charge result are given for cases where the minimum possible number of interior singularities is larger than 1, and we give counterexamples to further extensions of the result.

[03999] From Volterra's dislocations to strain-gradient plasticity

Format : Talk at Waseda University
Author(s) : Raz Kupferman (The Hebrew University)Cy Maor (The Hebrew university)
Abstract : Dislocations, first classified by Volterra, can be viewed as generated by cut and weld procedures. It is only in the last 15 years that plasticity models have been derived rigorously as limits of models of finitely-many dislocations. In most of these works, the elemental dislocation is modeled as an “admissible” strain field, which is in a sense, a pre-assumed linearization of Volterra's model. I will show how strain gradient plasticity are obtained from Volterra's model.

[01900] Harmonic dipoles in elasticity

Format : Talk at Waseda University
Author(s) : Duvan Henao (Universidad de O'Higgins)Marco Barchiesi (Università degli Studi di Trieste)Carlos Mora-Corral (Universidad Autónoma de Madrid)Rémy Rodiac (Université Paris Saclay)
Abstract : Malý (1993) proved that the relaxation of the neoHookean energy coincides with the neoHookean energy at diffeomorphisms, thus establishing the first existence result for neoHookean materials in 3D. We present some progress on the more explicit understanding of what deformations can fall into the weak closure of regular (injective, orientation-preserving, controlled Jacobian) maps and of the relaxed energy evaluated at deformations with singularities. For the pathological example of Conti & De Lellis (2003) we show that the singular energy is precisely twice the length of the dipole times the area of the bubble across which two portions of the elastic body which were separated in the reference configuration are now in contact in the deformed configuration. This, in turns, coincides with twice the total variation of the singular part of the derivative of the inverse map. We show that in the weak closure all maps have inverses with BV regularity, and in the axisymmetric case establish the Sobolev regularity for the first two components. In this axisymmetric case we obtain, as a lower bound for the singular energy, precise twice the variation of the singular part of the inverse. In the case of map with further SBV regularity for the inverse, we show that the singularities are dipoles, showing that the example of Conti & De Lellis is very generic.

00746 (2/2) : 5C @F312 [Chair: Adriana Garroni]

[03156] effective geometric motions of Ginzburg--Landau equations with potentials of high-dimensional wells

Format : Talk at Waseda University
Author(s) : Yuning Liu (NYU shanghai)
Abstract : We study the co-dimensional one interface limit and geometric motions of parabolic   Ginzburg--Landau systems   with potentials of high-dimensional wells. In particular combining modulated energy methods and weak

convergence methods, we derive a sharp interface limit and the limiting harmonic heat flows in the inner and outer bulk regions segregated by the sharp interface.

[02113] Quasistatic evolution problems for models of geomaterials coupling plasticity and damage

Format : Talk at Waseda University
Author(s) : Vito Crismale (Sapienza Università di Roma)
Abstract : I will discuss existence of quasistatic evolutions for a model proposed by Kazymyrenko and Marigo in 2019, which uses a suitable coupling between plasticity and damage to study the behavior of geomaterials under compression.

[04281] Liquid crystal colloids: from the electrostatic analogy to interaction energies

Format : Talk at Waseda University
Author(s) : Raghavendra Venkatraman (Courant Institute)
Abstract : We discuss some recent progress on nematic liquid crystal colloids, with the goal of deriving simplified descriptions of colloidal suspensions in a liquid crystal matrix. The first half of the talk will provide justification of the so-called "electrostatic analogy" frequently used in physics (and proposed by Brochard and De Gennes in the 70s). The second half will be about interaction energies for paranematic colloids.

[03855] Evolution of vector fields on flexible curves and surfaces

Format : Talk at Waseda University
Author(s) : Georg Dolzmann (University of Regensburg)
Abstract : We discuss some recent progress on a model system consisting of a flexible surface and a vector field defined on the surface in the case in which an interaction between the vector field and the conformation of the surface is present. Recent approaches towards the existence of solutions will be reviewed and short time existence will be established.

The lecture is based on joint work with Christopher Brand (Regensburg), Julia Menzel (Regensburg) and Alessandra Pluda (Pisa).

[00747] Analysis and Numerics on Deep Learning Based Methods for Solving PDEs

Session Time & Room :

00747 (1/3) : 3C (Aug.23, 13:20-15:00) @F403

00747 (2/3) : 3D (Aug.23, 15:30-17:10) @F403

00747 (3/3) : 3E (Aug.23, 17:40-19:20) @F403

Type : Proposal of Minisymposium
Abstract : Various difficult PDE problems from the science and engineering now tend to be solved by numerical methods based on deep learning. This minisymposium focuses on both analytic and numerical aspects of these new methods. The speakers will talk about their recent works on the mechanism and further improvement of variational or/and physics-informed DNN-based solvers with applications to scientific computing problems.

[02903] Deep adaptive sampling for numerical PDEs

Author(s) : Tao Zhou (Chinese Academy of Sciences)
Abstract : Physics-informed neural networks (PINNs) have emerged as an effective technique for solving PDEs in a wide range of domains. It is noticed, however, the performance of PINNs can vary dramatically with different sampling procedures. For instance, a fixed set of (prior chosen) training points may fail to capture the effective solution region (especially for problems with singularities). To

overcome this issue, we present in this work an adaptive strategy, termed the failure-informed PINNs (FI-PINNs), which is inspired by the viewpoint of reliability analysis. The key idea is to define an effective failure probability based on the residual, and then, with the aim of placing more samples in the failure region, the FI-PINNs employs a failure-informed enrichment technique to adaptively add new collocation points to the training set, such that the numerical accuracy is dramatically improved. In short, similar as adaptive finite element methods, the proposed FI-PINNs adopts the failure probability as the posterior error indicator to generate new training points. We prove rigorous error bounds of FI-PINNs and illustrate its performance through several problems.

[03007] Deep Learning for PDEs: Domain Decomposition and Adaptivity

Author(s) : Qifeng Liao (ShanghaiTech University)
Abstract : Deep learning methods currently gain a lot of interest for solving partial differential equations (PDEs). However, significant challenges still exist for these new methods to achieve high accuracy, which include properly defining loss functions and choosing effective collocation points and network structures. In our work, we propose domain decomposition and adaptive procedures to improve the accuracy and efficiency of deep learning based methods.

[03091] Bridging Traditional and Machine Learning-based Algorithms for Solving PDEs: The Random Feature Method

Author(s) : JINGRUN CHEN (University of Science and Technology of China)XURONG CHI (University ofUniversity of Science and Technology of China Science and Technology of China)WEINAN E (AI for Science Institute, Beijing and Center for Machine Learning Research and School of Mathematical Sciences, Peking University)ZHOUWANG YANG (School of Mathematical Sciences, University of Science and Technology of China)
Abstract : One of the oldest and most studied subject in scientific computing is algorithms for solving partial differential equations (PDEs). A long list of numerical methods have been proposed and successfully used for various applications. In recent years, deep learning methods have shown their superiority for highdimensional PDEs where traditional methods fail. However, for low dimensional problems, it remains unclear whether these methods have a real advantage over traditional algorithms as a direct solver. In this work, we propose the random feature method (RFM) for solving PDEs, a natural bridge between traditional and machine learning-based algorithms. RFM is based on a combination of well-known ideas: 1. representation of the approximate solution using random feature functions; 2. collocation method to take care of the PDE; 3. penalty method to treat the boundary conditions, which allows us to treat the boundary condition and the PDE in the same footing. We find it crucial to add several additional components including multi-scale representatio and adaptive weight rescaling in the loss function. We demonstrate that the method exhibits spectral accuracy and can compete with traditional solvers in terms of both accuracy and efficiency. In addition, we find that RFM is particularly suited for problems with complex geometry, where both traditional and machine learning-based algorithms encounter difficulties.

[03011] On deep learning techniques for solving convection-dominated convection-diffusion equations

Author(s) : Derk Frerichs-Mihov (Weierstrass Institute for Applied Analysis and Stochastics)Linus Henning (Free University of Berlin)Derk Frerichs-Mihov (Weierstrass Institute for Applied Analysis and Stochastics / Free University of Berlin)
Abstract : Convection-diffusion equations model the distribution of a scalar quantity in fluids, e.g., the concentration of drugs in blood. Many classical numerical methods produce unphysical values in practical applications when convection is
much stronger than diffusion ([1,2]).
In the last decades, the popularity of deep learning methods has risen sharply due to many success stories, e.g., ([3,4]). This talk brings together deep learning techniques and convection-diffusion equations. It shows challenges and proposes solutions to overcome them.

[04381] Learning Functional Priors and Posteriors from Data and Physics

Author(s) : Xuhui Meng (Huazhong University of Science and Technology)

Abstract : We develop a new Bayesian framework based on deep generative models to quantify uncertainties arising from both noisy and gappy data in predictions of physics-informed neural networks (PINNs) as well as deep operator networks (DeepONets). We test the proposed method for (1) forward/inverse PDE problems; (2) PDE-agnostic physical problems, e.g., 100-dimensional Darcy problem. The results demonstrate that the proposed approach can provide accurate predictions as well as uncertainties given limited and noisy data.

[03134] AI for Combustion

Author(s) : Zhiqin Xu (Shanghai Jiao Tong University)

Abstract : The development of detailed chemistry mechanisms of hydrocarbon fuels paves the way to realistic simulations of practical combustors. However, due to chemistry stiffness, the simulation of large-size detailed mechanisms become forbiddingly expensive, especially for very large-scale simulation. In this talk, I will introduce a deep learning based model reduction method for simplifying chemical kinetics. We also use a deep learning based method to overcome the limitation of using small step-size in simulating the combustion ODE systems.

[03476] DOSnet as a Non-Black-Box PDE Solver: When Deep Learning Meets Operator Splitting

Author(s) : Yuan Lan (Huawei Theory Lab)Zhen Li (Huawei Theory Lab)Jie Sun (Huawei Theory Lab)Yang Xiang (Hong Kong University of Science and Technology)

Abstract : Deep neural networks (DNNs) recently emerged as a promising tool for analyzing and solving complex differential equations arising in science and engineering applications. Alternative to traditional numerical schemes, learning-based solvers utilize the representation power of DNNs to approximate the input-output relations in an automated manner. However, the lack of physics-in-the-loop often makes it difficult to construct a neural network solver that simultaneously achieves high accuracy, low computational burden, and interpretability. In this work, focusing on a class of evolutionary PDEs characterized by decomposable operators, we show that the classical ``operator splitting'' technique can be adapted to design neural network architectures. This gives rise to a learning-based PDE solver, which we name Deep Operator-Splitting Network (DOSnet). Such non-black-box network design is constructed from the physical rules and operators governing the underlying dynamics, and is more efficient and flexible than the classical numerical schemes and standard DNNs. To demonstrate the advantages of our new AI-enhanced PDE solver, we train and validate it on several types of operator-decomposable differential equations. We also apply DOSnet to nonlinear Schr"odinger equations which have important applications in the signal processing for modern optical fiber transmission systems, and experimental results show that our model has better accuracy and lower computational complexity than numerical schemes and the baseline DNNs.

[04359] Residual Minimization for PDEs: Failure of PINN and Implicit Bias

Author(s) : Qixuan Zhou (Shanghai Jiao Tong University)Tao Luo (Shanghai Jiao Tong University)

Abstract : In this talk, we discuss the performance of PINN methods for problems with discontinuities. For linear elliptic PDEs with discontinuous coefficients, we present by experiments that PINN cannot approximate the true solution. We then prove this by introducing a modified equation. And we point out there is still some pattern behind this failure, which is a type of implicit bias. Finally, we will extend some of these results to quasilinear elliptic equations and systems.

00747 (3/3) : 3E @F403 [Chair: Tao Luo]

[03475] Feature Flow Regularization: Improving Structured Sparsity in Deep Neural Networks

Author(s) : YUE WU (The Hong Kong University of Science and Technology)YUAN LAN (The Hong Kong University of Science and Technology)Luchan Zhang (Shenzhen University)Yang Xiang (Hong Kong University of Science and Technology)

Abstract : Pruning is a model compression method that removes redundant parameters and accelerates the inference speed of deep neural networks while maintaining accuracy. We propose a regularization strategy from a new perspective of evolution of features. We propose feature flow regularization (FFR) to penalize the length and total absolute curvature of the trajectories, which implicitly increases the structured sparsity of the parameters. The principle is that short and straight trajectories will lead to an efficient network.

[04428] Asymptotic-Preserving Neural Networks for Multiscale Time-Dependent Linear Transport Equations

Author(s) : Shi Jin (Shanghai Jiao Tong University)Zheng Ma (Shanghai Jiao Tong University)Keke Wu (Shanghai Jiao Tong University)

Abstract : In this paper we develop a neural network for the numerical simulation of time-dependent linear transport equations with diffusive scaling and uncertainties. The goal of the network is to resolve the computational challenges of curse-of-dimensionality and multiple scales of the problem. We first show that a standard Physics-Informed Neural Network (PINN) fails to capture the multiscale nature of the problem, hence justifies the need to use Asymptotic-Preserving Neural Networks (APNNs). We show that not all classical AP formulations are directly fit for the neural network approach.We construct a micro-macro decomposition based neural network, and also build in a mass conservation mechanism into the loss function, in order to capture the dynamic and multiscale nature of the solutions. Numerical examples are used to demonstrate the effectiveness of this APNNs.

[00749] Recent Advances on Preconditioners and Fast Solvers for Nonlinear PDEs

Session Time & Room :

00749 (1/3) : 1C (Aug.21, 13:20-15:00) @E703

00749 (2/3) : 1D (Aug.21, 15:30-17:10) @E703

00749 (3/3) : 1E (Aug.21, 17:40-19:20) @E703

Type : Proposal of Minisymposium

Abstract : Numerical methods for solving nonlinear PDEs are at the heart of many scientific applications in physics, engineering, and biology. Recent advances in developing preconditioners and fast solvers bring significant improvement to the robustness and efficiency of numerical methods for nonlinear PDEs. A variety of novel techniques have been introduced such as nonlinear preconditioning, model order reduction, multiscale methods, heterogeneous computing, and machine learning. This minisymposium is to encourage communication among experts in these fields to discuss cutting-edge topics of numerical methods for nonlinear PDEs and their applications.

[04011] Nonlinear FETI-DP domain decomposition methods combined with deep learning

Format : Talk at Waseda University

Author(s) : Axel Klawonn (University of Cologne)Martin Lanser (University of Cologne)Janine Weber (University of Cologne)

Abstract : In nonlinear-FETI-DP domain decomposition methods the choice of the nonlinear elimination set and of the coarse space have a huge impact on the nonlinear and linear convergence behavior. In this talk, we will show new results combining recently developed approaches for the adaptive choice of the nonlinear elimination set with adaptive coarse spaces. Additionally, we will discuss approaches to improve the computational efficiency and nonlinear convergence by enhancing Nonlinear-FETI-DP with techniques from machine learning.

[03539] A quasi-Newton method with a secant-like diagonal approximation of Jacobian for symmetric sparse nonlinear equations

Format : Talk at Waseda University

Author(s) : Duc Quoc Huynh (National Central University)Feng-Nan Hwang (National Central University)

Abstract : We propose and study a new variant of the quasi-Newton method with a secant-like diagonal approximation of Jacobian (QN-SDAJ) for solving sparse symmetric nonlinear equations (SSNEs). Such problems appear in various scientific computing applications, such as finding critical points that satisfy the first-order necessary condition of unconstrained optimization problems and numerical semilinear elliptic partial differential equations. The advantages of the proposed method are conceptually simple and easy to implement. We establish the global convergence of the proposed method in conjunction with a nonmonotone line search technique under some appropriate assumptions.

Several numerical experiments for some benchmark problems demonstrate the efficiency of QN-SDAJ, which outperforms the alternatives, including exact Newton, nonlinear conjugate gradient, and Broyden--Fletcher--Goldfarb--Shanno (BFGS) methods. In addition, the proposed method can also be used as an effective nonlinear preconditioner to enhance the robustness and speed up the convergence of BFGS, especially for test cases with large dimensions.

[02038] Robustness and Adaptivity of Iterative Solvers

Format : Talk at Waseda University
Author(s) : Chensong Zhang (AMSS)
Abstract : Linear systems arising from coupled PDEs in multiphysics applications could cause robustness problems for iterative solution methods. Solving large-scale linear algebraic systems in an efficient and robust manner is a dream for many computational scientists who work on practical engineering applications. In this talk, we review some old and new techniques for improving the robustness of iterative solvers for large-scale sparse linear equations. In particular, we will discuss methods based on machine learning to select solver components automatically to improve overall simulation performance. Based on this algorithm selection model, a self-adaptive procedure can be derived to improve the robustness of iterative solvers.

[01782] Generalized multiscale finite element method for highly heterogeneous compressible flow

Format : Talk at Waseda University
Author(s) : Shubin Fu (Eastern Institute for Advanced Study)Lina Zhao (City University of Hong Kong)Eric Chung (The Chinese University of Hong Kong)
Abstract : I will present generalized multiscale finite element method for highly heterogeneous compressible flow. We follow the major steps of the GMsFEM to construct a permeability dependent offline basis for fast coarse-grid simulation. To further increase the accuracy of the multiscale method, a residual driven online multiscale basis is added to the offline space. Rich numerical tests on typical 3D highly heterogeneous media are presented to demonstrate the impressive computational advantages of the proposed multiscale method.

[03859] Efficient Schwarz Preconditioning Techniques for Nonlinear Problems Using FROSch

Format : Talk at Waseda University
Author(s) : Alexander Heinlein (Delft University of Technology (TU Delft))Axel Klawonn (University of Cologne)Mauro Perego (Sandia National Laboratories)Sivasankaran Rajamanickam (Sandia National Laboratories)Lea Saßmannshausen (University of Cologne)Ichitaro Yamazaki (Sandia National Laboratories)
Abstract : FROSch (Fast and Robust Overlapping Schwarz) is a framework for parallel Schwarz domain decomposition preconditioners in Trilinos. Due an algebraic approach, meaning that the preconditioners can be constructed from a fully assembled matrix, FROSch is applicable to a wide range of problems. This talk is focused on the application to nonlinear problems, including computational fluid dynamics and land ice simulations. Techniques for improving the efficiency and the use of GPU architectures are discussed.

[01916] BDDC Algorithms for Oseen problems with HDG Discretizations

Format : Talk at Waseda University
Author(s) : Xuemin Tu (University of Kansas)
Abstract : In this talk, the balancing domain decomposition by constraints methods (BDDC) are applied to the linear system arising from the Oseen equation with the hybridizable discontinuous Galerkin (HDG) discretization. The original system is reduced to a subdomain interface problem which is asymmetric indefinite but can be positive definite in a special subspace. Edge/face average constraints can ensure all BDDC preconditioned GMRES iterates stay in this special subspace. Some additional edge/face constraints are used to improve the convergence. When the viscosity is large and the subdomain size is small enough, the number of iterations is independent of the number of subdomains and depends only slightly on the subdomain problem size. When the viscosity is small, the convergence can deteriorate.

[02272] Fully implicit multi-physics solver for advanced fission nuclear power plant

Format : Talk at Waseda University
Author(s) : Han Zhang (Tsinghua University)
Abstract : The fission nuclear reactor power plant is a multi-physics, multi-scale and multi-component coupling system, resulting in a nonlinear partial differential equation system. Fully-implicit methods, such as the Jacobian-free Newton-Krylov method and the Newton-Krylov method, are promising choices for effectively solving such complex nonlinear systems due to their super-linear convergence rate. This talk focuses on the development of fully-implicit solution method for the advanced nuclear reactor power plant, as well as its engineering application.

[01417] Recent advances on high-performance computing algorithms for patient-specific blood flow simulations

Format : Talk at Waseda University
Author(s) : Rongliang Chen (Shenzhen Institutes of Advanced Technology Chinese Academy of Sciences)
Abstract : Patient-specific blood flow simulations have the potential to provide quantitative predictive tools for virtual surgery, treatment planning, and risk stratification. To accurately resolve the blood flows based on the patient-specific geometry and parameters is still a big challenge because of the complex geometry and the turbulence, and it is also important to obtain the results in a short amount of computing time so that the simulation can be used in surgery planning. In this talk, we will precent some recent results of the multi-organ blood flow simulations with patient-specific geometry and parameters on a large-scale supercomputer. Several mathematical, biomechanical, and supercomputing issues will be discussed in detail. We will also report the parallel performance of the methods on a supercomputer with a large number of processors.

00749 (3/3) : 1E @E703 [Chair: Rongliang Chen]

[01407] Nonlinear Preconditioning Strategies Based on Residual Learning for PDEs

Format : Talk at Waseda University
Author(s) : Li Luo (University of Macau)Xiao-Chuan Cai (University of Macau)
Abstract : We present nonlinearly preconditioned inexact Newton methods for solving highly nonlinear system of algebraic equations from the discretization of PDEs. From a large number of numerical experiments, we observe that when the inexact Newton stagnates or fails to converge, the space of residuals often contains a subspace that is difficult to resolve by Newton iteration. We introduce a learning technique to identify this subspace and then improve the convergence.

[02019] ENO schemes with adaptive order for solving hyperbolic conservation laws

Format : Talk at Waseda University
Author(s) : Hua Shen (University of Electronic Science and Technology of China)
Abstract : We present a class of ENO schemes with adaptive order for solving hyperbolic conservation laws. The proposed schemes select the optimal polynomial from several candidates that are reconstructed on stencils of unequal sizes by using a novel strategy. In this way, the schemes give high-order accuracy whenever the data is smooth but avoid the Gibbs phenomenon at discontinuities.

[03281] Energy stable schemes for gradient flows based on the DVD method

Format : Talk at Waseda University
Author(s) : Jizu Huang (Academy of mathematics and systems science, Chinese academy sciences)
Abstract : In this talk, we propose a new framework to construct energy stable scheme for gradient flows based on the discrete variational derivative method. Combined with the Runge--Kutta process, we can build an arbitrary high-order and unconditionally energy stable scheme based on the discrete variational derivative method. The new energy stable scheme is implicit and leads to a large sparse nonlinear algebraic system at each time step, which can be efficiently solved by using an inexact Newton type algorithm. To avoid solving nonlinear algebraic systems, we then present a relaxed discrete variational derivative method, which can construct linear unconditionally second-order energy stable schemes. Several numerical simulations are performed to investigate the efficiency, stability, and accuracy of the newly proposed schemes.

[01460] Scalable multilevel preconditioners for hybrid-DG discretizations of nonlinear cell-by-cell cardiac models

Format : Online Talk on Zoom

Author(s) : Ngoc Mai Monica Huynh (University of Pavia)

Abstract : We present theoretical and numerical results for a scalable and quasi-optimal BDDC preconditioner for Discontinuous Galerkin discretizations of cardiac cell-by-cell models in order to approximate the discontinuous nature of cellular networks.

The resulting discrete cell-by-cell models have discontinuous global solutions across the cell boundaries, hence the proposed BDDC preconditioner is based on appropriate dual and primal spaces with additional constraints which transfer information between cells/subdomains without influencing the overall discontinuity of the global solution.

[00752] Theory and efficient methods for large-scale structured optimization models

Session Time & Room : 2E (Aug.22, 17:40-19:20) @D408

Type : Proposal of Minisymposium
Abstract : This mini-symposium is mainly on large-scale structured optimization models popular in statistical or machine learning community. We focus on the design of efficient algorithms for solving those large-scale structured optimization problems and the analysis of convergence theory of the proposed algorithms.
Organizer(s) : Yangjing ZHANG
Classification : 90C22, 90C46
Minisymposium Program :

00752 (1/1) : 2E @D408 [Chair: Yangjing ZHANG]

[01213] Augmented Lagrangian method for matrix optimization

Format : Talk at Waseda University
Author(s) : Chao Ding (Chinese Academy of Sciences)
Abstract : In this talk, we will introduce some new convergence results on the matrix optimization problems including nonlinear semidefinite programming and nonsmooth optimization on Riemannian manifold.

[02195] Determinantal point processes for sampling minibatches in SGD

Format : Online Talk on Zoom
Author(s) : Rémi Bardenet (Université de Lille)Subhroshekhar Ghosh (National University of Singapore)Meixia Lin (Singapore University of Technology and Design)
Abstract : In this work, we contribute an orthogonal polynomial-based determinantal point process paradigm for performing minibatch sampling in SGD. Our approach leverages the specific data distribution at hand, which endows it with greater sensitivity and power over existing data-agnostic methods. We substantiate our method via a detailed theoretical analysis of its convergence properties, interweaving between the discrete data set and the underlying continuous domain. In particular, we show how specific DPPs and a string of controlled approximations can lead to gradient estimators with a variance that decays faster with the batchsize than under uniform sampling. Coupled with existing finite-time guarantees for SGD on convex objectives, this entails that, for a large enough batchsize and a fixed budget of item-level gradients to evaluate, DPP minibatches lead to a smaller bound on the mean square approximation error than uniform minibatches. Moreover, our estimators are amenable to a recent algorithm that directly samples linear statistics of DPPs without sampling the underlying DPP, thereby reducing computational overhead.

[02194] Bregman Proximal Point Algorithm Revisited: A New Inexact Version and its Inertial Variant

Format : Talk at Waseda University
Author(s) : Lei Yang (Sun Yat-Sen University)Kim-Chuan Toh (National University of Singapore)
Abstract : In this talk, we focus on a general convex optimization problem, which covers various classic problems in different areas and particularly includes many optimal transport related problems arising in recent years. To solve this problem, we revisit the classic Bregman proximal point algorithm (BPPA) and introduce a new inexact stopping condition for solving the subproblems, which can circumvent the underlying feasibility difficulty often appearing in existing inexact conditions when the problem has a complex feasible set. Our inexact condition also covers several existing inexact conditions as special cases and hence makes our inexact BPPA (iBPPA) more flexible to fit different scenarios in practice. As an application to the standard optimal transport (OT) problem, our iBPPA with the entropic proximal term can bypass some numerical instability issues that usually plague the popular Sinkhorn's algorithm in the OT community. The iteration complexity of $O(1/k)$ and the convergence of the sequence are also established for our iBPPA under some mild conditions. Moreover, inspired by Nesterov's acceleration technique, we develop an inertial variant of our iBPPA, denoted by V-iBPPA, and establish the iteration complexity of $O(1/k^{\lambda})$, where $\lambda \geq 1$ is a quadrangle scaling exponent of the kernel function. In particular, when the proximal parameter is a constant and the kernel function is strongly convex with Lipschitz continuous gradient (hence $\lambda = 2$), our V-iBPPA achieves a faster rate of $O(1/k^2)$ just as existing accelerated inexact proximal point algorithms. Some preliminary numerical experiments for solving the standard OT problem are conducted to show the convergence behaviors of our iBPPA and V-iBPPA under different inexactness settings. The experiments also empirically verify the potential of our V-iBPPA for improving the convergence speed.

[02388] On efficient and scalable computation of the nonparametric maximum likelihood estimator in mixture models

Format : Talk at Waseda University
Author(s) : Yangjing ZHANG (Chinese Academy of Sciences)Ying Cui (University of Minnesota)Bodhisattva Sen (Columbia University)Kim-Chuan Toh (National University of Singapore)
Abstract : The nonparametric maximum likelihood estimation is a classic and important method to estimate the mixture models
from finite observations. In this talk, we propose an efficient semismooth Newton based augmented Lagrangian method (ALM). By carefully exploring the structure of the ALM subproblem, we show that the computational cost of the generalized Hessian is independent of the number of grid points. Extensive experiments are conducted to show the effectiveness of our approach.

[00753] Numerical methods for high-dimensional problems

Session Time & Room :

00753 (1/2) : 4C (Aug.24, 13:20-15:00) @G704

00753 (2/2) : 4D (Aug.24, 15:30-17:10) @G704

Type : Proposal of Minisymposium
Abstract : High-dimensional problems appear in various scientific areas and suffers from the notorious “curse of dimensionality” issue. This mini-symposium brings together the scientists working on quantum chemistry, classical and quantum kinetic theory and geophysics, etc., to share and exchanges their ideas in solving high-dimensional problems. Our mini-symposium will highlight the recent developments in both deterministic and particle-based methods. It is expected to elucidate the following questions: 1. Why do we need to solve high-dimensional problems? 2. What are common difficulties? 3. How to alleviate the curse of dimensionality by either novel mathematical methodologies or sophisticated usage of high-performance computing environment?
Organizer(s) : Yingzhou Li, Yunfeng Xiong
Classification : 35Q40, 35Q86, 82C05, 82C10, 65C20

00753 (1/2) : 4C @G704 [Chair: Yingzhou Li]

[04360] An efficient stochastic particle method for high-dimensional nonlinear PDEs

Format : Talk at Waseda University
Author(s) : Sihong Shao (Peking University)
Abstract : We introduce a stochastic particle method (SPM) to solve high-dimensional nonlinear PDEs in the weak sense. The weak formulation is a time-dependent high-dimensional integral, and different test functions can bring us various information about the solution. To determine the dynamics of the particle system, we linearize the nonlinear terms using the previous time step solutions and establish a relationship of weak formulation between adjacent time steps via the Lawson-Euler scheme. The resulting stochastic particles follow the behavior of the solution in an adaptive manner, therefore mitigating curse of dimensionality to a certain extent. Numerical experiments on the 6-D Allen-Cahn equation and 7-D Hamiltonian-Jacobi-Bellman equation demonstrate the accuracy and efficiency of SPM. This work is joint with Zhengyang Lei and Yunfeng Xiong.

[04066] Overcoming the dynamical sign problem via adaptive particle annihilation

Format : Talk at Waseda University
Author(s) : Yunfeng Xiong (Beijing Normal University)
Abstract : The dynamical sign problem poses a fundamental obstacle to particle-based simulations in high dimensional space. To resolve it, we propose an adaptive particle annihilation algorithm, termed Sequential-clustering Particle Annihilation via Discrepancy Estimation (SPADE). SPADE follows a divide-and-conquer strategy: Adaptive clustering of particles via controlling their number-theoretic discrepancies and independent random matching in each cluster. Combining SPADE with the stationary phase approximation, we attempt to simulate the Wigner dynamics in 6-D and 12-D phase space.

[02525] A splitting Hamiltonian Monte Carlo method for efficient sampling

Format : Talk at Waseda University
Author(s) : Lei Li (Shanghai Jiao Tong University)Lin Liu (Shanghai Jiao Tong University)Yuzhou Peng (Shanghai Jiao Tong University)
Abstract : In this talk, I will introduce a splitting Hamiltonian Monte Carlo algorithm, which can be computationally efficient when combined with the random mini-batch strategy. By splitting the potential energy into numerically nonstiff and stiff parts, one makes a proposal using the nonstiff part, followed by a Metropolis

rejection step using the stiff part that is often easy to compute. The splitting allows efficient sampling from systems with singular potentials and/or multiple potential barriers. We also use random batch strategies to reduce the computational cost in generating the proposals for problems arising from many-body systems and Bayesian inference, and estimate both the strong and the weak errors in the Hamiltonian induced by the random batch approximation.

[02255] Ergodicity and sharp error estimate of Stochastic Gradient Langevin Dynamics

Format : Talk at Waseda University
Author(s) : Yuliang Wang (Shanghai Jiao Tong University)
Abstract : We establish a sharp error estimate for the Stochastic Gradient Langevin Dynamics (SGLD). Under mild assumptions, we obtain a uniform-in-time $O(\eta^2)$ bound for the KL-divergence between SGLD and the Langevin diffusion, where η is the step size. Based on this, we are able to obtain an $O(\eta)$ bound for its sampling error in terms of Wasserstein or total variation distances. Moreover, we prove the geometric ergodicity of SGLD algorithm under W_1 distance without global convexity.

00753 (2/2) : 4D @G704 [Chair: Yunfeng Xiong]

[04069] Multi-level Monte Carlo methods in stochastic density functional theory

Format : Talk at Waseda University
Author(s) : Huajie Chen (Beijing Normal University)
Abstract : The stochastic density functional theory (sDFT) has become an attractive approach in electronic structure calculations. The computational complexity of Hamiltonian diagonalization is replaced by introducing a set of random orbitals leading to sub-linear scaling of evaluating the ground-state observables. This work investigates the convergence and acceleration of the self-consistent field (SCF) iterations for sDFT in the presence of statistical error. We also study some variance reduction schemes by multi-level Monte Carlo methods that can accelerate the SCF convergence.

[04185] Inchworm Monte Carlo Method for Spin Chain Models in Open Quantum Systems

Format : Talk at Waseda University
Author(s) : Zhenning Cai (National University of Singapore)
Abstract : We consider open quantum systems where the quantum system is coupled to a harmonic bath. When the coupling is weak, we can mimic Feynman's methodology to represent the dynamics as the sum of infinite integrals represented by diagrams. In this talk, we will discuss an efficient diagrammatic approach, known as the inchworm Monte Carlo method, to compute the observables in open quantum systems. Applications to spin chain models will be considered in the numerical tests.

[04220] A short-memory operator splitting scheme for constant-Q viscoelastic wave equation

Format : Talk at Waseda University
Author(s) : Yunfeng Xiong (Beijing Normal University)Xu Guo (Shandong University)
Abstract : We propose a short-memory operator splitting scheme for solving the constant-Q wave equation, where the fractional stress-strain relation contains multiple Caputo fractional derivatives with order much smaller than 1. The key is to exploit its extension problem by converting the flat singular kernels into strongly localized ones, so that the major contribution of weakly singular integrals over a semi-infinite interval can be captured by a few Laguerre functions with proper asymptotic behavior. An operator splitting scheme is introduced to solve the resulting set of equations, where the auxiliary dynamics can be solved exactly, so that it gets rid of the numerical stiffness and discretization errors. Numerical experiments on both 1-D diffusive wave equation and 2-D constant-Q P-and S-wave equations are presented to validate the accuracy and efficiency of the proposed scheme.

[04363] Solving Boltzmann equation with neural sparse representation

Format : Talk at Waseda University
Author(s) : Zhengyi Li (Peking Univeristy)Yanli Wang (Beijing Computational Science Research Center)Hongsheng Liu (Huawei Technologies Co. Ltd)Zidong Wang (Huawei Technologies Co. Ltd)Bin Dong (Beijing International Center for Mathematical Research & Center for Machine Learning Research, Peking University)
Abstract : We consider the neural sparse representation to solve Boltzmann equation. The different low-rank representations are utilized in the microscopic velocity for the BGK and quadratic collision model, resulting in a significant reduction in the degree of freedom. We approximate the discrete velocity distribution in the BGK model using the canonical polyadic decomposition. For the quadratic collision model, a data-driven, SVD-based linear basis is built based on the BGK solution.

[00754] Regularization models and sampling algorithms in statistics and inverse problems

Session Time & Room :

00754 (1/2) : 1E (Aug.21, 17:40-19:20) @E503

00754 (2/2) : 2C (Aug.22, 13:20-15:00) @E503

Type : Proposal of Minisymposium
Abstract : Inverse problems involve the determination of unknown parameters from observational data and mathematical models linking those parameters to the data. Bayesian inference offers a framework to estimate the solution in terms of a posterior probability distribution. Oftentimes, the computation of the posterior requires application of Markov chain Monte Carlo (MCMC) methods. Direct implementation of these techniques becomes a challenge when the target parameters have a particular structure and are high-dimensional. This mini-symposium aims at presenting recent developments in sampling methods and prior/regularization models in statistics and inverse problems, including novel MCMC techniques, Monte Carlo estimators, and priors encoding structural information.
Organizer(s) : Felipe Uribe, Andreas Rupp
Classification : 62F15, 65C05, 65R32

[03567] Efficient Bernoulli Factory MCMC

Format : Talk at Waseda University
Author(s) : Dootika Vats (Indian Institute of Technology Kanpur)Flávio Gonçalves (Universidade Federal de Minas Gerais)Krzysztof Łatuszyński (University of Warwick)Gareth Roberts (University of Warwick)
Abstract : Accept-reject based Markov chain Monte Carlo (MCMC) algorithms have traditionally utilised acceptance probabilities that can be explicitly written as a function of the ratio of the target density at the two contested points. This feature is rendered almost useless in Bayesian posteriors with unknown functional forms. We introduce a new family of MCMC acceptance probabilities that has the distinguishing feature of not being a function of the ratio of the target density at the two points. We present a stable Bernoulli factory that generates events within this class of acceptance probabilities. The efficiency of our methods rely on obtaining reasonable local upper or lower bounds on the target density and we present an application of MCMC on constrained spaces where this is reasonable.

[03753] Sampling of Student's t and stable priors for edge-preserving Bayesian inversion

Format : Talk at Waseda University
Author(s) : Felipe Uribe (Lappeenranta-Lahti University of Technology)
Abstract : The identification of sharp features in the solution is a critical aspect of many large-scale Bayesian inverse problems. Markov random field (MRF) priors based on heavy-tailed distributions have proven effective in achieving piecewise constant behavior. This study reexamines the use of Student's t and alpha stable MRFs in this context. To facilitate computation of the resulting posterior distribution, we propose a scale mixture formulation of the MRF priors. This formulation has the advantage of expressing the prior as a conditionally Gaussian distribution that depends on auxiliary hyperparameters. We discuss a Gibbs sampler to solve the hierarchical formulation of the Bayesian inverse problem. The approach is illustrated using applications from imaging science.

[04286] Comparison of pseudo-marginal Markov chains via weak Poincaré inequalities

Format : Talk at Waseda University
Author(s) : Andi Qi Wang (University of Warwick)Christophe Andrieu (University of Bristol)Anthony Lee (University of Bristol)Sam Power (University of Bristol)
Abstract : I will discuss the use of a certain class of functional inequalities known as weak Poincaré inequalities to bound convergence of Markov chains to equilibrium. This enables the straightforward and transparent derivation of subgeometric convergence bounds for methods such pseudo-marginal MCMC methods for intractable likelihoods, which have been used extensively in the context of Bayesian Inverse Problems.

[04985] CUQIpy: Computational Uncertainty Quantification for Inverse Problems in Python

Format : Talk at Waseda University
Author(s) : Nicolai André Brogaard Riis (Technical University of Denmark)
Abstract : We present CUQIpy, a versatile open-source Python package for computational uncertainty quantification (UQ) in inverse problems using a Bayesian framework. This talk highlights CUQIpy's high-level modeling framework with concise syntax, enabling intuitive problem specification, and showcasing its efficient sampling strategies, automatic sampler selection, and test problem library. Designed to handle large-scale problems and support various probability distributions, CUQIpy streamlines the UQ process, serving as a powerful tool for a diverse set of inverse problems.

00754 (2/2) : 2C @E503 [Chair: Felipe Uribe]

[05558] Gaussian likelihoods for non-Gaussian data

Format : Talk at Waseda University
Author(s) : Heikki Haario (University of Lappeenranta)
Abstract : Various modelling situations – chaotic dynamics, stochastic differential equations, random patterns by the Turing reaction-diffusion systems, cellular automata– share the analogy that a fixed model parameter corresponds to a family of solutions rather than a fixed deterministic one. This may be due to extreme sensitivity with respect to the initial values, randomized or unknown initial values, or explicit stochasticity of the system. Standard methods based on directly measuring the distance between model and data are no more available. We discuss a unified construction of Gaussian likelihoods for such 'intractable' situation, where the raw data is far from Gaussian. Examples cover the cases in the above list of modelling situations.

[05515] Multi-output multilevel best linear unbiased estimators via semidefinite programming

Format : Talk at Waseda University
Author(s) : Matteo Croci (University of Texas at Austin)Karen E. Willcox (University of Texas at Austin)Stephen J. Wright (University of Wisconsin - Madison)
Abstract : Multifidelity forward uncertainty quantification (UQ) problems often involve multiple quantities of interest and heterogeneous models (e.g., different grids, equations, dimensions, physics, surrogate and reduced-order models). While computational efficiency is key in this context, multi-output strategies in multilevel/multifidelity methods are either sub-optimal or non-existent. In this talk we extend multilevel best

linear unbiased estimators (MLBLUE) to multi-output forward UQ problems and we present new semidefinite programming formulations for their optimal setup. Not only do these formulations yield the optimal number of samples required, but also the optimal selection of low-fidelity models to use. While existing MLBLUE approaches are single-output only and require a non-trivial nonlinear optimization procedure, the new multi-output formulations can be solved reliably and efficiently. We demonstrate the efficacy of the new methods and formulations in practical UQ problems with model heterogeneity.

[03923] Simulating rare events with Stein variational gradient descent

Format : Talk at Waseda University
Author(s) : Max Ehre (Technical University of Munich)Iason Papaioannou (Technical University of Munich)Daniel Straub (Technical University of Munich)
Abstract : Stein variational gradient descent (SVGD) is an approach to sampling from Bayesian posterior distributions. We repurpose SVGD for simulating rare events with probabilities 10^{-5} -- 10^{-12}. We employ a tempered version of SVGD to sample from an approximately optimal importance sampling density. Several examples are used to benchmark the efficacy of our approach against state-of-the-art methods for estimating rare event probabilities.

[00760] Improving Reproducibility, Trustworthiness and Fairness in Machine Learning

Session Time & Room :

00760 (1/2) : 2C (Aug.22, 13:20-15:00) @E803

00760 (2/2) : 2D (Aug.22, 15:30-17:10) @E803

Type : Proposal of Minisymposium
Abstract : The widespread uptake of machine learning for completing routine and complex tasks has been an ambition that feels closer and closer every year. There is currently a well-known reproducibility crisis impacting machine learning-based science which could damage public confidence in the tools and hamper a rapid uptake. The diverse array of speakers in this minisymposium will present a range of talks focussing on practical solutions to different aspects of the reproducibility crisis, ways to address inequalities in algorithm performance to improve fairness, improving explainability of models, and methods to assess the robustness of algorithms.
Organizer(s) : Michael Roberts, Daniel Kreuter
Classification : 68T01, 68T07, 68P27, 92C50
Minisymposium Program :

00760 (1/2) : 2C @E803

[01736] Improving reproducibility, trustworthiness and fairness for diverse applications of machine learning

Author(s) : Hirotaka Takahashi (Tokyo City University)
Abstract : Machine learning is applied to a diverse set of problems in our group. For example, research on gravitational wave physics and astronomy, development of traffic safety training and skills education methods, athlete support system of various sports, application to education to collaborate between teachers and machine learning etc.. In this presentation, we would like to focus on various applications and discuss how we can improve reproducibility, trustworthiness and fairness in machine learning.

[01850] Multi-domain & Multi-task Generalisation on Real-World Clinical Data

Author(s) : Daniel Kreuter (University of Cambridge)Samuel Tull (University of Cambridge)
Abstract : Machine learning models have been holding the promise to revolutionise healthcare for several years. However, we rarely see promising approaches translate into deployment in the clinic. Often, this is due to an unexpected drop in performance when deploying the model on unseen test data due to domain shift. Our novel "Disentanglement Autoencoder" approach allows for multiple domains and tasks, both continuous and categorical, creating a disentangled embedding which can be used for multiple classification tasks.

[01993] Classification of datasets with imputed missing values: does imputation quality matter?

Author(s) : Tolou Shadbahr (University of Helsinki)Michael Thomas Roberts (University of Cambridge)Jan Stanczuk (University of Cambridge)Julian Gilbey (University of Cambridge)Philip Teare (AstraZeneca)Sören Dittmer (University of Cambridge)MAtthew Thorpe (University of Manchester)Ramon Vinas Torne (University of Cambridge)Evis Sala (University of Cambridge)Pietro Lio (University of Cambridge)Mishal Patel (AstraZeneca)James H.F. Rudd (University of Cambridge)Tuomas Mirtti (university of Helsinki)Antti Sakari Rannikko (universiity of Helsinki)John Aston (University of Cambridge)Jing Tang (University of Helsinki)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : Classifying samples in incomplete datasets is a common non-trivial task. Missing data is commonly observed in real-world datasets. Missing values are typically imputed, followed by classification of the now complete samples. Often, the focus is to optimize the downstream classification performance. In this talk, we highlight the serious consequences of using poorly imputed data, demonstrate how the common quality measures for measuring imputation quality are flawed, and introduce an improved class of imputation quality measures.

[02088] A critical look: overly optimistic results on the TPEHGDB dataset

Author(s) : Gilles Vandewiele (IDLab, Ghent)
Abstract : I will discuss the overly optimistic prediction results that arise when applying oversampling on data before partitioning into a train and test set. Specifically, I will present a case study on predicting preterm birth using the TPEHG database where many studies report near-perfect predictive performances due to making a fundamental mistake. After correcting this mistake, the predictive power of the models becomes similar to a coin toss.

00760 (2/2) : 2D @E803

[02239] Software engineering for data science

Author(s) : Sören Dittmer (Uni Cambridge)
Abstract : Despite democratized data science tools, developing a trustworthy and effective data science system (DSS) is becoming increasingly challenging. The lack of software engineering (SE) skills and perverse incentives are among the root causes. We analyze why SE and building large complex systems, in general, is hard. We identify how SE addresses those difficulties and discuss how to adapt the insides to DSSs. We emphasize two key development philosophies: incremental growth and feedback loops.

[02265] Leakage and the reproducibility crisis in ML-based science

Author(s) : Sayash Kapoor (Princeton University)Arvind Narayanan (Princeton University)
Abstract : As quantitative fields adopt ML methods, it is important to ensure reproducibility. We show that data leakage is a widespread problem and has led to severe reproducibility failures. Through a literature survey of research in communities that adopted ML methods, we show that errors have been found in 17 fields, collectively affecting hundreds of papers and leading to wildly overoptimistic conclusions. We propose model info sheets to detect and prevent leakage in ML-based science.

[02340] ShearletX: A Mathematical Approach Towards Explainability

Author(s) : Gitta Kutyniok (LMU Munich)Stefan Kolek (LMU Munich)Robert Windesheim (LMU Munich)Hector Andrade Loarca (LMU Munich)Ron Levie (Technion)
Abstract : Automated decision making using machine learning, in particular deep learning, is becoming an increasingly important component of modern technical systems and often affects humans directly. In this talk, we will present an explainability approach, coined ShearletX, based on a combination of information theory and applied harmonic analysis, which not only often outperforms state-of-the-art methods, but is also accessible to a mathematical analysis.

[02574] A tale of two crises: COVID-19 and ML reproducibility

Author(s) : Michael Thomas Roberts (University of Cambridge)
Abstract : Machine learning, like many fields before it, is suffering from a reproducibility crisis. In this talk we will give an overview of four different domains in which issues have been identified: (a) imaging, (b) missing data imputation, (c) learning at scale and (d) engineering of codebases. We also present solutions to problems identified.

[00761] Recent Advances on quadrature methods for integral equations and their applications

Session Time & Room :

00761 (1/3) : 1C (Aug.21, 13:20-15:00) @A510

00761 (2/3) : 1D (Aug.21, 15:30-17:10) @A510

00761 (3/3) : 1E (Aug.21, 17:40-19:20) @A510

Type : Proposal of Minisymposium
Abstract : Numerical methods based on integral equations are powerful tools for simulating physical systems that arise in fluid mechanics, acoustics, electromagnetics, and many other fields. A crucial component of any efficient integral equation solver is a specialized quadrature method for the discretization of the underlying integral operators. This mini-symposium will focus on the main challenges in quadrature research including accurate evaluation of singular and near-singular integrals associated with surface and volume potentials, adaptive discretization in complex geometries, and the efficient implementation of quadrature schemes in practical applications.
Organizer(s) : Anna-Karin Tornberg, Hai Zhu, Bowei Wu
Classification : 65R20, 65N38
Minisymposium Program :

00761 (1/3) : 1C @A510 [Chair: Bowei Wu]

[04432] A High-Order Close Evaluation Scheme of Helmholtz Layer Potentials in 3D

Format : Talk at Waseda University
Author(s) : Hai Zhu (Flatiron Institute)Shidong Jiang (Flatiron Institute)
Abstract : We present an efficient high-order discretization scheme for the evaluation of the Helmholtz layer potentials on smooth surfaces in three dimensions. The scheme is panel based and applies an analytical surface to line integral conversion on each panel to evaluate single layer, double layer, adjoint double layer, and hypersingular potentials accurately. A new basis approximation scheme tailed for Helmholtz kernels is proposed. Both nearly singular and singular cases are supported via the same recursive framework.

[04811] Special quadrature via line extrapolation, with application to Stokes flow

Format : Talk at Waseda University
Author(s) : Joar Bagge (KTH Royal Institute of Technology)Anna-Karin Tornberg (KTH Royal Institute of Technology)
Abstract : In integral equations, special quadrature methods are needed to perform singular or nearly singular integration. We consider one such method, sometimes called the "Hedgehog method", based on extrapolation (or interpolation) along a line. Different strategies for selecting the placement of sampling points along the line are investigated. We consider extrapolation using polynomials or rational functions. The resulting methods are compared with quadrature by expansion (QBX) in the context of Stokes flow containing rigid rodlike particles.

[05076] Corrected trapezoidal rules for boundary integral methods on non-parametrized surfaces

Format : Talk at Waseda University
Author(s) : Olof Runborg (KTH Royal Institute of Technology)Richard Tsai (The University of Texas at Austin)Yimin Zhong (Auburn University)Federico Izzo (KTH Royal Institute of Technology)
Abstract : We present higher-order quadratures for a family of boundary integral operators with application to the linearized Poisson-Boltzmann equation. Using the Implicit Boundary Integral formulation, surface point singularities in a layer potential extend along the surface normal lines. In this volumetric setting, we use the trapezoidal rule, and develop higher-order quadratures by correcting it in nodes close to the singularity line with weights dependent on the singularity type and geometrical information extracted from the non-parametrized surface.

[03610] Quadrature errors for layer potentials near surfaces with spherical topology

Format : Talk at Waseda University
Author(s) : Chiara Sorgentone (Sapienza, Università di Roma)Anna-Karin Tornberg (KTH Royal Institute of Technology)
Abstract : Numerical simulations often involve 3D objects with spherical topology, e.g. rigid particles, drops, vesicles. When the underlying numerical method is based on boundary integral equations, standard quadrature rules can yield large errors in computing the layer potentials if the distance between the surfaces is too small and the associated integrals become nearly singular. We will present numerical and analytical approaches to efficiently evaluate the quadrature error estimates for these situations.

00761 (2/3) : 1D @A510 [Chair: Anna-Karin Tornberg]

[03612] Euler-Maclaurin formulas for near-singular integrals

Format : Talk at Waseda University
Author(s) : Bowei Wu (University of Massachusetts Lowell)
Abstract : Near-singular integrals frequently arise in fluid dynamics, material science, and many other scientific applications, where close fluid-structure interactions are common. Numerical approximation of near-singular integrals thus has practical importance. Approximating near-singular integrals using regular quadrature methods is in general inefficient and expensive. But more efficient quadrature rules can be developed by modifying regular quadrature rules using an error correction approach. We introduce new generalized Euler-Maclaurin formulas that are tailored to a family of near-singular functions. High-order accurate modified Trapezoidal quadrature rules are then derived based on these formulas.

[03009] Near singularity errors in boundary integrals: identification, estimation and swapping

Format : Talk at Waseda University
Author(s) : Ludvig af Klinteberg (Mälardalen University)
Abstract : Evaluating a layer potential close to its source geometry poses numerical difficulties due to the presence of a near singularity. In this presentation I will discuss how the singularity can be understood in terms of its complexified preimage in the parametrization of the source geometry. Finding the preimage numerically allows us to both estimate quadrature errors to high precision, and derive new and more capable quadrature methods.

[04640] An adaptive discretization technique for boundary integral equations in the plane

Format : Talk at Waseda University
Author(s) : Adrianna Gillman (University of Colorado, Boulder)Yabin Zhang (Westlake University)
Abstract : Typically the discretization of integral equations on two dimensional complex geometries involves the use of a panel based quadrature (such as variants of Gaussian quadrature). The placement of the panels is often ad hoc and based on being able to integrate quantities such as arc-length and/or curvature to a desired accuracy. These quantities do not necessarily correspond to what is needed to achieve accuracy in the solution to a partial differential equation. Alternatively, a refinement strategy based on looking at relative error and wisely choosing which part of the geometry to refine can be done but this involves global solves which can be prohibitively expensive. In this talk, we will present an adaptive discretization technique which is guaranteed to achieve the desired accuracy and does not require the inversion of a full discretized integral equation at each step in the refinement process. Numerical results will illustrate the performance of the method.

[05159] A fully adaptive, high-order, fast Poisson solver for complex two-dimensional geometries

Format : Talk at Waseda University
Author(s) : Daniel Fortunato (Flatiron Institute)David B Stein (Flatiron Institute)Alex H Barnett (Flatiron Institute)
Abstract : We present a new framework for the fast solution of inhomogeneous elliptic boundary value problems in domains with smooth boundaries. High-order solvers based on adaptive box codes or the fast Fourier transform can efficiently treat the volumetric inhomogeneity, but require care to be taken near the boundary to ensure that the volume data is globally smooth. We avoid function extension or cut-cell quadratures near the boundary by dividing the domain into two regions: a bulk region away from the boundary that is efficiently treated with a truncated free-space box code, and a variable-width boundary-conforming strip region that is treated with a spectral collocation method and accompanying fast direct solver. Particular solutions in each region are then combined with layer potentials to yield the global solution. The resulting solver has an optimal computational complexity of $O(N)$ for an adaptive discretization with N degrees of freedom. We demonstrate adaptive resolution of volumetric data, boundary data, and geometric features across a wide range of length scales, to typically 10-digit accuracy.

00761 (3/3) : 1E @A510 [Chair: Hai Zhu]

[02383] Is polynomial interpolation in the monomial basis unstable?

Format : Talk at Waseda University
Author(s) : Zewen Shen (University of Toronto)Kirill Serkh (University of Toronto)
Abstract : Polynomial interpolation in the monomial basis is a key step in a number of popular quadrature methods for integral equations. We will show that, despite its ill-conditioning, the monomial basis is generally as good as a
well-conditioned polynomial basis for interpolation, provided that the Vandermonde matrix has a condition number smaller than the reciprocal of machine epsilon. We will also explore some applications of our analysis.

[04278] A new boundary integral equation solver for problems in exteriors of open arcs

Format : Talk at Waseda University
Author(s) : Abinand Gopal (Yale University)Shidong Jiang (Flatiron Institute)Vladimir Rokhlin (Yale University)
Abstract : When solving a constant-coefficient elliptic PDE, it is often convenient to first reformulate the problem as a boundary integral equation. This is usually done by representing the solution as an unknown density function times a kernel function integrated over the boundary of the domain. The choice of kernel is usually dictated by the

boundary conditions and made such that the resulting equation for the density is a second kind Fredholm integral equation.

However, when the problem is posed on the exterior of an arc in 2D or a surface in 3D, this becomes more complicated and the usual single layer and double layer representations run into difficulties. In this talk, we present a new solver for this regime. We use a representation based on the composition of standard layer potential with a hypersingular operator and compute the kernel of the composite operator directly. We then solve the resulting linear system with a direct solver.

[04717] Density interpolation methods for volume integral operators

Format : Talk at Waseda University
Author(s) : Carlos Perez-Arancibia (University of Twente)Thomas G. Anderson (Rice University)Luiz M. Faria (INRIA/ENSTA Paris)Marc Bonnet (CNRS/ENSTA Paris)
Abstract : This talk outlines a novel class of high-order methods for the efficient numerical evaluation of volume potentials (VPs) defined by volume integrals over complex geometries. Inspired by the Density Interpolation Method (DIM) for boundary integral operators, the proposed methodology leverages Green's third identity and a local polynomial interpolation of the density function to recast a given VP as a linear combination of surface-layer potentials and a volume integral with a regularized (bounded or smoother) integrand. The layer potentials can be accurately and efficiently evaluated inside and outside the integration domain using existing methods (e.g. DIM), while the regularized volume integral can be accurately evaluated by applying elementary quadrature rules to integrate over structured or unstructured domain decompositions without local numerical treatment at and around the kernel singularity. The proposed methodology is flexible, easy to implement, and fully compatible with well-established fast algorithms such as the Fast Multipole Method and H-matrices, enabling VP evaluations to achieve linearithmic computational complexity. To demonstrate the merits of the proposed methodology, we applied it to the Nyström discretization of the Lippmann-Schwinger volume integral equation for frequency-domain Helmholtz scattering problems in piecewise-smooth variable media.

[05303] Recursive product integration schemes for volume potentials on irregular domains

Format : Talk at Waseda University
Author(s) : shravan veerapaneni Hai Zhu (Flatiron Institute)
Abstract : We will discuss a new volume potential evaluation scheme for Gaussian and Laplace kernel in complex domains. The volume integral is computed by applying Green's theorem to convert these smooth or singular domain integrals on a volume mesh to a set of line integrals on the boundary skeleton of the volume mesh. This new approach allows easier integral-equation based solver implementation in complex domains, with much fewer restrictions on leaf level box refinement.

[00763] Long-time dynamics of numerical methods for nonlinear evolution equations

Session Time & Room :

00763 (1/3) : 4C (Aug.24, 13:20-15:00) @E606

00763 (2/3) : 4D (Aug.24, 15:30-17:10) @E606

00763 (3/3) : 4E (Aug.24, 17:40-19:20) @E606

Type : Proposal of Minisymposium
Abstract : The numerical simulation of many physical systems requires an understanding of solutions which goes beyond mere numerical accuracy - they possess invariant structure and qualitative features that distinguish physically meaningful from spurious behaviour. This leads to the fundamental question to what extend such features of the underlying system can be preserved in the numerical flow, in particular over times much longer than is guaranteed by local error estimates. The proposed minisymposium brings together experts from computational mathematics to provide an overview of current state-of-the-art and recent advances in the study and design of methods for evolution equations with favourable long-time behaviour.
Organizer(s) : Yue Feng, Georg Maierhofer, Katharina Schratz

Classification : 65M15, 65M70, 35Q99, Long-time Dynamics, Geometric Numerical Integration, Error Analysis
Minisymposium Program :

00763 (1/3) : 4C @E606 [Chair: Yue Feng]

[03792] Bourgain techniques for error estimates at low regularity

Format : Talk at Waseda University
Author(s) : Alexander Ostermann (Universität Innsbruck)Lun Ji (Universität Innsbruck)Frédéric Rousset (Université Paris-Saclay)Katharina Schratz (Sorbonne Université)
Abstract : Standard numerical integrators suffer from order reduction when applied to nonlinear dispersive equations with non-smooth initial data. For such problems, we present filtered integrators that exhibit superior convergence rates at low regularity. Furthermore, due to the nonexistence of suitable embedding results, the error analysis at very low regularity cannot be carried out in standard Sobolev spaces. Instead, new techniques are required. They are based on Bourgain's seminal work and will be sketched in the talk.

[01832] Improved uniform error bounds of the time-splitting methods for the long-time (nonlinear) Schr"odinger equation

Format : Talk at Waseda University
Author(s) : Yue Feng (Laboratoire Jacques-Louis Lions)
Abstract : In this talk, I will present the improved uniform error bounds of the time-splitting Fourier pseudospectral methods for the long-time dynamics of the Schr"odinger equation with small potential and the nonlinear Schr"odinger equation with weak nonlinearity. The main technique introduced is the regularity compensation oscillation (RCO), which control the high frequency modes by the regularity of the exact solution and the low frequency modes by phase cancellation and energy method.

[04274] A symmetric low-regularity approximation to the nonlinear Schrödinger equation

Format : Talk at Waseda University
Author(s) : Yvonne Alama Bronsard (Sorbonne Université, LJLL)
Abstract : In this talk we will discuss the approximation to nonlinear dispersive equations which ask for low-regularity assumptions on the initial data, both for deterministic and random initial data.
We will put forth a novel time discretization to the nonlinear Schrödinger equation which allows for low-regularity approximation while maintaining good long-time preservation of the density and energy on the discrete level

[04742] Symmetric low regularity integrators via a forest formula

Format : Talk at Waseda University
Author(s) : Yvain Bruned (Université de Lorraine)
Abstract : In this work, we will present general low regularity schemes that should encompass some of the symmetries of a given dispersive PDEs. We extend the low resonance decorated trees approach to a richer framework where we explore different ways of iterating Duhamel'formula and interpolating the lower part of the resonance for a Taylor approximation. This gives more degrees of freedom, encapsulated via a new forest formula that provides the general form for these new schemes. From this formula, we are able to derive conditions on the coefficients for finding new symmetric schemes. We believe that such an approach could tackle other symmetries.

00763 (2/3) : 4D @E606 [Chair: Georg Maierhofer]

[04423] Quantum computation of partial differential equations

Format : Talk at Waseda University
Author(s) : Shi Jin (Shanghai Jiao Tong University)
Abstract : Quantum computers have the potential to gain algebraic and even up to exponential speed up compared with its classical counterparts, and can lead to technology revolution in the 21st century. Since quantum computers are designed based on quantum mechanics principle, they are most suitable to solve the Schrodinger equation, and linear PDEs (and ODEs) evolved by unitary operators. The most efficient quantum PDE solver is quantum simulation based on solving the Schrodinger equation. It became challenging for general PDEs, more so for nonlinear ones. Our talk will cover two topics:

1. We introduce the "warped phase transform" to map general linear PDEs and ODEs to Schrodinger equation or with unitary evolution operators in higher dimension so they are suitable for quantum simulation;
2. For (nonlinear) Hamilton-Jacobi equation and scalar nonlinear hyperbolic equations we use the level set method to map them—exactly—to phase space linear PDEs so they can be implemented with quantum algorithms and we gain quantum advantages for various physical and numerical parameters.

[05333] Asymptotic expansions for the linear PDEs with oscillatory input terms: Analytical form and error analysis

Format : Talk at Waseda University
Author(s) : Karolina Joanna Kropielnicka (Institute of Mathematics of Polish Academy of Sciences)
Abstract : Partial differential equations with highly oscillatory input term are hardly ever solvable analytically and they are difficult to treat numerically. Modulated Fourier expansion used as an ansatz is a well known and extensively investigated tool in asymptotic numerical approach for this kind of problems.

In this talk I will consider input term with single frequency and will show that the ansatz need not be assumed – it can be derived naturally while developing formulas for expansion coefficients. Moreover I will present the formula describing the error term and its estimates. Theoretical investigations will be illustrated by results of the computational simulations.

[03756] A new picture on the Strang Splitting

Format : Talk at Waseda University
Author(s) : Juan Del Valle (University of Gdansk)Karolina Kropielnicka (Polish Academy of Sciences)
Abstract : Strang splitting is a well-established and widely used technique for finding approximate solutions of linear differential equations of the type u'=(A+B)u, where A and B are time-independent components. However, it can also be used for the case of time-dependent component B(t) after the application of the mid-point quadrature rule at the level of the Magnus expansion. However, the error estimate is absent in the case of singular cases of unbounded operators B(t).

In this talk, I will show how Strang splitting scheme for time-dependent components can be derived using the Duhamel formula. Based on this approach, I will (i) present a new proof of convergence of this scheme and (ii) elaborate on the possibilities brought by this approach for higher order methods. A concrete analysis of the error estimated and numerical simulations will be presented for the physically relevant example of a hydrogen atom featuring the singular Coulomb potential.

[05308] The role of breathers in the formation of extreme ocean waves

Format : Talk at Waseda University
Author(s) : Amin Chabchoub (Kyoto University)
Abstract : The modulation instability is a fundamental mechanism, which explains localized wave focusing processes in dispersive wave systems. When considering the nonlinear Schrödinger equation as underlying wave model, exact breather solutions are particularly useful to initiate and control unstable wave dynamics in a numerical or laboratory experiment. This talk will summarize the main experimental achievements on breathers and connect these findings to the dynamics of ocean rogue waves.

00763 (3/3) : 4E @E606 [Chair: Georg Maierhofer]

[04908] Structure-preserving finite element discretization of nonlinear PDEs

Format : Talk at Waseda University
Author(s) : Ari Stern (Washington University in St. Louis)
Abstract : This talk discusses some recent advances in structure-preserving methods for nonlinear PDEs, combining finite elements in space and geometric integration in time. In particular, we extend some earlier methods and results to a broader class of Hamiltonian PDEs than previously considered, showing that multisymplectic and other conservation laws are preserved. These methods apply on unstructured meshes, not just structured grids, and may be arbitrarily high-order.

[01990] High-order mass- and energy-conserving methods for the nonlinear Schrödinger equation

Format : Talk at Waseda University
Author(s) : Genming Bai (The Hong Kong Polytechnic University)Jiashun Hu (The Hong Kong Polytechnic University)Buyang Li (The Hong Kong Polytechnic University)
Abstract : A class of high-order mass- and energy-conserving methods is proposed for the nonlinear Schr"odinger equation based on Gauss collocation in time and finite element discretization in space, by introducing a mass- and energy-correction post-process at every time level. The existence, uniqueness and high-order convergence of the numerical solutions are proved. In particular, the error of the numerical solution is $O(\tau^{k+1} + h^p)$ in the $L^\infty(0,T;H^1)$ norm after incorporating the accumulation errors arising from the post-processing correction procedure at all time levels, where k and p denote the degrees of finite elements in time and space, respectively, which can be arbitrarily large. Several numerical examples are provided to illustrate the performance of the proposed new method, including the conservation of mass and energy, and the high-order convergence in simulating solitons and bi-solitons.

[03931] Geometric two-scale integrators for highly oscillatory system

Format : Talk at Waseda University
Author(s) : Bin Wang (Xi'an Jiaotong University)
Abstract : In this talk, we consider a class of highly oscillatory Hamiltonian systems which involve a scaling parameter. We apply the two-scale formulation approach to the problem and propose two new time-symmetric numerical integrators. The methods are proved to have the uniform second order accuracy at finite times and some near-conservation laws in long times.

[03985] Structure preserving schemes for Allen--Cahn type equations

Format : Talk at Waseda University
Author(s) : Yongyong Cai (Beijing Normal University)
Abstract : In comparison with the Cahn--Hilliard equation, the classic Allen--Cahn equation satisfies the maximum bound principle (MBP) but fails to conserve the mass. Here, we report the MBP and corresponding numerical schemes for the Allen--Cahn equation with nonlocal constraint for the mass conservation. As an extension, we discuss the case of the convective Allen--Cahn equation.

[00766] Deep learning techniques for inverse problems and imaging

Session Time & Room : 5D (Aug.25, 15:30-17:10) @G808

Type : Proposal of Minisymposium
Abstract : Inverse problems involve identifying parameters of interest from indirect data. A main challenge for solving inverse problems is that their solutions are often not well posed, i.e., not unique and/or unstable with respect to small perturbations in the data. Deep techniques have been successfully applied to a wide variety of inverse problems, especially those arising in medical imaging. The main purpose of this mini-symposium is to discuss recent developments of the deep learning techniques for solving inverse problems and the open challenges that need to be addressed in the future.

[03603] Deep learning-based medical image reconstruction from incomplete data

Format : Online Talk on Zoom
Author(s) : Qiaoqiao Ding (Shanghai Jiao Tong University)
Abstract : Image reconstruction from down-sampled and corrupted measurements, such as fast MRI and sparse-view/low-dose CT, is mathematically ill-posed inverse problem. Deep neural network (DNN) has been becoming a prominent tool in the recent development of medical image reconstruction methods. In this talk, I will introduce our work on incorporating classical image reconstruction method and deep learning methods. The experiments on both sparse-view CT and low-dose CT problem show that the proposed method provided state-of-the-art performance.

[05360] Deep Unrolling Networks with Recurrent Momentum Acceleration

Format : Talk at Waseda University
Author(s) : Qingping Zhou (School of Mathematics and Statistics, Central South University)Junqi Tang (School of Mathematics, University of Birmingham)Jinglai Li (School of Mathematics, University of Birmingham)
Abstract : Leveraging model-based iterative algorithms and deep learning, deep unrolling networks (DuNets) address inverse imaging problems. However, nonlinear problems hinder their efficacy. Our proposed recurrent momentum acceleration (RMA) framework employs a LSTM-RNN to simulate momentum acceleration, enhancing DuNets' performance. Applied to the learned proximal gradient descent (LPGD) and the learned primal-dual (LPD) methods, it results in LPGD-RMA and LPD-RMA, respectively. Experimental results on nonlinear deconvolution and electrical impedance tomography indicate significant improvements, particularly for strongly ill-posed problems.

[05368] Spatiotemoral Imaging with Diffeomorphic Optimal Transportation

Format : Talk at Waseda University
Author(s) : Chong Chen (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : This talk introduces a concept called diffeomorphic optimal transportation (DOT), which combines the Wasserstein distance with Benamou--Brenier formula in optimal transportation and the flow of diffeomorphisms in large deformation diffeomorphic metric mapping. Using DOT, a new variational model for joint image reconstruction and motion estimation is proposed, which is suitable for spatiotemporal imaging involving mass-preserving large diffeomorphic deformations. The performance is validated by several numerical experiments in spatiotemporal tomography.

[05387] Self-supervised deep learning for imaging

Format : Talk at Waseda University
Author(s) : Hui Ji (National University of Singapore)
Abstract : Deep learning has proved to be a powerful tool in many domains, including inverse imaging problems. However, most existing successful deep learning solutions to these inverse problems are based on supervised learning, which requires many ground-truth images for training a deep neural network (DNN). This prerequisite on training datasets limits their applicability in data-limited domains, such as medicine and science. In this talk, we will introduce a series of works on self-supervised learning for solving inverse imaging problems. Our approach teaches a DNN to predict images from their noisy and partial measurements without seeing any related truth image, which is achieved by neuralization of Bayesian inference with DNN-based over-parametrization of images. Surprisingly, our proposed self-supervised method can compete well against supervised learning methods in many real-world imaging tasks..

[00768] Recent Advances in Computational Tools of Scientific Machine Learning towards Digital Twins

Session Time & Room :

00768 (1/2) : 2C (Aug.22, 13:20-15:00) @E818

00768 (2/2) : 2D (Aug.22, 15:30-17:10) @E818

Type : Proposal of Minisymposium

Abstract : Scientific Machine Learning is a new discipline that integrates traditional scientific computing and modern machine learning. It has grown explosively in recent years and is recognized as a fundamental research field that develops computational tools enabling Digital Twins. This mini-symposium will highlight recent progress in scientific machine learning techniques for Digital Twins and gather experts working on theory, algorithms, and applications to discuss and identify urgent current agendas and challenges.

[03527] Digital Twins and Machine Learning from an Inverse Problem Perspective

Author(s) : Mark Asch (Université de Picardie Jules Verne)

Abstract : Digital Twins that are exchanging data with their real-world counterparts can be considered as instances of inverse
problems—either of parameter identification type (static, or quasi-static), or of data assimilation type (dynamic). Many classical methods exist for solving inverse problems, but inverse problems remain complex, time-consuming and difficult to solve, especially with limited resources. However, machine learning can also be viewed as a parameter
identification inverse problem, where for example in a neutral network we seek to identify the weights (parameters) of
the network. Moreover, the machine learning community has developed extremely efficient frameworks and tools for
solving their inverse problems, such as stochastic gradient, backpropagation, and others. In this talk I will review machine learning methods with respect to the solution of inverse problems and I will present some examples of Digital Twins that have been developed on this basis.

[03528] Physics-guided data-driven simulations for a digital twin

Author(s) : Youngsoo Choi (Lawrence Livermore National Laboratory)

Abstract : A computationally expensive physical simulation is a huge bottleneck for a digital twin. Fortunately, many data-driven approaches have emerged to accelerate those simulations, thanks to the recent advance in machine learning (ML) and artificial intelligence. For example, a well-trained 2D convolutional deep neural network can predict the solution of complex Richtmyer–Meshkov instability problem with a speed-up of 100,000x (1). However, the traditional black-box ML models do not incorporate existing governing equations, which embed underlying physics, such as conservation of mass, momentum, and energy. Therefore, the black-box ML models often violate important physics law, which greatly concerns physicists, and require big data to compensate the missing physics information. Additionally, it comes with other disadvantages, such as non-structure-preserving, computationally expensive training phase, non-interpretability, and vulnerability in extrapolation. To resolve these issues, we can bring physics into data-driven framework. Physics can be incorporated in different stages of data-driven modeling, i.e., sampling stage and model-building stage. Physics-informed greedy sampling procedure minimizes the number of required training data for a target accuracy (2). Physics-guided data-driven model better preserves physical structure and more robust in extrapolation than traditional black-box ML models. Numerical results, e.g., hydrodynamics (3,4), particle transport (5), plasma physics, and 3D printing, will be shown to

demonstrate the performance of the data-driven approaches. The benefits of the data-driven approaches will also be illustrated in multi-query decision-making applications, such as design optimization (6,7).

[03532] Attributing anomalies from black-box predictions

Author(s) : Tsuyoshi Ide (IBM Research)
Abstract : One of the most important problems with digital twins is how to explain an unusual event observed as a significant discrepancy from the prediction of an AI model. Although this problem encompasses various different scenarios, we are particularly interested in the task of anomaly attribution in the black-box regression setting. The question is how we can quantify the contribution of each input variable in the face of an unexpected deviation between observation and prediction.
In this talk, I will first review existing attribution approaches recently developed in the machine learning community, including linear surrogate modeling, Shapley values, and integrated gradient. After summarizing the challenges of these methods in the particular context of anomaly explanation, I will touch upon a newer notion of likelihood compensation as one of the major counterfactual-type explanations. If time permits, I will share some experimental results, including the one conducted for IBM IoT Business Unit.

[03536] AI Based Medical Twin System: Investigation on Focused Ultrasound Therapeutics

Author(s) : Kyungho Yoon (Yonsei University)
Abstract : In the huge paradigm shift of 4th industrial revolution driven by AI technique, the medical industry is also pursuing personalized precision medicine through digital transformation and smart transformation from analogue, standard, and empirical medical procedure. At the center of this change, IT technology is acting as key driving force. In particular, personalized digital twin model of human body and therapeutic tool will be the core engine of smart medicine. In this presentation, I will introduce research on the development of artificial intelligence-based medical twin systems for digital/smart therapeutics by convergence of computational science, medical engineering, and artificial intelligence technologies as the core technologies of the 4th medical revolution. In particular, investigation on the focused ultrasound device will be presented, which has recently been emerging as a non-invasive brain stimulation tool.

00768 (2/2) : 2D @E818

[03635] Learning reduced-order operators with Bayesian inference and Gaussian processes

Author(s) : Mengwu Guo (University of Twente)
Abstract : Credible real-time simulation is a critical enabling factor for digital twin technology, and data-driven model reduction is a natural choice for achieving it. In this talk, we will discuss a probabilistic strategy for the learning of reduced-order representations of high-dimensional dynamical systems, with which a significantly reduced dimensionality guarantees improved efficiency, and the endowed uncertainty quantification certifies computational reliability. The strategy is based on Bayesian reduced-order operator inference, a data-driven

method that inherits the formulation structure of projection-based reduced-state governing equations yet without requiring access to full-order solvers. The reduced-order operators are estimated using Bayesian inference with Gaussian priors, and two fundamentally different strategies of likelihood definition will be discussed – one formulated as linear regression, and the other through Gaussian processes. Given by posterior Gaussian distributions conditioning on solution data, the reduced-order operators probabilistically define a low-dimensional dynamical system for the predominant latent states, and provide an inherently embedded Tikhonov regularization together with a quantification of modeling uncertainties.

[04330] Operator learning for stochastic closures of complex dynamical systems

Author(s) : Jinlong Wu (University of Wisconsin-Madison)Chuanqi Chen (University of Wisconsin-Madison)
Abstract : Closure models are widely used in simulating complex multiscale dynamical systems such as turbulence and Earth's climate, for which direct numerical simulation that resolves all scales is often too expensive. For those systems without a clear scale separation, deterministic and local closure models often lack enough generalization capability, which limits their performance in many real-world applications. In this talk, we present a data-driven modeling framework for constructing stochastic and nonlocal closure models from (i) abundant data, and (ii) a limited amount of data. Specifically, operator learning with indirect data will be demonstrated in the context of stochastic differential equations. We also show how different types of regularization can be imposed to improve the performance of the learned closure models. The results show that the proposed methodology provides a systematic approach to constructing generalizable data-driven closure models for multiscale dynamical systems even if there is no clear scale separation between resolved and unresolved scales.

[05255] ClimaX: A foundation model for weather and climate

Author(s) : Johannes Brandstetter (Microsoft Research)
Abstract : Most state-of-the-art approaches for weather and climate modeling are based on physics-informed numerical models of the atmosphere. These approaches aim to model the non-linear dynamics and complex interactions between multiple variables, which are challenging to approximate. Additionally, many such numerical models are computationally intensive, especially when modeling the atmospheric phenomenon at a fine-grained spatial and temporal resolution. Recent data-driven approaches based on machine learning instead aim to directly solve a downstream forecasting or projection task by learning a data-driven functional mapping using deep neural networks. However, these networks are trained using curated and homogeneous climate datasets for specific spatiotemporal tasks, and thus lack the generality of numerical models. We develop and demonstrate ClimaX, a flexible and generalizable deep learning model for weather and climate science that can be trained using heterogeneous datasets spanning different variables, spatio-temporal coverage, and physical groundings. ClimaX extends the Transformer architecture with novel encoding and aggregation blocks that allow effective use of available compute while maintaining general utility. ClimaX is pre-trained with a self-supervised learning objective on climate datasets derived from CMIP6. The pre-trained ClimaX can then be fine-tuned to address a breadth of climate and weather tasks, including those that involve atmospheric variables and spatio-temporal scales unseen during pretraining. Compared to existing data-driven baselines, we show that this generality in ClimaX results in superior performance on benchmarks for weather forecasting and climate projections, even when pretrained at lower resolutions and compute budgets.

[00774] Applications of machine learning to analyzing time-series and imaging data

Session Time & Room :

00774 (1/2) : 2C (Aug.22, 13:20-15:00) @E817

00774 (2/2) : 2D (Aug.22, 15:30-17:10) @E817

Type : Proposal of Minisymposium
Abstract : Considerable increases in GPU and high-performance computing have led to significant advances in machine learning methodologies. This mini-symposium will focus on recent advances in methodologies and applications of deep and machine learning to analyze two types of data. In the first session, our speakers will discuss recent advances in machine learning based methods for predicting time series data. The second session will focus on deep learning for analyzing and interpreting imaging data. Mathematical topics of this mini symposium

include, but are not limited to, physics-driven machine learning, deep learning, reinforcement learning, computer vision, and optimal transport.

[03788] Predicting Bladder Pressure and Contractions from Non-Invasive Time-Series Data

Author(s) : Erica M Rutter (University of California, Merced)

Abstract : Symptoms of bladder dysfunction can be alleviated by electrical stimulation of nerves at the start of a contraction. However, determining when a bladder contraction will occur remains an active area of research. Due to the extremely dense time-series data, we employ statistical and machine learning methods to predict bladder pressure from external nerve data. These bladder pressures are used to predict the onset of bladder contractions with high sensitivity and specificity.

[04294] Leveraging topological data analysis for parameter estimation of an agent-based model of collective motion

Author(s) : Kyle Nguyen (North Carolina State University)Carter Jameson (North Carolina State University)John Nardini (The College of New Jersey)Kevin Flores (North Carolina State University)

Abstract : Understanding the social interaction between members of groups in the context of collective motion is significant to gain the insights on the link between local and global behaviors. By leveraging topological data analysis, we use dimensional reduction techniques on topological features to visually cluster different time series of collective motion simulations of an agent-based model into groups. We also propose inverse problem approaches for parameter estimation of this particular agent-based model of collective motion.

[04425] Few-Shot Learning for Leaf and Vein Segmentation

Author(s) : John Lagergren (Oak Ridge National Laboratory)

Abstract : Plant phenotyping is a primary bottleneck in understanding plant adaptation and the genetic architectures underlying complex traits at population scale. We address this challenge by leveraging few-shot learning with convolutional neural networks (CNNs) to segment the leaf body and visible venation of P. trichocarpa leaf images obtained in the field. Biological traits are extracted from the resulting segmentations, validated using real-world measurements, and used to conduct a genome-wide analysis to identify genes controlling the traits.

[04513] Analysis of spatial transcriptomics using deep learning and optimal transport

Author(s) : Zixuan Cang (North Carolina State University)

Abstract : The emerging single-cell and spatial genomics techniques allow us to elucidate the governing rules of multicellular systems with unprecedented resolution and depth. These datasets are often high-dimensional, complex, and heterogeneous. Mathematical tools are needed to extract biological insights from such data. In this talk, we will discuss several computational methods for exploring tissue structures, temporal signatures, and cell-cell communication processes on spatial transcriptomics data as well as supervised optimal transport motivated by the biological applications.

00774 (2/2) : 2D @E817

[04520] Applied Machine Learning for Overhead Imagery

Author(s) : Adam Attarian (Pacific Northwest National Laboratory)

Abstract : Applying machine learning techniques to collected overhead imagery presents many challenges not normally encountered in traditional object detection and classification problems. Complex sensing geometries, small target size, and lack of sufficient training data are all problems that must be mitigated. In this talk, we provide an overview of machine learning approaches and techniques to derive meaningful information from overhead imagery.

[04949] Introduction to miniymposium session: Applications of machine learning to analyzing time-series and imaging data

Author(s) : Kevin Flores (NC State University)
Abstract : This talk is an introduction to the minisymposium session on "Applications of machine learning to analyzing time-series and imaging data".

[05230] Reinforcement Learning in a Digital Twin Framework for the Stabilization of an Inverted Pendulum

Author(s) : Hien Tran (North Carolina State University)
Abstract : In this talk we benchmark common reinforcement learning algorithms on a modified version of OpenAI Gym's Cartpole: a virtual environment simulating the dynamics of an inverted pendulum. The reinforcement learning algorithms that we used to stabilize the virtual inverted pendulum included the Policy Gradient, Actor-Critic, and Proximal Policy Optimization. We then transferred the trained neural network models from the virtual environment to the real physical inverted pendulum to verify their performances. While all of the reinforcement learning algorithms were able to satisfactorily balance the real inverted pendulum, Actor-Critic is best able to adequately reject disturbances.

[05238] Solving inverse and forward problems in the water quality model by neutral networks

Author(s) : Quy Muoi Pham (The University of Danang - University of Science and Education)
Abstract : In this talk, we study the forward and inverse problems in BOD-DO models and present the Physic Inform Neural Network method to solve these problems. We first introduce the fully deep neural network and some well-known results about the approximation of fully deep neural networks to functions of classes. Then, we present the Physic Inform Neural Network method to solve the forward and inverse problems in BOD-DO models. We apply the method to solve some specific numerical examples. The method can be generalized for complex river quality models, e.g., 2D or 3D BOD-DO models or river quality models with more than two indicators. For complex river systems, we can use segmentation techniques to divide the river into some segments and in each segment, we can use the proposed method to solve the forward and inverse problems.

[00778] Analysis, Applications, and Advances in Metamaterials and Composites

Session Time & Room :

00778 (1/3) : 4E (Aug.24, 17:40-19:20) @G801

00778 (2/3) : 5B (Aug.25, 10:40-12:20) @G801

00778 (3/3) : 5C (Aug.25, 13:20-15:00) @G801

Type : Proposal of Minisymposium
Abstract : Composites are inhomogeneous mixtures of their component materials. Metamaterials are composites with properties that go beyond those of the constituent phases and possibly beyond naturally occurring materials. These have attracted increasing attention in the past twenty years. Many important mathematical questions have been addressed, yet many remain. For example, composites and metamaterials can guide fields and waves in desired ways, e.g., cloaking, but the limitations of this are not so clear. Also, what unusual effective behaviors are possible? Incorporating dispersion, dissipation, anisotropy, extreme moduli, etc. adds to the challenge. This minisymposium will present exciting new developments in the field.

[03353] Double-Zero-Index metamaterials

Format : Talk at Waseda University
Author(s) : Ying Wu (KAUST)Changqing Xu (KAUST)Keqiang Lyu (KAUST)Guancong Ma (Hong Kong Baptist University)Yun Lai (Nanjing University)
Abstract : Wave propagating in a medium with two constitutive parameters vanishing (double-zero index media) does not accumulate any phase retardation. Such a medium is not mathematically interesting but also bears unusual functionalities, such as wave front engineering, cloaking of objects and wave tunnelling. I will report our progresses on realizing double-zero index materials in two and three dimensions for electromagnetic and acoustic waves and discuss their special characteristics.

[04938] Rigidity and Elasticity of Kirigami and Origami Metamaterials

Format : Talk at Waseda University
Author(s) : Ian Tobasco (University of Illinois Chicago)
Abstract : Kirigami metamaterials combine elasticity and geometry to create unusual bulk deformations. We derive a partial differential equation (PDE) for periodic kirigami, along with a strain-gradient like homogenized energy. Minimizing this energy amongst PDE solutions predicts the kirigami's deformation, as we demonstrate via experiments and simulations. Time permitting, we present analogous results for origami. A key step in our analysis is a rigidity inequality showing that the metamaterial's deformation is approximated by local mechanism motions.

[03863] The macroscopic behavior of the Kagome lattice metamaterial

Format : Talk at Waseda University
Author(s) : Xuenan Li (New York University)
Abstract : Mechanism-based metamaterials are synthetic materials that exhibit microscale buckling in response to mechanical deformation. These artificial materials are like elastic composites, but more degenerate, since they can deform with zero elastic energy. We call such deformations with zero elastic energy mechanisms. My research focuses mainly on a rich example, the Kagome lattice metamaterial. This particular material has a huge variety of mechanisms, which might seem incompatible with having a meaningful macroscopic energy at first sight. In this talk, I will discuss the large-scale behavior of the kagome lattice metamaterial as a nonlinear homogenization problem and present our analysis of the well-defined macroscopic energy on this highly degenerate metamaterial. Our macroscopic theory reveals that compressive conformal maps achieve zero effective energy. I will also discuss the adequacy of our macroscopic theory with various numerical experiments. The theory is joint work with Robert Kohn, and the numerical results are joint work with Katia Bertoldi and Bolei Deng.

[04196] Rayleigh waves in 2D extremal materials

Format : Online Talk on Zoom
Author(s) : Gengkai Hu (School of Aerospace Engineering, Beijing Institute of Technology)Yu Wei (School of Aerospace Engineering, Beijing Institute of Technology)
Abstract : Rayleigh waves are guaranteed in Cauchy materials with positive definite elasticity tensors. However it's proved that 2D extremal materials with Rank-deficient elasticity tensors cannot support Rayleigh waves, they can appear if the second gradient effect is considered. Microstructural models corresponding to the examined continuum models of Cauchy and second gradient elasticity are constructed, both continuum and discrete models agree very well in terms of the velocity and ellipticity for the predicted Rayleigh waves.

00778 (2/3) : 5B @G801 [Chair: Anthony Stefan]

[04081] Large-scale metasurface design with fast direct solvers

Format : Talk at Waseda University
Author(s) : Owen Miller (Yale University)
Abstract : Metasurfaces offer nanophotonic performance for centimeter-scale optics applications. Yet simulating such large structures is beyond current simulation capabilities. We demonstrate a 2D "fast direct" integral-equation solver that can simulate and design a high-efficiency, high-numerical-aperture metalens that is 20,000 wavelengths in diameter. For a visible wavelength of 500nm, this corresponds to a design diameter of 1cm, achieved with full simulations of Maxwell's equations.

[04889] Relaxation of variational principles for bounding the effective operators of composites

Format : Talk at Waseda University

Author(s) : Aaron Welters (Florida Institute of Technology)

Abstract : An approach to the theory of composites is presented that allows a relaxation of the direct and dual minimization principles used to bound effective operators. This is based on representing the effective operator as the Schur complement of a positive semidefinite operator on a Hilbert space having a Hodge decomposition. We show the theory also applies in electric circuit theory for the Dirichlet-to-Neumann map and for the classical effective conductivity on a finite linear graph.

[04890] Bessmertnyĭ realizations of effective tensors for metamaterial synthesis: conjectures and counterexamples

Format : Talk at Waseda University

Author(s) : Anthony Dean Stefan (Florida Institute of Technology)

Abstract : Effective tensors of isotropic n-phase composites are known to be homogeneous multivariate Herglotz functions. Recently, M. Bessmertnyĭ claimed to characterize any such rational function as being in the Bessmertnyĭ class because each partial Wronskian associated with it has a polynomial sum-of-squares representation. We disprove this claim by providing a counterexample derived from the basis generating polynomial for the Vámos matroid and give a conjecture on the realizability of effective tensors. Joint work with Aaron Welters.

00778 (3/3) : 5C @G801 [Chair: Maxence Cassier]

[05015] Time domain analysis of resonant plasmonic nano-particles

Format : Talk at Waseda University

Author(s) : Pierre Millien (CNRS)Alice L. Vanel (CERN)Lorenzo Baldassari (RICE)Habib Ammari (ETHZ)

Abstract : We study the possible expansion of the electromagnetic field scattered by a strictly convex metallic nanoparticle with dispersive material parameters placed in a homogeneous medium in a low-frequency regime as a sum of modes oscillating at complex frequencies (diverging at infinity), known in the physics literature as the quasi-normal modes expansion. We show that such an expansion is valid in the static regime and that we can approximate the electric field with a finite number of modes. We then use perturbative spectral theory to show the existence, in a certain regime, of plasmonic resonances as poles of the resolvent for Maxwell's equations with non-zero frequency. We show that, in the time domain, the electric field can be written as a sum of modes oscillating at complex frequencies. We introduce renormalised quantities that do not diverge exponentially at infinity.

[05234] Active exterior thermal cloaking

Format : Talk at Waseda University

Author(s) : Trent DeGiovanni (University of Utah)Fernando Guevara Vasquez (University of Utah)Maxence Cassier (CNRS, Institut Fresnel)Sébastien Guenneau (Imperial College London)

Abstract : We consider the problem of concealing an object, in the presence of a known probing fielding, from the perspective of thermal measurements. This is achieved using specially designed sources. Such a cloak can be constructed by using the Green identities; however, this requires a continuous strip of sources that encloses the object. In this talk, we demonstrate an alternative approach to this cloaking problem that uses only a few sources.

[04994] Imaging conductivity with thermal noise induced currents

Format : Online Talk on Zoom

Author(s) : Fernando Guevara Vasquez (University of Utah)Trent DeGiovanni (University of Utah)

Abstract : Thermal fluctuations of charge carriers in a conductive body create small but detectable currents. We show that the variance of such currents can be used to image the conductivity of a body, including for complex conductivities. This is done by relating the stochastic problem to a deterministic inverse problem that is close to one arising in acousto-electric tomography.

[00779] Advances in numerical methods for evolutionary PDEs and applications

Session Time & Room :

00779 (1/3) : 1C (Aug.21, 13:20-15:00) @A511

00779 (2/3) : 1D (Aug.21, 15:30-17:10) @A511

00779 (3/3) : 1E (Aug.21, 17:40-19:20) @A511

Type : Proposal of Minisymposium
Abstract : Several models in science, physics and engineering, are described by evolutionary systems of partial differential equations (PDEs). The purpose of the MS is to gather researcher interested in the development of innovative techniques for the numerical solution of a wide class of evolutionary problems, in several contexts: kinetic theory of rarefied gases, linear and nonlinear waves, viscoelasticity, multiphase flows, radiation hydrodynamics, traffic flows, shallow water, just to mention some examples. The mini-symposium will deal with several issues related to the numerical solution of such equations, including, among others, multi-scale issues, asymptotic preserving schemes, high order discretization in space and time, and stability analysis.
Organizer(s) : Sebastiano Boscarino, Giuseppe Izzo, Giovanni Russo

[05243] Implicit-explicit time integration for thermal radiative transfer and radiation hydrodynamics

Format : Talk at Waseda University
Author(s) : Ben Scott Southworth (Los Alamos National Laboratory)
Abstract : Thermal radiative transfer (TRT) is an extremely stiff high-dimensional partial-integro-differential equation, which requires partitioned integration when coupled to hydrodynamics. I introduce an approximation of TRT that captures both stiff asymptotic limits, and IMEX framework requiring only one transport-sweep per timestep. I then discuss nonlinear coupling to hydrodynamics, which is complicated via equation-of-state relations. We derive a temperature closure and framework for semi-implicit-explicit integration of radiation hydrodynamics, demonstrating excellent convergence on stiff radiative shock problems.

[03444] Semi-implicit numerical methods for level set equations

Format : Talk at Waseda University
Author(s) : Nikola Gajdošová (Slovak University of Technology in Bratislava)Katarína Lacková (Slovak University of Technology in Bratislava)Peter Frolkovič (Slovak University of Technology in Bratislava)
Abstract : We present semi-implicit higher order numerical methods to solve nonlinear level set equations for evolving interfaces. We introduce up to third order accurate unconditionally stable numerical schemes to solve advection by external velocity and speed in normal direction, and, eventually, regularized by a small curvature term. The methods have fully upwinded stencil in its implicit part so efficient algebraic solvers like fast sweeping methods can be applied.

[05021] Efficient implicit methods for the Euler equations in Lagrangian coordinates

Format : Talk at Waseda University
Author(s) : Simone Chiocchetti (University of Stuttgart)Giovanni Russo (University of Catania)Sebastiano Boscarino (University of Catania)
Abstract : In this talk, we introduce a novel implicit numerical scheme for the multimaterial Euler equations in Lagrangian coordinates. The method takes advantage of the remarkable structure of the governing equations in Lagrangian coordinates, which admits a single scalar wave equation for the pressure field, generating a symmetric positive definite system of linear equations. At the same time, contacts are resolved exactly, due to the Lagrangian nature of the method, even without a Riemann solver.

[03910] High-order semi-implicit schemes for evolutionary partial differential equations with higher order derivatives

Format : Talk at Waseda University
Author(s) : Sebastiano Boscarino (University of Catania, Italy)
Abstract : The aim of this work is to apply a semi-implicit (SI) strategy in an implicit-explicit (IMEX) Runge-Kutta (RK) setting introduced in (S. Boscarino- F. Filbet, G. Russo, JSC 2016) to a sequence of 1D time-dependent partial differential equations (PDEs) with high order spatial derivatives. This strategy gives a great flexibility to treat these equations, and allows the construction of simple linearly implicit schemes without any Newton's iteration. Furthermore, the SI IMEX- RK schemes so designed does not need any severe time step restriction that usually one has using explicit methods for the stability, i.e. Δt = O(Δt^k) for the k-th (k ≥ 2) order PDEs. For the space discretization, this strategy is combined with finite differ- ence schemes. We illustrate the effectiveness of the schemes with many applications to dissipative, dispersive and biharmonic-type equations. Numerical experiments show that the proposed schemes are stable and can achieve optimal orders of accuracy.

00779 (2/3) : 1D @A511 [Chair: Sebastiano Boscarino]

[05310] Carbuncle-free, well-balanced, positivity preserving methods for the shallow water equations, with application to the circular hydraulic jump

Format : Talk at Waseda University
Author(s) : David I Ketcheson (King Abdullah University of Science and Technology)
Abstract : When a jet of fluid hits a flat plate, the resulting flow consists of two regimes separated by a hydraulic jump.   We investigate the behavior of the jump for the shallow water equations. Numerical solvers tend to either exhibit artificial numerical instabilities or suppress the chaotic behavior at high Froude numbers. We propose a new entropy-based Riemann solver that is capable of avoiding carbuncles while allowing the fluid instability to manifest itself.

[04458] New highly stiff-stable schemes for linear and nonlinear parabolic equations

Format : Talk at Waseda University
Author(s) : JIE SHEN (Purdue University)
Abstract : We construct a class of new highly stiff-stable schemes for linear and nonlinear parabolic equations based on Taylor expansions at time t_{n+k} where $k \geq 1$ is a tunable parameter. We show that their numerical solutions are bounded unconditionally (resp. for sufficiently small time steps) for linear (resp. nonlinear) parabolic equations, and derive their optimal error estimates for a large class of nonlinear parabolic equations. We also present numerical results to show the advantages of the new schemes compared with the classic IMEX schemes based on Taylor expansions at time t_{n+1}.

[05011] Finite-differences scheme for a tensor PDE model of bionetwork formation and applications

Format : Talk at Waseda University
Author(s) : Clarissa Astuto Giovanni Russo (University of Catania)Peter Markowich (King Abdullah University of Science and Technology)Daniele Boffi (KAUST)Jan Haskovec (KAUST)
Abstract : We propose a numerical method for the resolution of a complex biological network. We refer to the Cai-Hu model, where they hypothesized that the topology of the leaf pattern is governed by an optimization of the global energy consumption. The evolution in time of the fluid is governed by an elliptic-parabolic system of partial differential equations and we explore the resulting graph, showing important structural differences when changing the parameters.

[04882] Asymptotic preserving scheme for ExB drift

Format : Talk at Waseda University
Author(s) : Umberto Zerbinati (University of Oxford)Giovanni Russo (University of Catania)
Abstract : In this talk, we explore an asymptotic preserving scheme for ExB drift. The key idea behind the scheme here presented is to treat the highly oscillatory component of the velocity using an exponential integrator. We will

apply this numerical scheme to particles in cell plasma simulation under the effect of a strong constant magnetic field.

[03846] Efficient simulation of high-dimensional kinetic equation

Format : Talk at Waseda University
Author(s) : Lukas Einkemmer (University of Innsbruck)
Abstract : Solving high-dimensional kinetic equations (such as the Vlasov equation or the Boltzmann equations) numerically is extremely challenging. Methods that discretize phase space suffer from the exponential growth of the number of degrees of freedom, the so-called curse of dimensionality, while Monte Carlo methods converge slowly and suffer from numerical noise. In addition, standard complexity reduction techniques (such as sparse grids) usually perform rather poorly due to the lack of smoothness for such problems. Dynamical low-rank techniques approximate the dynamics by a set of lower-dimensional objects. For those low-rank factors, partial differential equations are derived that can then be solved numerically. We will show that such dynamical low-rank approximations work well for a range of kinetic equations due to their capacity to handle non-smooth solutions and the fact that in many situations important physical limit regimes are represented very efficiently by such an approximation (e.g. fluid or diffusive limits).

[04978] A conservative semi-Lagrangian method for inhomogeneous Boltzmann equation

Format : Talk at Waseda University
Author(s) : Seung Yeon Cho (Gyeongsang National University)Sebastiano Boscarino (University of Catania)Giovanni Russo (University of Catania)
Abstract : In this work, we propose a conservative semi-Lagrangian method for the Boltzmann equation. Semi-Lagrangian approach enables us to avoid CFL-type restrictions on the time step. High order in time is obtained by Runge-Kutta or Adams-Bashforth methods. High order in space is obtained by a high order conservative reconstruction which also prevents spurious oscillations. The fast spectral method with L2-correction guarantees spectral accuracy and conservation. Numerical results confirm the accuracy and efficiency of the methods.

[03164] Asymptotic preserving and uniformly unconditionally stable schemes for kinetic transport equations

Format : Talk at Waseda University
Author(s) : Guoliang Zhang (Shanghai Jiaotong University)
Abstract : In this talk, we will give uniformly unconditionally stable finite difference schemes for kinetic transport equations in the diffusive scaling. The schemes are based on a coupling of macroscopic and microscopic equations, by utilizing a backward semi-Lagrangian approach for transport part, and implicit method for the diffusive part. The schemes can be shown to be asymptotic preserving in the diffusive limit. Uniformly unconditional stabilities are verified by Fourier analysis. Numerical experiments will demonstrate their good performances.

[04700] High order structure preserving schemes for MHD flows in all sonic Mach numbers

Format : Talk at Waseda University
Author(s) : Tao Xiong (Xiamen University)
Abstract : In this work, a high-order semi-implicit (SI) asymptotic preserving (AP) and divergence-free finite difference weighted essentially nonoscillatory (WENO) scheme is proposed for magnetohydrodynamic (MHD) equations. We consider the sonic Mach number ε ranging from 0 to $\mathcal{O}(1)$. High-order accuracy in time is obtained by SI implicit-explicit Runge–Kutta (IMEX-RK) time discretization. High-order accuracy in space is achieved by finite difference WENO schemes with characteristic-wise reconstructions. A constrained transport method is applied to maintain a discrete divergence-free condition. We formally prove that the scheme is AP. Asymptotic accuracy (AA) in the incompressible MHD limit is obtained if the implicit part of the SI IMEX-RK scheme is stiffly accurate. Numerical experiments are provided to validate the AP, AA, and divergence-free properties of our proposed approach. Besides, the scheme can well capture discontinuities such as shocks in an essentially non-oscillatory fashion in the compressible regime, while it is also a good incompressible solver with uniform large-time step conditions in the low sonic Mach limit.

[00781] Physical and Mathematical Research on Transport on Slippery Surfaces

Session Time & Room :

00781 (1/3) : 3D (Aug.23, 15:30-17:10) @D401

00781 (2/3) : 3E (Aug.23, 17:40-19:20) @D401

00781 (3/3) : 4C (Aug.24, 13:20-15:00) @D401

Type : Proposal of Minisymposium
Abstract : In the past two decades numerous laboratories have microfabricated surfaces with the chemical and textural properties to mimic slippery surfaces found in nature, e.g. the superhydrophobic lotus leaf. This has been made possible by the continuing advances in nano/micro fabrication technology. This 3-part minisymposium will bring together engineers, physicists, and applied mathematicians in a multi-physics framework to discuss recent modelling and experimental applications.
Organizer(s) : Toby Kirk, Darren Crowdy
Classification : 76D07, 76D45, 76D55
Minisymposium Program :

00781 (1/3) : 3D @D401 [Chair: Toby Kirk]

[03772] Flows through slippery tubes and annuli

Format : Talk at Waseda University
Author(s) : Sebastian Zimmermann (RPTU Kaiserslautern-Landau)Clarissa Schönecker (RPTU Kaiserlautern-Landau)
Abstract : We present analytical models for the flow through tubes and annuli that possess slippery longitudinal slits along their surface. Firstly, these expressions can be employed with an arbitrary local slip length or shear stress being predefined at the slits, corresponding to an arbitrary Newtonian fluid. Secondly, the two solutions for tubes and annuli can be combined such that there is one fluid in the tube and another one in the annulus surrounding the tube.

[03964] Numerical study of longitudinal flow over liquid infused surfaces

Format : Talk at Waseda University
Author(s) : Hiroyuki Miyoshi (Imperial College London)Darren G. Crowdy (Imperial College London)
Abstract : A numerical method for the computation of two-phase pressure-driven longitudinal flow over liquid-infused surfaces is presented. These surfaces feature a periodic array of circular surface-embedded grooves filled with a subphase fluid that can enhance slip of an upper fluid, of different viscosity, flowing over it. A novelty of the numerical approach is that it deploys techniques from conformal geometry and complex analysis.

[02965] Viscoplastic Flows through Grooved Superhydrophobic Channels

Format : Talk at Waseda University
Author(s) : Seyed Mohammad Taghavi (Université Laval)Hossein Rahmani (Université Laval)
Abstract : We study the transport of viscoplastic fluids through channels with grooved superhydrophobic walls. To this end, we employ a comprehensive modeling approach and high-resolution numerical simulations and, in particular, consider longitudinal, transverse, and oblique orientations of the grooves. We use the perturbation theory to derive semi-analytical and closed-form solutions for the velocity fields, whose results are validated against our numerical simulations. Finally, we highlight the strong nonlinear effect of viscoplastic rheology and analyze the stabilizing/destabilizing effects of slip conditions on the flow.

[04260] Jeffery’s paradox for the rotation of a single ‘stick-slip’ cylinder

Format : Talk at Waseda University
Author(s) : Michael S Siegel (New Jersey Institute of Technology)Ehud Yariv (Technion)
Abstract : The two-dimensional fluid velocity due to the rotation of a superhydrophobic or `stick-slip’ cylinder in Stokes flow is
determined. We find that in the general case of an aperiodic distribution of stick and slip boundaries there is no solution in which the fluid velocity vanishes at infinity. This is the first example of Jeffery’s paradox, typically associated with the flow due to the counter-rotation of two rigid cylinders, for a single cylinder.

00781 (2/3) : 3E @D401 [Chair: Darren Crowdy]

[03147] Experimental Applications of Slippery Liquid and Liquid-like-Solid Surfaces

Format : Talk at Waseda University
Author(s) : Glen McHale (The University of Edinburgh)Gary George Wells (The University of Edinburgh)Rodrigo Ledesma-Aguilar (The University of Edinburgh)
Abstract : The liquid Amontons’ laws relate drop friction along a surface to the normal component of the capillary force. Here I outline work on low pinning surfaces which minimize the coefficient of static liquid friction. Using a liquid version of Young’s law, I show low friction uni-directional and bi-directional droplet motion on liquid-infused surfaces. I also show surfaces with liquid-like solid coatings which overcome the risk of lubricant depletion and provide excellent anti-biofilm properties.

[03590] Drop movement on lubricant-impregnated random textures

Format : Talk at Waseda University
Author(s) : Ratan Bharat Ahuja (Indian Institute of Technology Bombay)Amit Agrawal (Indian Institute of Technology Bombay)Suhas S Joshi (Indian Institute of Technology Indore)
Abstract : Lubricant-impregnated surfaces (LIS), owing to their omniphobicity have shown remarkable success against Newtonian, non-Newtonian and yield stress fluids. These surfaces are, however, prone to failure due to lubricant drainage. In this work, we fabricate random textures using the micro-EDM process in an attempt to prolong lubricant retention within grooves. Drop motion and velocity against lubricant of three different viscosities are captured using digital imaging. The results would aid in designing a robust LIS system.

[05601] Asymptotic solutions for convection in longitudinal-fin heat sinks

Format : Talk at Waseda University
Author(s) : Toby Kirk (Imperial College London)Marc Hodes (Tufts University)
Abstract : We consider forced convection in a longitudinal-fin heat sink, i.e. a periodic array of thin, thermally conducting fins aligned with the direction of air flow. Sparrow, Baliga and Patankar (1978) solved this problem numerically, investigating the effect of the gap between the fin tips and the shroud. We solve the same problem in the realistic asymptotic limit of small fin spacing, and make connections to similar mathematical problems for liquid flow over superhydrophobic grooved surfaces.

[02837] Inertial effects on the flow resistance of axial-groove heat pipes

Format : Talk at Waseda University
Author(s) : Haotian Jia (Tufts Univeristy)Marc Hodes (Tufts University)Toby Kirk (Imperial College London)
Abstract : We captured the effects of slowly-varying meniscus curvature on the flow resistance of the adiabatic section of an axial-groove heat pipe in the presence of inertial effects due to the changes in the cross-sectional areas of the liquid and vapor phases along the adiabatic section. This was by done by extending a hybrid analytical-numerical method for a single-phase problem with slowly-varying meniscus curvature to two-phase.

00781 (3/3) : 4C @D401 [Chair: Marc Hodes]

[04287] Laminar drag reduction in surfactant-contaminated superhydrophobic channels

Format : Talk at Waseda University

Author(s) : Samuel Tomlinson (University of Manchester)Frédéric Gibou (University of California, Santa Barbara)Paolo Luzzatto-Fegiz (University of California, Santa Barbara)Fernando Temprano-Coleto (Princeton University)Oliver Jensen (University of Manchester)Julien Landel (University of Manchester)

Abstract : Although superhydrophobic surfaces (SHSs) show promise for drag reduction (DR) applications, their performance can be compromised by traces of surfactant. This question is addressed for a three-dimensional laminar flow in a periodic channel with SHSs along both walls, in the presence of soluble surfactant. The system exhibits multiple regimes where asymptotic solutions can be constructed, which compare favourably with numerics. This analysis provides a guide for designing surfactant-contaminated SHSs to maximise the DR for applications.

[04901] Hypermobilization of superhydrophobic microchannels using light

Format : Talk at Waseda University

Author(s) : Michael Mayer (Imperial College London)Marc Hodes (Tufts University)Xiaozhe Hu (Tufts University)James Adler (Tufts University)

Abstract : This talk seeks to reframe the role of superhydrophobic surfaces, transforming them from passive lubricants to sources of active flow control. Utilizing a new model for the transport of photosurfactants, chemicals that can reversibly switch between two different states under differing light wavelengths, we show that it is possible to use light to generate surface tension gradients across menisci on superhydrophobic surfaces large enough to pump stationary fluid or even “hypermobilize” pressure driven flow.

[04001] Analysis of surface diffusion on steady "stagnant caps" of surfactant

Format : Talk at Waseda University

Author(s) : Anna Elizabeth Curran (Imperial College London)Darren Crowdy (Imperial College London)

Abstract : We present a detailed analytical study, based on complex variable methods, which examines the remobilizing effects of surface diffusion on the structure of steady "stagnant caps" on a surfactant-loaded interface between a viscous fluid and a constant pressure region. Both insoluble and soluble surfactants are considered. We demonstrate mathematically how, in the presence of a convergent flow, stagnant caps can immobilize interfaces leading to sharp edges which can then be smoothed out by surface diffusion.

[04344] Slip flow enhanced by Marangoni Stresses at a superhydrophobic air-water interface

Format : Online Talk on Zoom

Author(s) : dong song (Northwestern Polytechnical University)Baowei Song (Northwestern Polytechnical University)guang pan (Northwestern Polytechnical University)

Abstract : Surfactant-induced Marangoni stress at an air-water interface would balance the shearing stress which causes the collapse of drag reduction of superhydrophobic surfaces, whereas few solutions have been proposed to overcome the adverse influence due to the difficulty in removing surfactant from water. In this work, we demonstrate that, by changing the orientation or shape of the air-water interface with respect to the bulk flow, the balance between Marangoni stress and shear stress can serve as a driving force of an apparent slip flow without the external input of surfactant. The theoretical model agrees well with the experiments.

[00782] Recent Advances on Mimetic Difference Methods

Session Time & Room : 1C (Aug.21, 13:20-15:00) @E802

Type : Proposal of Minisymposium

Abstract : Mimetic Difference Schemes are based on Mimetic Difference Operators which are discrete analogs of the continuous first order invariant operators divergence, gradient and curl. They have been used for quite some time to solve effectively a wide range of partial differential equations. In this mini symposium we will present recent advances on mimetic methods including energy conservation, stability analysis and extension of stability region via Mollification techniques. Numerical examples will be presented to illustrate the effectiveness of the methods

Organizer(s) : Jose E. Castillo

Classification : 65Nxx

Minisymposium Program :

00782 (1/1) : 1C @E802 [Chair: Jose E Castillo]

[01714] Fourth-order Mimetic Differential Operators Applied to the Convection-Diffusion Equation: A matrix Stability Analysis

Format : Talk at Waseda University

Author(s) : Jorge VILLAMIZAR (Universidad Industrial de Santander/Universidad de Los Andes)Larry Mendoza (Universidad Central de Venezuela)Giovanni Calderon (Universidad Industrial de Santander)Otilio Rojas (Universidad Central de Venezuela)Jose E Castillo (Computational Science Research Center at San Diego State University)

Abstract : The convection-diffusion equation describes physical phenomena where particles or energy are transferred within a physical system due to the processes of diffusion and convection. In this work, we investigate discretization framework based on the mimetic fourth-order finite-difference staggered-grid Castillo-Grone (CG) operators, which has a sextuple of free parameters. We study the dependency of the stability and precision properties of our numerical scheme based on these CG free parameters, and propose parameters that favor both properties. We compare our results with CG parameters previously mentioned in the literature, including those leading to mimetic operators of minimum bandwidth.

[01788] Discrete mollification results in mimetic difference schemes applied to the convection-diffusion-reaction equation

Format : Talk at Waseda University

Author(s) : Julio Cesar Carrillo-Escobar (Professor)Giovanni Ernesto Calderon-Silva (Universidad Industrial de Santander)

Abstract : It is usual to have stability restrictions when using either an explicit finite differences or a mimetic differences schemes, proposed by Castillo in 2003, to obtain numerical solutions for the convection-diffusion-reaction equation of an incompressible fluid with a source term. In this work, we analyze the effects, in precision and stability, when applying the discrete mollification proposed by Acosta in 2008 to these schemes in mimetic differences.

[01936] Numerical Energy Conservation Mimetic Scheme For The Advection Equation

Format : Online Talk on Zoom

Author(s) : Anand Srinivasan (San Diego State University)Jose E Castillo (Computational Science Research Center at San Diego State University)

Abstract : The advection equation $u_t + \nabla \cdot u = 0$ is a hyperbolic partial differential equation that conserves energy. The numerical solution of the advection equation obtained using the traditional finite difference methods often fails to discretely conserve this numerical energy. Mimetic finite difference methods are structure-preserving and are thus well-suited for hyperbolic problems such as the advection equation. The Mimetic methods of Castillo et al discretely mimic the extended Gauss' divergence theorem, and are therefore a faithful discretization of the continuum vector calculus identities. These methods work on a staggered spatial grid and achieve even order of accuracy at the boundaries as well as the interiors of the domain. The temporal discretization obtained from the Leapfrog scheme is staggered in time. The staggered Mimetic-Leapfrog scheme conserves the numerical energy for the advection equation. In this talk, we present the numerical results illustrating the energy-conserving property of the second order Mimetic-Leapfrog scheme. Stability results of the scheme are also presented.

[01939] Energy Conservation for Mimetic Scheme for Advection Equation

Format : Talk at Waseda University
Author(s) : Jose E Castillo (Computational Science Research Center at San Diego State University)
Abstract : Mimetic difference schemes are based on discrete analogs of differential operators, gradient, divergence, and curl, that not only preserve their vector calculus identities but also hold discrete counterparts of integral formulas.
A proof of the energy conservation property of second-order mimetic difference schemes is presented for the one-dimensional advection PDE. This proof leverages on the discrete analog of the integration by parts mimetic difference property

[00783] PDE Eigenvalue Problems: Computational Modeling and Numerical Analysis

Session Time & Room :

00783 (1/5) : 3C (Aug.23, 13:20-15:00) @G701

00783 (2/5) : 3D (Aug.23, 15:30-17:10) @G701

00783 (4/5) : 4C (Aug.24, 13:20-15:00) @G701

00783 (5/5) : 4D (Aug.24, 15:30-17:10) @G701

Type : Proposal of Minisymposium
Abstract : Eigenvalue problems of partial differential equations have many important applications in science and engineering, e.g., design of solar cells for clean energy, calculation of electronic structure in condensed matter, extraordinary optical transmission, non-destructive testing, photonic crystals, and biological sensing. This mini-symposium focuses on the computation modeling and numerical analysis for PDE eigenvalue problems. It intends to bring the leading researchers to discuss the recent developments and build collaborations among participants of various backgrounds.

[01926] Eigenvalues in Inverse Scattering

Format : Talk at Waseda University
Author(s) : Peter Monk (University of Delaware)
Abstract : Transmission eigenvalues can be determined from multistatic scattering data over a range of frequencies and have been suggested as target signatures in inverse scattering. To avoid the need for data over a range of frequencies other artificial eigenvalue problems can be derived by modifying the far field operator. We shall consider “modified transmission eigenvalues” for thin structures. Numerical results will show that a few eigenvalues of each type can be determined from multi-static scattering data.

[01744] Inverse eigenvalue problems for inferring crystal structure from neutron scattering data

Format : Talk at Waseda University
Author(s) : Guannan Zhang (Oak Ridge National Laboratory)
Abstract : We are interested in inferring the atomic structure of crystal materials from neutron scattering data. The atomic structure is modeled by a parameterized Hamiltonian matrix and the measurements in neutron scattering experiments are the eigenvalues and functionals of the eigenvectors of the Hamiltonian matrix. The goal is to find

the optimal parameter in the Hamiltonian matrix to match the scattering data. The main challenge is that the spectrum of the Hamiltonian matrix is very sensitive to its parameters, which leads to a very rough loss landscape. To address this issue, we propose a new loss function that utilize the characteristic polynomial of the Hamiltonian matrix as the loss function. When a matrix has the same eigenvalues as the measurement data, the characteristic loss is zero. Our experiments show that the new loss has a much smoother landscape for an optimization algorithm to find a satisfactory solution. We have demonstrated the effectiveness of our approach in solving the crystal field parameters from neutron scattering data.

[01689] Application of Prolate Eigensystem to Born Inverse Scattering

Format : Talk at Waseda University
Author(s) : Shixu Meng (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : This talk discusses the application of generalized prolate spheroidal wave functions and eigenvalues (in short prolate eigensystem) to Born inverse scattering problems. We first establish a Picard criterion to reconstruct the contrast. Further motivated by a Sturm-Liouville theory associated with the prolate eigensystem, we give a spectral cutoff regularization for noisy data and an explicit stability estimate for contrast in H^s, $0

[01864] Computational tools for exploring eigenvector localization

Format : Talk at Waseda University
Author(s) : Jeffrey Ovall (Portland State University)Robyn Reid (Portland State University)
Abstract : It is well-known that waves can often be decomposed as an infinite sum
where each term in the sum is a product of a function varying
only in time and a function varying only in space. The spatial functions are often called
standing waves in this context, and are eigenvectors
of a spatial differential operator associated with
the medium through which the waves are propagating.
It is not as well-known that properties of the
medium can cause some eigenvectors to be strongly spatially localized.
A practical consequence of eigenvector localization is that waves at certain
frequencies can be `trapped'' at some location or`channelled"
along some favorable path. Such features are of interest in the
design of structures having desired acoustic or electromagnetic
properties: sound-mitigating outdoor barriers and next generation
organic LEDs and solar cells are examples of this design principle in
action. There remain many open problems related to understanding and
exploiting this kind of localization, and we will discuss a
computational approach that we expect will provide useful insight. More
specifically, we focus on the issue of eigenvector localization, outlining our
computational approach and providing theoretical, heuristic, and
empirical support for it through several examples (with many
pictures).

00783 (2/5) : 3D @G701 [Chair: Jeffrey Ovall]

[01877] LOWER EIGENVALUE BOUNDS FOR THE HARMONIC AND BI-HARMONIC OPERATOR

Format : Talk at Waseda University
Author(s) : Carsten Carstensen (Humboldt-Universitaet zu Berlin umboldt-Universitaet zu Berlin)Sophie Puttkammer (Humboldt-Universitaet zu Berlin umboldt-Universitaet zu Berlin)
Abstract : Like guaranteed upper eigenvalue bounds with conforming finite element methods, guaranteed lower eigenvalue
bounds (GLB) follow from min-max principles. Part 1 recalls GLB for the simplest second-order and fourth-order
eigenvalue problems from a simple post-processing. The maximal mesh-size therein destroys nive adaptive
mesh-refining and motivates a new methodology. Prt 2 present a new method with fine-tuned stabilization
for the direct computation of GLB. Part 3 studies an optimal adaptive mesh-refining algorithm.

[01904] Reduced order models for parametric PDE eigenvalue problems

Format : Talk at Waseda University

Author(s) : Daniele Boffi (KAUST)

Abstract : It is well known that the approximation of parametric eigenvalue problems offer much more challenges than the the corresponding source problems. This is due in particular to the lack of smoothness of the solutions with respect to the parameters. Multiplicities, clusters, and crossing of eigenvalues must be dealt with in an appropriate way in order achieve meaningful and accurate solutions.
We discuss how to track the eigensolutions in presence of multidimensional parameters and we propose new ideas for the model order reduction of eigenvalues problems.

[01686] Verification of guaranteed lower eigenvalue bounds form a hybrid-high order method

Format : Talk at Waseda University

Author(s) : Carsten Carstensen (Humboldt-Universität zu Berlin)Benedikt Gräßle (Humboldt-Universität zu Berlin)Ngoc Tien Tran (Friedrich-Schiller-Universität Jena)

Abstract : A new class of skeletal methods provides direct guaranteed lower eigenvalue bounds (GLB) under verifiable assumptions on the maximal mesh-size and discretisation parameters.
The verification of the GLB condition requires the knowledge of some stability constants and its validity implies that the computed discrete eigenvalue is already a GLB. This talk discusses the explicit estimation of the stability constants for the hybrid-high order (HHO) eigenvalue solver of Carstensen-Ern-Puttkammer [Numer.Math. 149, 2021] and its recent modification with an even simpler p-robust parameter selection.
We prove an a priori quasi-best approximation property and establish stabilization-free reliable and efficient a posteriori error control. Computer benchmarks provide striking numerical evidence for optimal high-order convergence rates of the associated adaptive mesh-refining algorithm.

[01859] Poisson solvers for the biharmonic eigenvalue problem with the Navier boundary condition

Format : Talk at Waseda University

Author(s) : Baiju Zhang (Beijing Computational Science Research Center)Hengguang Li (Wayne State University)Zhimin Zhang (Wayne State University)

Abstract : Consider the biharmonic eigenvalue problem with the Navier boundary condition. The Ciarlet-Raviart mixed method solves this problem by decomposing the 4th-order operator into two Laplacians but can produce spurious eigenvalues in non-convex domains. To overcome this difficulty, we adopt a recently developed mixed method, which decomposes the biharmonic equation into three Poisson equations and still recovers the original solution. Using this idea, we design an efficient biharmonic eigenvalue algorithm, which contains only Poisson solvers. With this approach, eigenfunctions can be confined in the correct space and thereby spurious modes in non-convex domains are avoided. Numerical results will be reported to validate the algorithm.

00783 (3/5) : 3E @G701 [Chair: Hengguang Li]

[01910] Why Spectral Methods are preferred in PDE Eigenvalue Problems?

Format : Talk at Waseda University

Author(s) : Zhimin Zhang (CSRC & WSU)

Abstract : When approximating PDE eigenvalue problems by numerical methods such as finite difference and finite element, it is common knowledge that only a small portion of numerical eigenvalues are reliable. As a comparison, spectral methods may perform extremely well in some situation, especially for 1-D problems. In addition, we demonstrate that spectral methods can outperform traditional methods and the state-of-the-art method in 2-D problems even with singularities.

[01726] High-precision guaranteed eigenvalue bounds using higher order finite elements and graded meshes

Format : Talk at Waseda University

Author(s) : Xuefeng LIU (Niigata University)

Abstract : The projection residue error-based eigenvalue bound proposed by the author has a drawback that it is influenced by the worst-case projection error and is not able to take the advantage of non-uniform meshes such as

graded meshes. To address these issues, we propose a new method based on the Kato-Lehmann-Goerisch theorem to obtain high-precision eigenvalue bounds that take full advantage of higher-order FEMs, graded meshes, and possible strong regularities of eigenfunctions.

[01925] Comparison of guaranteed lower eigenvalue bounds with three skeletal methods

Format : Talk at Waseda University
Author(s) : Emilie Pirch (Friedrich-Schiller-Universität Jena)Carsten Carstensen (Humboldt-Universitaet zu Berlin)Benedikt Gräßle (Humboldt-Universität zu Berlin)
Abstract : The focus of this talk is the comparison of three specially tailored skeletal hybrid schemes which provide direct guaranteed lower eigenvalue bounds (GLB) for the Dirichlet eigenvalue problem of the Laplacian. While the scheme presented in (Carstensen-Zhai-Zhang2020) has established the groundwork with a first formulation of the conditions under which GLB can be computed with a hybridized discontinuous Galerkin (HDG) method, a further development in (Carstensen-Ern-Puttkammer2021) results in a modified hybrid-high order method with a simplified stabilization term. However, it involves two parameters whose choice can be unclear due to stability estimates with constants which depend on the polynomial degree p of the approximation spaces and numerical computations show a lack of robustness. (Carstensen-Grässle-Tran2022,subm.) presents a different stabilization which uses a p-robust parameter. Numerical examples for all three methods and various polynomial degrees with optimal orders of convergence will be shown in this talk. The details of the qualitative differences in the computation of GLB and possible further practical improvements will be discussed.

[02081] Novel spectral methods using multivariate Muntz polynomials/functions for Schrodinger eigenvalue problems with singular potentials

Format : Talk at Waseda University
Author(s) : Huiyuan Li (Institute of Software Chinese Academy of Sciences)
Abstract : In this talk, we first introduce multivariate Muntz ball polynomials and Muntz Hermite functions, and then propose novel spectral methods for solving the eigenvalue problems of the Schrodinger operators $[-\Delta + c/|x|^2] + z|x|^{q/p}$ and $-\nabla \cdot (|x|^{2\mu}\nabla) + c|x|^{2\mu-2}$. The Muntz polynomials/functions are tailored to fit the singularities of the eigenfunctions and are orthogonal with respect to the inner product associated with the underlying Schrodinger operator. Numerical experiments demonstrate the efficiency and the exponential order of convergence of our methods, and validate the superiority over other methods.

00783 (4/5) : 4C @G701 [Chair: Xuefeng Liu]

[02157] Continuity and differentiability of eigenvalues of Laplacian with respect to general domain perturbations

Format : Talk at Waseda University
Author(s) : Takuya Tsuchiya (Ehime University)
Abstract : We consider the eigenvalue problems of Laplacian on bounded domains with Lipschitz boundaries. Suppose that a domain is smoothly perturbed, and the perturbation is parametrized in t.
In this talk, we discuss about continuity and differentiability of perturbed eigenvalues with respect to the parameter t.

[01803] GPU-accelerated high order mimetic finite difference methods for Maxwell equations and eigenproblems

Format : Talk at Waseda University
Author(s) : Yan Xu (University of Science and Technology of China)
Abstract : In this paper, we consider the eigenvalue problem of the three-dimensional time-harmonic Maxwell equations. The problem is discretized by the general mimetic finite difference method (MFDM), which is based on L^2 de Rham complex and has a deep relation with finite element exterior calculus theory. The discretization for the shifted differential operator is also covered. The main challenge arises from the large null space of the approximate curl operator. We introduce an auxiliary scheme to reach nontrivial eigenpairs without going through null space. We design a multigrid-type preconditioner for the algorithm to reduce the iteration count of the iterative eigensolver. Most of the algorithm are basic matrix and vector operators, which are fine-grained parallelism and

can be easily accelerated by GPU. Numerical examples of the band structures of three-dimensional photonic crystals are presented to demonstrate the capability and efficiency of the algorithm.

[01881] Compatible Approximation of Holomorphic Eigenvalue Problems

Format : Online Talk on Zoom
Author(s) : Martin Halla (eorg-August Universität Göttingen, Institut für Numerische und Angewandte Mathematik)
Abstract : I consider Galerkin approximations of EVP for holomorphic operator functions, which arise e.g. from finite element discretizations of PDE eigenvalue problems. The convergence is ensured for "regular" approximations (Karma (1996)). This property is unconditionally satisfied for weakly coercive problems. However, for non weakly coercive problems there exist hardly any results. I present a technique to prove the regularity for such cases, which builds upon the weak T-coercivity of the continuous problem.

[01914] The new computational method on elastic transmission eigenvalue problem

Format : Online Talk on Zoom
Author(s) : Yingxia Xi (Nanjing University of Science and Technology)Xia Ji (Beijing Institute of Technology)Shuo Zhang (Academy of Mathematics and Systems Science)
Abstract : We will present a finite element scheme for the elastic transmission eigenvalue problem written as a fourth order eigenvalue problem. The scheme uses piecewise cubic polynomials and obtains optimal convergence rate. Compared with other low-degree and nonconforming finite element schemes, the scheme inherits the continuous bilinear form which does not need extra stabilizations and is thus simple to implement.

[00785] Learning Dynamical Systems by Preserving Symmetries, Energies, and Variational Principles

Session Time & Room :

00785 (1/2) : 5B (Aug.25, 10:40-12:20) @F308

00785 (2/2) : 5C (Aug.25, 13:20-15:00) @F308

Type : Proposal of Minisymposium
Abstract : Dynamical systems abound in engineering and science, and their accurate long-time simulation and outer-loop applications such as control, design and uncertainty quantification remains a computational challenge. From first principles modeling of physical systems, it is clear that many of these dynamical systems have a natural geometric structure (e.g., Hamiltonian, Lagrangian, metriplectic) or symmetry (translational, rotational). Exploiting and enforcing this structure in physics-based learning methods remains imperative for capturing the underlying physics accurately. This minisymposium highlights recent developments in physics-preserving learning for dynamical systems, such as: Lagrangian/Hamiltonian neural networks, sparse identification of nonlinear dynamics (SINDy), operator inference, preservation of conservation laws, the incorporation of interconnection and modular structure, structure-preserving system identification and other machine learning approaches.

[01395] Symplectic Model Reduction on Quadratic Manifolds

Format : Talk at Waseda University
Author(s) : Boris Kramer (University of California San Diego)
Abstract : When Hamiltonian models are used for long-term simulation, constraints on CPU hours need to be met. Structure-preserving model reduction for Hamiltonian systems addresses this computational issue by projecting Hamilton's equations of the full-order model onto linear symplectic subspaces, which can yield inaccurate results for problems with a slowly decaying Kolmogorov n-width. We present symplectic structure-preserving reduced-order modeling of Hamiltonian systems using quadratic manifolds. We demonstrate the proposed method on wave equations in 1-D and 2-D.

[01373] Identification of variational principles, symmetries, and conservation laws from data

Format : Talk at Waseda University
Author(s) : Yana Lishkova (University of Oxford)Paul Scherer (University of Cambridge)Steffen Ridderbusch (University of Oxford)Mateja Jamnik (University of Cambridge)Pietro Lio (University of Cambridge)Sina Ober-Blöbaum (Paderborn University)Christian Offen (Paderborn University)
Abstract : The identification of equations of motions of dynamical systems from data as well as dynamical properties such as symmetries and conservation laws is an important task in the context of system identification. I will show a framework based on Lie group theory to learn a variational principle governing a dynamical system which can identify variational symmetries and conservation laws along the way. Identified symmetries prove helpful when the learned equations of motions are integrated numerically.

[01597] Data-driven structure-preserving model reduction for stochastic Hamiltonian systems

Format : Talk at Waseda University
Author(s) : Tomasz Tyranowski (Max Planck Institute for Plasma Physics)
Abstract : In this work we demonstrate that SVD-based model reduction techniques known for ordinary differential equations, such as the proper orthogonal decomposition, can be extended to stochastic differential equations in order to reduce the computational cost arising from both the high dimension of the considered stochastic system and the large number of independent Monte Carlo runs. We also extend the proper symplectic decomposition method to stochastic Hamiltonian systems, both with and without external forcing, and argue that preserving the underlying symplectic or variational structures results in more accurate and stable solutions that conserve energy better than when the non-geometric approach is used. We validate our proposed techniques with numerical experiments for a semi-discretization of the stochastic nonlinear Schrödinger equation and the Kubo oscillator.

[01793] Learning video models with Lagrangian/Hamiltonian neural networks

Format : Talk at Waseda University
Author(s) : Christine Allen-Blanchette (Princeton University)
Abstract : The dynamics underlying object and camera motion in a video typically evolve on a low-dimensional manifold with unknown structure and dimension. While prior work has used the Hamiltonian formalism to give a physically meaningful interpretation to this manifold, the problem of discovering the manifold structure and dimension remains unaddressed. We introduce a Hamiltonian neural network for video generation where the structure and dimension of the phase-space are implicitly learned from data. To achieve this we introduce a GAN-based video generation pipeline which embeds a learned transformation from a Gaussian distribution to the phase-space manifold, and captures the underlying dynamics of the video in a Hamiltonian neural network motion model.

00785 (2/2) : 5C @F308 [Chair: Boris Kramer]

[02758] Structure-preserving exterior calculus for GNNs: surrogates, physics discovery, and causality

Format : Online Talk on Zoom
Author(s) : Nathaniel Trask (Sandia National Laboratories)
Abstract : We present a graph exterior calculus which may be used to design graph neural network which naturally preserve mathematical and physical structure without resorting to physics-informed regularizers. The calculus provides a framework for proving numerical stability, conservation, preservation of geometric symmetries, thermodynamic consistency, gauge conditions, and other properties more typical of traditional PDE discretization. In this setting we discover Whitney forms encoding physically relevant subdomains, their boundaries, and flux conservation laws for multiphysics/multiscale systems. We introduce ongoing applications work using this to discover structure-preserving surrogates which exhibit 100000x speedup for typical problems while guaranteeing mathematical robustness, and introduce recent extensions discovering causal relationships in scientific datasets.

[00787] Space Weather: Modeling, Surrogates and Uncertainty Quantification

Session Time & Room : 5D (Aug.25, 15:30-17:10) @F308

Type : Proposal of Minisymposium
Abstract : Electronic technologies that govern modern life, such as the Global Positioning System, are dependent on satellite technologies, which require accurate space weather models with quantified uncertainties to operate safely and efficiently. Uncertainties in space weather models are wide-ranging. They can stem from how the models are driven, e.g., parameters, initial conditions, forcing, and from the treatment of the internal physics and numerics. For example, predictions of thermospheric density must account for model-form and parametric uncertainty in models of thermal conductivity and Nitric Oxide cooling. This minisymposium presents broad class of novel UQ methods for the exciting application of space weather.

[02020] Model Calibration for Ensemble CME Simulation with the SWMF

Format : Talk at Waseda University
Author(s) : Hongfan Chen (University of Michigan)Yang Chen (University of Michigan)Xun Huan (University of Michigan)Bartholomeus van der Holst (University of Michigan)Shasha Zou (University of Michigan)Zhenguang Huang (University of Michigan) Nishtha Sachdeva (University of Michigan) Aniket Jivani (University of Michigan)Daniel Iong (University of Michigan)Ward Manchester (University of Michigan)Gabor Toth (University of Michigan)Yifu An (University of Michigan)
Abstract : The Space Weather Modeling Framework $(SWMF)$ enables ensemble coronal mass ejection (CME) simulation based on coupled first principles and/or empirical models. The main challenge of calibrating unknown parameters of such physics-based models lies in high computational complexity and potential model inadequacy. In this talk, we present model calibration for the parameters of Gibson-Low flux-rope-based CMEs. Leveraging machine learning tools, we quantify the uncertainty in flux-rope parameters by assimilating in-situ and remote observations.

[02101] Model reduction with data assimilation for thermospheric mass density forecasting

Format : Talk at Waseda University
Author(s) : Peng Mun Siew (Massachusetts Institute of Technology)Richard Linares (Massachusetts Institute of Technology)
Abstract : Earth atmospheric drag remains one of the main sources of uncertainties for orbit prediction of space objects residing in the Low Earth Orbit. In this work, we explore the usage of machine learning-based techniques to develop a data-driven dynamic reduced-order model for real-time forecasting of the thermospheric density field.

The high-dimensional thermospheric density field is projected onto a lower-dimensional latent space using nonlinear embedding via the deep encoder network.

[01696] Bayesian Parameter Estimation for Ambient Solar Wind Models

Format : Online Talk on Zoom
Author(s) : Opal Issan (University of California San Diego)Boris Kramer (University of California San Diego)Enrico Camporeale (National Oceanic and Atmospheric Administration)
Abstract : The solar wind is an essential driver of space weather geomagnetic storms. A significant challenge in using first-principle solar wind models is estimating input parameters that can not be directly measured. Thus, we need to quantify the uncertainty of such input parameters on the solar wind. We perform global sensitivity analysis to understand which parameters influence the model output the most and learn the posterior distribution of the most influential input parameters via Bayesian inference.

[02759] A multi-fidelity boosted method with built-in uncertainty quantification and its application to geomagnetic storms prediction

Format : Online Talk on Zoom
Author(s) : Andong Hu (CIRES, CU Boulder)Enrico camporeale (CIRES, CU Boulder)Brian swiger (CIRES, CU Boulder)
Abstract : An multi-fidelity based Gated Recurrent Unit (GRU) method is developed to assist ensemble technique to forecast extreme space weather events and their reliability. We have implemented this method on two space weather applications, i.e., 1) a one-to-six-hour lead-time model that predicts the value of Disturbance storm time (Dst) using solar wind (SW) data; and 2) an geoelectric field model with multi-hour leading time using SW and SuperMag data.

[00789] Algorithmic advances in computational quantum mechanics

Session Time & Room :

00789 (1/3) : 3C (Aug.23, 13:20-15:00) @D405

00789 (2/3) : 3D (Aug.23, 15:30-17:10) @D405

00789 (3/3) : 3E (Aug.23, 17:40-19:20) @D405

Type : Proposal of Minisymposium
Abstract : Chemistry, physics, and materials science have benefited tremendously from advances in algorithmic tools for the simulation of quantum systems. In recent years, ideas developed in collaboration with the applied mathematics community have played an increasingly prominent role. This minisymposium will focus on recent algorithmic advances in computational quantum mechanics driven by numerical linear algebra, numerical methods for partial differential equations and integral equations, fast algorithms for the manipulation of structured operators, convex optimization, tensor networks, randomized algorithms, and machine learning methods.
Organizer(s) : Jason Kaye, Michael Lindsey
Classification : 81-08, 65Z05, Computational Quantum Physics
Minisymposium Program :

00789 (1/3) : 3C @D405 [Chair: Jason Kaye]

[04860] Deterministic algorithms for the efficient evaluation of Feynman diagrams

Format : Talk at Waseda University
Author(s) : Jason Kaye (Flatiron Institute, Simons Foundation)Denis Golež (Jožef Stefan Institute)Hugo U. R. Strand (Örebro University)
Abstract : The evaluation of Feynman diagrams is a fundamental computational task, and bottleneck, in Green's function methods for quantum many-body calculations. Mathematically, diagrammatic expressions take the form of high-dimensional integrals involving products of low-dimensional functions. Numerical methods for the

efficient evaluation of these diagrams are predominantly based on Monte Carlo or quasi-Monte Carlo sampling. I will discuss recent progress in algorithms which exploit the structure of the diagrammatic expressions to obtain efficient deterministic algorithms. In particular, I will describe an algorithm for the evaluation of imaginary time diagrams based on sum-of-exponentials representations of Green's functions, and mention a related algorithm based on the decomposition of integrands into tensor trains using cross interpolation.

[04522] Quantics tensor trains meet quantum physics

Format : Talk at Waseda University

Author(s) : Hiroshi Shinaoka (Saitama University)

Abstract : In this talk, we apply quantics tensor train (QTT) to numerical simulations in quantum field theories[1]. Using QTT, we compress space-time dependence of correlation functions and solve equations in the compressed form. We also introduce quantics tensor cross interpolation to enhance the power of QTT-based calculations[2]. 1. H. Shinaoka et al., arXiv:2210.12984v2 (to appear in Phys. Rev. X), 2. M. K. Ritter et al., including H. Shinaoka, arXiv:2303.11819v2.

[03608] Circuit Forms of Compressed Functions and Operators with Applications

Format : Talk at Waseda University

Author(s) : Edwin Miles Stoudenmire (Flatiron Institute)

Abstract : Recently there has been growing interest in representing functions as tensor networks using the "quantized tensor train" format, which enables algorithms (integration, function optimization, ...) typically scaling logarithmically in the grid size. I will discuss techniques to construct functions and operators in this format using non-unitary analogues of quantum circuits. This leads to fast algorithms for Fourier and wavelet transforms, and has promising applications for systems of continuous variables in classical and quantum physics.

[05166] Tensor-network sketching and many-body physics

Format : Talk at Waseda University

Author(s) : Yuehaw Khoo (The University of Chicago)Yoonhaeng Hur (The University of Chicago)Yian Chen (The University of Chicago)Jeremy Hoskins (The University of Chicago)Michael Lindsey (UC Berkeley)Edwin Miles Stoudenmire (Flatiron Institute)

Abstract : We study how a function can be estimated as a low-rank tensor-network from Monte-Carlo samples, without the use of optimization and without the curse of dimensionality. We demonstrate the usefulness in generative modeling and many-body physics.

00789 (2/3) : 3D @D405 [Chair: Michael Lindsay]

[03946] Analyzing Non-equilibrium Quantum Many-body Dynamics by Dynamic Mode Decomposition

Format : Talk at Waseda University

Author(s) : Chao Yang (Lawrence Berkeley National Lab)Jia Yin (Lawrence Berkeley National Lab)Yuanran Zhu (Lawrence Berkeley National Lab)

Abstract : A practical way to compute time-dependent observables of an out-of-equilibrium quantum many-body system is to focus on the single-particle Green's function defined on the Keldysh contour. The equation of motion satisfied by such a Green's function is a set of nonlinear integro-differential equations called the Kadanoff-Baym equations. We will describe numerical methods for solving these equations and show how to use dynamic mode decomposition to reduce their computational complexity.

[05317] Some mathematical insights on DMET

Format : Talk at Waseda University

Author(s) : Fabian Maximilian Faulstich (Rensselaer Polytechnic Institute)

Abstract : High-accuracy methods are crucial for simulating static correlated systems, but they often scale severely. DMET can solve this by scaling highly accurate solvers. This talk shows that the exact ground-state density matrix is a fixed point of DMET for non-interacting systems, with a unique physical solution in the weakly-interacting regime. DMET is exact to first order in the coupling parameter, and numerical simulations confirm these results. Assumptions behind their validity are also discussed.

[04977] Efficient algorithms for Brillouin zone and frequency integration

Format : Talk at Waseda University
Author(s) : Lorenzo Xavier Van Munoz (Massachusetts Institute of Technology)Jason Kaye (Flatiron Institute, Simons Foundation)Sophie Beck (Flatiron Institute, Simons Foundation)
Abstract : Brillouin zone integration is a standard operation in electronic structure calculations used to compute numerous physical observables. For integrands with broad features at scale η, standard equispaced integration methods are highly effective. However, when η is small, adaptive methods become necessary to achieve converged results. We extend these adaptive, high-order accurate methods to problems with an additional frequency integral, such as the optical conductivity, and discuss how to control the error in these iterated integrals.

[04273] Extraction of resonant states in systems with defects

Format : Talk at Waseda University
Author(s) : Eloise Letournel (CERMICS)Antoine Levitt (Université Paris Saclay (LMO))Luigi Genovese (CEA Grenoble)Ivan Duchemin (CEA Grenoble)Simon Ruget (CERMICS)
Abstract : We introduce a numerical method to compute resonances induced by localized defects in crystals. We express the resonance in terms of a “resonance source" strictly localized within the defect region. We then compute a kernel equation, applying against this source the Green's function of the perfect crystal, which we show can be computed efficiently by a complex deformation of the Brillouin zone (BCD).

00789 (3/3) : 3E @D405 [Chair: Jason Kaye]

[03564] Density functional theories: reformulations and regularizations

Format : Talk at Waseda University
Author(s) : Michael Ruggenthaler (Max-Planck Institute for the Structure and Dynamics of Matter)
Abstract : Density functional theories try to reformulate quantum theories in terms of a set of reduced quantities, turning high-dimensional linear problems into low-dimensional but non-linear problems (1,2,3). In this talk I will give a short overview of open mathematical problems in density functional theories and provide potential solution strategies, either by Moreau-Yosida regularization (4) or by reformulating the the basic mappings (2,3).

[04839] Fine-grained parallelism is flow-based Monte Carlo algorithms

Format : Talk at Waseda University
Author(s) : Michael Samuel Albergo (New York University)Michael S Albergo (New York University)
Abstract : Transport-based generative models have become an active topic of inquiry in scientific computing and Monte Carlo-based numerical methods, with demonstrated applications ranging from lattice quantum field theory to molecular systems. In this will talk, I will discuss the flow-based Monte Carlo approach and present some results related to taking advantage of its embarrassingly parallel setup.

[04906] An unambiguous and robust formulation for Wannier localization

Format : Talk at Waseda University
Author(s) : Kangbo Li (Cornell University)
Abstract : We provide a new variational definition for the spread of an orbital under periodic boundary conditions (PBCs) that is continuous with respect to the gauge, well-suited to diffuse orbitals, and can be adapted for schemes to compute localized Wannier functions. Existing definitions do not satisfy all these desiderata, partly because they depend on an "orbital center"---an ill-defined concept under PBCs. Moreover, we illustrate a more robust and efficient ($10\times-70\times$ fewer iterations) localization scheme.

[00792] Recent Advances of Modeling and Computation of Moving Boundary Problems

Session Time & Room :

00792 (1/3) : 2C (Aug.22, 13:20-15:00) @D402

00792 (2/3) : 2D (Aug.22, 15:30-17:10) @D402

00792 (3/3) : 2E (Aug.22, 17:40-19:20) @D402

Type : Proposal of Minisymposium
Abstract : A great number of real-life problems, important for engineering and biological applications, involve time-dependent boundaries, whose motion is controlled by interactions among microscopic and macroscopic driving forces. At the continuum level, one derives models via energy variation approach so that the resulting formulation, usually posed as systems of coupled PDEs and boundary conditions, is consistent with physical laws. To date, grand challenges remain in high-fidelity modeling and efficient computation of these multiscale problems. This minisymposium will (1) address some of most recent topics in modeling and computation; (2) nurture collaborations among investigators in mathematics, biophysics, and engineering.

[01873] Solving motions of an incompressible interface with bending in Navier-Stokes flows

Format : Talk at Waseda University
Author(s) : Yunchang Seol (Sungkyunkwan University)Ming-Chih Lai (National Yang Ming Chiao Tung University, Taiwan)Kian Chuan Ong (Fields Institute for Research in Mathematical Sciences)Yongsam Kim (Chung-Ang University)
Abstract : We present two numerical approaches in the immersed boundary method for solving motions of an incompressible biological cell membrane, a vesicle structure sharing similar behaviors with red blood cells. In the original problem, the surface tension enforcing the interfacial incompressibility is unknown, so the fluid variables and the tension shall be found together via an iterative method which requires huge computational cost. To overcome this difficulty, we introduce a penalty idea and a projection approach.

[01918] Convergence of boundary integral methods for interfacial Stokes and Darcy flow with surface tension

Format : Online Talk on Zoom
Author(s) : David M Ambrose (Drexel University)
Abstract : We consider efficient numerical methods for interfacial fluid flow. For interfacial Darcy flow in three space dimensions and interfacial Stokes flow in two space dimensions, we demonstrate convergence of boundary integral methods. The problems are subject to the effect of surface tension and/or elastic membrane forces. The proofs rely on energy estimates. This will include joint work with Yang Liu, Michael Siegel, Svetlana Tlupova, and Keyang Zhang.

[02287] A Cartesian Grid-Based Boundary Integral Method for Moving Interface Problems

Format : Talk at Waseda University
Author(s) : Han Zhou (Shanghai Jiao Tong University)Wenjun Ying (Shanghai Jiao Tong University)
Abstract : Moving interface problems are ubiquitous in natural sciences. Often the interface motion is coupled with PDEs in the bulk domain. This talk will present a Cartesian grid-based boundary integral method for solving

moving interface problems. Layer potentials are evaluated by solving simple interface problems on a Cartesian grid to take advantage of fast solvers such as FFTs and the geometric multigrid method. Numerical simulations, including crystal growth and two-phase flows, will be reported.

[02762] An explicit numerical method for the Cahn-Hilliard equation

Format : Talk at Waseda University
Author(s) : Junseok Kim (Korea University)Soobin Kwak (Korea University)
Abstract : In this talk, I present an explicit conservative numerical method for the Cahn–Hilliard (CH) equation, which is a famous mathematical model for conservative phases. The CH equation has been applied in many important problems and a lot of computational methods were developed to numerically compute the CH equation. So far most of numerical methods were based on implicit numerical methods because of very stiff timestep restriction of the explicit scheme. To overcome this severe time-step restriction of the explicit scheme, we developed an explicit conservative numerical scheme. To demonstrate the superior performance of the proposed scheme, we present the computational experiments.

00792 (2/3) : 2D @D402

[02792] Viscous fingers in a Hele-Shaw cell under an electric field

Format : Talk at Waseda University
Author(s) : Meng Zhao (Huazhong University of Science and Technology)
Abstract : We investigate the nonlinear dynamics of a moving interface in a Hele-Shaw cell subject to an in-plane applied electric field. We develop a spectrally accurate numerical method for solving a coupled integral equation system. Our nonlinear results reveal that currents are able to promote/suppress the interface dynamics depending on its direction. When no fluid is injected, and a negative current is utilized, the interface tends to approach the origin and break up into several drops.

[02813] Computing viscoelastic and elastoplastic deformations induced by volumetric growth

Format : Talk at Waseda University
Author(s) : Min Wu (Worcester Polytechnic Institute)
Abstract : Based on a discretized energy formulation, I will present a numerical method to solve various nonlinear mechanical systems involving finite elastic deformation, Maxwell-type viscoelasticity, or elastoplasticity. I will show its application to simulate deformations of living and nonliving soft materials during volumetric growth with free boundaries. These simulations can give insight into swelling gel experiments, in vitro wound closure dynamics, and cell and tissue morphogenesis.

[02818] Disturbance flow generated by particles in linear viscoelastic fluids

Format : Talk at Waseda University
Author(s) : Xiaofan Li (Illinois Institute of Technology)Hualong Feng (California State Univ, Bakersfield)Amlan Barua (Indian Institute of Technology Dharwad)Shuwang Li (Illinois Institute of Technology)
Abstract : Studying effects of moving particles on fluids is of fundamental importance for understanding particle dynamics and binding kinetics. We compute the fluid dynamics using an accurate boundary integral method with 3rd order accuracy in space. A unique feature of our method is that we can calculate the stress on the particle surface for a prescribed particle velocity profile. It is well known that a boundary layer develops along an infinite plate under oscillatory motion in a Newtonian fluid. When the flow becomes viscoelastic, however, the boundary layers are fundamentally different than those observed in Newtonian fluids.

[02820] Mathematical Modeling and Computation of Tumor Growth

Format : Online Talk on Zoom
Author(s) : Min-Jhe Lu (University of California, Irvine)John Lowengrub (University of California, Irvine)Chun Liu (Illinois Tech)Shuwang Li (Illinois Tech)Yiwei Wang (University of California, Riverside)
Abstract : The building of the mechano-chemical tumor models aims to understand how the mechanical interaction and the biochemical reactions can influence the dynamics of tumor growth. The mechanical interaction within cells produces stress and the biochemical reactions involve chemical species supplying tumor with nutrients. In this talk I will demonstrate how we build the tumor models with energetic variational

approaches and the numerical simulation results in both sharp interface and diffuse interface formulation will also be given.

00792 (3/3) : 2E @D402

[02821] Hydrodynamics of Tunable Janus Particles

Format : Online Talk on Zoom
Author(s) : Rolf Josef Ryham (Fordham University)Yuan Nan Young (New Jersey Institute of Technology)Bryan Quaife (Florida State University)Szu-Pei Fu (Trinity College)
Abstract : We use a model recently developed for the many-body hydrodynamics of amphiphilic JPs under a viscous background flow to investigate distinct particle phases that arise when accounting for asymmetric and polar hydrophobes. We quantify the macroscopic properties of novel JP phases under a linear shear and a Taylor-Green mixing background flow and quantify their macroscopic, complex-fluid behavior. These numerical results provide insight into dynamic control of non-equilibrium active biological systems with similar self-organization.

[02823] Sharp interface problem of Ohta-Kawasaki Model

Format : Talk at Waseda University
Author(s) : Amlan K Barua (IIT Dharwad)
Abstract : The Ohta Kawasaki (OK) model investigates mesoscopic phase separation in block copolymers. In this talk, we discuss a sharp interface version of OK equations using matched asymptotic expansions. The resultant equations resemble a Hele-Shaw type system. We suggest a boundary integral formulation of the problem and propose highly accurate numerical techniques to solve the equations. We conduct long-time simulation using our numerical methods. The simulation results show the emergence of various interesting configurations.

[02835] Phase-field modeling and simulation of controllable dendritic growth

Format : Talk at Waseda University
Author(s) : Darae Jeong (Kangwon National University)
Abstract : In this study, we consider the controllable dendritic growth model with phase-field method. The governing system consists of three equations that are for capturing the interface between solid and melt phases, diffusion of the temperature, and structure by molecular orientations in solid. We propose the time-dependent adaptive mesh and finite-difference algorithm, which is designed to efficiently solve the governing system. After that, we present several numerical simulation to show the various patterns and its corresponding parameter effect for crystal formation. And we demonstrate the effectiveness of our approach by comparing numerical results with other method.

[00793] SIAM Student Chapter Research Presentations

Session Time & Room :

00793 (1/3) : 2E (Aug.22, 17:40-19:20) @E818

00793 (2/3) : 3C (Aug.23, 13:20-15:00) @E818

00793 (3/3) : 3D (Aug.23, 15:30-17:10) @E818

Type : Proposal of Minisymposium
Abstract : The SIAM Student Chapter Research Presentations minisymposium is designed to encourage student participation, to meet with both peers and professionals in their field and to promote interaction between newly established Student Chapters in the East Asia Section. The presentations given by students include recent advances in applied mathematics and computational science. Organizers also hope to encourage those in the learning community to establish new student chapters of SIAM and to strengthen collaboration opportunities between students and the SIAM leadership.

[03324] Continuum Limit of Nonlocal Diffusion on Inhomogeneous Networks

Author(s) : Itsuki Watanabe (Waseda University)
Abstract : We present two limit theorems for the zero-range process with nonlocal diffusion on inhomogeneous networks. The deterministic model is governed by the reaction–diffusion equation with an integral term in space instead of a Laplacian. By constructing the reproducing kernel Hilbert space to consider the inhomogeneities of the network structure, we prove that the law of large numbers and the central limit theorem hold for our models.

[03390] Computing the invariant measure of the N-vortex problem on the sphere by Hamiltonian Monte Carlo

Author(s) : Kota Takeda (Kyoto University)Takashi Sakajo (Kyoto University)
Abstract : We consider Hamiltonian Monte Carlo(HMC) to approximates a given target distribution on manifolds embedded in Euclidean space. Its efficiency is guaranteed by the exponential convergence property called geometric ergodicity. We have proven that HMC has geometric ergodicity for smooth distributions on compact manifolds. As an application, we compute the invariant measure of the N-vortex problem on the unit sphere by HMC.

[03516] REGULARIZED ADAPTIVE HUBER MATRIX REGRESSION AND DISTRIBUTED LEARNING

Author(s) : YUE WANG (City University of Hong Kong)
Abstract : Matrix regression provides a powerful technique for analyzing matrix-type data, as exemplified by many contemporary applications. Despite the rapid advance, distributed learning for robust matrix regression to deal with heavy-tailed noises in the big data regime still remains untouched. In this paper, we first consider adaptive Huber matrix regression with a nuclear norm penalty, which enjoys insensitivity to heavy-tailed noises without losing statistical accuracy. To further enhance the scalability in massive data applications, we employ the communication-efficient surrogate likelihood framework to develop distributed robust matrix regression, which can be efficiently implemented through the ADMM algorithms. Under only bounded $(1+\delta)$-th moment on the nose for some $\delta \in (0,1]$, we provide upper bounds for the estimation error of the central estimator and the distributed estimator and prove they can achieve the same rate as established with sub-Gaussian tails when only the second moment of noise exists. Numerical studies verify the advantage of the proposed method over existing methods in heavy-tailed noise settings.

[03650] Optimal Contextual Bandits with Knapsacks under Realizability via Regression Oracles

Author(s) : Jialin ZENG (Hong Kong University of Science and Technology)Yuxuan HAN (Hong Kong University of Science and Technology)Yang WANG (Hong Kong University of Science and Technology)Yang XIANG (Hong Kong University of Science and Technology)Jiheng ZHANG (Hong Kong University of Science and Technology)
Abstract : We study the stochastic contextual bandit with knapsacks (CBwK) problem, where each action, taken upon a context, not only leads to a random reward but also costs a random resource consumption in a vector form. The challenge is to maximize the total reward without violating the budget for each resource. We study this problem under a general realizability setting where the expected reward and expected cost are functions of contexts and actions in some given general function classes F and G, respectively. Existing works on CBwK are restricted to the linear function class since they use UCB-type algorithms, which heavily rely on the linear form and thus are difficult to extend to general function classes. Motivated by online regression oracles that have been successfully applied to contextual bandits, we propose the first universal and optimal algorithmic framework for CBwK by reducing it to online regression. We also establish the lower regret bound to show the optimality of our algorithm for a variety of function classes.

00793 (2/3) : 3C @E818

[03692] Differentially Private Confidence Interval for Extrema of Parameters

Author(s) : Xiaowen Fu (Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)Xinzhou Guo (Hong Kong University of Science and Technology)
Abstract : We aim to construct a valid and efficient confidence interval for the extrema of parameters under privacy protection. The usual statistical inference on the extrema of parameters often suffers from the selection bias issue, and the problem becomes more acute, as in many application scenarios of extrema parameters, we often need to protect the privacy of the data. In this work, we focus on the exponential family of distributions and propose a privatized parametric bootstrap method to address selection bias in the extrema of parameters problem under the scheme of differential privacy. While the usual privatized parametric bootstrap does not address selection bias appropriately, we prove that with a privatized bias correction term, the proposed parametric bootstrap method can lead to a valid and efficient confidence interval for the extrema of parameters. We illustrate the proposed method with the Gaussian case and regression case and demonstrate the advantages of the proposed method via numerical experiments and real data examples.

[03749] Spherical signal processing via framelets and convolutional neural networks

Author(s) : Jianfei Li (City University of Hong Kong)
Abstract : In this talk, we would like to introduce a general theoretical framework for constructing Haar-type tight framelets on any compact set with a hierarchical partition. In particular, we develop novel spherical framelets with directionality and combine them with CNNs for image denoising and inpainting tasks. The experiment results show that our proposed CNN model outperforms threshold methods.

[03813] O(N) dense direct factorization with near-perfect weak scaling.

Author(s) : Sameer Satish Deshmukh (Tokyo Institute of Technology)Rio Yokota (Tokyo Institute of Technology)George Bosilca (University of Tennessee at Knoxville)
Abstract : Approximating the off-diagonal blocks of dense matrices arising from the Boundary Element Method can reduce the time of a dense direct factorization from $O(N^3)$ to $O(N)$ with controllable error.

Distributed factorization of such algorithms is challenging due to the presence of small, irregular computations. In this talk, we show how asynchronous execution can achieve good weak scaling on FUGAKU for a variety of Green's functions on a 2D geometry.

[03907] Distributed Optimization with Imperfect Communication

Author(s) : Jie Liu (City University of Hong Kong)
Abstract : In distributed optimization over multi-agent networks, each agent is endowed with a local private objective function. The purpose of distributed optimization is to minimize the sum of all agents' local objective functions cooperatively through information communication between different agents. However, the communication channels in the real life are not always perfect due to limited data rates, communication delays, noises, etc. In this presentation, we shall discuss distributed optimization with imperfect communication.

00793 (3/3) : 3D @E818

[04039] SPHERICAL FRAMELETS FROM SPHERICAL DESIGNS

Author(s) : Yuchen XIAO (City University of Hong Kong)
Abstract : In this paper, we investigate in detail the structures of the variational characterization $A_{N,t}$ of the spherical t-design, its gradient $\nabla A_{N,t}$, and its Hessian $H(A_{N,t})$ in terms of fast spherical harmonic transforms. Moreover, we propose solving the minimization problem of $A_{N,t}$ using the trust-region method to provide spherical t-designs with large values of t. Based on the obtained spherical t-designs, we develop (semi-discrete) spherical tight framelets as well as their truncated systems and their fast spherical framelet transforms for the practical spherical signal/image processing. Thanks to the large spherical t-designs and localization property of our spherical framelets, we are able to provide signal/image denoising using local thresholding techniques based on a fine-tuned spherical cap restriction. Many numerical experiments are conducted to demonstrate the efficiency and

effectiveness of our spherical framelets, including Wendland function approximation, ETOPO data processing, and spherical image denoising.

[04179] Introducing Deep Unfolding: Incorporating Prior Knowledge into Deep Learning Models

Author(s) : Yumeng REN (City University of Hong Kong)
Abstract : Deep unfolding (DU) methods accelerate iterations for inverse problems by incorporating prior knowledge into deep learning models, which can be based on backbone iterations such as the ADMM algorithm for reconstruction tasks and a PDE discretization scheme for learning PDEs from data. In this talk, I will introduce the basics of DU methods, ADMM-type backbone iterations and recent advances.

[05002] Koopman analysis and Dynamic mode decomposition of Elementary Cellular Automata

Author(s) : Keisuke Taga (Waseda University)Yuzuru Kato (Future University Hakodate)Yoshihiro Yamazaki (Waseda University)Hiroya Nakao (Tokyo Institute of Technology)
Abstract : We perform Koopman spectral analysis and Dynamic mode decomposition (DMD) for Elementary Cellular Automata (ECA). Koopman operator is a linear operator describing the time evolution of observables of a dynamical system, and DMD is a data-driven approach to Koopman analysis. ECA is the simplest example of finite-state systems that describe spatiotemporal patterns and, thus, a good testbed for assessing the performance of DMD. We report the reproducibility of the dynamics and spectral properties of ECA by different DMD algorithms and explain the linear algebraic background.

[00794] Mathematical Modelling and Disease

Session Time & Room : 2E (Aug.22, 17:40-19:20) @A512

Type : Proposal of Minisymposium
Abstract : Mathematical modeling and estimation strategies are especially useful in the fight against disease be it through diagnosis, prediction, or management. Examples include analyzing medical device performance and providing simulation, constructing probabilistic/stochastic models that define classification strategies that in turn guide diagnostic testing. In this minisymposium, these themes will be investigated through specific ‘real world’ examples emphasizing metrology and the importance of measurement science in using mathematics to treat disease.
Organizer(s) : Anthony Kearsley, Luis Melara
Classification : 92-10, 92-08, 92C75
Minisymposium Program :

00794 (1/1) : 2E @A512 [Chair: Luis Melara]

[01627] Transboundary management of ecological systems with applications to diseases

Format : Talk at Waseda University
Author(s) : Julie Blackwood (Williams College)
Abstract : Human migration and infectious diseases often span multiple administrative jurisdictions that might have different systems of government and management objectives. I'll introduce two examples in which spatial coordination may be critical for disease control. First, I’ll demonstrate that spatial interactions of vampire bats likely play a key role in driving rabies persistence. Second, I’ll describe a more general infectious disease in humans and show that successful management may depend on the actions of multiple managers.

[04446] Separating Populations in Flow Cytometry Experiments: A Probabilistic Approach

Format : Talk at Waseda University
Author(s) : Danielle J Middlebrooks (National Institute of Standards and Technology)
Abstract : Flow cytometry (FC) is used in many areas of clinical testing, measuring cell characteristics of roughly one million cells. Data analysis is critical for interpreting FC measurements, but traditional techniques are often time-consuming and subjective. Our methodology identifies an unknown population by constructing probability density functions of specific biomarker expression levels in a sample. Once we estimate the unknown distribution, we compute the relative fraction of the unknown population and estimates of the uncertainty.

[04840] Case Studies in Modeling and Optimization for Diagnostics

Format : Talk at Waseda University
Author(s) : Prajakta Purushottam Bedekar (National Institute of Standards and Technology)Paul Patrone (National Institute of Standards and Technology)Anthony Kearsley (National Institute of Standards and Technology)
Abstract : We demonstrate that modeling and optimization are crucial tools for interpretation of diagnostic measurements through case studies. First we model the errors in dilution and find a best-fit to minimize variability of biological antibody measurements, enabling us to compare results across experiments. Secondly, we use optimal decision theory to develop a time-dependent, probabilistic classification and adaptive prevalence estimation scheme using antibody testing measurements. We demonstrate the results by using SARS-CoV-2 datasets.

[03298] Optimal Bandwith Selection in Bio-FET Measurements

Format : Talk at Waseda University
Author(s) : Luis Melara (Shippensburg University)
Abstract : The use of stochastic regression to separate signal from noise produced by Bio-FETs will be discussed in this talk. The noise realized by BioFETs interferes with quantitative and qualitative analysis, thus determining optimal bandwidth associated with experimental Bio-FET data measurements is an important task. Presented results suggest consistent across aspect rations and a choice of stochastic regression kernel function and yield what appear to be good results.

[00795] Topological data analysis and machine learning

Session Time & Room :

00795 (1/3) : 1C (Aug.21, 13:20-15:00) @G301

00795 (2/3) : 1D (Aug.21, 15:30-17:10) @G301

00795 (3/3) : 1E (Aug.21, 17:40-19:20) @G301

Type : Proposal of Minisymposium
Abstract : Topological Data Analysis (TDA), a relatively new field of data analysis, has proved highly useful in a variety of applications. Recently, much TDA research has been devoted to not only developing theories but also developing TDA compatible in machine learning workflow. This workshop will bring together researchers working on the areas of TDA and machine learning and provide an opportunity where they present their recent research and share ideas both in theory and applications. Further, this workshop will also provide recent progresses of computational tools developed for TDA combined with machine learning in various applications.
Organizer(s) : Jae-Hun Jung, Shizuo Kaji, Moo K. Chung
Classification : 00A65, 55N31
Minisymposium Program :

00795 (1/3) : 1C @G301 [Chair: Moo K. Chung]

[03334] Topological Data Analysis of Spatial Systems

Format : Talk at Waseda University

Author(s) : Mason Alexander Porter (UCLA)

Abstract : I discuss several applications of topological data analysis to spatial systems. I will consider examples from voting, city streets, the spread of COVID-19.

[03341] Bigraded persistence barcodes and their stability

Format : Talk at Waseda University

Author(s) : Anthony Bahri (Rider University)Ivan Limonchenko (Higher School of Economics)Taras Evgenievich Panov (Moscow State University)Jongbaek Song (Pusan National University)Donald Stanley (University of Regina)

Abstract : We define the bigraded persistent homology modules and the bigraded barcodes of a finite pseudo-metric space X using the ordinary and double homology of the moment-angle complex associated with the Vietoris-Rips filtration of X. Then we discuss the stability for the bigraded persistent double homology modules and corresponding bigraded barcodes.

[03617] Learning visual representation with homological labels

Format : Talk at Waseda University

Author(s) : Shizuo Kaji (Kyushu University)Yohsuke Watanabe (ZOZO inc.)

Abstract : We propose a new scheme for convolutional neural networks to learn visual representation with synthetic images and mathematically-defined labels that capture topological information. Our scheme can be viewed as a type of self-supervised learning, where the regression of vectorised persistent homology of an image is learned. We show that the acquired visual representation supplements the one obtained by the usual supervised learning with manually-defined labels by confirming an improved convergence in training for image classification. Our method provides a simple way to encourage the model to learn global features through a specifically designed task based on topology. It requires no real images nor manual labels and can be utilised at a minimal extra cost.

[03647] Exact multi-parameter persistent homology of time-series data: Fast and variable one-dimensional reduction of multi-parameter persistence theory

Format : Talk at Waseda University

Author(s) : Keunsu Kim (POSTECH)Jae-Hun Jung (POSTECH)

Abstract : Time-series data can be inferred as a periodic signal, enabling a continuous approximation with discrete Fourier transform to reveal the relation between its Fourier modes and topology of the data. We introduce an exact multi-parameter persistent homology construction utilizing the fast Fourier transform and Künneth formula, which computes and interprets the corresponding persistent barcode in a fast and efficient manner. This work is based on https://arxiv.org/abs/2211.03337

00795 (2/3) : 1D @G301 [Chair: Shizuo Kaji]

[03657] Generic transitions for flows on surfaces with or without constraints

Format : Talk at Waseda University

Author(s) : Tomoo Yokoyama (Saitama University)

Abstract : This talk describes the generic time evolutions of gradient flows and Hamiltonian flows on surfaces with or without physical constraints. Moreover, we show the non-contractibility of connected components of the spaces of such flows, respectively, under the non-existence of creations and annihilations of singular points by using combinatorics and simple homotopy theory.

[04624] Topological learning for multiscale biology

Format : Talk at Waseda University

Author(s) : Heather Harrington (University of Oxford)

Abstract : Biological processes are multi-scale. Spatial structures and patterns vary across levels of organisation, from molecular to multi-cellular to multi-organism. With more sophisticated mechanistic models and data available, quantitative tools are needed to study their evolution in space and time. The most prominent tool in

topological data analysis is persistent homology (PH), which provides a multi-scale summary of data. Here we present extensions to the PH pipeline and highlight its utility with concrete case studies.

[04715] Topological Data Analysis for Biological Images and Video

Format : Online Talk on Zoom
Author(s) : Peter Bubenik (University of Florida)
Abstract : I will present the results of two projects applying topological data analysis (TDA) and machine learning (ML) to biological data. In the first, we have developed a tool, TDAExplore, that combines TDA and ML to both classify biological images and to provide a visualization that is biologically informative. In the second, we use TDA and ML to classify quasi-periodic biological videos and we apply TDA to such a video to produce synthetic periodic videos.

[05453] Topological data analysis of music data and AI composition

Format : Talk at Waseda University
Author(s) : Jae-Hun Jung (POSTECH)Mai Lan Tran (POSTECH)Dongjin Lee (POSTECH)
Abstract : We employ topological data analysis to analyze music. Initially, the provided music data is transformed into a graph and we identify embedded cycles within the music using persistent homology. We elucidate how the cycle structure changes based on the metric definition between music nodes, with theoretical justifications. Then, we introduce the overlap matrix, which shows the interconnectedness of these cycles. We explain an AI algorithm utilizing the overlap matrix to facilitate new music compositions.

00795 (3/3) : 1E @G301 [Chair: Jae-Hun Jung]

[05456] GRIL: A 2-parameter Persistence Based Vectorization for Machine Learning

Format : Talk at Waseda University
Author(s) : Soham Mukherjee (PhD Student)Tamal Krishna Dey (Purdue University)
Abstract : 1-parameter persistent homology, a cornerstone in Topological Data Analysis (TDA), studies the evolution of topological features such as connected components and cycles hidden in data. It has been applied to enhance the representation power of deep learning models, such as Graph Neural Networks (GNNs). To enrich the representations of topological features, here we propose to study 2-parameter persistence modules induced by bi-filtration functions. In order to incorporate these representations into machine learning models, we introduce a novel vector representation called Generalized Rank Invariant Landscape (GRIL) for 2-parameter persistence modules. We show that this vector representation is 1-Lipschitz stable and differentiable with respect to underlying filtration functions and can be easily integrated into machine learning models to augment encoding topological features. We present an algorithm to compute the vector representation efficiently. We also test our methods on synthetic and benchmark graph datasets, and compare the results with previous vector representations of 1-parameter and 2-parameter persistence modules.

[05457] Topological Classification of Zero Sum Games

Format : Talk at Waseda University
Author(s) : Alexander Strang (University of Chicago)
Abstract : Zero-sum two-player games are widely used to model competitive interactions in biology, economics, and reinforcement learning. Unlike classical game theory, which focuses on optima, empirical game theory studies the structure of games and decision problems via observations of play by a population. We study a classification scheme for games based on their topology after embedding into a latent space. Using observed interactions, we infer the spectrum of the payout function when treated as the kernel of an integral operator. The eigenfunctions of the operator can be used to embed agents. The embedded agents form a scatter cloud whose topology provides a natural framework for classifying games. We study the classification of a series of randomly generated extensive form games and decision problems.

[05458] Topological Embedding of Brain Networks for Differentiating Temporal Lobe Epilepsy

Format : Talk at Waseda University
Author(s) : Moo K Chung (University of Wisconsin-Madison)
Abstract : In this study, we approach the discrimination of functional brain networks in temporal lobe epilepsy patients from those of healthy controls through persistent homology. Starting with a weighted graph, we perform a graph filtration, yielding the birth-death decomposition. This process allows us to uniquely decompose each graph into two subgraphs characterized by 0D and 1D topology. The 0D subgraph arises from the birth of connected components, whereas the 1D subgraph manifests through the death of 1-cycles during the filtration. The distinguishing features of each graph are thus represented by the sorted birth and death values. To compare multiple weighted graphs, we propose a topological version of multidimensional scaling, which embeds these graphs into a 2D plane. This technique offers potential insights for resting-state functional magnetic resonance imaging (rs-fMRI) studies, particularly in distinguishing the functional brain networks associated with temporal lobe epilepsy. This presentation draws upon the findings from the paper available on arXiv:2302.06673.

[05459] Barcodes and Kernels for multiparameter persistence

Format : Online Talk on Zoom
Author(s) : Mathieu Carrière (Centre Inria d'Université Côte d'Azur)
Abstract : Multiparameter persistence is a generalization of persistent homology that allows for more than a single filtration function. Such constructions arise naturally when considering data with outliers or variations in density, time-varying data, or functional data.

In single-parameter persistence, the barcode is equivalent to the “rank invariant”: the function that associates the rank of the corresponding linear map to every pair of comparable points. However, nearly all of the tools developed in persistent homology are based on the barcode. This is because it is a concise and geometric descriptor that lends well to data analysis and visualization. Therefore, it is crucial, and perhaps imperative, to construct a generalized barcode to work with the rank-invariant for multiparameter persistence efficiently.

Perhaps surprisingly, recent work has shown that if we allow the elements of the barcode to be signed intervals, then such a generalization is possible. I will discuss how one can use homological algebra to obtain a signed barcode in a stable manner. Furthermore, I will discuss how signed barcodes can be used in machine learning pipelines and report on recent computational results obtained using generalizations of the so-called sliced Wasserstein kernel to such signed barcodes.

[00802] Numerical Algorithms for the Eikonal Equation and Its Applications

Session Time & Room :

00802 (1/3) : 2D (Aug.22, 15:30-17:10) @F402

00802 (2/3) : 2E (Aug.22, 17:40-19:20) @F402

00802 (3/3) : 3C (Aug.23, 13:20-15:00) @F402

Type : Proposal of Minisymposium
Abstract : The minisymposium focuses on the recent state-of-art for the eikonal equation in view of the mathematical theories, diverse applications such as image processing, seismic wave travel time in layered media, 3D shape reconstruction, 3D printing, optimal control, homogenization, mean field games, and distance on a non-convex domain with polyhedral meshes, and their numerical algorithms; semi-discretization method, finite volume method, mimetic discretization method, using the Hopf-Lax formula, Jet marching method, variational methods, neural network approaches, etc. We also include a variant of the eikonal partial differential equation induced by Randers metric and a high order accurate efficient eikonal solvers on surfaces.
Organizer(s) : Jooyoung Hahn, Laurent Cohen
Classification : 49L25, 35D40, 65N22
Minisymposium Program :

00802 (1/3) : 2D @F402 [Chair: Jooyoung Hahn]

[03439] Eikonal methods applied to image segmentation

Format : Talk at Waseda University
Author(s) : Laurent D. Cohen (CEREMADE, Universite Paris dauphine, PSL, CNRS)
Abstract : Minimal paths have been used for long as an interactive tool to find contours or segment tubular and tree structures, like vessels in medical images. These minimal paths correspond to minimal geodesics according to some relevant metric defined on the image domain. Finding a geodesic distance and geodesic paths can be solved by the Eikonal equation using the fast and efficient Fast Marching method. We will present various applications to image segmentation.

[04713] Casualty and anisotropy in the design of eikonal solvers

Format : Talk at Waseda University
Author(s) : Jean-Marie Mirebeau (Centre Borelli, CNRS, ENS Paris-Saclay)
Abstract : The eikonal equation characterizes the arrival time of a front, propagating at a speed which is locally dictated by the front position and normal direction, and which crucially is always positive.
The causality property is the discrete counterpart of the monotonic progression of the front, and is at the foundation of efficient numerical solvers of the eikonal equation such as the fast marching method. I will describe an eikonal solver enjoying this property and applying to the tilted transversely anisotropy encountered in some geological media, as well as recent efforts on the formalization of the causality property, and its application to models which advect a state.

[03987] Learning to Measure Distances: High Order Accurate Efficient Eikonal Solvers on Surfaces

Format : Talk at Waseda University
Author(s) : Ron Kimmel (Technion - Israel Institute of Technologyn)
Abstract : The intimate relation between Eikonal equations and distance maps would be our starting point. When introducing a numerical solver, the balance between accuracy and complexity is at the core of computer science and a measure of quality of our solution. We will present a high accuracy deep learning method for approximating geodesic distances on surfaces at linear computational complexity. For training an accurate local solver a bootstrapping mechanism is employed.

[03578] An Artificial Neural Network Approach for Re-distancing Implicit Surfaces

Format : Talk at Waseda University
Author(s) : Yesom Park (Seoul National University)Chang hoon Song (Seoul National University)Jooyoung Hahn (Slovak University of Technology in Bratislava)Myungjoo Kang (Seoul National University)
Abstract : Following the success of machine learning tasks, the use of neural networks for solving PDEs has begun to show promising results. In this talk, we introduce a deep-learning-based method for recovering the signed distance function (SDF) from an implicit level set function representation of the hypersurface. By exploiting one of the main advantages of neural network approaches which is flexibility in network design and optimization objectives, our developments have two-fold: First, in order to increase the expressiveness of the network, we propose an augmented network that parameterizes the SDF together with the gradient of SDF as an auxiliary output while keeping the number of parameters. Second, we introduce a new objective that exploits a more global property and regularizes the singularity of the SDF by harnessing the geometric properties of the SDF. Numerical experiments on a diverse range of interfaces on two and three-dimensional domains validate the effectiveness and accuracy of the proposed method.

00802 (2/3) : 2E @F402 [Chair: Jooyoung Hahn]

[03777] Approximate viscosity solutions of hamilton-Jacobi equations: a review

Format : Online Talk on Zoom
Author(s) : Italo Capuzzo Dolcetta Italo (Sapienza Università di Roma)
Abstract : Semi-discretization methods to approximate viscosity solutions of Hamilton-Jacobi equations arising in different applied contexts such as optimal control, shape from shading, homogenization, and mean field games

[04731] Eikonal equation in 3D shape reconstruction and 3D printing

Format : Online Talk on Zoom
Author(s) : Silvia Tozza (Dept. of Mathematics, University of Bologna)
Abstract : The topic of this talk is related to Hamilton-Jacobi equations and their numerical resolution in the context of Image Processing. More in details, we will deal with the 3D reconstruction of the shape of an object (the resolution of the so-called Shape-from-Shading problem via a differential approach) and some problems related to 3D printing of the reconstructed object. In particular cases, the Hamilton-Jacobi equation describing these problems reduces to the eikonal equation.

[04972] The redistancing problem using Hopf-Lax formula and its applications

Format : Talk at Waseda University
Author(s) : Byungjoon Lee (The Catholic University of Korea)
Abstract : The redistancing, or reinitialization, problem is an important subject when one considers the signed distance function to the interface. There have been many researches on redistancing a given function to a signed distance function, based on numerical methods to solve the following eikonal equation:
$\frac{\partial \phi}{\partial t}(x,t) + \|\nabla_x \phi(x,t)\|_2 = 0,\ \ (x,t) \in \mathbb{R}^n \times (0,\infty)$
In this talk, we review the novel redistancing technique based on Hopf-Lax formula equipped with the split Bregman approach and discuss on its applications.

[04630] Comparison study of image-segmentation techniques by a curvature-driven flow of planes curves

Format : Talk at Waseda University
Author(s) : Shigetoshi Yazaki (Meiji University)
Abstract : In this talk, we deal with image segmentation by a curvature-driven flow of curves in the plane.
We focus on images in the plane. Several methods to image segmentation are discussed.
For instance, the minimum radius method, L2-gradient flow method, stepwise method, etc.
Then, all methods are compared in the qualitative computational study.

00802 (3/3) : 3C @F402 [Chair: Laurent D. Cohen]

[03535] Variational methods for distance function approximation and applications

Format : Talk at Waseda University
Author(s) : Pierre-Alain Fayolle (University of Aizu)Alexander Belyaev (Heriot-Watt University)
Abstract : The distance function (signed or unsigned) to the boundary (curve or surface) of a given geometric domain is a useful tool in geometry processing, shape and solid modeling, as well as other related domains. It has various applications in several fields including surface reconstruction from scattered data, meshing, shape interrogation, computational fluid dynamics (turbulence modeling), computational mechanics, and robot path planning. In this talk, I will focus on several recent variational methods for computing the distance function or its approximation. Efficient numerical algorithms corresponding to these methods will also be discussed.

[02323] Solving the eikonal equation utilizing mimetic methods

Format : Talk at Waseda University
Author(s) : Miguel Dumett (San Diego State University)
Abstract : The Eikonal equation with Soner boundary conditions is solved utilizing high-order mimetic differences. Mimetic difference methods construct PDE discrete analogs. These preserve vector calculus identities as well as its integral theorems while keeping constant order of accuracy over the whole grid, including the boundary. The proposed algorithm leverages on the Fast Marching method and resembles a quasi-Newton iterative scheme.

[03845] Jet marching on unstructured meshes: algorithms and applications

Format : Talk at Waseda University
Author(s) : Samuel F Potter (Courant Institute of Mathematical Sciences)
Abstract : The jet marching method (JMM) solves the eikonal equation by marching its jet using semi-Lagrangian updates (i.e., local raytracing). Marching jets enables a compact Hermite interpolation-based scheme,
enabling the use of paraxial raytracing for marching the amplitude of the associated geometric optic wave. We use the JMM to solve high-frequency wave problems on unstructured meshes, with applications motivated by computational room acoustics and light transport in miniwasp ommatidia.

[03445] Regularized eikonal equation on polyhedral meshes

Format : Talk at Waseda University
Author(s) : Jooyoung Hahn (Slovak University of Technology in Bratislava)Karol Mikula (Slovak University of Technology in Bratislava)Peter Frolkovič (Slovak University of Technology in Bratislava)
Abstract : A cell-centered finite volume method (FVM) is discussed to compute a distance from objects on a 3D computational domain discretized by polyhedral cells. Time-relaxed and Laplacian-regularized eikonal equations are compared numerically and we show how the Soner boundary condition is straightforwardly combined in a conventional FVM code. The Laplacian regularization is more practical for large numbers of cells or distant regions of interest. Additionally, the algorithms can be implemented with parallel computing using domain decomposition.

[00810] Recent Developments on the Numerical Solution of Least Squares Problems

Session Time & Room :

00810 (1/3) : 1C (Aug.21, 13:20-15:00) @E508

00810 (2/3) : 1D (Aug.21, 15:30-17:10) @E508

00810 (3/3) : 1E (Aug.21, 17:40-19:20) @E508

Type : Proposal of Minisymposium
Abstract : Talks will be presented on recent developments in the numerical solution of least squares problems. Topics included are, numerical solution of least squares problems including preconditioners, rank-deficient and singular systems, quaternion least squares problems, total least squares problems including condition numbers and quantum-inspired algorithms, randomized algorithms such as the randomized Kaczmarz method, and regularization methods for the solution of ill-posed problems.
Organizer(s) : Ken Hayami, Yimin Wei
Classification : 65F10, 65F20, 65F08, 65F22, 68W20
Minisymposium Program :

00810 (1/3) : 1C @E508 [Chair: Ken Hayami]

[01652] MinAres: An Iterative Solver for Symmetric Linear Systems

Format : Talk at Waseda University
Author(s) : Alexis Montoison (GERAD and Polytechnique Montréal)Dominique Orban (GERAD and Polytechnique Montréal)Michael Saunders (Stanford University)
Abstract : We introduce an iterative solver named MinAres for symmetric linear systems $Ax \approx b$, where A is possibly singular.
MinAres is based on the symmetric Lanczos process, like Minres and Minres-QLP, but it minimizes $\|Ar_k\|$ in each Krylov subspace rather than $\|r_k\|$, where r_k is the current residual vector.
In our experiments, MinAres terminates significantly earlier than Minres on ill-conditioned and singular linear systems.

[02064] Fast inverse LU preconditioner based on the Sherman--Morrison formula

Format : Talk at Waseda University
Author(s) : José Mas (Universitat Politècnica de València)José Marín (Universitat Politècnica de València)Juana Cerdán (Universitat Politècnica de València)Rafael Bru (Universitat Politècnica de València)
Abstract : A fast version of an approximate inverse LU preconditioner to solve linear systems is constructed based on the Sherman--Morrison formula. A multiplicative decomposition of the approximate inverse of the coefficient matrix is obtained applying recursively the inversion formula. Moreover, this recursion can be expresed in a compact form which is used to compute the preconditioner.
The method is stable for nonsingular M-matrices and H-matrices.
Numerical results show that the new proposal is robust and competitive compared with other preconditioners.

[01679] GMRES using pseudoinverse for range symmetric singular systems

Format : Talk at Waseda University
Author(s) : Kota Sugihara (National institute of informatics)Ken Hayami (Professor Emeritus, National Institute of Informatics/The Graduate University for Advanced Studies (SOKENDAI))
Abstract : For range symmetric singular linear systems, GMRES converges to the least squares solution in exact arithmetic. We derive necessary and sufficient conditions for GMRES to converge assuming exact arithmetic except for the computation of the elements of the Hessenberg matrix. In practice, GMRES may not converge due to numerical instability. Thus, we propose using the pseudoinverse for the solution of severely ill-conditioned Hessenberg systems. Numerical experiments indicate that the method is effective.

[02051] Solving rank deficient mixed sparse-dense linear least-squares problems by updating preconditioned iterative methods

Format : Talk at Waseda University
Author(s) : Ning Zheng (The Institute of Statistical Mathematics)
Abstract : We consider the preconditioning of linear least squares problem when the large sparse coefficient matrix contains a few dense rows. Such mixed sparse dense least squares problem arises from many scientific practical problems. We propose preconditioned iterative methods for solving the problem when the sparse part is rank deficient and the whole system is rank deficient, respectively. Numerical experiments are presented to show the feasibility and efficiency of the proposed methods.

00810 (2/3) : 1D @E508 [Chair: Raymond Chan]

[02061] Preconditioners based on random sampling for solving least squares problems

Format : Talk at Waseda University
Author(s) : Junfeng Yin (Tongji University)Yuxin Ye (Tongji University)Aqin Xiao (Tongji University)Nan Li (Tongji University)Ning Zheng (Tongji University)
Abstract : For the solution of large sparse least squares problems, preconditioned Krylov subspace methods are usually the fist choice and the preconditioners play the important roles in accelerating the convergence of the iteration. After the study on incomplete QR decomposition preconditioners based on Givens rotation, we proposed the preconditioners on random sampling and QR decomposition for solving least squares problems. Theoretical analysis and numerical experiments are presented to show the efficiency of the preconditioners, compared with the existing preconditioners.

[01654] On Convergence Analysis of the Randomized Gauss-Seidel Method

Format : Online Talk on Zoom
Author(s) : Lu Wang (Hebei Normal University)
Abstract : The Gauss-Seidel and Kaczmarz methods are two classical iteration methods for solving systems of linear equations, which operate in column and row spaces, respectively. In this report, by utilizing the inner connections between these two methods and the convergence analysis of the randomized Kaczmarz method, we give a new upper bound for the convergence rate of the randomized Gauss-Seidel method. Moreover, these convergence results are extended to the more general extrapolated randomized Gauss-Seidel method.

[01890] Condition numbers for the total least squares problems

Format : Online Talk on Zoom
Author(s) : Huaian Diao (Jilin University)
Abstract : The total least squares problems (TLS) is a generalization of the linear least squares problem and has many applications in linear system theory, computer vision, image reconstruction, system identification, speech and audio processing, modal and spectral analysis, etc. Perturbation analysis and algorithms for TLS have been studied extensively in the past decades. In this talk, I shall report our recent progresses on condition numbers for TLS.

[02050] Quantum-inspired algorithm for truncated total least squares solution

Format : Talk at Waseda University
Author(s) : Yimin Wei (Fudan University)
Abstract : Compared with the ordinary least squares method, for total least squares (TLS) problem we take into account not only the observation errors, but also the errors in the measurement matrix, which is more realistic in practical applications. For the large-scale discrete ill-posed problem $Ax \approx b$, we introduce the quantum-inspired techniques to approximate the truncated total least squares (TTLS) solution.

00810 (3/3) : 1E @E508 [Chair: José Mas]

[01317] Selecting Regularization Parameters for Nuclear Norm Type Minimization Problems

Format : Talk at Waseda University
Author(s) : Raymond Honfu Chan (City University of Hong Kong)Kexin Li (Hunan Normal University)Hongwei Li (Captial Normal University)Youwei Wen (Hunan Normal University)
Abstract : The reconstruction of low-rank matrix from its noisy observation is a constrained nuclear norm minimization problem, where the constraint bound η can be estimated from the noise variance. Its solution can be obtained by the singular value thresholding operator where the thresholding parameter λ is the same as the regularization parameter. We derive a closed-form solution for λ in terms of η which allows us to automatically choose λ by the discrepancy principle.

[01895] A nonconvexly regularized least squares approach for sparsity aware estimation

Format : Talk at Waseda University
Author(s) : Masao Yamagishi (Tokyo Institute of Technology)Isao Yamada (Tokyo Institute of Technology)
Abstract : We present basic ideas and applications of a nonconvexly regularized least squares model ((\text{LiGME model})), which can achieve its overall convexity through strategic tuning of a matrix-valued parameter called the Generalized Moreau Enhancement ((\text{GME})) matrix. The LiGME model can exploit sparsity in a linearly transformed domain. Recent related advancements will also be introduced briefly.

[02058] Separable Quaternion Matrix Factorization

Author(s) : Junjun Pan (The University of Hong Kong)Michael Ng (The University of Hong Kong)
Abstract : This presentation proposes a separable low-rank quaternion linear mixed model for polarized signals. The corresponding problem is called Separable Quaternion Matrix Factorization (SQMF). We discussed some properties of matrices that SQMF can decompose. We propose a heuristic algorithm called the quaternion successive projection algorithm to determine the source matrix. To compute the activation matrix, we use the block coordinate descent algorithm. Polarization and spectro-polarimetric images are tested to verify the model's effectiveness.

[01543] GMRES methods for tomographic reconstruction with an unmatched back projector

Format : Talk at Waseda University

Author(s) : Ken Hayami (Professor Emeritus, National Institute of Informatics/The Graduate University for Advanced Studies (SOKENDAI))Per Christian Hansen (Technical University of Denmark)Keiichi Morikuni (University of Tsukuba)

Abstract : Unmatched pairs of forward and back projectors are common in X-ray CT computations due to the need for fast algorithms that best utilize the computer hardware. We propose using preconditioned GMRES, namely, AB-, BA- GMRES, to handle the unmatched normal equations. They are simple to implement and rely only on available forward and back projectors. Numerical experiments show that they exhibit a desired semi-convergence behavior and are suited for large-scale CT reconstruction problems with noisy data.

[00814] Inverse Problems for Moving Targets

Session Time & Room :

00814 (1/2) : 1C (Aug.21, 13:20-15:00) @D405

00814 (2/2) : 1D (Aug.21, 15:30-17:10) @D405

Type : Proposal of Minisymposium

Abstract : The inverse problems of determining the trajectory of a moving target arise from many significant industrial, medical and military applications such as radar imaging, underwater sonar system， auto target recognition etc. There has been growing interest from the mathematical community, because the design of efficient and stable numerical schemes relies heavily on deep mathematical understandings. The purpose of this symposium is to bring together researchers in this area to discuss mathematical models and inverse problems (including uniqueness, stability and numerics) for identifying moving objects governed by time-dependent PDEs.

00814 (1/2) : 1C @D405 [Chair: Guanghui Hu]

[03803] Direct reconstruction methods for moving sources in the wave equation

Format : Talk at Waseda University

Author(s) : Takashi Ohe (Okayama University of Science)

Abstract : In this talk, we consider the reconstruction problem of moving wave sources under different observation conditions; one is observations on the boundary, and the other is observations on a small number of points. For each observation condition, we propose a direct reconstruction procedure for the parameters of moving wave sources. We also discuss the common and different issues between reconstruction procedures.

[03831] An inverse problem in mean field game from partial boundary measurement

Format : Online Talk on Zoom

Author(s) : Yat Tin Chow (University of California, Riverside)Samy Wu Fung (Colorado School of Mines)Siting Liu (University of California, Los Angeles)Levon Nurbekyan (University of California, Los Angeles)Stanley Osher (University of California, Los Angeles)

Abstract : In this work, we consider a novel inverse problem in mean-field games (MFG). We aim to recover the MFG model parameters that govern the underlying interactions among the population based on a limited set of noisy partial observations of the population dynamics under the limited aperture. Due to its severe ill-posedness, obtaining a good quality reconstruction is very difficult. Nonetheless, it is vital to recover the model parameters stably and efficiently in order to uncover the underlying causes for population dynamics for practical needs.

Our work focuses on the simultaneous recovery of running cost and interaction energy in the MFG equations

from a finite number of boundary measurements of population profile and boundary movement. To achieve this goal, we formalize the inverse problem as a constrained optimization problem of a least squares residual functional under suitable norms with L1 regularization. We then develop a fast and robust operator splitting algorithm to solve the optimization using techniques including harmonic extensions, three-operator splitting scheme, and primal-dual hybrid gradient method. Numerical experiments illustrate the effectiveness and robustness of the algorithm.

This is a joint work with Samy W. Fung (Colorado School of Mines), Siting Liu (UCLA), Levon Nurbekyan (UCLA), and Stanley J. Osher (UCLA)

[02996] Factorization method for recovering moving objects with dynamic near-field data

Format : Online Talk on Zoom
Author(s) : Hongxia Guo (Nankai University)
Abstract : In this talk, I will present the factorization method for recovering the trajectory of a moving point source from multi-frequency data with one or sparse dynamic near-field observation points . The observable and non-observable points in the near field region are introduced. At an observable point, it is verified that the smallest annular containing the trajectory and centered at the observable point can be imaged, provided the orbit function possessing a certain property.

[04620] Imaging a moving point source from multi-frequency data measured at one and sparse observation directions (part I): far-field case

Format : Online Talk on Zoom
Author(s) : Hongxia Guo (Nankai University)Guanghui Hu (Nankai University, Tianjin, China)Guanqiu Ma (Nankai University)
Abstract : We propose a multi-frequency algorithm for recovering partial information on the trajectory of a moving point source from one and sparse far-field observation directions in the frequency domain. The starting and terminal time points of the moving source are both supposed to be known.

We introduce the concept of observable directions (angles) in the far-field region and derive all observable directions (angles) for straight and circular motions. The existence of non-observable directions makes this paper much different from inverse stationary source problems.

At an observable direction, it is verified that the smallest trip containing the trajectory and perpendicular to the direction can be imaged, provided the angle between the observation direction and the velocity vector of the moving source lies in $

[0,\pi/2]$.

If otherwise, one can only expect to recover a strip thinner than this smallest strip for straight and circular motions. The far-field data measured at sparse observable directions can be used to recover the Θ-convex domain of the trajectory. Both two- and three-dimensional numerical examples are implemented to show effectiveness and feasibility of the approach.

00814 (2/2) : 1D @D405

[00815] Recent trends in continuous optimization

Session Time & Room :

00815 (1/4) : 1C (Aug.21, 13:20-15:00) @A502

00815 (2/4) : 1D (Aug.21, 15:30-17:10) @A502

00815 (3/4) : 1E (Aug.21, 17:40-19:20) @A502

00815 (4/4) : 2C (Aug.22, 13:20-15:00) @A502

Type : Proposal of Minisymposium

Abstract : Continuous optimization is a branch of optimization with applications in many fields. In view of their usefulness, in this minisymposium we will focus on: (i) nonlinear programming, where an objective function is minimized or maximized while satisfying some constraints; (ii) multiobjective optimization, where multiple objective functions are considered; and (iii) conic optimization, which deals with more general conic constraints. The goal of this minisymposium is to present some recent developments on those topics. In particular, proposals of efficient algorithms, advanced theoretical results and applications in machine learning will be discussed.

Minisymposium Program :

00815 (1/4) : 1C @A502 [Chair: Ellen Hidemi Fukuda]

[03738] Recent developments in multiobjective fast iterative shrinkage-thresholding algorithms

Format : Talk at Waseda University
Author(s) : Ellen Hidemi Fukuda (Kyoto University)
Abstract : In this talk, we will present an overview of multiobjective proximal gradient methods, that solve problems of the type $\min f(x) + g(x)$, where $f: \Re^n \to \Re^m$ is continuously differentiable and $g: \Re^n \to (\Re \cup \{+\infty\})^m$ is closed, proper and convex. We will also discuss their accelerated versions, including the multiobjective fast iterative shrinkage-thresholding algorithm (FISTA), monotone FISTA, and restarting FISTA. We will show the associated convergence results and some numerical experiments.

[04395] Adaptive Gradient-Based Method for Convex Optimization Problems Under Error Bounds

Format : Talk at Waseda University
Author(s) : Masaru Ito (Nihon University)
Abstract : First-order methods for smooth convex optimization problems is a fundamental methodology for large-scale optimization arising in machine learning. We present an adaptive first-order method to find an approximate solution in terms of small gradient norm that does not require the problem dependent parameters and automatically accelerates under error bound condition like strong convexity. The iteration complexity to find an approximate solution is shown to be optimal.

[03739] Accelerated distributed proximal conjugate gradient methods for multi-agent constrained optimization problems

Format : Talk at Waseda University
Author(s) : Gebrie Anteneh Getachew (Debre Berhan University)Stefan Volkwein (University of Konstanz)
Abstract : We introduce two new classes of accelerated distributed proximal conjugate gradient algorithms for multi-agent constrained optimization problems; given as minimization of a function decomposed as a sum of M number of smooth and M number of non-smooth functions over the common fixed points of M number of nonlinear mappings. Exploiting the special properties of the cost component function of the objective function and the nonlinear mapping of the constraint problem of each agent, a new inertial accelerated incremental and parallel computing distributed algorithms will be presented based on the combinations of computations of proximal, conjugate gradient and Halpern methods. Some numerical experiments and comparisons are given to illustrate our results.

[03850] Extensions of Constant Rank Qualification Constrains condition to Nonlinear Conic Programming

Format : Talk at Waseda University
Author(s) : Hector Ramirez (Universidad de Chile)
Abstract : We present new constraint qualification conditions for nonlinear conic programming that extend some of the constant rank-type conditions from nonlinear programming. Specifically, we propose a general and geometric approach, based on the study of the faces of the cone, for defining a new extension of this condition to the conic context. We then compare these new conditions with some of the existing ones, including the nondegeneracy condition, Robinson's constraint qualification, and the metric subregularity constraint qualification. The main advantage of the latter is that we are able to recast the strong second-order properties of the

constant rank condition in a conic context. In particular, we obtain a second-order necessary optimality condition that is stronger than the classical one obtained under Robinson's constraint qualification, in the sense that it holds for every Lagrange multiplier, even though our condition is independent of Robinson's condition.

00815 (2/4) : 1D @A502 [Chair: Pierre-Louis Poirion]

[03316] Derivative-free Low Order-Value Optimization

Format : Online Talk on Zoom
Author(s) : Anderson Ervino Schwertner (State University of Maringá)Francisco Nogueira Calmon Sobral (State University of Maringá)
Abstract : The Low Order-Value Optimization (LOVO) problem seeks to minimize the minimum among a finite number of function values within a feasible set and has several applications, such as protein alignment and portfolio optimization, among others. In this work, we are interested in the constrained black-box LOVO problem, whose feasible set is convex, closed, and nonempty. We developed and implemented a derivative-free trust-region algorithm, and established global convergence and worst-case complexity results.

[04101] A Stochastic Variance Reduced Gradient using Second Order Information

Format : Talk at Waseda University
Author(s) : Hardik Tankaria (Kyoto University)Nobuo Yamashita (Kyoto University)
Abstract : In this talk, we consider to improve the stochastic variance reduced gradient (SVRG) method via incorporating the curvature information of the objective function. We propose to reduce the variance of stochastic gradients using the computationally efficient method of second order approximation by incorporating it into the SVRG. We also incorporate a (Barzilai-Borwein) BB-step size as its variant. We show linear convergence for not only the proposed method but also for the other existing SVRG variants that use second-order information as a variance reduction. We show the numerical experiments on the benchmark datasets and demonstrate the comparison of proposed methods with existing variance reduced methods.

[03875] Post-Processing with Projection and Rescaling Algorithm for Symmetric Cone Programs

Format : Talk at Waseda University
Author(s) : Shinichi Kanoh (University of Tsukuba)Akiko Yoshise (University of Tsukuba)
Abstract : We propose a post-processing algorithm for symmetric cone programs based on the Projection and Rescaling Algorithm (PRA). Our algorithm is devised to return a more accurate solution using the output solution from MOSEK solver and the PRA proposed by Kanoh & Yoshise (2021). Numerical experiments with SDPLIB instances show that our algorithm outputs a solution with a very small value of DIMACS error compared to the solution that MOSEK solver returned.

[04338] Random Subsapce Newton method for unconstrained non-convex optimization

Format : Talk at Waseda University
Author(s) : Pierre-Louis Poirion (RIKEN -AIP)
Abstract : In this talk, we present a randomized subspace regularized Newton method for a non-convex function. We will be interested in particular to the local convergence rate of the method.

00815 (3/4) : 1E @A502 [Chair: Yasushi Narushima]

[01619] Generalized Levenberg-Marquardt method with oracle complexity bound and local convergence

Format : Talk at Waseda University
Author(s) : Naoki Marumo (University of Tokyo)Akiko Takeda (University of Tokyo)Takayuki Okuno (Seikei University)
Abstract : The generalized Levenberg–Marquardt, abbreviated as LM, method has been developed for minimizing the sum of a possibly nonsmooth convex function and a smooth composite function. In this talk, we propose a new

generalized LM method with three theoretical guarantees: iteration complexity bound, oracle complexity bound, and local convergence under a Holderian growth condition. These theoretical guarantees are achieved by use of an accelerated gradient method for solving convex subproblems.

[04603] Line search methods for nonconvex optimization in deep learning

Format : Online Talk on Zoom
Author(s) : Yuki Tsukada (Meiji University)Hideaki Iiduka (Meiji University)
Abstract : Stochastic gradient descent (SGD) using line search methods achieves high accuracies for several classification tasks in deep learning. Moreover, it can find optimal parameters for deep neural network models by using nonconvex optimization. This talk experimentally investigates the convergence speed of SGD using line search methods with several batch sizes. Our results indicate that the smaller the batch size is, the smaller the stochastic first-order oracle complexity becomes.

[01615] Proximal structured quasi-Newton method for nonlinear least squares with nonsmooth regularizer

Format : Talk at Waseda University
Author(s) : Shummin Nakayama (The University of Electro-Communications)Yasushi Narushima (Keio University)Hiroshi Yabe (Tokyo University of Science)
Abstract : We consider composite minimization problems whose objective function is the sum of a nonlinear least squares formed smooth function and a nonsmooth regularizer. Structured quasi-Newton methods are efficient for solving nonlinear least squares problems and proximal Newton-type methods are efficient for composite minimization problems. In this talk, combining the above two methods, we propose a proximal structured quasi-Newton-type method. Finally, we present some numerical experiments to investigate the efficiency of the proposed method.

[03538] Newton-type proximal gradient method for multi-objective optimization with composite D.C. functions

Format : Talk at Waseda University
Author(s) : Yasushi Narushima (Keio University)Antoine J.V. Vadès (Keio University)Hiroshi Ben (Keio University)
Abstract : In this talk, we propose a Newton-type proximal gradient method for multi-objective optimization whose objective functions are the sum of a continuously differentiable function and a Difference of Convex (D.C.) function. The proposed method is an extension of Newton-type proximal gradient methods for single-objective optimization. We give an algorithm of the proposed method with the Armijo-type line search and show its global convergence. Finally, we present some numerical results for comparison with the existing methods.

00815 (4/4) : 2C @A502 [Chair: Bruno F. Lourenço]

[04582] Sharp convex exact penalty formulations in statistical signal recovery

Format : Talk at Waseda University
Author(s) : Alex Liheng Wang (Purdue University)Lijun Ding (University of Wisconsin Madison)
Abstract : This talk presents a sample complexity vs. conditioning tradeoff in signal recovery problems including sparse recovery, low-rank matrix sensing, and phase retrieval. We introduce condition numbers related to the "sharpness" of these problems and show that they can be used to control the accuracy of the recovery procedure in the presence of noise and the convergence rates of a new first-order method. These condition numbers approach constants a small factor above the statistical thresholds.

[02314] Accelerating nuclear-norm regularized low-rank matrix optimization through Burer-Monteiro decomposition

Format : Talk at Waseda University
Author(s) : Ching-pei Lee (Institute of Statistical Mathematics)Ling Liang (National University of Singapore)Tianyun Tang (National University of Singapore)Kim-Chuan Toh (National University of Singapore)
Abstract : This work proposes a rapid algorithm, BM-Global, for nuclear-norm-regularized convex and low-rank matrix optimization problems. BM-Global efficiently decreases the objective value via low-cost steps leveraging the

nonconvex but smooth Burer-Monteiro (BM) decomposition, while effectively escapes saddle points and spurious local minima ubiquitous in the BM form to obtain guarantees of fast convergence rates to the global optima of the original nuclear-norm-regularized problem through aperiodic inexact proximal gradient steps on it. The proposed approach adaptively adjusts the rank for the BM decomposition and can provably identify an optimal rank for the BM decomposition problem automatically in the course of optimization through tools of manifold identification. BM-Global hence also spends significantly less time on parameter tuning than existing matrix-factorization methods, which require an exhaustive search for finding this optimal rank. Extensive experiments on real-world large-scale problems of recommendation systems, regularized kernel estimation, and molecular conformation confirm that BM-Global can indeed effectively escapes spurious local minima at which existing BM approaches are stuck, and is a magnitude faster than state-of-the-art algorithms for low-rank matrix optimization problems involving a nuclear-norm regularizer.

[05168] The Goemans and Williamson Algorithm Extended to Fractional Cut Covering

Format : Talk at Waseda University
Author(s) : Nathan Benedetto Proença (University of Waterloo)Marcel K. de Carli Silva (University of São Paulo)Cristiane Sato (Federal University of ABC Region)Levent Tunçel (University of Waterloo)
Abstract : The fractional cut-covering number is the optimal value of a linear
programming relaxation for the problem of covering each edge by a set
of cuts.
By exploiting the relationship of this problem with the maximum cut
problem, we obtain a primal-dual extension to the celebrated work of
Goemans and Williamson, including an approximation algorithm and new
optimality certificates.

[01270] Solving graph equipartition SDPs on an algebraic variety

Format : Talk at Waseda University
Author(s) : Tianyun Tang (National University of Singapore)Kim-Chuan Toh (National University of Singapore)
Abstract : In this talk, we focus on using the Burer-Monteiro method to solve the graph equipartition SDP. The constraints of the low rank SDP problem is an algebraic variety with conducive geometric properties which we analyse. This allows us to develop an algorithm based on Riemannian optimization that can escape from a non-optimal singular point. Numerical experiments are conducted to verify the efficiency of our algorithm.

[00819] Secure Computing: Maintaining Personal Privacy while Analyzing Data

Session Time & Room : 3D (Aug.23, 15:30-17:10) @E804

Type : Proposal of Industrial Minisymposium
Abstract : The proliferation of IoT machine and sensor devices are major contributors to the surge in production and storage of mostly private, sensitive data. Deloitte projects, "by 2025 our global volume will reach 175 zeta bytes" (www2.deloitte.com/cy/en/pages/technology/articles/data-grown-big-value.html). Many data owners seek to analyze the data to uncover insights and improve their decision-making processes. However, compliance with privacy regulations and the threat of cyberattacks pose heretofore unknown challenges. Approaches to address this issue, collectively known as secure computing, include: privacy-preserving data analysis, differential privacy, federated learning, multi-party computation, and homomorphic encryption. This mini-symposium seeks to gather practitioners/specialists for active debate and dialog.
Organizer(s) : Mei Kobayashi

[04041] Construction of Differentially Private Summary with Homomorphic Encryption

Format : Talk at Waseda University
Author(s) : HAYATO YAMANA (Waseda University)Shojiro USHIYAMA (Waseda University)Tsubasa TAKAHASHI (LINE Corp.)
Abstract : A differentially private summary for range queries is constructed using homomorphic encryption to hide the raw data from the computation server. To shorten the processing time, we proposed a new method to merge adjacent close values in the histogram if the difference between the adjacent data is small. Then, we confirmed that the accuracy of the proposed method was equivalent to a state-of-the-art algorithm and the processing time is O(n).

[04961] Federated Learning with Differential Privacy and Secure Computing

Format : Talk at Waseda University
Author(s) : Tsubasa Takahashi (LINE Corporation)
Abstract : Improving user experience while respecting user privacy is important nowadays. Last year we released federated learning in LINE messenger’s keyboard area to make users sticker selection easier and more personalized while preserving user privacy. Our FL also employs Differential Privacy (DP) to make exploiting user privacy more difficult. This talk presents our FL+DP, and recent advancement of privacy amplification with secure computing.

[05348] Network Security and Analytics for Reliability

Format : Talk at Waseda University
Author(s) : Yukio Uematsu (Tokyo University of Science/Nokia)
Abstract : In recent years, a vast number of IoT devices have been connected to the cloud through mobile networks. This talk will address two fundamental issues, namely security and data reliability, in the context of mobile network data analytics. We will present some use cases for data management that combine edge and cloud computing while ensuring data reliability.

[00825] Numerical Time Integration Algorithms and Software for Machine Learning

Session Time & Room : 4E (Aug.24, 17:40-19:20) @E508

Type : Proposal of Minisymposium
Abstract : Decades of research and development in numerical time integration algorithms and software has been focused on solving time-dependent differential equations that arise from mathematical models of physical phenomena. Recently, a clear nexus between time integration and machine learning (ML) has been established, giving rise to many new opportunities for novel time-integration algorithm research and software development. The goal of this minisymposium is to shine a light on the ML application area by featuring talks that demonstrate numerical time integration algorithms and software benefiting ML, or discuss how they can be geared towards ML. Prepared by LLNL under Contract DE-AC52-07NA27344. LLNL-ABS-843420.

[04991] The Roles of Numerical Time Integration Algorithms and Software in the Machine Learning Revolution

Format : Talk at Waseda University

Author(s) : Cody Balos (Lawrence Livermore National Lab)

Abstract : Recently large language models like OpenAI's ChatGPT have sparked mainstream discussion of Artificial Intelligence and Machine Learning. Meanwhile, in the scientific community there has been an increased interest in Scientific Machine Learning (SciML) and a substantial shift in funding opportunities towards work with at least some ML component. In this talk, I will explore some examples of how numerical time integration algorithms and software, which have been critical to scientific computing for decades, are playing a part in this ML revolution. As part of this exploration, I will also discuss what we are doing in the SUNDIALS time integration library to enable ML applications. LLNL-ABS-847841.

[03318] TransNet: Transferable Neural Networks for Partial Differential Equations

Format : Online Talk on Zoom

Author(s) : Zezhong Zhang (Florida State University)Feng Bao (Florida State University)Lili Ju (University of South Carolina)Guannan Zhang (Oak Ridge National Laboratory)

Abstract : Transfer learning for partial differential equations (PDEs) is to develop a pre-trained neural network that can be used to solve a wide class of PDEs. Existing transfer learning approaches require much information of the target PDEs such as its formulation and/or data of its solution for pre-training. In this work, we propose to construct transferable neural feature spaces from purely function approximation perspectives without using PDE information. The construction of the feature space involves re-parameterization of the hidden neurons and uses auxiliary functions to tune the resulting feature space. Theoretical analysis shows the high quality of the produced feature space, i.e., uniformly distributed neurons. Extensive numerical experiments verify the outstanding performance of our method, including significantly improved transferability, e.g., using the same feature space for various PDEs with different domains and boundary conditions, and the superior accuracy, e.g., several orders of magnitude smaller mean squared error than the state of the art methods.

[04020] Dissipative residual layers for unsupervised implicit parameterization of data manifolds

Format : Online Talk on Zoom

Author(s) : Viktor Reshniak (Oak Ridge National Laboratory)

Abstract : We propose an unsupervised technique for implicit parameterization of data manifolds. In our approach, the data is assumed to belong to a lower dimensional manifold in a higher dimensional space, and the data points are viewed as the endpoints of the trajectories originating outside the manifold. Under this assumption, the data manifold is an attractive manifold of a dynamical system to be estimated. We parameterize such a dynamical system with a residual neural network and propose a spectral localization technique to ensure it is locally attractive in the vicinity of data. We also present initialization and discuss the regularization of the proposed residual layers that we call dissipative bottlenecks.

[03338] Improved Parallelism and Memory Performance for Differentiating Stiff Differential Equations

Format : Online Talk on Zoom

Author(s) : Christopher Vincent Rackauckas (Julia Hub, Pumas-AI, MIT)

Abstract : Previous work demonstrated trade-offs in performance, numerical stability, and memory usage for ODE solving and differentiation of solutions. Our new time stepping methods expose more parallelism is shown to accelerate small ODE solves, while new GPU-based ODE solvers demonstrate a 10x performance improvement over Jax and PyTorch-based solvers. New adjoint methods achieve linear cost scaling with respect to parameters in stiff ODEs, as opposed to the cubic of Jax/PyTorch, while limiting the memory scaling.

[00827] Stochastic Rounding for Reduced-Precision Arithmetic in Scientific Computing

Session Time & Room : 2E (Aug.22, 17:40-19:20) @E709

Type : Proposal of Minisymposium
Abstract : The comeback that stochastic rounding has made in the last few years can be attributed to the availability of hardware implementing low-precision floating-point arithmetic, as well as to the recognition that, in some applications, this rounding mode can control the growth of rounding errors better than commonly used alternatives. Research has focused not only on obtaining efficient hardware and software implementations, but also on understanding the numerical properties of algorithms that replace round-to-nearest with stochastic rounding. In this minisymposium, we will have an opportunity to learn about recent advances in both directions.
Organizer(s) : Massimiliano Fasi, Mantas Mikaitis

[03817] Implementation of Stochastic Rounding

Format : Online Talk on Zoom
Author(s) : Mantas Mikaitis (University of Leeds)
Abstract : In this talk we will review the latest developments in implementing stochastic rounding. We will first revisit the current methods of implementing stochastic rounding in hardware and software packages, such as CPFloat and MATLAB chop. We will present the main challenges and open problems, such as the reproducibility and precision of pseudo-random numbers. We will also review the commercial hardware that currently includes stochastic rounding, such as Graphcore IPU, Amazon Trainium, and Tesla Dojo devices. Finally, we will outline the list of features required for stochastic rounding to be standardized.

[04133] Software Simulation of Stochastic Rounding

Format : Online Talk on Zoom
Author(s) : Massimiliano Fasi (Durham University)Mantas Mikaitis (University of Leeds)
Abstract : Implementing a stochastically rounded mathematical function requires three steps: 1) evaluating the function using a high-precision floating-point arithmetic; 2) drawing a pseudo-random number from some uniform distribution; and 3) rounding the high-precision result to the target precision. We describe how stochastic rounding can be performed using only integer arithmetic and bit-level operations, and we summarize the major challenges and open questions surrounding the implementation of this rounding mode.

[04508] Bounds on Non-linear Errors for Variance Computation with Stochastic Rounding

Format : Talk at Waseda University
Author(s) : El-Mehdi El Arar (Paris-Saclay University-UVSQ- LI-PaRAD)Devan Sohier (Paris-Saclay University-UVSQ- LI-PaRAD)Pablo de Oliveira Castro (Paris-Saclay University-UVSQ- LI-PaRAD)Eric Petit (Intel Corp)
Abstract : This work's main objective is to investigate non-linear errors and pairwise summation using stochastic rounding (SR) in variance computation algorithms. We estimate the forward error of computations under SR through two methods: 1 a bound of the variance and Bienaymé–Chebyshev inequality, 2 martingales and Azuma–Hoeffding inequality. We examine two algorithms, "textbook" and "two-pass", both with non-linear errors. We show that they have probabilistic bounds under SR in $O(\sqrt{n}u)$ instead of nu for the deterministic bounds.

[04837] Trace estimation via asynchronous stochastic rounding

Format : Online Talk on Zoom
Author(s) : Lior Horesh (IBM T. J. Watson Research Center)Vasileios Kalantzis (IBM T. J. Watson Research Center)Georgios Kollias (IBM T. J. Watson Research Center)Shashanka Ubaru (IBM T. J. Watson Research Center)Chai Wah Wu (IBM T. J. Watson Research Center)
Abstract : We present a framework of randomized algorithms that include stochastic rounding and asynchronous updates and apply it to randomized linear algebra algorithms. In particular, we analyze an application to trace estimation and show its efficacy on various real-world datasets.

[00831] Randomization for Simplified Machine Learning: Random Features and Reservoir Computers

Session Time & Room :

00831 (1/3) : 2C (Aug.22, 13:20-15:00) @E507

00831 (2/3) : 2D (Aug.22, 15:30-17:10) @E507

00831 (3/3) : 2E (Aug.22, 17:40-19:20) @E507

Type : Proposal of Minisymposium
Abstract : Training neural networks remains challenging for complex or recurrent architectures. The random feature approach side steps training deep layers by sampling random weights and fitting only the final output layer to data with linear least squares. When applied to recurrent networks, this is called a reservoir computer. These methods can approximate functions, operators, and dynamical systems. This minisymposium seeks to unify knowledge and experiences of both communities on topics of 1) scaling to high-dimensional large-volume data, 2) hyperparameter learning, 3) performance evaluation and comparison, and 4) theoretical understanding of features and reservoirs.

[02997] Scalable Gaussian Process Regression with Quadrature-based Features

Format : Talk at Waseda University
Author(s) : Paz Fink Shustin (Tel Aviv University)
Abstract : Gaussian processes provide a powerful probabilistic kernel learning framework, which allows high-quality nonparametric learning via methods such as Gaussian process regression. Nevertheless, its learning phase requires unrealistic massive computations for large datasets. In this talk, we present a quadrature-based approach for scaling up Gaussian process regression via a low-rank approximation of the kernel matrix. The low-rank structure is utilized to achieve effective hyperparameter learning, training, and prediction. Our Gauss-Legendre features method is inspired by the well-known random Fourier features approach, which also builds low-rank approximations via numerical integration. However, our method is capable of generating high-quality kernel approximation using a number of features that is poly-logarithmic in the number of training points, while similar guarantees will require an amount that is at the very least linear in the number of training points when using random Fourier features. The utility of our method for learning with low-dimensional datasets is demonstrated using numerical experiments.

[03226] Advances in Time Series Analysis With Reservoir Computing

Format : Talk at Waseda University
Author(s) : Braden John Thorne (University of Western Australia)Michael Small (University of Western Australia)Débora Cristina Corrêa (University of Western Australia)Ayham Zaitouny (University of Doha for Science and Technology)
Abstract : Reservoir computers have proven to be powerful embedding machines for dynamical systems. However, bridging the gap from their machine learning origins to time series analysis is still relatively new, with great potential for novel discoveries. In this talk, we will outline what reservoir time series analysis is and why one should care about it amidst the ecosystem of other embedding-based techniques. We will then present some use cases and applications to motivate future work.

[03272] Error analysis of random feature neural networks for Black-Scholes-type PDEs

Format : Online Talk on Zoom
Author(s) : Lukas Gonon (Imperial College London)
Abstract : We mathematically analyse the learning performance of random feature neural networks for learning solutions to a class of PDEs which includes the Black-Scholes PDE as special case. In contrast to other existing mathematical results on neural network-based PDE-learning, in our context it is possible to obtain a full error analysis addressing all error components (approximation, generalization and optimization) with the derived bounds (convergence rates and constants) not suffering from the curse of dimensionality.

[04091] Theoretical advances for learning functions and operators with random features

Format : Talk at Waseda University
Author(s) : Nicholas H. Nelsen (California Institute of Technology)
Abstract : This talk provides a complete error analysis of operator learning with random features (RF). The theoretical results are developed in a fully general infinite-dimensional input-output setting. The highlights include strong consistency of RF estimators under model misspecification and minimax optimal convergence rates. This work also contributes theory for rigorous uncertainty quantification by establishing (i) new pointwise error bounds for vector-valued Gaussian process (GP) regression and (ii) strong consistency of RF estimators of GPs.

00831 (2/3) : 2D @E507 [Chair: Matthew Levine]

[04530] Photonic reservoir computing with small networks

Format : Online Talk on Zoom
Author(s) : Joseph David Hart (US Naval Research Laboratory)Thomas Carroll (US Naval Research Laboratory)Francesco Sorrentino (University of New Mexico)Joel Q Grim (US Naval Research Laboratory)Allan Bracker (US Naval Research Laboratory)
Abstract : The model-free training permitted by reservoir computing makes it particularly attractive for implementation in analog physical hardware, which can offer significant improvements in speed and power requirements over digital hardware. In many cases, however, it can be difficult or undesirable to build a large, tunable analog network. In this talk, we will present recent results using photonic analog hardware to implement reservoir computers made up of small networks.

[04854] Latent GP-ODEs with Informative Priors

Format : Online Talk on Zoom
Author(s) : Ilze Amanda Auzina (University of Amsterdam)Cagatay Yildiz (University of Tuebingen)Efstratios Gavves (University of Amsterdam)
Abstract : We propose a novel framework by combining a generative and a Bayesian nonparametric model which learns a physically meaningful latent representation and solves an ODE system in latent space. The model is able to account for uncertainty as well as to be constrained with informative physical priors. The method demonstrates its ability to learn dynamics from high dimensional data and we obtain state-of-the-art performance compared to earlier nonparametric ODE models on dynamic forecasting.

[04314] A Framework for Hyperparameter Optimization for Randomized Machine Learning

Format : Talk at Waseda University
Author(s) : Oliver Dunbar (Division of Geological and Planetary Sciences, California Institute of Technology)Nicholas Nelsen (California Institute of Technology)Maya Mutic (Princeton University)
Abstract : Randomization can be used to replace layers of neural networks or kernel matrices of Gaussian processes. This approach accelerates numerical methods and converts training to a least-squares problem. In practice however, necessary hyperparameter optimization becomes more challenging, as optimization objective functions are non-deterministic. In the context of the random features, we present a framework and algorithm based on the ensemble Kalman filter, that can automate this optimization, and demonstrate practical performance through illustrative examples.

00831 (3/3) : 2E @E507 [Chair: Georg Gottwald]

[04861] Next-Generation Reservoir Computing, and On Explaining the Surprising Success of a Random Neural Network for Forecasting Chaos

Format : Online Talk on Zoom
Author(s) : Erik Matthew Bollt (Clarkson University)
Abstract : Machine learning is widely popular and successful, including for data-driven science, especially for forecasting complex dynamical systems. Reservoir computers (RC) have emerged as random neural networks, for simplicity and computational advantage, where only read-out weights are trained. That it is cheap is clear, but that it works at all is perhaps a surprise, which we explain here. Furthermore our discussion leads to a new, equivalent even simpler variant we call, next generation reservoir computing, NG-RC.

[05356] Minimax optimal inference of inhomogeneous diffusions

Format : Online Talk on Zoom
Author(s) : Grant Rotskoff (Stanford University)
Abstract : Inferring a diffusion equation from discretely-observed measurements is a statistical challenge of significant importance in a variety of fields, from single-molecule tracking in biophysical systems to modeling financial instruments. Assuming that the underlying dynamical process obeys a d-dimensional stochastic differential equation of the form

$$d\boldsymbol{x}_t = \boldsymbol{b}(\boldsymbol{x}_t)dt + \Sigma(\boldsymbol{x}_t)d\boldsymbol{w}_t,$$

we show that no diffusion estimator using N discretely sampled data points converges faster than $N^{-\frac{2s+2}{2s+2+d}}$ when the drift $\boldsymbol{b}$ and diffusion tensor $D = \Sigma\Sigma^T$ are s and $s+1$-Hölder continuous, respectively. We further propose neural network estimators for both D and $\boldsymbol{b}$, establish convergence guarantees, and show that the estimators achieve a nearly optimal rate for correlated data.

[05361] Nonlinear Time Series Analysis and Data Driven Forecasting: Regional Weather Prediction & Earth's Geodynamo

Format : Online Talk on Zoom
Author(s) : Luke Fairbanks (UCSD)Ashley Thorshov (UCSD)
Abstract : Amongst the zoo of complex systems analysis frameworks and methods exist some which leverage tools from mathematics and physics with machine learning to attempt a more interpretable and possibly better results with respect to time series prediction of said systems. Our work in the domains of weather prediction and the geodynamo is a model for the interdisciplinary union between experimentalists, theorists, and computational researchers such as ourselves in the pursuit of complex system algorithmic synchronization.

[04474] Random Features for Epidemic Prediction

Format : Online Talk on Zoom
Author(s) : Esha Saha (University of Waterloo)Lam Ho (Dalhousie University)Giang Tran (University of Waterloo)
Abstract : Predicting the evolution of diseases is challenging. Compartmental models stratify the population into compartments and model the dynamics using dynamical systems. These predefined systems may not capture the true dynamics of the epidemic due to the complexity variable interactions. We propose Sparsity and Delay

Embedding based Forecasting (SPADE4) for predicting epidemics for predicting the future trajectory of a variable without the knowledge of the underlying system using random features and Takens' delay embedding theorem.

[00837] Particle Methods for Bayesian Inference

Session Time & Room :

00837 (1/3) : 4C (Aug.24, 13:20-15:00) @E709

00837 (2/3) : 4D (Aug.24, 15:30-17:10) @E709

00837 (3/3) : 4E (Aug.24, 17:40-19:20) @E709

Type : Proposal of Minisymposium
Abstract : Particle methods have become a popular method for sampling, optimization, inversion, and filtering. Moreover gradient-free versions of particle systems may implicitly carry gradient information that can be leveraged for better performance. In this minisymposium we bring together experts in
Ensemble Kalman filtering, Ensemble Kalman inversion, and Ensemble Kalman sampling as well as other particle-based algorithms like Consensus-based optimization, Affine invariant Langevin dynamics,
Stein Variational Gradient Descent and collect recent advances based on homotopy approaches, ensemble enrichment, Wasserstein gradient flows and discrepancy flows.

[05135] Improving Ensemble Kalman Filter performance by adaptively controlling the ensemble

Format : Talk at Waseda University
Author(s) : Ruben Harris (FU Berlin)Claudia Schillings (FU Berlin)
Abstract : Efficient strategies to improve the performance of the Ensemble Kalman Inversion by adaptively controlling the ensemble.

Due to their low computational costs and straightforward implementation, filtering methods such as the Ensemble Kalman Filter have become very popular for inverse problems over the last few years. They have been demonstrated to work well even for highly nonlinear, complex models. We discuss variants of the Ensemble Kalman Inversion (EKI) aiming to improve the accuracy of the estimate by adaptively choosing the particles in the ensemble.

[03030] Ensemble-based gradient inference for particle methods in optimization and sampling

Format : Talk at Waseda University
Author(s) : Philipp Wacker (University of Canterbury)Claudia Schillings (FU Berlin)Claudia Totzeck (University of Wuppertal)
Abstract : We discuss how some ensemble-based methods for optimization and sampling can be augmented by inexact estimates of the gradient of a potential function, approximated in a straightforward way from pointwise evaluation of the potential in the ensemble. This approximated gradient can be inserted in place of an exact gradient in the context of sampling methods derived from Langevin dynamics, and it can be used as an additional term in global optimization methods like Consensus-based optimization

[05138] Less interaction with forward models in Langevin dynamics: Enrichment and Homotopy

Format : Talk at Waseda University

Author(s) : Robert Gruhlke (FU Berlin)Martin Eigel (WIAS Berlin)David Sommer (WIAS Berlin)

Abstract : Ensemble methods like EKS and ALDI are widely used for Bayesian inference problems but suffer from a large number of forward calls and possible lack of convergence for multimodal distributions. We propose adaptive ensemble enrichment strategies to reduce the total number of forward calls. The method is extended for more complex distributions using adapted Langevin dynamics based on a homotopy formalism. Numerical investigations on benchmark problems demonstrate the method's advantages over state-of-the-art Langevin samplers.

00837 (2/3) : 4D @E709 [Chair: Robert Gruhlke]

[04703] Metropolis-adjusted interacting particle sampling

Format : Talk at Waseda University

Author(s) : Bjoern Sprungk (TU Bergakademie Freiberg)Simon Weissmann (University of Mannheim)Jakob Zech (Universität Heidelberg)

Abstract : In recent years, various interacting particle samplers have been developed to sample from complex target distributions, such as those found in Bayesian inverse problems. These samplers are motivated by the mean-field limit perspective and implemented as ensembles of particles that move in the product state space according to coupled stochastic differential equations. The ensemble approximation and numerical time stepping used to simulate these systems can introduce bias and affect the invariance of the particle system with respect to the target distribution. To correct for this, we investigate the use of a Metropolization step, similar to the Metropolis-adjusted Langevin algorithm. We examine both ensemble- and particle-wise Metropolization and prove basic convergence of the resulting ensemble Markov chain to the target distribution. Our results demonstrate the benefits of this correction in numerical examples for popular interacting particle samplers such as ALDI, CBS, and stochastic SVGD.

[05149] Computing log-densities of time-reversed diffusion processes through Hamilton-Jacobi-Bellman equations

Format : Talk at Waseda University

Author(s) : David Sommer Robert Gruhlke (FU Berlin)Martin Eigel (WIAS Berlin)

Abstract : Sampling from densities is a common challenge in uncertainty quantification. Langevin dynamics are a popular tool for this task but rely on certain properties of the log-density. To assimilate a larger class of distributions, a time-inhomogeneous drift term can be defined using intermediate log-densities. We propose learning these log-densities by propagation of the target distribution through an Ornstein-Uhlenbeck process, solving the associated Hamilton-Jabobi-Bellman equation using an implicit scheme and compressed polynomials for spatial discretization.

[04723] Simulation of Wasserstein gradient flows with low-rank tensor methods for sampling

Format : Talk at Waseda University

Author(s) : Vitalii Aksenov (Weierstrass Institute for Applied Analysis and Stochastics)Martin Eigel (Weierstrass Institute for Applied Analysis and Stochastics)

Abstract : We try to adapt the Eulerian methods for Wasserstein gradient flows for high-dimensional problems such as Bayesian inversion, importance sampling and generative modelling by utilizing low-rank tensor methods. The normalized density is approximated in tractable format, which allows additional application to density estimation and rare event detection. An ODE governing the evolution of samples can be defined with help of intermediate density and flux variables, linking the approach to particle methods.

[05014] Overparameterization of Deep ResNet: Zero Loss and Mean-Field Analysis

Format : Talk at Waseda University
Author(s) : Zhiyan Ding (University of California, Berkeley)Qin Li (University of Wisconsin, Madison)Shi Chen (University of Wisconsin, Madison)Stephen Wright (University of Wisconsin, Madison)
Abstract : In this talk, I will mainly focus on using mean-field analysis to analyze the overparameterization of neural networks. Finding parameters in a deep neural network (NN) that fit training data is a nonconvex optimization problem, but a basic first-order optimization method (gradient descent) finds a global optimizer with the perfect fit (zero-loss) in many practical situations. In this talk, I will investigate this phenomenon in the case of Residual Neural Networks (ResNet) with smooth activation functions in a limiting regime in which both the number of layers (depth) and the number of weights in each layer (width) go to infinity. First, I will rigorously show that the gradient descent for parameter training becomes a gradient flow for a probability distribution that is characterized by a partial differential equation (PDE) in the large-NN limit. Next, I will introduce the conditions that make sure the solution to the PDE converges in the training time to a zero-loss solution. Together, these results suggest that the training of the ResNet gives a near-zero loss if the ResNet is large enough.

00837 (3/3) : 4E @E709 [Chair: Philipp Wacker]

[04766] Wasserstein Steepest Descent Flows for Discrepancy Flows with Riesz Kernels

Format : Talk at Waseda University
Author(s) : Johannes Hertrich (TU Berlin)Robert Beinert (TU Berlin)Gabriele Steidl (TU Berlin)
Abstract : We introduce Wasserstein steepest descent flows based on the geometric Wasserstein tangent space. These are locally absolutely continuous curves in the Wasserstein space whose tangent vectors point into a steepest descent direction of a given functional. This allows the use of Euler forward schemes instead of minimizing movement schemes introduced by Jordan, Kinderlehrer and Otto. Under certain assumptions, we show that there exists a unique Wasserstein steepest descent flow which coincides with the Wasserstein gradient flow. For the special example of interaction energies with non-smooth Riesz kernels, we derive analytic formulas for the corresponding Wasserstein steepest descent flows.

[04729] Neural Wasserstein Gradient Flows for Discrepancies with Riesz Kernels

Format : Talk at Waseda University
Author(s) : Fabian Altekrüger (HU Berlin/ TU Berlin)Johannes Hertrich (TU Berlin)Gabriele Steidl (TU Berlin)
Abstract : Wasserstein gradient flows of maximum mean discrepancy (MMD) functionals with non-smooth Riesz kernels show a rich structure as singular measures can become absolutely continuous ones and conversely. We propose to approximate the backward scheme of Jordan, Kinderlehrer and Otto for computing such Wasserstein gradient flows as well as a forward scheme for so-called Wasserstein steepest descent flows by neural networks (NNs). Since we cannot restrict ourselves to absolutely continuous measures, we have to deal with transport plans and velocity plans instead of usual transport maps and velocity fields. Indeed, we approximate the disintegration of both plans by generative
NNs which are learned with respect to appropriate loss functions. For the interaction energy we provide analytic formulas for Wasserstein schemes starting at a Dirac measure. Finally, we illustrate our neural MMD flows by numerical examples.

[00838] Perspectives in Artificial Intelligence and Machine Learning in Materials Chemistry, 2nd edition

Session Time & Room :

00838 (1/2) : 3C (Aug.23, 13:20-15:00) @D102

00838 (2/2) : 3D (Aug.23, 15:30-17:10) @D102

Type : Proposal of Minisymposium
Abstract : Artificial Intelligence has led to a paradigm shift in investigation in Materials Chemistry, with Machine Learning allowing informatics-based systematic calculations, predictions and discovery based on material databases pushing beyond the intrinsic limitations of first-principles calculations. The successful application requires development of novel methodologies inspired by the frontends of materials development in close synergy between Mathematics and Information Technology, areas where interdisciplinary collaborations are crucial and yet to date in their early phases.

[01431] Discovery of New Materials by Quantum Calculations and Artificial Intelligence

Format : Talk at Waseda University
Author(s) : David Samuel Rivera Rocabado (Hiroshima University)Mika Aizawa (Hiroshima University)Takayoshi Ishimoto (Hiroshima University)
Abstract : Integrating artificial intelligence into real system first-principles calculations has the potential to transform the field of materials science and, ultimately, the world in which we live. In this presentation, the modeling and the prediction of the CO adsorption/activation on Ru nanoparticles exemplify that our new approach can be universally applied to predict the catalytic properties of any existing material and be used for the discovery of more functionalized materials.

[05452] Causal analysis of materials functionality by combining topological data analysis and physical model

Format : Talk at Waseda University
Author(s) : Masato Kotsugi (Tokyo University of Science)
Abstract : Microscopic image data is key to developing low-power, high-speed electronic devices. However, the complex interactions in nanoscale magnetic materials are difficult to understand. We developed a new functional design theory called “extended Landau free energy model” that combines persistent homology and machine learning with free energy to automate the interpretation of the microscopic image. This model illustrates the physical mechanism and critical location of magnetization reversal and proposes a device structure with low energy consumption.

[05575] Machine learning for materials chemistry and chemical biology

Format : Talk at Waseda University
Author(s) : Daniel Packwood (Kyoto University)
Abstract : This talk will review three recent success stories involving machine learning in materials science and chemistry: (1) the simulation of on-surface molecular self-assembly processes using machine-learned potentials and a novel genetic algorithm; (2) the design of a new organic semiconducting material with targeted band gap by a combination of unsupervised and supervised learning; (3) the prediction and verification of a new chemical compound for inducing cardiac tissue differentiation of stem cells.

[01449] Topological descriptor of thermal conductivity in amorphous Si

Format : Online Talk on Zoom
Author(s) : Emi Minamitani (Osaka University)Takuma Shiga (AIST)Makoto Kashiwagi (Aoyama Gakuin University)Ippei Obayashi (Okayama University)
Abstract : In this talk, we analyze the relationship between the atomic configuration of amorphous Si and the thermal conductivity of the material. A topological descriptor constructed by persistent homology successfully predicts the thermal conductivity using machine learning, and from the machine learning model, we can extract medium-range order structures related to thermal conductivity using inverse analysis of persistent homology. https://doi.org/10.1063/5.0093441

00838 (2/2) : 3D @D102 [Chair: NGUYEN DINH Hoa]

[05561] Fully automatized optimization of ring-opening reactions in lactone derivatives via 2-step machine learning

Format : Talk at Waseda University
Author(s) : Aleksandar Staykov (Kyushu University)Pierluigi Cesana (kyushu university)
Abstract : Cyclization and cycloreversion of organic compounds are fundamental kinetic processes in the design of functional molecules, molecular machines, and nano-switches. We present a fully automatic computational platform for the design of a class of 5- and 6- membered ring lactones by optimizing the ring-opening reaction rate. Starting from a minimal initial parent set, our program generates iteratively cascades of pools of candidate lactone derivatives where optimization and down-selection are performed not requiring human supervision at any stage. We use Density Functional Theory combined with transition state theory to elucidate the exact mechanism leading to the lactone ring opening. Based on the analysis of the reaction pathway and the frontier molecular orbitals, we identify a simple descriptor that can easily correlate with the reaction rate. The program is successful in identifying a large class of lactone derivatives with enhanced ring-opening properties. Our platform is modular and our current implementation for lactone could be further generalized to more complex systems via substitution of the quantum chemical and fingerprinting modules.

[01724] A Trial for the Realization of Material Pattern Informatics Using Interpretable AI

Format : Talk at Waseda University
Author(s) : Yoh-ichi Mototake (Hitotsubashi University)
Abstract : It has been recently reported that highly accurate classification, regression, and generation can be achieved by interpolative modeling of complex scientific data using machine learning models with high expressive power, such as deep neural networks (DNNs). However, many of the machine learning models used there are nonlinear functions with a large number of parameters, making the interpretation of the training results very difficult. In thermodynamics, Gibbs extended the theory of thermodynamics, which was the theory of heat engines, to chemical reactions, which was a great development in science. This shows that science has been greatly advanced by the scientific insight of human beings, who derive general principles beyond mere interpolation models and boldly extrapolate them. On the other hand, it is sometimes difficult to apply such insights to systems with complex non-periodic structures, such as those found in nonlinear and nonequilibrium phenomena. To address this situation, we believe that it is important to collaborate between machine learning, which is good at building interpolation models for complex data, and humans, who can make bold extrapolations based on scientific insights, and are developing methods for interpreting machine learning training results to bridge the gap between the two.
In this presentation, we will discuss our recent research on machine learning frameworks that collaborate with scientists trying to reveal complex pattern dynamics in materials and their applications.

[01688] Toward Functional Polymer Informatics

Format : Talk at Waseda University
Author(s) : Koichiro Kato (Kyushu University)
Abstract : Although materials informatics has made remarkable progress in recent years, its application to functional polymers remains unexplored. Reasons for this include the lack of established methods for incorporating the higher-order structure of functional polymers as a feature in machine learning and the lack of data. In this talk, I will present our recent results on building models for predicting properties from published data and extracting features of functional polymers using coarse-grained simulation.

[01335] Understanding the role of defects and disorder in polycrystalline materials

Format : Talk at Waseda University
Author(s) : Kulbir K Ghuman (Institut national de la recherche scientifique)
Abstract : The functionality of the materials used for energy applications is critically determined by the physical properties of small active regions such as dopants, dislocations, interfaces, grain boundaries, etc. The capability to manipulate and utilize the inevitable disorder in materials, whether due to the finite-dimensional defects (such as vacancies, dopants, grain boundaries) or due to the complete atomic randomness (as in amorphous materials), can bring innovation in designing energy materials. With the increase in computational material science capabilities, it is now possible to understand the complexity present in materials due to various defects resulting in pathways

required for optimizing their efficiencies. In this talk, I will provide a critical overview of such computational advancements specifically for designing realistic materials with various types of defects. I will discuss the traditional approaches (implemented via tools such as density functional theory, and molecular dynamics) as well as modern approaches such as machine learning that exist for understanding the impact of defects and disorder present in polycrystalline materials, thereby identifying future opportunities for energy materials design and discovery.

[00840] Efficient and scalable solvers and algorithms for multiscale phenomena

Session Time & Room :

00840 (1/3) : 1D (Aug.21, 15:30-17:10) @E802

00840 (2/3) : 1E (Aug.21, 17:40-19:20) @E802

00840 (3/3) : 2C (Aug.22, 13:20-15:00) @E802

Type : Proposal of Minisymposium
Abstract : Many physical systems involve interactions between different scales in space and/or time, which usually stem from the coexistence of complex micro-structures and phenomena taking place at much larger scales.
Prominent examples of multiscale systems are biological tissues, composed of millions of cells but treated as a continuum, with scale separations in both space and time.
The focus of this minisymposium is on efficient and scalable numerical methods, solvers and high performance software, which can solve such complex systems on modern HPC computing architectures.

[02988] A multiscale preconditioner for simulating blood flows in artery with aneurysm

Format : Talk at Waseda University
Author(s) : Xiao-Chuan Cai (University of Macau)
Abstract : In this talk, we discuss some recent development of numerical methods for the simulation of blood flows in patient-specific arteries with aneurysm. Depending on the branching geometry and the patient parameters, the flow can be quite complicated with local vortex structures, but the principal component of the flow is always along the centerline of the artery. Based on this observation, we introduce a two-scale domain decomposition method for unsteady incompressible Navier-Stokes equations in three-dimensional complex patient-specific arteries, and the key component of the preconditioner is a parameterized one-dimensional unsteady Navier-Stokes or Stokes coarse problem defined along the centerline of the artery. The one-dimensional preconditioner and some overlapping three-dimensional subdomain preconditioners are combined additively to form the two-scale method via interpolations using radial basis functions. The most important feature of the method is that the cost of solving the coarse problem is nearly neglectable compared with the subdomain solver. Numerical experiments indicate that the proposed method is highly effective and robust for complex arteries with many branches and aneurysm. This is a joint work with Yingzhi Liu and Fenfen Qi.

[04469] Spectral Element discretizations in cardiac electrophysiology: a matrix-free approach

Format : Talk at Waseda University
Author(s) : Pasquale Claudio Africa (mathLab, SISSA International School for Advanced Studies, Trieste)Matteo Salvador (Stanford University)Paola Gervasio (Università degli Studi di Brescia)
Abstract : We propose a high-order Spectral Element Method (SEM) matrix-free solver for the numerical solution of cardiac electrophysiology. We compare it to SEM with Numerical Integration and demonstrate that increasing the local polynomial degree leads to improved accuracy and faster computations than reducing the mesh size. Our matrix-free approach, enhanced by a suitable implementation of a Geometric Multigrid (GMG) preconditioner,

yields up to 45(\times) speed-up compared to a conventional matrix-based solver. Several numerical experiments are analyzed.

[03783] Monolithic solution strategies for large-scale computational problems from physiology and astrophysics

Format : Online Talk on Zoom
Author(s) : pietro benedusi (Simula Research Laboratory)Rolf Krause (Università della Svizzera italiana)Patrick Zulian (Università della Svizzera italiana)
Abstract : Currently, many problems in applied mathematics result in large-scale computational challenges which require the use of massively parallel machines and scalable solution strategies to minimize the time to solution. In this talk, we present monolithic strategies to numerically solve partial differential equations, for various applications. These strategies consist in framing, whenever possible, a computational problem in a large and possibly sparse (non) linear system which can be solved, in parallel, combining efficient preconditioning techniques and Krylov methods. By contrast, many traditional staggered approaches are based on the solution of a sequence of smaller computational problems. An example of such a paradigm can be found when solving evolutionary problems, where a monolithic strategy (also known as all-at-once approach) can be used, resulting in the assembly of large a space-time system with a block Toeplitz structure, in contrast to standard sequential time-stepping techniques. In this context, we consider the space-time discretization of the anisotropic diffusion equation, using isogeometric analysis in space and a discontinuous Galerkin approximation in time. Drawing inspiration from a former spectral analysis of space-time operators, we propose a parallel multigrid preconditioned GMRES method. The application of this multilevel space-time strategy to non-linear reaction-diffusion problems from electrophysiology (i.e. the monodomain equation and the EMI model) will be also discussed, considering comparison with other recently developed methods. Moreover, we present a monolithic approach to simulate radiative transfer in stellar atmospheres; in this scenario, we present a matrix-free implementation of a multi-fidelity preconditioner. Through simulations on massively parallel systems, we show how monolithic strategies can improve software scalability and discuss the trade-offs of this approach.

[04869] Platform Portable Distributed Solvers and Preconditioners in Cardiac Simulations

Format : Talk at Waseda University
Author(s) : Fritz Goebel (Karlsruhe Institute of Technology)Hartwig Anzt (Karlsruhe Institute of Technology)Terry Cojean (Karlsruhe Institute of technology)Marcel Koch (Karlsruhe Institute of Technology)
Abstract : In the European MICROCARD project we work on simulating the electrophysiology of the human heart with a new Cell-by-Cell model. The model's high resolution and the resulting linear systems pose a computational challenge. In this talk we report on recent developments on scaleable Krylov Methods and Preconditioners in the open source library Ginkgo that we aim to leverage in these simulations.

00840 (2/3) : 1E @E802 [Chair: Luca Pavarino]

[03815] Overlapping Schwarz methods for Isogeometric analysis based on generalized B-splines

Format : Talk at Waseda University
Author(s) : Durkbin Cho (Dongguk University)
Abstract : Isogeometric analysis (IGA) is an innovative numerical methodology for the solution of partial differential equations (PDEs), introduced by Hughes, that potentially allows for a direct connection with CAD, thus providing a much easier and exact representation of the computational domain in a wide range of applications. Generalized B-splines (GB-splines) are a special class of Tchebycheff B-splines that are smooth piecewise function with sections in more general spaces. GB-splines allow for an exact representation of conic sections as well as transcendental curves and thus they become very attractive for geometrical modeling and numerical simulation. They have been proposed as an attractive tool in isogeometric analysis. Since then, isogeometric analysis based on GB-splines have been studied. In this talk, we present overlapping Schwarz preconditioners for {\sf elliptic} and {\sf biharmonic} problems discretized with isogeometric analysis based on GB-splines. An h-analysis of the proposed preconditioners shows an optimal convergence rate bound. Numerical results in two- and three-dimensional tests confirm our theory and also illustrate the good convergence properties of the preconditioner with respect to the discretization parameters.

[03711] Higher Order Time Integration for EMI Cardiac Electrophysiology Simulations with Nested Subset Selection and BDDC Preconditioning

Format : Talk at Waseda University

Author(s) : Fatemeh Chegini (Zuse Institute Berlin(ZIB))Martin Weiser (Zuse Institute Berlin(ZIB))

Abstract : Cardiac electrophysiology simulations call for adaptive methods due to locality of solution features. Traditional mesh refinement and coarsening approaches incur significant overheads. We investigate a novel approach using nested subset selection for algebraic degrees of freedom in hierarchical spectral deferred correction methods. This enables multi-rate integration with minimal overhead, and reduces the computational cost significantly. We also propose a novel domain decomposition preconditioner of BDDC type for cell-by-cell electrophysiology models and show numerical results.

[03593] Adaptive BDDC preconditioners for 3D divergence free virtual element discretizations of the Stokes equations.

Format : Talk at Waseda University

Author(s) : Tommaso Bevilacqua (University of Milan)Franco Dassi (University of Milano-Bicocca)Stefano Zampini (King Abdullah University of Science and Tecnology,)Simone Scacchi (University of Milan)

Abstract : The balancing domain decomposition by constraints (BDDC) preconditioners are domain decomposition methods based on the subdivision of the computational domain of a partial differential equation (PDE) into non-overlapping subdomains.

We apply BDDC to solve PDEs discretized by Virtual Element Methods (VEM) proving scalability and quasi-optimality of the algorithm. Numerical results with adaptively generated coarse spaces confirm the method's robustness in the presence of large jumps in the viscosity and with high-order VEM discretizations.

[03487] Efficient solvers for models of personalized whole heart electromechanics

Format : Talk at Waseda University

Author(s) : Matthias Gsell (Medical University of Graz)Christop Augustin (Medical University of Graz)Karli Gillette (Medical University of Graz)Alexander Jung (Medical University of Graz)Gernot Plank (Medical University of Graz)

Abstract : Anatomically accurate computer models of four-chamber electromechanics, which are able to replicate electromechanical function of an individual patient's heart show high potential for both clinical and industrial applications such as diagnostics, treatment optimization and device development. Methodology used to obtain a first fully mechanistic whole-heart electromechanics models with non-invasively personalized electrophysiology and calibrated mechanical and vascular function will be presented. We demonstrate goodness of fit of the calibrated model, and validation against common physiological principles.

00840 (3/3) : 2C @E802 [Chair: Nicolas A. Barnafi]

[02611] An efficient parallel interpolation algorithm with applications to multi-physics simulation of cardiac radiofrequency ablation

Format : Talk at Waseda University

Author(s) : Massimiliano Leoni (Johann Radon Institute for Computational and Applied Mathematics)Argyrios Petras (RICAM-Johann Radon Institute for Computational and Applied Mathematics)Luca Gerardo-Giorda (JKU and RICAM)

Abstract : In this talk we discuss modelling and simulation of Cardiac Radiofrequency Ablation, a clinical procedure used to treat some forms of cardiac arrhythmia by accessing the patient's heart with a catheter and burning it locally to make it electrically insulating.

By its nature, this problem requires a complex multi-physics approach, which in turn yields many computational challenges.

In particular, we will focus on parallel interpolation, a trivial-looking step that is crucial to a performant implementation

[04831] A nonlinear preconditioning strategy for solving phase-field fracture problems in a constrained minimization framework

Format : Talk at Waseda University
Author(s) : Hardik Kothari (Università della Svizzera Italiana)Alena Kopaničáková (Brown Universitty)Rolf Krause (Università della Svizzera Italiana)
Abstract : The phase-field approach to fracture allows one to model crack propagation, branching, and merging. Despite its robust modeling properties, solving this problem is computationally challenging due to the non-convex, non-smooth, highly nonlinear, and ill-conditioned nature of the underlying energy function. We propose a field-split-based additive/multiplicative Schwarz preconditioned Newton method to solve the fracture problem by employing a right preconditioner that can handle inequality constraints. The robustness of the method will be shown using numerical examples.

[04801] Multi-scale modelling and simulation: EMI models, 3D-1D transport, and DG methods

Format : Talk at Waseda University
Author(s) : Rami Masri (Simula Research Laboratory)Marius Zeinhofer (Simula Research Laboratory)Miroslav Kuchta (Simula Research Laboratory)Marie Rognes (Simula Research Laboratory)
Abstract : In this presentation, we discuss several of our findings on a variety of multi-scale models and their discretizations. First for the EMI equations which are used to model excitable tissue, we formulate and analyse discontinuous Galerkin interior penalty formulations. The practical advantages of such an approach are that (i) it can be implemented in any finite element library without additional multimesh/mixed-dimensional features, and that (ii) black box multigrid solvers perform well. Second, we formulate coupled time dependent 3D-1D models of transport used to model a variety of phenomena. The modeling and the discretisation errors for finite element approximations are discussed.

[04846] SCALABLE SOLVERS FOR BULK-SURFACE MATERIALS UNDERGOING SPINODAL DECOMPOSITION

Format : Talk at Waseda University
Author(s) : stefano zampini (KAUST)Luis Espath (University of Nottingham)Luca Heltai (SISSA)Hector Gomez (Purdue University)
Abstract : In this work, we present numerical results for two- and three-dimensional bulk-surface materials undergoing spinodal decomposition. The emphasis will be on the numerical implementation using the deal.II framework, and on the solution of the nonlinear equations using the PETSc library.

[00843] Innovative numerical methods for complex PDEs

Session Time & Room :

00843 (1/2) : 4D (Aug.24, 15:30-17:10) @E702

00843 (2/2) : 4E (Aug.24, 17:40-19:20) @E702

Type : Proposal of Minisymposium
Abstract : Many problems in science and engineering involve multi-physical processes where their complex interactions occur at a wide range of spatial and temporal scales. They can be modeled by a set of nonlinear PDEs, each representing different physical phenomena. Numerical solutions of such problems remain a quite challenging task due to the presence of multiple spatial and time scales. The goals of this minisymposium are first to present some of latest developments in numerical methods for such complex PDEs, and second to bring together experts, young researchers, and students working in this field to exchange ideas and to initiate collaborations.

Organizer(s) : Vu Thai Luan, Amanda Diegel, Aaron Rapp

Minisymposium Program :

00843 (1/2) : 4D @E702 [Chair: Vu Thai Luan]

[01855] Accelerating nonlinear solvers with continuous data assimilation

Format : Talk at Waseda University
Author(s) : Leo Rebholz (Clemson University)
Abstract : We show how continuous data assimilation can be used to accelerate convergence in nonlinear solvers for steady PDE. We prove that for incompressible flow problems, with sufficient measurement data the linear convergence rate of Picard iterations can be improved. Numerical tests illustrate the theory.

[01739] Unconditionally stable numerical methods for Cahn-Hilliard-Navier-Stokes-Darcy system with different densities and viscosities

Format : Online Talk on Zoom
Author(s) : Xiaoming He (Missouri University of Science and Technology)Yali Gao (Northwestern Polytechnical University)Daozhi Han (University at Buffalo)Ulrich Rüde (Friedrich-Alexander-University of Erlangen-Nuremberg)
Abstract : In this presentation, we consider the numerical modeling and simulation via the phase field approach for coupled two-phase free flow and two-phase porous media flow of different densities and viscosities. The model consists of the Cahn-Hilliard-Navier-Stokes equations in the free flow region and the Cahn-Hilliard-Darcy equations in porous media that are coupled by several domain interface conditions. It is showed that the coupled model satisfies an energy law. Then we first propose a coupled unconditionally stable finite element method for solving this model and analyze the energy stability for this method. Furthermore, based on the ideas of pressure stabilization and artificial compressibility, we propose an unconditionally stable time stepping method that decouples the computation of the phase field variable, the velocity and pressure of free flow, the velocity and pressure of porous media, hence significantly reduces the computational cost. The energy stability of this decoupled scheme with the finite element spatial discretization is rigorously established. We verify numerically that our schemes are convergent and energy-law preserving. Numerical experiments are also performed to illustrate the features of two-phase flows in the coupled free flow and porous media setting.

[01884] Modified exponential Rosenbrock methods to increase their accuracy

Format : Online Talk on Zoom
Author(s) : Begoña Cano (Universidad de Valladolid)María Jesús Moreta (Universidad Complutense de Madrid)
Abstract : In this talk a technique will be described to avoid order reduction when integrating nonlinear initial boundary value
problems with exponential Rosenbrock methods. The technique does not require to impose any stiff order conditions
but to add some terms related to the information on the boundary. Theoretical results on local and global error will be
given as well as some numerical comparisons.

[01971] Low Regularity Integrators for Semilinear Parabolic Equations with Maximum Bound Principles

Format : Talk at Waseda University
Author(s) : Cao-Kha Doan (Auburn University)Lili Ju (University of South Carolina)Thi-Thao-Phuong Hoang (Auburn University)Katharina Schratz (Sorbonne Université)
Abstract : This work is concerned with structure-preserving, low regularity time integration methods for a class of semilinear parabolic equations of Allen-Cahn type. Important properties of such equations include maximum bound principle (MBP) and energy dissipation law; for the former, that means the absolute value of the solution is pointwisely bounded for all the time by some constant imposed by appropriate initial and boundary conditions. The model equation is first discretized in space by the central finite difference, then by iteratively using Duhamel's formula, first and second-order low regularity integrators (LRIs) are constructed for time discretization of the semi-discrete system. The proposed LRI schemes are proved to preserve the MBP and the energy stability in the discrete sense. Furthermore, some semi-discrete and fully-discrete error estimates are also successfully derived under the

low regularity requirement that the corresponding exact solution is only assumed to be continuous in time. Numerical results show that the proposed LRI schemes can be more accurate and achieve better convergence than classic exponential time differencing (ETD) schemes, especially when the interfacial parameter approaches zero.

00843 (2/2) : 4E @E702 [Chair: Amanda Diegel]

[02261] A tourist's guide to operator splitting

Format : Talk at Waseda University
Author(s) : Raymond Spiteri (University of Saskatchewan)Siqi Wei (University of Saskatchewan)
Abstract : Operator splitting is the dirty little thing we all do when a differential equation is too hard to solve monolithically. Many questions abound, however, regarding how to split a given problem, and many observations and "common knowledge" lack a theoretical understanding. In this talk, I take you on a tour through some of the practical aspects of operator splitting and while touching on some of the folklore that exists around it.

[02294] Adaptive exponential Runge--Kutta methods for stiff PDEs

Format : Talk at Waseda University
Author(s) : Luan Vu Thai (Mississippi State University)
Abstract : Exponential Runge-Kutta methods have shown to be well-suited for stiff parabolic PDEs. Their constructions require solving stiff order conditions which involve matrix functions. Current schemes allow using with constant stepsizes only. In this talk, we will derive new schemes of high order which not only fulfill the stiff order conditions in the strong sense and but also support variable step sizes implementation. Numerical experiments are given to illustrate accuracy and efficiency of the new schemes.

[02660] The Dual-Wind Discontinuous Galerkin Method for Hamilton-Jacobi Equations

Format : Talk at Waseda University
Author(s) : Aaron Rapp (University of the Virgin Islands)
Abstract : A discontinuous Galerkin (DG) finite-element interior calculus is used as a common framework to describe various DG approximation methods for second-order elliptic problems. This framework allows for the approximation of both primal and variational forms of second order differential equations. In this presentation, we will study the error from using the dual-wind DG derivatives to approximate the the solution to stationary and time-dependent Hamilton-Jacobi equations. Some analytical results will be presented, along with numerical examples that verify these results.

[00851] Mathematics for Big Data and Artificial Intelligence: models and challenges

Session Time & Room : 4C (Aug.24, 13:20-15:00) @E504

Type : Proposal of Minisymposium
Abstract : The availability of huge amounts of data and the application of AI techniques are considered as the fourth industrial revolution, but extracting meaningful knowledge and transparent decisions from the data is not a trivial task.
Mathematics is the 'language' on which are based the existing algorithms for data processing and for AI. This minisymposium is organized within the ECMI SIG "Mathematics for Big Data and AI". The talks in this minisymposium will present and discuss how Mathematics can play a leading role in improving the reliability, computational efficiency, and transparency of the existing techniques for big data analysis and AI.

Organizer(s) : Alessandra Micheletti, Natasa Krejic
Classification : 62Pxx, 62R40, 68T07, 65K10, 68Txx
Minisymposium Program :

00851 (1/1) : 4C @E504 [Chair: Alessandra Micheletti]

[01685] Equivariant non-expansive operators as a bridge between TDA and geometric deep learning

Format : Talk at Waseda University
Author(s) : Patrizio Frosini (University of Bologna)
Abstract : Group equivariant non-expansive operators (GENEOs) have been recently introduced as mathematical tools for approximating data observers when data are represented by real-valued or vector-valued functions (https://rdcu.be/bP6HV). The use of these operators is based on the assumption that data interpretation depends on the observers' geometric properties. In this talk we will illustrate some recent results, showing how GENEOs can make available an interesting link between topological data analysis and geometric deep learning.

[01623] a new machine learning paradigm for protein pocket detection based on Group Equivariant Non Expansive Operators

Format : Talk at Waseda University
Author(s) : Alessandra Micheletti (Università degli Studi di Milano)Giovanni Bocchi (Università degli Studi di Milano)Patrizio Frosini (Università degli Studi di Bologna)Carmine Talarico (Dompè Farmaceutici)Filippo Lunghini (Dompè Farmaceutici)Andrea Beccari (Dompè Farmaceutici)Carmen Gratteri (University Magna Grecia Catanzaro)Alessandro Pedretti (Università degli Studi di Milano)
Abstract : Protein pockets detection is a key problem in the context of drug development, since the ability to identify a small number of potential binding sites, allows to speed up drug discovery procedures. In this talk we will show how Group Equivariant Non Expansive Operators (GENEOs) can be used to build a geometrical machine learning method, able to detect protein pockets better than ML techniques already in use, but being based only on 17 unknown parameters.

[01528] SLiSeS: Subsampled Line Search Spectral Gradient Method for Finite Sums

Format : Online Talk on Zoom
Author(s) : Stefania Bellavia (University of Florence)Natasa Krejic (University of Novi Sad)Natasa Krklec Jerinkic (University of Novi Sad)Marcos Alejandro Raydan (NOVA University Lisbon)
Abstract : In this paper, we aim to exploit advantages of spectral method in stochastic optimization framework, especially in mini-batch subsampling case which is often used in Big Data setup. In order to let the spectral coefficient explore the spectrum of the approximate Hessian, we keep the same sample for several iterations before we subsample again. We analyze conditions for almost sure convergence and present initial numerical results that show the advantages of the proposed method.

[01698] Interpretable models for large-scale tabular datasets

Format : Online Talk on Zoom
Author(s) : Claudia Soares (NOVA School of Science and Technology)
Abstract :
The purpose of this work is two-fold: on the one hand, to demonstrate that machine learning models can be considered a powerful alternative to predicting real-world variables in high-stakes scenarios, and, on the other hand, to propose a new method that is empirically the state-of-the-art rule-based method for large datasets. We accompany our method with tailored algorithms for fast learning in large datasets.

[00854] Control and stabilization of PDEs: recent advances and applications

Session Time & Room :

00854 (1/3) : 2C (Aug.22, 13:20-15:00) @G605

00854 (2/3) : 2D (Aug.22, 15:30-17:10) @G605

00854 (3/3) : 2E (Aug.22, 17:40-19:20) @G605

Type : Proposal of Minisymposium
Abstract : As control problems arise naturally from engineering and physics, control theory has attracted a lot of attention in the last century. In recent decades, the study of control problems from PDEs' point of view has developed quickly, finding natural connections with fluid mechanics, microlocal analysis, stochastic analysis, and many applications such as traffic flow regulations, lane manufacturing, crowd motion, and biology, etc. We focus on these new developments, which cover a wide range of problems from observability to quantitative stabilization and finite-time stabilization across many different types of systems from subelliptic equations to conservation laws to hybrid systems.

Classification : 35L04, 76B15, 49J20, 93D15, 93C95
Minisymposium Program :

00854 (1/3) : 2C @G605 [Chair: Amaury Hayat]

[02524] Quantitative rapid stabilization of some PDE models

Format : Talk at Waseda University
Author(s) : Shengquan Xiang (Peking University)
Abstract : Quantitative stabilization is an active research topic in PDEs' control theory, namely to construct explicit feedback laws as a control to make the closed-loop system stable together with quantitative estimates. In this presentation, we will talk about some recent progress in this topic including the Frequency Lyapunov method for the stabilization of Navier-Stokes equations and the Fredholm backstepping method for the stabilization of water waves.

[02863] Generalized Fredholm-backstepping transformation

Format : Talk at Waseda University
Author(s) : Ludovick Gagnon (Inria Nancy)Christophe Zhang (Inria Nancy)Amaury Hayat (Ecole des Ponts Paristech)Shengquan Xiang (Peking University)Swann Marx (CNRS)
Abstract : The backstepping method for PDEs, introduced over 20 years ago, is a powerful method to prove the rapid stabilisation of linear PDEs. The Fredholm alternative, introduced by Coron and Lü, quickly proved to provide a systematic approach to the backstepping method based on the spectral behaviour of the PDE as well as controllability assumptions. We present in this talk recent advances on sufficient conditions for the Fredholm-backstepping method in an abstract setting.

[02944] Indirect controllability of linear constant coefficients parabolic-transport systems

Format : Talk at Waseda University
Author(s) : Pierre Lissy (Université Paris-Dauphine)
Abstract : I will present controllability properties of mixed systems of linear parabolic-transport equations, with possibly nondiagonalizable diffusion matrix, on the 1D torus, coupled by constant coupling terms. The distributed control acts through a constant matrix, with possibly less controls than equations. In small time or for not regular enough initial data, these systems are never controllable, whereas in large time, null-controllability holds, for regular initial data, iff a spectral Kalman rank condition is verified.

[03571] Optimal Control of Moving Sets

Format : Talk at Waseda University
Author(s) : Maria Teresa Chiri (Queen's University)
Abstract : We consider a controlled reaction-diffusion equation, modeling the spreading of an invasive population. Our goal is to derive a simpler model, describing the controlled evolution of a contaminated set. We first analyze the optimal control of 1-dimensional traveling wave profiles. Using Stokes' formula, explicit solutions are obtained, which in some cases require measure-valued optimal controls. Then we introduce a family of optimization problems for a moving set and show how these can be derived from the original parabolic problems, by taking a sharp interface limit. Assuming that the initial contaminated set is convex, we prove that an eradication strategy is optimal if an only if at each given time the control is active along the portion of the boundary where the curvature is maximal. We then consider the eradication problem with geographical constraints, and derive necessary and sufficient conditions for the existence of a solution.

00854 (2/3) : 2D @G605 [Chair: Maria Teresa Chiri]

[04439] On the boundary controllability of conservation laws with boundary and source controls

Format : Talk at Waseda University
Author(s) : Fabio Ancona (University of Padova)Khai Tien Nguyen (North Carolina State University)
Abstract : We will discuss local and global controllability results for hyperbolic conservation laws on a bounded domain, where the control acts through a time dependent source term in combination with the boundary controls. We shall investigate first this problem for scalar conservation laws with a not necessarily convex flux. Next, we shall address the problem of extending these results to the case of rich systems of conservation laws.

[02947] Advances on structural controllability of ensembles

Format : Talk at Waseda University
Author(s) : Bahman Gharesifard (UCLA)
Abstract : Ensemble control studies the problem of steering the state of a large population of systems, or a continuum, using a finite number of controllers. The problem has historic ties to control of partial differential equations, with many applications including quantum ensembles in spectroscopy, control of large limits of complex networks with few inputs, and recently in the study of universal approximation of neural networks. The purpose of this talk is to study a suit of structural controllability results for linear ensemble systems, where the objective is to identify structural properties that generically render the state of the ensemble — or some statistical properties of the profile over the parametrization space, for instance the average or higher moments — controllable. The latter provides a necessary and critical complement to full structural ensemble controllability which is hard to achieve in multiparameter settings. For the case where the statistical property of interest is the average, we provide a graph-theoretic characterization of structural controllability. Along the way of establishing this result, we hint at a conjecture on minimal ``complexity'' controllers and relate it a conjecture on invertibility of a sparse version of Hilbert matrices, which is open for most parts.

[03282] Second microlocalization and optimal decay for the Bouendi-Grushin damped wave equation

Format : Talk at Waseda University
Author(s) : Chenmin Sun (CNRS(Université Paris Est Créteil))Victor Arnaiz (Nantes Université)
Abstract : The Bouendi-Grushin damped-wave operator is a hypoelliptic operator with a distributional damping. This presentation introduces the second microlocalization method for obtaining the optimal resolvent estimate for the operator under varying damping conditions.

[04573] Controls on Networks: Modeling, Learning and Applications

Format : Talk at Waseda University
Author(s) : Yue Wang (Friedrich-Alexander-Universität Erlangen-Nürnberg)
Abstract : This talk is an introduction of controllability properties and methods for networked 1D hyperbolic systems based on results obtained by the speaker and her collaborators in recent years. Modelling, analysis of the underlying dynamics and exact controllability of several physical models will be presented at first. Some recent numerical experiments with Physics-Informed Neural Networks (PINNs) show interesting possibilities for future research on the interface between control and machine learning.

00854 (3/3) : 2E @G605 [Chair: Shengquan Xiang]

[03018] Stabilization of 1D evolution systems: new approaches

Format : Talk at Waseda University
Author(s) : Amaury Hayat (Ecole des Ponts Paristech)
Abstract : We discuss recent advances in the F-equivalence (or Fredholm backstepping) method. This consists in reformulating the stabilization problem and to find a control operator such that the PDE system can be inversely mapped to a simpler PDE system. Surprisingly powerful, this approach offers the possibility to treat very general classes of systems. We will also examine traffic flow stabilization. Finally, we will briefly discuss some results on AI for mathematics.

[02943] Feedback stabilization and inverse problem for a nonlocal transport equation

Format : Talk at Waseda University
Author(s) : Zhiqiang Wang (Fudan University)
Abstract : In this talk, we will show some results on feedback stabilization and inverse problems for a transport equation with nonlocal velocity. This model arises in the control of semiconductor manufacturing systems which have a highly re-entrant character. Firstly we obtain a semi-global stabilization result by using a time-varying feedback control. Secondly with the help of certain feedback control, we recover the velocity function from the measurements.

[04252] The controllability of a special class of coupled wave systems

Format : Talk at Waseda University
Author(s) : Jingrui Niu (Sorbonne Université)Pierre Lissy (Université Paris-Dauphine)
Abstract : I will present an exact controllability result for coupled wave systems with two distinct speeds. A distributed scalar control function is effective in a subdomain satisfying the geometric control conditions and acts on only one speed. We establish compatibility conditions, which are associated with the particular coupling structure. Furthermore, the exact controllability holds in these compatible spaces if and only if the coupling structure satisfies an operator Kalman rank condition.

[02522] Geometry of observable sets

Format : Talk at Waseda University
Author(s) : gengsheng wang (Tianjin University)
Abstract : We introduce several observability inequalities in some abstract setting. Then for some concrete evolution equations, such as the heat equation and the Schrodinger equations on the whole space, we give the characterizations of the observable sets such that the aforementioned inequalities hold. We further give some comments.

[00866] BEM and related methods for advanced applications

Session Time & Room : 5D (Aug.25, 15:30-17:10) @E704

Type : Proposal of Minisymposium
Abstract : Since its early days, the Boundary Element Method (BEM) has been selected as an accurate, scalable and reliable tool in computational science and engineering. In particular, in the last three decades, the number of its applications to cutting edge academic/industrial fields has impressively grown up. This Minisymposium is devoted to application aspects of BEM and its main goal is to bring together experts in this field, belonging to different international research groups, to discuss on the most recent advances and current open challenges on fast and innovative strategies for real-life applications.
Organizer(s) : Luca Desiderio, Alessandra Aimi, Chiara Guardasoni
Classification : 65N38
Minisymposium Program :

00866 (1/1) : 5D @E704 [Chair: Luca Desiderio]

[04974] Time domain boundary elements and mesh refinements

Format : Online Talk on Zoom
Author(s) : Heiko Gimperlein (University of Innsbruck)
Abstract : We discuss recent and on-going progress for time-domain boundary element methods for wave and elastodynamic problems, with a focus on locally refined meshes. Solutions of the time-dependent equations exhibit singularities due to geometry (corners), mixed or nonlinear (contact) boundary conditions. We discuss well-posed formulations for such problems as well as their approximation on locally refined meshes by h- and hp-versions. A priori and a posteriori esti-
mates for the approximation error are presented for both the weakly singular and the hypersingular integral part_2

equations. The a posteriori estimates lead to an adaptive mesh refinement procedure. Numerical experiments illustrate the theoretical results. (joint with A. Aimi, G. Di Credico, C. Oezdemir and E. P. Stephan)

[05091] On improving the flexibility of an IgA-BEM multi-patch code

Format : Online Talk on Zoom
Author(s) : Alessandra Sestini (Università di Firenze)
Abstract : Two flexibility improvements are introduced of a 3D multi-patch IgA-BEM approach for Helmholtz based on B-spline tailored numerical integration. The first concerns the possibility of developing the discretization in non-conforming C^0 multi-patch spline spaces, thus ensuring adaptivity at the patch level. The second consists in the capability of using non uniform tensor product formulations of the adopted quadrature rules which are based on quasi-interpolation. This allows us to deal with non-smooth inter-patch junctions.

[04013] Solving 2D linear elastic wave equations by scalar potentials

Format : Online Talk on Zoom
Author(s) : Silvia Falletta (Polytechnic University of Turin)
Abstract : This talk focuses on the simulation of 2D soft scattering elastic wave propagation in isotropic homogeneous media, using the scalar potential decomposition in the time-harmonic regime. For problems defined in bounded domains, a Virtual Element Method (VEM) with varying mesh sizes and degrees of accuracy is proposed to approximate the two scalar potentials. For unbounded domains, a boundary element method is coupled with the VEM.

[04853] Time-Domain BEM for the resolution of Elastodynamic Contact Problems

Format : Online Talk on Zoom
Author(s) : Giulia Di Credico (University of Parma)Alessandra Aimi (University of Parma)Heiko Gimperlein (University of Innsbruck)
Abstract : We investigate a boundary element method (BEM) for the dynamic contact between a linearly elastic body and a rigid obstacle. The so-called Signorini problem is formulated on the boundary as a variational inequality for the elastodynamic equations, for which we consider a mixed formulation solvable by time-domain BEM coupled with Uzawa algorithm. Both theoretical and algorithmic aspects are discussed and numerical experiments, presented for different 2D geometries, show the optimal performance of the proposed approach.

[00869] Theory, numerics and data driven methods for fluids

Session Time & Room :

00869 (1/3) : 5B (Aug.25, 10:40-12:20) @D403

00869 (2/3) : 5C (Aug.25, 13:20-15:00) @D403

00869 (3/3) : 5D (Aug.25, 15:30-17:10) @D403

Type : Proposal of Minisymposium
Abstract : Despite recent progress in the study of turbulent fluids, to date our mathematical understanding of it remains fundamentally incomplete. Furthermore, recent work on non-uniqueness of weak solutions and lack of global well-posedness of fluid equations, make their study even more pertinent and urgent. This mini-symposium will bring together researchers at all career stages to share their recent results on the interplay of topics such as uniqueness, regularity, boundary-layer theory, asymptotic dynamics and their connections to data assimilation, parameter estimation, machine and physics-informed deep learning algorithms, porous media flow simulations, and the study of statistical and stochastic solutions.

[01423] Parameter analysis in continuous data assimilation for three-dimensional Brinkman-Forchheimer-extended Darcy model

Format : Online Talk on Zoom
Author(s) : Débora Aparecida Francisco Albanez (Universidade Tecnológica Federal do Parana)
Abstract : Analytical results of the long-time behavior of three-dimensional Brinkman-Forchheimer-extended Darcy model in the context that the parameters related to the damping nonlinear term are unknown is presented. We show estimates in L^2 and H^1 for large-time error between the true solution and the assimilated solution, which is constructed with the unknown damping parameters and observational measurements obtained continuously in time from a continuous data assimilation technique.

[04819] Boundary layers for a viscous fluid in a corner domain

Format : Online Talk on Zoom
Author(s) : Anna Mazzucato (Penn State University)
Abstract : We study boundary layers for incompressible slightly viscous fluids in a rectangular domain when steady shears are applied to the top and bottom side. We establish the vanishing viscosity limit using various types of correctors. In particular, we introduce suitable corner layer correctors at the corners. This is joint work with Gung-Min Gie (U. Louisville) and James Kelliher (UC Riverside).

[03465] Numerical schemes for various stochastic models in hydrodynamic

Format : Online Talk on Zoom
Author(s) : Hakima Bessaih (Florida International University)
Abstract : We will introduce space-time numerical schemes for some stochastic models in hydrodynamic. The models include, the stochastic Navier-Stokes equations, the Boussinesq equations and some other models in porous media. We will also discuss various rates of convergences in probability and in mean square.

[01351] Coupling of free flow and flow in porous media

Format : Talk at Waseda University
Author(s) : Xiaoming Wang (Missouri University of Science and Technology and Southern University of Science and Technology)
Abstract : We present some recent progress in the study of coupled free flow and porous media flow. In particular, we show that the several competing interface boundary conditions are asymptotically equivalent at the physically importance small Darcy number regime. We also offer a coarse-grained theory in predicting the deep vs shallow convections in the case when heat convection is involved. Effective numerical algorithms will be presented if time permits.

00869 (2/3) : 5C @D403 [Chair: Vincent R Martinez]

[01798] Wellposedness of stochastic PDEs arising in fluid dynamics

Format : Online Talk on Zoom
Author(s) : Krutika Tawri (University of California Berkeley)
Abstract : Stochastic forcing terms are commonly added to the governing equations to account for numerical and physical uncertainties in applications. In this talk, we will discuss recent results and new techniques in the analysis of stochastic models, arising in fluid dynamics.

[03526] Error estimates for deep learning methods in fluid dynamics

Format : Talk at Waseda University
Author(s) : Jing Tian (Towson university)Animikh Biswas (University of Maryland, Baltimore County)Suleyman Ulusoy (American University of Ras Al Khaimah)
Abstract : In this talk, we provide error estimates and stability analysis of deep learning techniques for certain partial differential equations including the incompressible Navier–Stokes equations. In particular, we obtain explicit error estimates for the solution computed by optimizing a loss function in a Deep Neural Network approximation of the solution, with a fixed complexity.

[01243] Reconstructing external driving forces in incompressible flow via low-mode observation

Format : Talk at Waseda University
Author(s) : Vincent R Martinez (CUNY Hunter College & Graduate Center)
Abstract : In this talk, we describe a "spectral filtering" algorithm that reconstructs an apriori unknown external force in the 2D Navier-Stokes equations. This approach was developed by Celik, Olson, and Titi (2019) in order to recover the unobserved high-mode motion of the flow provided that sufficiently many low-modes are observed and that the external force is known. It is shown how this idea can be used to simultaneously recover both the unobserved motion and unknown forcing.

[04541] Analysis of a rotationally constrained convection model

Format : Talk at Waseda University
Author(s) : Yanqiu Guo (Florida International University)
Abstract : This talk is about the analysis of an asymptotically reduced system for rotationally constrained convection. This reduced system was derived from the 3D Boussinesq equations using the asymptotic theory. On the one hand, the nonlinear convection term has a reduced complexity since it contains only the horizontal gradient. On the other hand, the regularizing viscosity acts in the horizontal direction only. I will present some of our results motivated by the global regularity problem.

00869 (3/3) : 5D @D403 [Chair: Jing Tian]

[04953] Estimation of parameters on the fly via nudging methods

Format : Talk at Waseda University
Author(s) : Jared P Whitehead (Brigham Young University)
Abstract : We demonstrate the utility of an algorithm that allows for the estimation and recovery of parameters in a dissipative dynamical system. Rigorous justification of the algorithm is established for specific settings, and numerical simulations are used to demonstrate that it works in various settings and for different circumstances including the estimation of a full forcing function and additive and multiplicative parameters.

[04093] Uniform Boundedness of Entropy to Compressible Navier-Stokes Equations with Vacuum

Format : Talk at Waseda University
Author(s) : Jinkai Li (South China Normal University)
Abstract : In the presence of vacuum, the physical entropy for polytropic gases behave singularly and it is thus hard to study its dynamics. In this talk, we present some recent studies on the uniform boundedness of the entropy to the viscous compressible ideal gas in the presence of vacuum either at the far field or on the gas-vacuum interface. It will be shown in this talk that, in the case that the vacuum presents at the far fields only, the uniform boundedness of the entropy can be propagated locally or globally if the initial density decays slowly, while if the initial density decays sufficiently fast, the entropy becomes unbounded immediately after the initial time, in particular, the entropy tends to infinity at the far field.

[05089] A unified framework for the analysis of accuracy and stability of a class of data assimilation methods for the Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Michal Branicki (University of Edinburgh)Animikh Biswas (University of Maryland Baltimore County)
Abstract : Bayesian state estimation of a dynamical system utilising a stream of noisy measurements is important in many geophysical and engineering applications, where nonlinearities, high (or infinite) dimensionality of the state space, and sparse observations pose key challenges for deriving efficient and accurate data assimilation techniques. We develop a unified framework for the analysis of several well-known and empirically efficient data assimilation techniques derived from various Gaussian approximations of the Bayesian filtering problem for geophysical-type dissipative dynamics with quadratic nonlinearities. Our approach also elucidates the links between the approximate-Bayesian and control-theoretic approaches to data assimilation. We consider the `model' dynamics governed by the two-dimensional incompressible Navier–Stokes equations and observations given by noisy measurements of finite volume elements, modal or nodal points of the velocity field. In this setup the

continuous-time data assimilation techniques, the so-called 3DVar and EnKF (Ensemble Kalman filter), are given by stochastically forced Navier–Stokes equations. We derive rigorous conditions for the (time-asymptotic) accuracy and stability of these algorithms and show the relevance of the so-called covariance inflation and localisation for assuring the necessary bounds. These conditions involve an interplay between the resolution of the observations associated with the covariance operator underlying the data assimilation algorithms and, for the first time, elucidate the properties of the EnKF as well as of the 3DVar for a general covariance operator which is common and relevant for volume and nodal observations.

[00874] Recent advances in the analysis and numerics for phase-field models

Session Time & Room : 2E (Aug.22, 17:40-19:20) @G606

Type : Proposal of Minisymposium

Abstract : Phase-field models are a powerful tool for studying the dynamics of phase transformations and internal structures in materials. In recent years, there have been significant advances in the analysis and numerical techniques for phase-field models. These advances range from innovative solution concepts and modelling approaches to structure inheriting numerical schemes together with adaptive mesh refinements.
These methods have led to a deeper understanding of the underlying physics and have had a wide range of applications in areas such as materials science, biology, and engineering.

[02784] Existence of weak solutions to an anisotropic electrokinetic flow model

Format : Talk at Waseda University

Author(s) : Luisa Plato (WIAS)Robert Lasarzik (Weierstrass Institut of Applied Analysis and Stochastics Berlin)Dietmar Hömberg (Weierstrass Institut of Applied Analysis and Stochastics Berlin)

Abstract : In this talk the existence proof of weak solutions in three space dimensions to an anisotropic Navier—Stokes—Nernst—Planck—Poisson system is presented.
This models the electrokinetic flow induced by charged particles dissolved in a liquid crystals with constant director field. The existence proof relies on an approximating scheme and weak sequential compactness of the approximating sequence, which follows from the energy law. Weak—strong uniqueness is proven via the relative energy inequality.

[02502] Global existence for a singular nonlocal phase field system with inertial term

Format : Talk at Waseda University

Author(s) : Shunsuke Kurima (Tokyo University of Science)

Abstract : This talk deals with a nonlocal phase field system with inertial term. Colli-Colturato (2018) have established existence of solutions to a phase field system related to the entropy balance. Also, Colli-Grasselli-Ito (2002) have proved existence for a parabolic-hyperbolic Penrose-Fife phase field system. However, singular nonlocal phase field systems with inertial term seem to be not studied yet.
The present work asserts that we can derive existence for a singular nonlocal phase field system with inertial term.

[02824] A structure-preserving scheme for the Liu-Wu model

Format : Talk at Waseda University

Author(s) : Makoto Okumura (Konan University)

Abstract : Recently, the Cahn-Hilliard equation with new dynamical boundary conditions has been proposed by Liu and Wu. This model has characteristic conservation laws in that each mass of the interior of the domain and the boundary are conserved. In addition, the total energy dissipation law holds. In this talk, we propose a structure-

preserving scheme for the Liu-Wu model that retains the conservation and dissipation laws in a discrete sense and show the mathematical and numerical results.

[02783] Analysis of an Allen--Cahn system in two scale topology optimization

Format : Talk at Waseda University

Abstract : In this talk, we consider an Allen—Cahn system with the obstacle potential that guarantees mass conservation. This equation is coupled to two linear elasticity equations and a nonlocal operator. This system emerged from an algorithm for a problem in two-scale topology optimization using the phase-field approach. We prove the existence of weak solutions for the associated inclusion and comment on different connections of the solvability concept and the numerical algorithm.

[00876] Inverse Problems in Partial Differential Equations and Graphs

Session Time & Room :

00876 (1/2) : 1C (Aug.21, 13:20-15:00) @G809

00876 (2/2) : 1D (Aug.21, 15:30-17:10) @G809

Type : Proposal of Minisymposium
Abstract : The minisymposium discusses recent development on inverse problems for partial differential equations on manifolds and inverse problems on graphs. Inverse problems typically study the reconstruction of system parameters and geometric or combinatorial structures from indirect measurements. They naturally appear in various imaging problems such as in geophysics, medical imaging, network tomography, material science and non-destructive testing. Many inverse problems are highly sensitive to noise, and understanding this unstable nature is important to applications. Inverse problems on manifolds and graphs in general exhibit different nature, and this minisymposium seeks new connections between them.

[04431] Geophysics and algebraic geometry

Format : Talk at Waseda University
Author(s) : Joonas Ilmavirta (University of Jyväskylä)
Abstract : Many areas of interest within the Earth are anisotropic, meaning that the speed of sound is different in different directions. It turns out that pressure waves are far better behaved than shear waves, but fortunately the different polarizations are coupled together through algebraic geometry. I will explain the surprising power of algebraic geometry in the study of anisotropic inverse problems.

[03655] Retrieving coupled Yang-Mills-Higgs fields

Format : Talk at Waseda University
Author(s) : Xi Chen (Fudan University)Matti Lassas (University of Helsinki)Gabriel Paternain (University of Cambridge)Lauri Oksanen (University of Helsinki)
Abstract : The pure Yang-Mills theory is only able to describe the behavior of massless gauge bosons. But experiments show massive gauge bosons do exist. According to the Higgs mechanism of mass generation, the mass of gauge bosons is acquired through the interactions with Higgs bosons. Therefore, the combined Yang-Mills-Higgs

Lagrangian together with its Euler-Lagrange equation is of great scientific significance. We show that one can detect the coupled Yang-Mills-Higgs fields from active local measurements of Yang-Mills-Higgs equations.

[03095] Inverse problems for the graph Laplacian

Format : Talk at Waseda University
Author(s) : Jinpeng Lu (University of Helsinki)
Abstract : We study the discrete version of Gel'fand's inverse spectral problem, of determining the graph structure of a finite weighted graph from the spectral data of its graph Laplacian. We prove that the problem is uniquely solvable under a novel Two-Points Condition. We also consider an inverse problem for random walks on finite graphs and its unique solvability under this condition. This is a joint work with E. Blåsten, H. Isozaki and M. Lassas.

[03169] Quantum computing algorithms for inverse problems on graphs

Format : Talk at Waseda University
Author(s) : Joonas Ilmavirta (University of Jyväskylä)Matti Lassas (University of Helsinki)Jinpeng Lu (University of Helsinki)Lauri Oksanen (University of Helsinki)Lauri Ylinen (University of Helsinki)
Abstract : We consider a quantum algorithm for an inverse travel time problem on a graph. This problem is a discrete version of the inverse travel time problem encountered in seismic and medical imaging and the boundary rigidity problem studied in Riemannian geometry. We also consider the computational complexity of the inverse problem, and show that the quantum algorithm has a quadratic improvement in computational cost when compared to the standard classical algorithm.

00876 (2/2) : 1D @G809

[05146] Density results in the Calderon problem

Format : Online Talk on Zoom
Author(s) : Mikko Salo (University of Jyvaskyla)
Abstract : We will discuss recent density results for products of harmonic functions, and applications of these results to inverse problems such as the linearized Calderon problem and the Calderon problem for nonlinear partial differential equations. The emphasis will be on the geometric setting that corresponds to anisotropic conductivity coefficients given by a Riemannian metric.

[03644] Rellich type theorem for lattice Hamiltonians

Format : Talk at Waseda University
Author(s) : Hiroshi Isozaki (University of Tsukuba)
Abstract :
We announce results for a Rellich type theorem on a locally perturbed periodic
lattice containing square, triangular and hexagonal lattices.
This is a joint work with K. Ando and H. Morioka.

[04868] Continuum limits of discrete Schr"odinger operators on lattices

Format : Talk at Waseda University
Author(s) : Yukihide Tadano (Tokyo University of Science)
Abstract : We consider continuum limit problems of discrete Schr\"odinger operators defined on lattices.
We show that the corresponding Schr\"odinger operators on the Euclidean space are obtained as the above continuum limits in the generalized norm resolvent sense.
This talk is based on joint work with Shu Nakamura.

[00877] Mathematical and Computational Methods for Topological Materials

Session Time & Room :

00877 (1/2) : 5B (Aug.25, 10:40-12:20) @D405

00877 (2/2) : 5C (Aug.25, 13:20-15:00) @D405

Type : Proposal of Minisymposium
Abstract : Topological materials are a class of quantum materials whose properties are preserved under topological transformations. The delicate structures of these materials admit novel and subtle propagating wave patterns which are immune to backscattering from disorder and defects. Recent years have witnessed vast of new experiments and theories about the wave phenomena in topological materials. The goal of this minisymposium is to bring together theoretical and applied researchers in these areas to discuss recent advances in the mathematical theories and physical applications. Topics will include analysis of the underlying governing equations, numerical methods on computing edge states, and experimental realizations.

[03694] Computation of phononic crystals using the PG finite element method

Format : Talk at Waseda University
Author(s) : Liqun Wang (China University of Petroleum-Beijing)
Abstract : Phononic crystals are composite materials with periodic distribution of two or more media. The difficulty of computing the band structure of the phononic crystals lies in capturing the complex geometry and jump conditions effectively on the interface between the scatterer and the matrix. This talk will present the Petrov-Galerkin Finite Element Method for the band structure computation of phononic crystals, and the properties of various materials are also discussed.

[05337] Conically degenerate spectral points of the periodic Schrödinger operator

Format : Talk at Waseda University
Author(s) : Yi Zhu (Tsinghua University)
Abstract : Conical spectral points on the dispersion bands are the origin of many novel topological phenomena, including various topological phases. I will first review recent mathematical theories on these points, especially Fefferman & Weinstein's results (JAMS 2012) on 2D Dirac points, which paved the way for rigorous justifications of such points. Then I will focus on our recent progress in constructing 3-fold Weyl points at which two energy bands intersect conically with an extra band sandwiched in between. We give the existence of such points in the spectrum of the 3-dimensional Schrödinger operator $H = -\Delta + V(x)$ with $V(x)$ being in a large class of periodic potentials. This is the first rigorous result on the existence of 3-fold Weyl points for a broad family of 3D continuous Schrödinger equations. Our result extends Fefferman-Weinstein's pioneering work to higher dimensions and multiplicities.

[02726] Frozen Gaussian sampling for wave equations

Format : Talk at Waseda University
Author(s) : Lihui Chai (Sun Yat-sen University)Ye Feng (Sun Yat-sen University)Zhennan Zhou (Peking University)
Abstract : We introduce the frozen Gaussian sampling (FGS) algorithm to solve the wave equation in the high-frequency regime. The FGS algorithm is a Monte Carlo sampling strategy based on the frozen Gaussian approximation, which greatly reduces the computation workload in wave propagation and reconstruction. We propose feasible and detailed procedures to implement the FGS algorithm, and we analyze the error caused by the sampling algorithm with Gaussian initial conditions and WKB initial conditions respectively.

00877 (2/2) : 5C @D405

[05595] Unfitted Computation of edge modes in photonic graphene

Author(s) : Hailong Guo (The University of Melbourne)Yi Zhu (Tsinghua University)Xu Yang (University of California Santa Barbara)
Abstract : Photonic graphene, a photonic crystal with honeycomb structures, has been intensively studied in both theoretical and applied fields. In this paper, we propose a new unfitted Nitsche's method of computing edge modes in photonic graphene with some defect. The unique feather of the methods is that they can arbitrary handle high contrast with geometric unfitted meshes. We establish the optimal convergence of methods.

[00879] Stochastic analysis in mathematical finance

Session Time & Room : 4E (Aug.24, 17:40-19:20) @F412

Type : Proposal of Minisymposium
Abstract : In this minisymposium the recent advances in mathematical finance will be discussed. The topics include stochastic analysis of jump processes, stochastic optimization, partial differential equations, stochastic calculus of variations, and mathematical aspects of data science for pricing and hedging of financial products. This minisymposium will bring together researchers with the aim to stimulate discussions for both theoretical and practical advancement.

Organizer(s) : Takuji Arai, Tomoyuki IchibaSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.

Minisymposium Program :

00879 (1/1) : 4E @F412 [Chair: Tomoyuki Ichiba]

[03804] Constrained optimal stopping under a regime-switching model

Format : Talk at Waseda University
Author(s) : Takuji Arai (Keio University)
Abstract : We investigate an optimal stopping problem for the expected value of a discounted payoff on a regime-switching geometric Brownian motion under two constraints on the possible stopping times: only at exogenous random times and only during a specific regime. The main objectives are to show that an optimal stopping time exists as a threshold type and to derive expressions of the value functions and the optimal threshold. To this end, we solve the corresponding variational inequality and show that its solution coincides with the value functions. Some numerical results are also introduced. Furthermore, we investigate some asymptotic behaviors.

[04565] Remarks on pathwise Itô calculus in infinite dimensions

Format : Talk at Waseda University
Author(s) : Yuki Hirai (National Institute of Technology, Tsuruoka College)
Abstract : The Itô–Föllmer calculus, pioneered by Föllmer (1981), is a deterministic counterpart to classical Itô's stochastic calculus. It has recently been receiving increasing attention from the viewpoint of its financial applications. In this talk, we extend some results in the Itô–Föllmer calculus to infinite dimensional settings.

[03809] Systemic Risk and Overconfidence under Stochastic Environment

Format : Talk at Waseda University
Author(s) : Li-Hsien Sun (National Central University)
Abstract : We propose an optimal portfolio problem based on the mean variance criterion based on the relative performance with the feature of overconfidence. Namely, investors intend to maximize the distance between the average and minimize the their own variance as well. In the meantime, they also consider the better return than the real one due to overconfidence. We illustrate systemic risk by applying the probability of the large number of defaults. Finally, the influence of overconfidence is discussed through numerical analysis.

[03808] Smoothness of Directed Chain Stochastic Differential Equations and Its Applications

Format : Talk at Waseda University
Author(s) : Tomoyuki Ichiba (University of California Santa Barbara)
Abstract : On a filtered probability space for the space of continuous functions, we shall consider a system of stochastic equations called directed chain stochastic differential equations for a pair of stochastic processes whose marginal distributions in the path space are identical and their joint distribution is uniquely determined by the system of equations with the distributional constraints. In this talk we discuss the smoothness of the solutions of the equations under some regular conditions and introduce its applications of such systems to the stochastic filtering problem and to the generative adversarial network problem in finance.

[00882] Geometric Shape Generation II: Design

Session Time & Room :

00882 (1/3) : 5B (Aug.25, 10:40-12:20) @F403

00882 (2/3) : 5C (Aug.25, 13:20-15:00) @F403

00882 (3/3) : 5D (Aug.25, 15:30-17:10) @F403

Type : Proposal of Minisymposium
Abstract : This mini-symposium is based on the JSIAM activity group “Geometric Shape Generation”, and aims at exhibiting the latest research in this activity group and relevant researchers, especially putting its focus on the design. We discuss the mathematical aspects of design and analysis of shapes under various settings, and special curves and surfaces useful for generating desirable shapes on CAD.

[01784] Construcion of discrete zero mean curvature surfaces in Euclidean and Lorentz-Minkowski spaces

Format : Talk at Waseda University
Author(s) : Masashi Yasumoto (Tokushima University)
Abstract : In this talk we first introduce discrete timelike minimal surfaces in Lorentz-Minkowski 3-space. Compared with other dicrete zero mean surfaces, discrete timelike minimal surfaces possess richer mathematical structures. Starting from discrete timelike minimal surfaces, we construct discrete zero mean curvature surfaces in Lorentz-Minkowski 3-space that can have both spacelike and timelike parts. As an application, we construct discrete holomorphhic functions and new discrete minimal surfaces in Euclidean space.

[01406] Bifurcation of the trajectory shape in self-propelled motions

Format : Talk at Waseda University
Author(s) : Hiroyuki Kitahata (Chiba University)
Abstract : We consider the motion of a self-propelled particle which is driven by the surface tension gradient originating from the concentration of the chemicals released from the particle itself. First, we discuss the trajectory shape of the particle confined in a circular region. Next, we discuss the bifurcation of the motion for the motion observed in the system with a self-propelled particle and a passive particle.

[01771] Construction of weaving structures by standard realizations with repulsive interactions

Format : Talk at Waseda University
Author(s) : Eriko Shinkawa Motoko Kotani (Tohoku University)Hisashi Naito (Nagoya University)
Abstract : We consider weaving structures. Let T be two sets of threads in 2-dimensional Euclidean space, where all the threads in each set are parallel and assign up/down information at their intersections. To find a suitable configuration of T in 3-dimensional Euclidean space, we take the energy that is given by the standard realization with repulsive interactions introduced by A. Dechant et al. We discuss the existence of energy minimizing configurations, which are called weaving structures.

00882 (2/3) : 5C @F403 [Chair: Yoshiki Jikumaru]

[01581] Generation of κ-Space Curve

Format : Talk at Waseda University
Author(s) : DAN WANG (Shizuoka University)Tadatoshi Sekine (Shizuoka University)Shin Usuki (Shizuoka University)Kenjiro Takai Miura (Department of Mechanical Engineering, Shizuoka University)
Abstract : The κ-curve is a recently published interpolating spline which consists of quadratic Bezier segments passing through input points at the loci of local curvature extrema. But their interpolation can only deal with planar curves. Therefore, in this research We propose a method that enables to extend this representation to deal with space curves in a new scheme called κ-space curves

[01561] The uniqueness theorem on the shape of free-form curves

Format : Talk at Waseda University
Author(s) : Kenjiro Takai Miura (Shizuoka University)R.U. Gobithaasan (University Malaysia Terengganu)Md Yushalify Misro (University Science Malaysia)Tadatoshi Sekine (Shizuoka University)Shin Usuki (Shizuoka University)
Abstract : We will discuss about the shape uniqueness theorem for curves defined by three or more control points and show several examples of applications ofthe theorem.

[01775] Construction of κ-Curve Using Fractional Bézier Curve

Format : Talk at Waseda University
Author(s) : Syed Ahmad Aidil Adha Said Mad Zain (Universiti Sains Malaysia)Md Yushalify Misro (Universiti Sains Malaysia)Kenjiro Takai Miura (Department of Mechanical Engineering, Shizuoka University)
Abstract : The κ-curve is one of the famous curves that has been applied as a curvature pen tool in Adobe Illustrator® and Photoshop®. The κ-curve has an excellent property where the local maxima of curvature have occurred at the control points. This will prevent the formation of cusps and loops. In this work, the construction of the κ-curve will be shown by using the fractional Bézier curve with the help of fractional continuity.

00882 (3/3) : 5D @F403 [Chair: Kenjiro Takai Miura]

[01764] Generation of Aesthetic Shape by Integrable Geometry

Format : Talk at Waseda University
Author(s) : Kenji Kajiwara (Institute of Mathematics for Industry, Kyushu University)
Abstract : We consider log-aesthetic curves (LAC), a family of planar curves developed in industrial design, as curves that car designers regard as “aesthetic.” We present a new mathematical framework of LAC on the theory of integrable systems and similarity geometry. Using this framework, LAC is shown to be a similarity geometry analogue of Euler’s Elastica. Based on this, we present generalizations of LAC to space curves and surfaces, which may be useful for generating aesthetic shapes.

[01613] On the relationship between mimetic discretization and discrete exterior calculus

Format : Talk at Waseda University
Author(s) : Sampei Hirose (Shibaura Institute of Technology)
Abstract : The mimetic discretization is a general framework for the discretization of differential operators using differential forms, including finite element and finite volume methods. On the other hand, the discrete exterior calculus is a method for dealing with differential forms on discrete spaces and is used in computer graphics and other applications. In this talk, the relationship between the mimetic discretization and the discrete exterior calculus developed by Anil Hirani and others will be discussed.

[01640] Quantifying the shape of data using Topological Data Analysis

Format : Talk at Waseda University
Author(s) : R U Gobithaasan (University Malaysia Terengganu)Kenjiro Takai Miura (Shizuoka University)Pawel Dlotko (Dioscuri Centre in Topological Data Analysis, Mathematical Institute, Polish Academy.)
Abstract : Topological Data Analysis (TDA) encodes the global structure and overall connectivity of high dimensional dataset, hence revealing the linearity, distribution, clusters and groups abnormality. TDA has two methodologies namely Persistent homology which produces Persistence Diagram and, TDA Mapper which is a graph representing the structure of the data. In this talk, we will discuss both the methodologies with numerical examples for efficient implementation.

[01713] Biangular coordinates: moving forward

Format : Talk at Waseda University
Author(s) : Rushan Ziatdinov (Keimyung University)
Abstract : A bipolar coordinate system, known as biangular coordinates, uses two angles rather than one to describe the location of a point in a plane. Most common curves' equations in biangular coordinates are still unknown, and little research has been done on the features of this coordinate system and its potential uses. This work aims to advance our understanding of biangular coordinates.

[00886] Numerical methods for stochastic partial differential equations

Session Time & Room :

00886 (1/2) : 1C (Aug.21, 13:20-15:00) @E506

00886 (2/2) : 1D (Aug.21, 15:30-17:10) @E506

Type : Proposal of Minisymposium
Abstract : Nowadays, the stochastic partial differential equations (SPDEs) are widely accepted as suitable models to understand complex phenomena and have been successfully applied in a broad range of areas including acoustics, electromagnetic and fluid dynamics. It is highly desirable to build efficient and reliable numerical methods, and to analyze their qualitative and quantitative properties: convergence rates (in strong and weak senses), long time behavior, approximation of invariant distributions, preservation of invariants, etc. This Minisymposium aims to provide a platform to show the significance and recent developments in numerical methods for SPDEs, and to foster interactions between academic and industrial researchers.

[05603] Convergence Analysis of splitting up method for nonlinear filtering problem

Format : Talk at Waseda University
Author(s) : Yanzhao Cao (Auburn University)
Abstract : Abstract: We consider a nonlinear filtering model where correlated Wiener processes and point processes drive observations. We first derive a Zakai equation that provides the filter solution's unnormalized probability density function. We then use a splitting-up technique to decompose the Zakai equation into three stochastic differential equations. Based on this, we construct a splitting-up approximate solution. We will present a half-order convergence result. Additionally, we will present a finite difference method to create a time semi-discrete approximate solution to the splitting-up system and prove its half-order convergence to the exact solution of the Zakai equation. Finally, we present some numerical experiments to demonstrate the theoretical analysis.

[04327] CLT for approximating ergodic limit of SPDEs via a full discretization

Format : Talk at Waseda University
Author(s) : Chuchu Chen (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Tonghe Dang (Academy of Mathematics and Systems Science， Chinese Academy of Sciences)Jialin Hong (Academy of Mathematics and Systems Science， Chinese Academy of Sciences)Tau Zhou (Academy of Mathematics and Systems Science，Chinese Academy of Sciences)
Abstract : The approximation of the ergodic limit is of fundamental importance in many applications. In this talk, we focus on characterizing quantitatively the fluctuations between the ergodic limit and the time-averaging estimator of the full discretization for the parabolic stochastic partial differential equation. We establish a central limit theorem, which shows that the normalized time-averaging estimator converges to a normal distribution with the variance being the same as that of the continuous case, where the scale used for the normalization corresponds to the temporal strong convergence rate of the considered full discretization.

[04355] Energy regularized approximations for stochastic logarithmic Schrodinger equation

Format : Talk at Waseda University
Author(s) : Jianbo Cui (Hong Kong Polytechnic University)Jialin Hong (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Liying Sun (Capital Normal University)
Abstract : In this talk, we first prove the global existence and uniqueness of the solution of the stochastic logarithmic Schroedinger (SlogS) equation driven by additive noise or multiplicative noise. The key ingredient lies on the regularized stochastic logarithmic Schroedinger (RSlogS) equation with regularized energy and the strong convergence analysis of the solutions of RSlogS equations. Then we present energy regularized numerical schemes and their strong convergence rates.

[05599] Density approximation for stochastic heat equation

Format : Online Talk on Zoom
Author(s) : Derui Sheng (The Hong Kong Polytechnic University)Chuchu Chen (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Jianbo Cui (Department of Applied Mathematics, The Hong Kong Polytechnic University)Jialin Hong (Academy of Mathematics and Systems Science， Chinese Academy of Sciences)
Abstract : This talk presents the numerical approximation of the density of the stochastic heat equation via the accelerated
exponential Euler scheme. The existence and smoothness of the density of the numerical solution are proved through Malliavin calculus. By presenting a test-function-independent weak convergence analysis, we show that the
convergence orders of the density in uniform convergence topology are 1/2 and nearly 1 in the nonlinear drift case and in the affine drift case, respectively.

00886 (2/2) : 1D @E506 [Chair: Jianbo Cui]

[03909] Space-time Discontinuous Galerkin Methods for the ε-dependent Stochastic Allen-Cahn Equation with mild noise

Format : Online Talk on Zoom

Author(s) : Dimitra Antonopoulou (University of Chester)

Abstract : We consider the ε-dependent stochastic Allen-Cahn equation with mild space-time noise posed on a bounded domain in $\mathbb{R}^d$, $d \geq 1$. The noise tends to rough on the sharp interface limit. This equation is numerically approximated by a space-time discontinuous in time nonlinear Galerkin scheme for which we prove existence and uniqueness. A priori and a posteriori error
analysis is applied and error estimates are established.

[05156] Finite differences method for stochastic heat equation with singular drifts.

Format : Online Talk on Zoom

Author(s) : Ludovic Michel Goudenège (CNRS)El Mehdi Haress (Paris-Saclay University)Alexandre Richard (Paris-Saclay University)

Abstract : I will present the numerical approximation of the unique solution to a stochastic heat equation in dimension 1 with distributional drifts under Besov regularity and additive space-time white noise.
The approximation is based on a tamed Euler finite-difference scheme with mollified drift.
The rate of convergence of the numerical approximation towards the unique strong solution is related to the regularity of the drift.
When the Besov regularity increases and the drift becomes a bounded measurable function, we recover the rate of convergence 1/2 in space and 1/4 in time.
Some numerical simulations of the stochastic heat equation with Dirac drift or penalization drift will be presented.

[04362] Numerical schemes and related qualitative properties for degenerate PDEs driven by $L\acute{e}vy$ noise.

Format : Online Talk on Zoom

Author(s) : Ananta Kumar Majee (Indian Institute of Technology Delhi)Soumya Ranjan Behera (Indian Institute of Technology Delhi)

Abstract : In this talk, we consider an operator splitting scheme and semi-discrete finite difference scheme for fractional degenerate conserva1on laws driven by $L\acute{e}vy$ noise and degenerate parabolic-hyperbolic PDE with $L\acute{e}vy$ noise respectively. By using necessary a-priori bounds for approximate solutions, generated by splitting scheme, and average time continuity of regularized viscous solutions together with a variant of classical Kružkov's doubling of variables approach, we prove convergence of approximate solutions to the unique BV entropy solution of the underlying problem. Moreover, the convergence analysis is illustrated by several numerical examples. Furthermore, for compactly supported initial data, we prove that the expected value of the $L1$ -difference between the unique entropy solution and the approximate solutions, generated by finite difference scheme, converges at a rate of order 1/7.

[04784] Linear implicit time-stepping schemes for SPDEs with super-linearly growing coefficients

Format : Online Talk on Zoom

Author(s) : Xiaojie Wang (Central South University)Mengchao Wang (Central South University)

Abstract : The present talk is on strong approximations of stochastic partial differential equations (SPDEs) with polynomially growing nonlinearity and multiplicative trace-class noise. We propose and analyze a spatio-temporal discretization of the SPDEs, by incorporating a standard finite element method in space and a linear implicit Euler-type scheme for the temporal discretization. We recover the strong convergence rates of the fully discrete scheme.

[00888] Geometric Shape Generation I: Structures

Session Time & Room :

00888 (1/3) : 4D (Aug.24, 15:30-17:10) @F411

00888 (2/3) : 4E (Aug.24, 17:40-19:20) @F411

00888 (3/3) : 5B (Aug.25, 10:40-12:20) @F411

Type : Proposal of Minisymposium
Abstract : This mini-symposium is based on the JSIAM activity group “Geometric Shape Generation”, and aims at exhibiting the latest research in this activity group and relevant researchers, especially putting its focus on the structures, mechanics and analysis. We discuss origami structures and applications, discrete surfaces and shell structures, geometric modeling of specific surfaces and vibration analysis.
Organizer(s) : Miyuki Koiso, Makoto Ohsaki, Jun Mitani, Kento Okuda
Classification : 53A05, 53A17, 53Z30, 74G65, 74H45
Minisymposium Program :

00888 (1/3) : 4D @F411 [Chair: Jun Mitani]

[02770] Shape modeling of umbrella surfaces

Format : Talk at Waseda University
Author(s) : Takashi Maekawa (Waseda University)Kenji Takizawa (Waseda University)Takuya Terahara (Waseda University)
Abstract : We introduce a geometric modeling method of the umbrella by defining the rib curves as the intersection of two bilinear patches. Furthermore, we investigate various differential geometric properties of the umbrella surface and introduce a method to unfold it onto a plane that can be used to fabricate a wooden template for cutting canopy fabrics.

[04221] Geometrical and structural design of pseudo-geodesic gridshells

Format : Talk at Waseda University
Author(s) : Romain Mesnil (Ecole des Ponts ParisTech)Olivier Baverel (Ecole des Ponts ParisTech)
Abstract : Gridshells are efficient structures built using a network of straight members that are deformed into doubly curved shapes. In this presentation, we propose to construct gridshells with pseudo-geodesic curves, which are characterized by the equality between torsion and geodesic torsion. We show that existence of parametrization by pseudo-geodesic network is impossible when integral of Gaussian curvature is superior to an upper bound. Structural performance and fabrication are discussed with the case-study of an architectural pavilion.

[02774] Preliminary research on shape searching method for curved crease origami using bending deformation

Format : Talk at Waseda University
Author(s) : Tianhao Zhang (The University of Tokyo)Ken'ichi Kawaguchi (The University of Tokyo)
Abstract : Curved crease origami is focused on by the researchers and designers in the field of building structure owing to the foldability and mechanical properties. In this paper, a shape searching method is proposed based on an optimization approach. This approach can form a shape close to the target surface defined by the designers. This research aims to search the shape concerning bending deformation to explores the application of curved origami to architectural structures.

[02924] Shape design of free-form shells with specified projected membrane forces

Format : Talk at Waseda University
Author(s) : Makoto Ohsaki (Kyoto University)Yusuke Sakai (Sony Computer Science Laboratories)Taku Nakajima (Kyoto University)Riree Takeoka (Takenaka Corporation)
Abstract : A shape design method is proposed for membrane free-form shells modeled as a graph surface. The distribution of membrane forces projected to the plane is specified to satisfy horizontal equilibrium as a function of shear stress. The shape is determined as a solution to the vertical equilibrium equations discretized by the finite difference method. The shape is iteratively corrected to achieve the specified projected stress distribution considering the material property.

00888 (2/3) : 4E @F411 [Chair: Makoto Ohsaki]

[05391] Singularity of Arc- and Spiral-shaped Miura-ori as Rigid-Flat-Foldable Origami Pattern

Format : Talk at Waseda University
Author(s) : Hiroyuki Tagawa (Mukogawa Women's University)
Abstract : Arc- and spiral-shaped Miura-ori is rigid flat-folding Origami pattern and one variational type of Miura-ori. Geometric folding lines of the spiral-shaped Miura-ori are obtained by arraying quadrilaterals with identical internal angles in the same column. The arc-shaped Miura-ori is obtained by setting equal edge lengths of the quadrilaterals in the radial direction. This study investigates the singularity of an arc- and spiral-shaped Miura-ori among the generalized Miura-ori.

[03876] A first-order method for large-scale eigenvalue optimization problems in topology optimization

Format : Talk at Waseda University
Author(s) : Akatsuki Nishioka (The University of Tokyo)Mitsuru Toyoda (Tokyo Metropolitan University)Mirai Tanaka (The Institute of Statistical Mathematics)Yoshihiro Kanno (The University of Tokyo)
Abstract : Eigenvalue optimization problems arise in many situations in topology optimization when considering robustness, vibration and buckling. As topology optimization problems are often very large-scale, the semidefinite programming approach is sometimes too computationally costly. We propose an efficient optimization algorithm based on the smoothing method for large-scale eigenvalue problems. The proposed method only uses the first-order derivative of the objective function, and thus has low computational cost per iteration. It also has convergence guarantee.

[03320] Recent advances on tension-compression mixed shell form-finding

Format : Talk at Waseda University
Author(s) : Masaaki Miki (The University of Tokyo)
Abstract : In architecture, thin surface structures that can withstand gravity with no bending action are called shells. Shells have special geometries that enable them to stream gravitational force toward the ground along their forms with in-plane stresses only; the process of finding these special forms is called form-finding. Researchers have pointed out that in shell form-finding, the problem can be formulated using two surfaces: the shell itself and another surface called Airy's stress function. In 2022, a novel NURBS-based computational approach that can properly handle mixed tension–compression stress states was presented by Miki et al. (note that similar methods were first introduced in Ciang Yu-Chou). Because the solutions are repretented by NURBS, the partial derviatvies can be computed at any point. This enables many kind of computations. In this talk, we present what kind of compuation turns possible based on the solutions obatined by the proposed method.

[02771] Developable surfaces with curved folds

Format : Talk at Waseda University
Author(s) : Miyuki Koiso (Kyushu University)
Abstract : Developable surfaces are surfaces which can be unfolded into the plane preserving the length of all curves on the surface. Since developable surfaces with curved folds are constructed by bending a flat sheet, they have many applications in manufacturing objects. In this talk, we give conditions of piecewise-smooth surfaces for

being developable in terms of curvatures. We also discuss variational problems for developable surfaces, geometric characterizations of their optimal solutions, and their applications to architecture.

00888 (3/3) : 5B @F411 [Chair: Miyuki Koiso]

[02773] Variational principle for generating discrete surfaces with piecewise constant Gaussian curvatures

Format : Talk at Waseda University
Author(s) : Kazuki Hayashi (Kyoto University)Yoshiki Jikumaru (Kyushu University)Makoto Ohsaki (Kyoto University)Takashi Kagaya (Muroran Institute of Technology)Yohei Yokosuka (Kagoshima University)
Abstract : We derive a method to generate triangular meshes with piecewise constant Gaussian curvatures, in which the connection between the patches is G0 continuous. Gaussian curvature flows at interior vertices and those at the internal boundary are derived from the variational principle of the energy functional. The proposed method can generate the shape of the whole surface integrally using the derived flows.

[02776] Geometric shape generation of hanging membranes

Format : Talk at Waseda University
Author(s) : Yoshiki Jikumaru (Toyo University)Yohei Yokosuka (Kagoshima University)
Abstract : In this talk, we present a differential geometric formulation of hanging membranes based on the equilibrium equations in the shell membrane theory and the variational principle.
We also propose a geometric shape generation of hanging membranes.

[05556] Proposal for a temporary structure with a mechanism capable of curved folding

Format : Talk at Waseda University
Author(s) : Yohei Yokosuka (Kagoshima University)Miyuki Koiso (Kyushu University)Kento Okuda (National Institute of Technology, Sasebo College)Toshio Honma (Kagoshima University)Jun Mitani (University of Tsukuba)
Abstract : Temporary housing requires the rapid supply of numerous houses after a disaster. Therefore, it is useful to use architectural structures that utilizes curved folding, which enables the immediate development of a flat board into a three-dimensional structure.
In this presentation, a pillow type box that maximizes the inner volume is adopted for the design shape, we demonstrate numerical analysis of rigid folding and scaled models of temporary structures with a mechanism capable of curved folding.

[05623] Topology of vibrating shapes

Format : Talk at Waseda University
Author(s) : Konrad Polthier (FU Berlin)Jakub Rondomanski (FU Berlin)Carlos Andres Palma (HU Berlin)José D. Cojal González (HU Berlin)Jürgen P. Rabe (HU Berlin)
Abstract : Vibrations of a parameter dependent set of physical shapes exhibit characterizing topological properties.
We will discuss the topology of such vibrations based on a carefully selected metric and its holonomy.
Overall, the choice of the metric embarks beyond the classical Berry connection. Applications aim
at a better understanding of the topology of vibrating crystals.

[00891] Derivative-Free Optimization Theory, Methods, and Software

Session Time & Room :

00891 (1/2) : 5B (Aug.25, 10:40-12:20) @D501

00891 (2/2) : 5C (Aug.25, 13:20-15:00) @D501

Type : Proposal of Minisymposium

Abstract : Derivative-free optimization methods aim to solve optimization problems based on function values without using derivatives or other first-order information. They are motivated by problems where the first-order information is expensive or impossible to obtain. Such problems emerge frequently from industrial and engineering applications, including integrated circuit design, aircraft design, and hyperparameter tuning in artificial intelligence. This minisymposium will provide a platform for researchers and practitioners in derivative-free optimization to discuss the recent advances in theory, methods, and software in this area.

Organizer(s) : Serge Gratton, Zaikun Zhang

Classification : 90C56, 90C30, 90C26, 65K05, Derivative-Free Optimization, Numercical Optimization, Nonlinear Optimization, Nonconvex Optimization

Minisymposium Program :

00891 (1/2) : 5B @D501 [Chair: Zaikun Zhang]

[03615] Stochastic Average Model Methods

Format : Talk at Waseda University

Author(s) : Matt Menickelly (Argonne)Stefan M Wild (Lawrence Berkeley National Laboratory)

Abstract : We consider finite-sum minimization problems in which the summand functions are computationally expensive, making it undesirable to evaluate all summands on every iteration. We present the idea of stochastic average model methods, which sample component functions according to a probability distribution on component functions that minimizes an upper bound on the variance of the resulting stochastic model. We present promising numerical results on a corresponding extension to the derivative-free model-based trust-region solver POUNDERS.

[01372] DFO with Transformed Objectives and a Model-based Trust-region Method

Format : Talk at Waseda University

Author(s) : Pengcheng Xie (Academy of Mathematics and Systems Science (AMSS), Chinese Academy of Sciences (CAS))

Abstract : Derivative-free optimization, i.e., DFO, is the optimization where the derivative information is unavailable. The least Frobenius norm updating quadratic model is an essential under-determined model for derivative-free trust-region methods. We propose DFO with transformed objectives and give a model-based method with the least Frobenius norm model. We prove the existence and necessary and sufficient condition of model optimality-preserving transformations, and analyze the model, interpolation error and convergence property. Numerical results support our model and method.

[01341] COBYQA — A Derivative-Free Trust-Region SQP Method for Nonlinearly Constrained Optimization

Format : Talk at Waseda University

Author(s) : Tom M. Ragonneau (The Hong Kong Polytechnic University)Zaikun Zhang (The Hong Kong Polytechnic University)

Abstract : This talk introduces COBYQA, a derivative-free trust-region SQP method for nonlinear optimization. The method builds trust-region quadratic models using the derivative-free symmetric Broyden update. An important feature of COBYQA is that it always respects bound constraints. COBYQA is competitive with NEWUOA, BOBYQA, and LINCOA while being able to handle more general problems. Most importantly, COBYQA evidently outperforms COBYLA on all types of problems.

COBYQA is implemented in Python and is publicly available at https://www.cobyqa.com/.

[03192] A General Blackbox Optimization Framework for Hyperparameter Optimization in Deep Learning

Format : Talk at Waseda University

Author(s) : Edward Hallé-Hannan (Polytechnique Montréal)Sébastien Le Digabel (Polytechnique Montréal)Charles Audet (Polytechnique Montréal)

Abstract : Tuning the hyperparameters of a deep model is a mixed-variable BBO problem with an unfixed structure. For instance, the number of layers (a hyperparameter) affects the number of architectural hyperparameters: meta variables are introduced to model this unfixed structure. Moreover, the hyperparameter optimization problem (HPO) may also simultaneously contain categorical, integer and continuous variables. A

mathematical framework, which is compatible with direct search methods and Bayesian optimization, is proposed to tackle and model the HPO.

00891 (2/2) : 5C @D501 [Chair: Zaikun Zhang]

[01570] PRIMA: Reference Implementation for Powell's methods with Modernization and Amelioration

Format : Talk at Waseda University
Author(s) : Zaikun Zhang (The Hong Kong Polytechnic University)
Abstract : Powell developed five widely used DFO solvers, namely COBYLA, UOBYQA, NEWUOA, BOBYQA, and LINCOA. They were coded in Fortran 77 with a unique style, which poses a significant obstacle to maintaining, exploiting, or extending them. PRIMA is a project providing the reference implementation of these solvers in modern languages. We will present the current stage of PRIMA, including the bugs we have spotted in the Fortran 77 code and the improvements we have achieved.

[00893] Higher Order-type Optimization Methods for Machine Learning

Session Time & Room :

00893 (1/3) : 1E (Aug.21, 17:40-19:20) @D501

00893 (2/3) : 2C (Aug.22, 13:20-15:00) @D501

00893 (3/3) : 2D (Aug.22, 15:30-17:10) @D501

Type : Proposal of Minisymposium
Abstract : Higher order optimization mechanisms are popular and powerful tools to accelerate, robustify, and enhance the performance of first order algorithms. Albeit the high and general prevalence of first order schemes, deterministic and stochastic higher order-type methods have recently gained increasing attention and have been successfully utilized to solve challenging large-scale learning tasks, reinforcement learning problems, and other big data applications. The purpose of this minisymposium is to highlight recent advances and discuss novel techniques and strategies in the development and analysis of deterministic and stochastic higher order-type methods for large-scale minimization problems and machine learning applications.
Organizer(s) : Andre Milzarek, Zaiwen Wen
Classification : 90C06, 90C30
Minisymposium Program :

00893 (1/3) : 1E @D501 [Chair: Andre Milzarek]

[03305] An efficient skipping BFGS algorithm with nice Hessian correction properties

Author(s) : Yu-Hong Dai (AMSS)
Abstract : An efficient skipping BFGS algorithm is designed with nice Hessian correction properties. We analyze the skipping method from the perspective of improving quasi-Newton equations by operators and derive stronger quadratic termination properties. Global convergence and superlinear convergence results are established under classical assumptions. Numerical experiments illustrate the efficiency of the proposed method compared with the standard BFGS method.

[02797] An Overview of Stochastic Quasi-Newton Methods for Large-Scale Machine Learning

Author(s) : Tiande Guo (University of Chinese Academy of Sciences)Yan Liu (Naikai University)Congying Han (University of Chinese Academy of Sciences)
Abstract : Numerous intriguing optimization problems arise as a result of the advancement of machine learning. Second-order algorithms have their typical advantages in dealing with highly nonlinear and ill-conditioning

problems. This paper provides a review on recent developments in stochastic variants of quasi-Newton methods, which construct the Hessian approximations using only gradient information. We concentrate on BFGS-based methods in stochastic settings and highlight the algorithmic improvements that enable the algorithm to work in various scenarios. Future research on stochastic quasi-Newton methods should focus on enhancing its applicability, lowering the computational and storage costs, and improving the convergence rate.

[02795] Riemannian Natural Gradient Methods

Format : Talk at Waseda University

Author(s) : Zaiwen Wen (Peking University)Jiang Hu (The Chinese University of Hong Kong)Ruicheng Ao (Peking University)Anthony Man-Cho So (The Chinese University of Hong Kong)Minghan Yang (Peking University)

Abstract : In this talk, we present a Riemannian natural gradient method for large-scale optimization problems on Riemannian manifolds. Such problems arise in various machine learning and signal processing applications. The notion of Fisher information matrix is extended from the Euclidean setting. We establish the almost-sure global convergence and local convergence of our proposed method under standard assumptions. Numerical experiments on applications arising from machine learning demonstrate the advantages of the proposed method over state-of-the-art ones.

[04755] Newton-PMR: Newton Subspace Methods with Complexity Guarantees for Non-convex Optimization

Format : Talk at Waseda University

Author(s) : Yang Liu (University of Oxford)Andre Milzarek (The Chinese University of HThe Chinese University of Hong Kong, Shenzhenong Kong, Shenzhen)Fred Roosta (the University of Queensland)

Abstract : Recently, Newton-MR methods have been introduced for solving nonconvex unconstrained smooth optimization problems. Leveraging the inherent ability of the minimum residual (MINRES) inner solver to detect directions of nonpositive curvature (NPC), Newton-MR variants enjoy a variety of optimal complexity guarantees. However, the application of these methods to modern high-dimensional problems remains challenging. To address this, we present novel variants that incorporate certain dimensionality reduction techniques. In particular, our proposed methods are based on recent results that have shown that preconditioning MINRES with a positive semi-definite but singular preconditioner is in fact equivalent to solving a low-dimensional problem whose dimension corresponds to the nullity of the preconditioning matrix. Utilizing these dimensionality reduction properties of preconditioned MINRES, we present novel variants of Newton-MR, called Newton-PMR, which can be readily applied to high-dimensional problems, while achieving desirable complexity guarantees.

00893 (2/3) : 2C @D501 [Chair: Yu-Hong Dai]

[02799] Real-time tool path planning using deep learning for subtractive manufacturing

Author(s) : Yi-Fei Feng (University of Chinese Academy of Sciences)Li-Yong Shen (University of Chinese Academy of Sciences)Hong-YU Ma (University of Chinese Academy of Sciences)Chun-Ming Yuan (Academy of Mathematics and Systems Sciences, CAS)Xin Jiang (University of Chinese Academy of Sciences)

Abstract : Tool path planning is a crucial factor of computer-aided design and manufacturing.

To generate suitable tool paths, the previous methods bases on traditional optimization often take to a long computational time.

To achieve real-time planning, we propose an efficient neural network-based direct tool path generating method, and the whole process only takes a few microseconds.

As an auxiliary result, a new tool path dataset with confined scallop height is first established for tool path training.

[02796] NeuroPrim: An Attention-based Model for Solving NP-hard Spanning Tree Problems

Author(s) : Yuchen Shi (University of Chinese Academy of Sciences)Congying Han (University of Chinese Academy of Sciences)Tiande Guo (University of Chinese Academy of Sciences)

Abstract : We define the Markov Decision Process (MDP) for general combinatorial optimization problems on graphs and propose NeuroPrim, a novel framework for reducing the action and state space using the technique of Prim algorithm, which is trained by REINFORCE to solve various spanning tree problems. We apply it to three difficult problems on Euclidean spaces, namely Degree-constrained Minimum Spanning Tree (DCMST) problem, Minimum Routing Cost Spanning Tree (MRCST) problem and Steiner Tree Problem in graphs (STP). Experimental

results on literature instances show that our model is able to outperform strong heuristics and obtain small optimality gaps up to 250 vertices. In addition, we find no significant degradation on problem instances as large as 1000, which demonstrates our model has strong generalization ability.

[02832] Streaming Algorithms for Maximizing the Difference of Submodular Functions

Author(s) : Wenguo Yang Cheng LU (UCAS)Suixiang GAO (UCAS)
Abstract : In this paper, we study the problem of maximizing the Difference of two Submodular (DS) functions in the streaming model, where elements of the ground set arrive one at a time in an arbitrary order. We present one-pass streaming algorithms for both the unconstrained and cardinality-constrained problems. Our analysis shows that the algorithms we propose are able to pro�duce solutions with provable approximation guarantees. To the best of our knowledge, this is the first theoretical guarantee for the DS maximization problem in the streaming model.

[03350] Recursive Importance Sketching for Rank Constrained Least Squares

Author(s) : Xudong Li (Fudan University)Yuetian Luo (University of Wisconsin-Madison)Anru Zhang (Duke University)Wen Huang (Xiamen University)
Abstract : In this talk, we propose a new Recursive Importance Sketching algorithm for rank constrained least squares optimization (RISRO). As its name suggests, the algorithm is based on a new sketching framework, recursive importance sketching. Several existing algorithms in the literature can be reinterpreted under the new sketching framework and RISRO offers clear advantages over them. RISRO is easy to implement and computationally efficient, where the core procedure in each iteration is only solving a dimension reduced least squares problem. Different from numerous existing algorithms with locally geometric convergence rate, we establish the local quadratic-linear and quadratic rate of convergence for RISRO under some mild conditions. In addition, we discover a deep connection of RISRO to Riemannian manifold optimization on fixed rank matrices. The effectiveness of RISRO is demonstrated in two applications in machine learning and statistics: low-rank matrix trace regression and phase retrieval. Simulation studies demonstrate the superior numerical performance of RISRO.

00893 (3/3) : 2D @D501 [Chair: Tiande Guo]

[03278] A semismooth Newton stochastic proximal point algorithm with variance reduction

Format : Talk at Waseda University
Author(s) : Andre Milzarek (The Chinese University of Hong Kong, Shenzhen)Fabian Schaipp (Technical University of Munich)Michael Ulbrich (Technical University of Munich)
Abstract : We present an implementable stochastic proximal point (SPP) method for a class of weakly convex, composite optimization problems. The proposed stochastic proximal point algorithm incorporates a variance reduction mechanism and the resulting SPP updates are solved using an inexact semismooth Newton framework. We establish detailed convergence results that take the inexactness of the SPP steps into account. Finally, numerical experiments are shown illustrating that SPP competes favorably with other state-of-the-art methods.

[00897] Nonlinear and nonlocal models: analysis and numerics

Session Time & Room :

00897 (1/2) : 2C (Aug.22, 13:20-15:00) @E504

00897 (2/2) : 2D (Aug.22, 15:30-17:10) @E504

Type : Proposal of Minisymposium
Abstract : The focus of the minisymposium will be on different aspects of nonlocal operators including regularity and numerical analysis of solutions to equations driven by fractional and nonlocal operators. In the recent years nonlocal models showed effectivity in describing phenomena involving different singularities. We aims to bring

together leading experts and young researchers interested in nonlocality, in particular for nonlinear problems, including:
Numerics and Scientific Computing, Modeling and Applications, Analysis of Partial Differential Equations, Calculus of Variations.

Classification : 65-00
Minisymposium Program :

00897 (1/2) : 2C @E504 [Chair: Abner Salgado]

[04670] Energy gap for nonlocal model

Format : Talk at Waseda University
Author(s) : Anna Kh. Balci (University of Bielefeld, Germany)
Abstract : The essential feature of many models with non-standard growth is the possible presence of Lavrentiev gap and related lack of regularity, non-density of smooth functions in the corresponding energy space. Finding assumptions for the presence of Lavrentiev phenomena is in particular important for regularity theory. We show that nonlocal and local-nonlocal models enjoy the presence of energy gap. We obtain the optimal conditions separating the regular case from the one with Lavrentiev gap for the different types of nonlocal and mixed local-nonlocal double phase models. The obtained conditions show the sharpness of resent regularity results for nonlocal double-phase problems.

[04387] Kacanov Iteration

Format : Talk at Waseda University
Author(s) : Lars Diening (Bielefeld University)Anna Kh. Balci (Bielefeld University)Johannes Storn (Bielefeld University)
Abstract : The p-Laplace equation is one of the model equations for non-linear
problems. Due to its non-linearity it is quite challenging to
approximate its solution numerically in particular in the
degenerate/singular case. Standard methods like gradient descent or
Newton's method have significant problems to approximate the
solution. We present an iterative, linear method that allows to solve
the p-Laplace equation efficiently both for small and large exponents.

[04258] Regularity results for fractional nonlocal equation with nonstandard growth and differentiability

Format : Talk at Waseda University
Author(s) : Jihoon Ok (Sogang University)
Abstract : We discuss on nonlocal problems with nonstandard growth and differentiability. In particular, we introduce local boundedness and Hölder continuity for nonlocal double phase problems and nonlocal problems with variable growth and differentiability, by identifying sharp assumptions on parameters and functions characterizing these nonlocal problems.

[05242] BBM-type theorem for fractional Sobolev spaces with variable exponents

Format : Talk at Waseda University
Author(s) : Minhyun Kim (Hanyang University)
Abstract : A Bourgain–Brezis–Mironescu-type theorem for fractional Sobolev spaces with variable exponents is established for sufficiently regular functions. We prove, however, that a limiting embedding theorem for these spaces fails to hold in general.

00897 (2/2) : 2D @E504 [Chair: Anna Balci]

[05189] Time fractional gradient flows: Theory and numerics

Author(s) : Abner J Salgado (University of Tennessee)Wenbo Li (Chinese Academy of Sciences)
Abstract : We develop the theory of fractional gradient flows: an evolution aimed at the minimization of a convex, lower semicontinuous energy, with memory effects. This memory is characterized by the fact that the negative of the (sub)gradient of the energy equals the so-called Caputo derivative of the state. We introduce the notion of energy solutions, for which we provide existence, uniqueness and certain regularizing effects. We also consider Lipschitz perturbations of this energy. For these problems we provide an a posteriori error estimate and show its reliability. This estimate depends only on the problem data, and imposes no constraints between consecutive time-steps. On the basis of this estimate we provide an a priori error analysis that makes no assumptions on the smoothness of the solution.

[05258] Semiconvexity estimates for integro-differential equations

Format : Talk at Waseda University
Author(s) : Marvin Weidner (Universitat de Barcelona)
Abstract : The Bernstein technique is a classical tool to establish derivative estimates for solutions to a large class of elliptic and parabolic equations. It is based on the maximum principle applied to suitable auxiliary functions.
We explain how the Bernstein technique can be extended to integro-differential equations. As an application, we establish semiconvexity estimates for solutions to the nonlocal obstacle problem, the optimal regularity of the solution and
the regularity of the free boundary. Based on a joint work with Xavier Ros-Oton and Damià Torres-Latorre.

[03356] Numerics and Analysis for Multi-Term Time-Fractional Burgers-Type Equation

Author(s) : Neetu Garg (National Institute of Technology Calicut)RaviKanth A.S.V. (National Institute of Technology Kurukshetra India)
Abstract : We present numerics and analysis for multi-term time-fractional Burgers-type. The proposed scheme consists of L_2 formula in time and exponential B-splines in space. We apply semi implicit approach for the nonlinear term $u\partial_x u$. We study stability using the Von–Neumann method. We also discuss the convergence analysis. We solve a few numerical examples to examine the efficiency of the numerical scheme. Comparisons with the recent works confirm the robustness of the proposed scheme.

[04692] The Spatially Variant Spectral Fractional Laplacian: Analytical Aspects and Parameter Selection

Format : Online Talk on Zoom
Author(s) : Carlos Rautenberg (George Mason University)Andrea Ceretani (University of Buenos Aires)
Abstract : We consider a variational definition for the spatially variant (spectral) fractional Laplacian and study the well-posedness of the associated Poisson's equation. The state space for the elliptic problem relies on non-standard Sobolev spaces with weights that are not of Muckenhoupt-type. The increased regularity of solutions is established together with the effectiveness of the fractional operator as a regularization for inverse problems. The latter leads to the optimal selection of the fractional order in image reconstruction.

[00908] Machine Learning and Data-Driven Applications using Geometric Integration

Session Time & Room :

00908 (1/2) : 2E (Aug.22, 17:40-19:20) @E817

00908 (2/2) : 3C (Aug.23, 13:20-15:00) @E817

Type : Proposal of Minisymposium

Abstract : Machine learning techniques are becoming increasingly prominent at solving complex dynamical systems and utilized in data-driven applications, such as inverse problems and model discovery. Yet, important geometric and physical structures have not traditionally been incorporated in such approaches, leading to loss of accuracy in long-term predictions. This minisymposium aims to bring together researchers from diverse groups to improve on machine learning techniques using ideas inspired by geometric integration.

Organizer(s) : Elena Celledoni, James Jackaman and Andy Wan

Classification : 68T07, 65P10, 37M15

Minisymposium Program :

00908 (1/2) : 2E @E817 [Chair: James Jackaman]

[03459] Geometric integration in machine learning

Format : Talk at Waseda University

Author(s) : James Jackaman (NTNU)

Abstract : Here, as a primer, we give an overview of the role geometric integration (of Hamiltonian systems) has played in the design of neural networks in recent years, with an empathsis on the stability guarantees this provides and the structures incorporated into the networks. Time permitting, we will move on to discuss how convolutional networks can be understood through finite differences and the theoretical benefits this comparison yields.

[03490] Application of the Kernel Method to Learning Hamiltonian Equations

Format : Talk at Waseda University

Author(s) : Taisei Ueda (Kobe University)Takashi Matsubara (Osaka University)Takaharu Yaguchi (Kobe University)

Abstract : Recently, methods for learning Hamiltonian systems from data have attracted much attention. While the most methods are based on neural networks, neural networks have some drawbacks, such as the possibility of falling into a local optimum. In this talk, we propose a method based on the kernel method, thereby overcoming the problems.

[03180] Structured neural networks and some applications

Format : Online Talk on Zoom

Author(s) : Davide Murari (Norwegian University of Science and Technology)Elena Celledoni (Norwegian University of Science and Technology)Brynjulf Owren (Norwegian University of Science and Technology)Ferdia Sherry (University of Cambridge)Carola-Bibiane Schönlieb (University of Cambridge)

Abstract : Neural networks have gained much interest because of their effectiveness in many applications related to high-dimensional function approximation problems. This success is often supported by experimental evidence, while the theoretical properties of these models need to be better understood. When one knows that the target function to approximate or the data being processed has some properties, it might be desirable to reproduce them in the neural network design. This talk presents a framework that makes ODEs and numerical methods work together to model neural networks having prescribed properties. Such an approach is supported by offering particular applications for data-driven modelling and image analysis.

00908 (2/2) : 3C @E817 [Chair: Andy Wan]

[02911] Auxiliary Functions as Koopman Observables

Format : Online Talk on Zoom

Author(s) : Jason John Bramburger (Concordia University)

Abstract : Many important statements about dynamical systems can be proved by finding scalar-valued auxiliary functions whose time evolution along trajectories obeys certain pointwise inequalities that imply the desired result. The most familiar of these auxiliary functions is a Lyapunov function to prove steady-state stability, but such functions can also be used to bound averages of ergodic systems, define trapping boundaries, and so much more. In this talk I will highlight a method of identifying auxiliary functions from data using polynomial optimization. The method leverages recent advances in approximating the Koopman operator from data, so-called extended dynamic mode decomposition, to provide system-level information without system identification. The result is a model-agnostic computational method that can be used to bound quantities of interest and develop optimal state-

dependent feedback controllers, while also functioning as a pre-conditioner to discovering accurate and parsimonious dynamical models from the data.

[03401] Conservative Hamiltonian Monte Carlo

Format : Online Talk on Zoom
Author(s) : Geoffrey McGregor (University of Toronto)Andy Wan (University of Northern British Columbia)
Abstract : Markov Chain Monte Carlo (MCMC) methods enable us to extract meaningful statistics from complex distributions which frequently appear in parameter estimation, Bayesian statistics, statistical mechanics and machine learning. However, as the dimensionality of the problem increases, the convergence rate of MCMC sequences toward the stationary distribution slows down dramatically. This has led to the development of Hamiltonian Monte Carlo (HMC) [Duane et al. '87, Neal '93], to improve performance by solving a Hamiltonian system using symplectic numerical methods. However, modern high-dimensional applications still pose a significant challenge for HMC.

In this talk, we introduce Conservative Hamiltonian Monte Carlo (CHMC), which alternatively utilizes an energy-preserving numerical method, known as the Discrete Multiplier Method. We show that CHMC converges to the correct stationary distribution under appropriate conditions, and provide numerical examples showcasing improvements in convergence rates over HMC in high-dimensional problems. Furthermore, we also will present numerical results on Bayesian parameter estimation using CHMC.

[03462] Model Reduction of Hamiltonian Systems based on Nonlinear Approximation Methods

Format : Talk at Waseda University
Author(s) : Silke Glas (University of Twente)
Abstract : In this talk we consider structure-preserving model reduction of Hamiltonian systems, such that the reduced model is again a Hamiltonian system. We extend the classical linear-subspace model reduction methods, where the best possible error is bounded by the Kolmogorov N-width to reduced models constructed via nonlinear approximations. In this talk, we will particularly choose symplectic quadratic embeddings as our nonlinear approximation function.

[00911] Sparse Linear Solvers for Computational Science at Extreme Scales

Session Time & Room :

00911 (1/2) : 2C (Aug.22, 13:20-15:00) @E508

00911 (2/2) : 2D (Aug.22, 15:30-17:10) @E508

Type : Proposal of Minisymposium
Abstract : Sparse linear solvers are a basic component in the tool chain for scientific applications; solution of spa
rse linear systems is indeed one of the main computational kernels in physics-driven models for numer
ical simulation and, more recently, also in data-driven models. The current challenge of exascale requir
es to rethink numerical algorithms for efficient exploitation of heterogeneous massively parallel comput
ers, embedding multi/many-core processors. In this MS we bring together some very active researcher
s in this field to discuss recent advancements in the development of highly scalable algorithms and sof
tware for solving and preconditioning sparse linear systems on modern high-end supercomputers.
Organizer(s) : Pasqua D'Ambra, Carlo Janna
Classification : 65F10, 65N55, HPC, Sparse Linear Algebra

00911 (1/2) : 2C @E508 [Chair: Pasqua D'Ambra]

[02685] GMRES+AMG Navier-Stokes Pressure Projection Solvers with RAS and ORAS Smoothers

Format : Talk at Waseda University
Author(s) : Stephen Thomas (Advanced Micro Devices)Amik St-Cyr (Shell)Erika Strakova (IT4-innovations Ostrava)Allison Baker (National Center for Atmospheric Research)
Abstract : PeleLM is a Navier-Stokes combustion model. Extremely ill-conditioned problems arise for incompressible and reacting flows in the low Mach flow regime, particularly for cut-cell meshes in complex geometries, Prenter (2020) improved convergence rates for cut-cells by employing PCG-AMG with Schwarz smoothers. We combine ILU smoothers using iterative triangular solves with RAS and ORAS smoothers adapted to hypre for a new low-synch MGS-CGS GMRES. The iteration counts tend to remain constant and these smoothers reduce run times on many-core GPU's in the strong-scaling limit.

[04144] Scalable domain decomposition solvers for cardiac reaction-diffusion cell-by-cell models

Format : Talk at Waseda University
Author(s) : Luca Franco Pavarino (University of Pavia)Ngoc Mai Monica Huynh (University of Pavia)Simone Scacchi (University of Milano)Fatemeh Chegini (Zuse Institute Berlin)Martin Weiser (Zuse Institute Berlin)
Abstract : Scalable preconditioners are constructed and analyzed for the iterative solution of composite Discontinuous Galerkin discretizations of reaction-diffusion systems of ordinary and partial differential equations arising in cardiac cell-by-cell models. These models lead to large-scale ill-conditioned discrete systems which have discontinuous global solutions across cells (subdomains) boundaries. A scalable convergence rate bound is proved for dual-primal cell-by-cell preconditioned operators. Numerical tests validate this bound and investigate its dependence on the discretization parameters.

[04198] An immersed approach to fluid-structure-contact interaction

Format : Talk at Waseda University
Author(s) : Patrick Zulian (Università della Svizzera italiana)Maria Giuseppina Chiara Nestola (Università della Svizzera italiana)Rolf Krause (Università della Svizzera italiana)
Abstract : We presents an immersed technique for solving fluid-structure interaction (FSI) problems using dual Lagrange multipliers, which enables the resampling of discrete fields with standard matrix-vector multiplication within the nonlinear solution procedure. The fluid and structure are coupled in the overlapping volume, while different structures in contact are coupled on the surface using mortar-based techniques.

[04292] Adapting Patch-based Relaxation to Generalized MHD Systems Within An Algebraic Multigrid Solver

Format : Talk at Waseda University
Author(s) : Raymond Tuminaro (Sandia National LaboratoriesWe discuss a multigrid algorithm for generalized magnetohydrodynamics (GMHD). This GMHD system has two different PDE terms that can each generate a large near null space, complicating the linear solution process. One expre)Michael Crockatt (Sandia National Laboratories)Graham Harper (Sandia National Laboratories)Allen Robinson (Sandia National Laboratories)
Abstract : We discuss multigrid solvers for generalized magnetohydrodynamics. This system has two PDE terms that each generate a large near null space. One expression contains the curl operator while the other arises from generalized Ohm's law. We propose a geometric multigrid algorithm based on Arnold-Falk-Winther relaxation. We then adapt the Rietzinger/Schoberl AMG scheme to the generalized system. We apply the resulting preconditioner to two test problems to illustrate its effectiveness.

00911 (2/2) : 2D @E508 [Chair: Pasqua D'Ambra]

[04535] JXPAMG: an auto-tuning parallel AMG solver for extreme-scale numerical simulations

Format : Talk at Waseda University
Author(s) : Xiaowen Xu (IAPCM)Silu Huang (IAPCM)Xiaoqiang Yue (Xiangtan University)Runzhang Mao (IAPCM)
Abstract : JXPAMG is a parallel algebraic multigrid (AMG) solver for solving the extreme-scale sparse linear systems on modern supercomputers. It is designed follows the auto-tuning mechanisms allow JXPAMG to use different AMG strategies for different application features and architecture features, and thereby JXPAMG becomes aware of changes in these features. This talk introduces the algorithms, implementation techniques, auto-tuning mechanisms and applications of JXPAMG.

[04594] PSCTOOLKIT: Parallel Sparse Computation Toolkit

Format : Talk at Waseda University
Author(s) : Fabio Durastante (University of Pisa)Pasqua D'Ambra (Institute for Applied Computing (IAC)-National Research Council of Italy (CNR))Salvatore Filippone (University of Rome "Tor Vergata")
Abstract : In this talk, we will describe a software framework for solving large and sparse linear systems on hybrid architectures, from small servers to high-end supercomputers, embedding multi-core CPUs and Nvidia GPUs. The framework has a tripartite modular structure, which separates basic functionalities for distributed sparse matrices and sparse matrix computations involved in Krylov methods, eventually exploiting multi-threading and CUDA-based programming models, from the setup and application of different types of preconditioners.

[04611] Recent Developments in Two-level Schwarz Domain Decomposition Preconditioners in Trilinos

Format : Talk at Waseda University
Author(s) : Ichitaro Yamazaki (Sandia National Labs)Alexander Heinlein (Delft University of Technology (TU Delft))Sivasankaran Rajamanickam (Sandia National Labs)
Abstract : Domain decomposition methods are used to build a class of effective parallel solvers for sparse linear systems arising from the discretization of partial differential equations. FROSch is a software package, which implements GDSW type Two-level Schwarz Domain Decomposition preconditioners in Trilinos. In this talk, we present several recent developments made in FROSch.

[05152] Preparing Algebraic Multigrid Solvers in hypre for Exascale Computers

Format : Talk at Waseda University
Author(s) : Rui Peng Li (LLNL)
Abstract : The emerging exascale computers provide opportunities to perform much larger scale simulations to obtain more accurate solutions than ever before. The increasing complexities of heterogeneous accelerators on such platforms have made the development of sparse linear solvers challenging to achieve high performance. In this talk, we will discuss the porting strategies, new developments and performance optimizations of the multigrid solvers in hypre in preparation for the exascale computers with the results from real application codes.

[00913] Geometric Mechanics and Related Topics

Session Time & Room :

00913 (1/2) : 2D (Aug.22, 15:30-17:10) @G710

00913 (2/2) : 2E (Aug.22, 17:40-19:20) @G710

Type : Proposal of Minisymposium
Abstract : Geometric mechanics is a research branch of modern differential geometric formulation for Lagrangian and Hamiltonian systems in mechanics, including related dynamical systems theory such as Hamiltonian bifurcations. Through the breakthrough of the famous symplectic reduction by Marsden and Weinstein and others,

the scope of the field has expanded from mathematics and physics towards numerical and data sciences. This minisymposium describes the overviews on the main streams of geometric mechanics, including geometric methods in fluids and thermodynamics, and bridges many contemporary related topics such as dynamical systems, numerical simulations, information geometry, and data sciences from the view point of geometric mechanics.

Organizer(s) : Daisuke Tarama, Hiroaki Yoshimura

Minisymposium Program :

00913 (1/2) : 2D @G710 [Chair: Daisuke Tarama]

[05487] Feedback Integrators for Mechanical Systems with Holonomic Constraints

Format : Talk at Waseda University

Author(s) : Joris Vankerschaver (Ghent University Global Campus)Dong Eui Chang (Korea Advanced Institute of Science and Technology)Matthew Perlmutter (Universidade Federal de Minas Gerais)

Abstract : We present a straightforward method for the numerical integration of the equations of motion of mechanical systems with holonomic constraints, to produce numerical trajectories that remain in the constraint set and preserve the values of constrained quantities. Our method only requires changes to the vector field and can be used in conjunction with any numerical integration scheme. This talk will describe the theoretical foundations of the method and compare its performance with other integrators.

[04689] Geometric Integrators for Neural Symplectic Forms

Format : Talk at Waseda University

Author(s) : Yuhan Chen (Kobe University)Takashi Matsubara (Osaka University)Takaharu Yaguchi (Kobe University)

Abstract : The neural symplectic form is a deep physical model for general Hamiltonian systems in arbitrary coordinates. A primal application of deep physical models is physical simulations; however, when general numerical integrators are used for discretization, the physical properties are destroyed. Structure-preserving numerical methods are effective to address this problem. Typical integrators are symplectic integrators, which can be derived as variational integrators. In this study, we show that variational integrators are available for neural symplectic forms.

[04691] Structure-Preserving Learning for GENERIC systems

Format : Talk at Waseda University

Author(s) : Baige Xu (Kobe University)Yuhan Chen (Kobe University)Takashi Matsubara (Osaka University)Takaharu Yaguchi (Kobe University)

Abstract : GENERIC (general equation for the non-equilibrium reversible-irreversible coupling) formulation is a key theory of non-equilibrium thermodynamics, with systems described by it having a unique geometric structure. We propose a neural network model that infers the equations of motion from observed data while preserving this geometric structure by applying the neural symplectic forms and introducing an equivalence relation between the models.

[05507] A discretization of Dirac structures and Lagrange-Dirac dynamical systems

Author(s) : Hiroaki Yoshimura (Waseda University)Linyu Peng (Keio University)

Abstract : Various physical systems such as circuits, nonholonomic systems, as well as nonequilibrium thermodynamic systems can be formulated as a Lagrange-Dirac dynamical systems, in which an induced Dirac structure that is constructed by the canonical two-form and a distribution plays an essential role. In this talk, we show a discretization of such an induced Dirac structure and then we demonstrate how the associated discrete Lagrange-Dirac systems can be developed ,consistently with the discrete Lagrange-d'Alembert principle.

00913 (2/2) : 2E @G710 [Chair: Hiroaki Yoshimura]

[03436] Noether's conservation laws via the modified formal Lagrangians

Format : Talk at Waseda University
Author(s) : Linyu Peng (Keio University)
Abstract : Noether's theorem establishes a one-to-one correspondence between variational symmetries and conservation laws of variational differential equations. In this talk, we extend Noether's theorem to general differential equations by defining the modified formal Lagrangians. This allows us to construct conservation laws of non-variational differential equations using their symmetries. Worked examples will be provided.

[05483] Harmonic exponential families on homogeneous spaces

Format : Talk at Waseda University
Author(s) : Koichi Tojo (RIKEN AIP)Taro Yoshino (The University of Tokyo)
Abstract : Exponential families play an significant role in the field of information geometry and are useful in Bayesian inference. Widely used families of probability measures, such as normal and gamma distributions can be considered as exponential families on homogeneous spaces with symmetry. Based on this observation, we presented a method to construct exponential families with symmetry using representation theory. In this talk, we will explain the method and its properties, illustrating them with examples.

[04618] Symmetries and bifurcations of resonant periodic orbits in perturbed Rayleigh-Bénard convection

Format : Talk at Waseda University
Author(s) : Masahito Watanabe (Waseda University)Hiroaki Yoshimura (Waseda University)
Abstract : Rayleigh-Bénard convection is natural convection that appears in a fluid layer with heated bottom and cooled top planes. When Rayleigh number is set just above a critical number, velocity fields of Rayleigh-Bénard convection may oscillate slightly. In such oscillatory convection both stable and chaotic fluid transport may occur. In this talk we explore the global structures of periodic fluid transport in two-dimensional perturbed Rayleigh-Bénard convection in the perspectives of resonance, symmetry, and bifurcation.

[05475] Geometric models in hydrodynamics

Format : Talk at Waseda University
Author(s) : Tudor Stefan Ratiu (Shanghai Jiao Tong UniversityShanghai Jiao Tong University)
Abstract : In this talk the classical geometric formulation of hydrodynamics will be extended by the use of a momentum map with values in Cheeger-Simons differential characters. It will be shown that this extended momentum map admits topological conservation laws. Clebsch variables will be introduced for which the helicity takes integer values.

[00915] The mathematics of quantum interaction models

Session Time & Room :

00915 (1/3) : 1C (Aug.21, 13:20-15:00) @D407

00915 (2/3) : 1D (Aug.21, 15:30-17:10) @D407

00915 (3/3) : 1E (Aug.21, 17:40-19:20) @D407

Type : Proposal of Minisymposium
Abstract : Research on quantum interaction models, describing the interaction of matter with light, has recently gained traction because of applications including quantum information science/technology and quantum computation. In contrast, despite the discovery of surprising relations with contemporary mathematical theory, including representation theory, geometry and number theory, the rich mathematical structure underlying these models has yet to be properly recognized. In this minisymposium we introduce the field and give an overview of recent results with a focus on the quantum Rabi model, the most fundamental model for light-matter interaction,

and discuss related models in quantum optics and solid-state physics.
Organizer(s) : Daniel Braak, Fumio Hiroshima, Cid Reyes Bustos, Masato Wakayama
Classification : 81V80, 81Q05, 47A10, 11M41, 81R40, Mathematical physics
Minisymposium Program :

00915 (1/3) : 1C @D407 [Chair: Fumio Hiroshima]

[03491] Quantum computation and its viewpoint from spectral zeta functions

Format : Talk at Waseda University
Author(s) : MASATO WAKAYAMA (NTT Institute for Fundamental Mathematics)
Abstract : We discuss the spectrum of the quantum interaction models such as the quantum Rabi models, non-commutative harmonic oscillators and their important derived models from the viewpoints of quantum computation and number theory via the corresponding heat kernels, partition functions and spectral zeta functions.

[03218] New mathematics and machine learning applications from qubits and oscillators

Format : Talk at Waseda University
Author(s) : Sahel Ashhab (National Institute of Information and Communications Technology (NICT))
Abstract : I will present some of our studies on the physics of qubits and oscillators that produced interesting results that go into the realms of mathematics and computer science. In studying the dynamics of strongly driven qubits, we obtained a new approximation for Bessel functions. Our studies on the Landau-Zener problem, a hard problem that has a simple solution, inspired us to explore the use of symbolic regression to solve theoretical physics and mathematics problems.

[03683] Design and optimization of fault-tolerant quantum computing

Format : Talk at Waseda University
Author(s) : Yasunari Suzuki (Nippon Telegraph and Telephone)
Abstract : To demonstrate scalable quantum computing, we need to suppress the high error rates of quantum devices. While they can be reduced with quantum error correction (QEC) technology, it requires large overheads on computing resources. Thus, optimization methods and co-design of hardware and software for fault-tolerant quantum computing are demanded. In this talk, I will explain the recent progress relevant to computer architecture and compiler optimization technologies based on the QEC framework.

[04189] Energy spacing and time evolution for asymmetric quantum Rabi models

Format : Talk at Waseda University
Author(s) : Linh Thi Hoai Nguyen (Institute of Mathematics for Industry, Kyushu University)Cid Reyes Bustos (NTT IFM)Masato Wakayama (NTT Institute for Fundamental Mathematics)
Abstract : In this study, we describe the methods for numerical computations of the energy spacing distribution and time evolution for the asymmetric (or biased) quantum Rabi model (AQRM). The first several tens of thousands of eigenvalues are achieved by using the Truncated Hamiltonians method. From that, we observe the periodicity and symmetry of the consecutive energy spacing distribution with respect to the bias parameter. The time evolution is studied based on an explicit heat kernel formula.

00915 (2/3) : 1D @D407 [Chair: Cid Reyes Bustos]

[03826] The spectral problem in Hilbert spaces of analytic functions

Format : Online Talk on Zoom
Author(s) : Daniel Braak (University of Augsburg)
Abstract : In the standard Hilbert space, the spectral problem of Hamilton operators with one
degree of freedom takes the form of a lateral connection problem for functions with diverging power series expansions. According to common lore, the solution would require to construct these functions on the whole real line which is usually impossible. It will

be demonstrated that this brute-force approach can be avoided by employing Hilbert spaces of analytic functions.

[03426] The weak limit of renormalized Rabi Hamiltonian

Format : Talk at Waseda University
Author(s) : Fumio Hiroshima (Kyushu Univerity)
Abstract : The weak limit of the renormalized Rabi Hamiltonian with a symmetry breaking term is investigated. It is shown that the spectral zeta function converges to the Riemann zeta function as the coupling constant goes to infinity. Furthermore the asymptotic behavior of the expectation of the number operator is also discussed.

[03971] PT-Symmetric Quantum Rabi Model

Format : Talk at Waseda University
Author(s) : Murray Batchelor (Australian National University)
Abstract : We explore a PT-symmetric qubit coupled to a quantized light field. The model is solved analytically using the adiabatic approximation (AA) in the parameter regime of interest. We investigate the static and dynamic properties, using both the AA and numerical diagonalization. A series of exceptional points vanish and revive depending on the light-matter coupling strength. This talk is based on arXiv:2212.06586 with X. Lu, H. Li, J.-K. Shi, L.-B. Fan, V. Mangazeev and Z.-M. Li.

[03421] Spectrum of the noncommutative harmonic oscillator and number theory

Format : Talk at Waseda University
Author(s) : Kazufumi Kimoto (University of the Ryukyus)
Abstract : The noncommutative harmonic oscillator (NCHO) is a system of differential equations defined by a certain matrix-valued operator, and it is connected to the quantum Rabi model via a confluent process in the Heun differential equation picture. In the talk, I will present number-theoretic aspects of the spectral zeta function of the NCHO, especially those arising from its special values (i.e. values at positive integers).

00915 (3/3) : 1E @D407 [Chair: Masato Wakayama]

[03466] On the Weyl spectral counting function of certain semiregular global systems

Format : Online Talk on Zoom
Author(s) : Alberto Parmeggiani (University of Bologna)
Abstract : In this talk I will be discussing some recent work with Marcello Malagutti about the spectral asymptotics of certain global semiregular pseudodifferential systems. The class considered here contains important models such as the Jaynes-Cummings system, which is fundamental in Quantum Optics, but also models of geometric differential complexes over $\mathbb{R}^n$.
We give the asymptotics of the Weyl spectral counting functions in terms of the principal, semiprincipal and subprincipal symbols of the system, along with (time permitting) quasi-clustering properties of the spectrum.

[03916] On The Spectral Zeta Function Of Second Order Semiregular Non-Commutative Harmonic Oscillators

Format : Online Talk on Zoom
Author(s) : Marcello Malagutti (University of Bologna)
Abstract : In this talk we give a meromorphic continuation of the spectral zeta function for semiregular Non-Commutative Harmonic Oscillators (NCHO). By “semiregular system” we mean a pseudodifferential systems with a step $-j$
in the homogeneity of the jth-term in the asymptotic expansion of the symbol. As an application of our results, we first compute the meromorphic continuation of the Jaynes-Cummings (JC) model spectral zeta function. Then we compute the spectral zeta function of the JC generalization to a 3-level atom in a cavity. For both of them we show that it has only one pole in 1.

[00917] High-dimensional regression and sampling

Session Time & Room :

00917 (1/3) : 3C (Aug.23, 13:20-15:00) @E507

00917 (2/3) : 3D (Aug.23, 15:30-17:10) @E507

00917 (3/3) : 3E (Aug.23, 17:40-19:20) @E507

Type : Proposal of Minisymposium
Abstract : The recovery of high-dimensional functions from point evaluations or more general linear measurements is a cornerstone of approximation theory and numerical analysis. While both are well-developed areas, the recent advances in learning theory and high-dimensional statistics sparked several new relations and tools for approximating functions. The research area hence has seen a quite remarkable synthesis of old and new results, especially in the context of nonlinear models such as neural networks and randomized techniques.
In this minisymposium we aim at highlighting recent developments of high-dimensional regression and sampling with modern applications in machine learning and function approximation.

[05486] Lattice-based algorithms for multivariate function approximation

Format : Talk at Waseda University
Author(s) : Frances Kuo (UNSW Sydney)
Abstract : This will be a talk on using lattices for multivariate function approximation.

[05565] Efficient recovery of non-periodic multivariate functions via samples

Format : Talk at Waseda University
Author(s) : Nicolas Nagel (Chemnitz University of Technology)Tino Ullrich (Chemnitz University of Technology)Kai Lüttgen (Chemnitz University of Technology)Felix Bartel (Chemnitz University of Technology)
Abstract : Based on previous observations on function recovery from samples via Chebyshev polynomials, we introduce a periodization technique which preserves smoothness and thus, via know results for the periodic case, yields an efficient recovery algorithm for non-periodic functions. Together with deterministic subsampling algorithms we can prove, for the first time, near optimal bounds on the approximation error and support these claims with numerical experiments. This talk is based on work together with Felix Bartel, Kai Lüttgen and Tino Ullrich.

[04593] Polynomial tractability for integrating functions with slowly decaying Fourier series

Format : Talk at Waseda University
Author(s) : Takashi Goda (The University of Tokyo)
Abstract : This talk is concerned with high-dimensional numerical integration problem. In this context, polynomial tractability refers to the scenario where the minimum number of function evaluations required to make the worst-case error less than or equal to a tolerance ε grows only polynomially with respect to ε^{-1} and the dimension d. For function spaces that are \emph{unweighted}, meaning that all variables contribute equally to the norm of functions, there are many negative results known in the literature that exhibit the curse of dimensionality.

The aim of this paper is to show a contrasting result by introducing a non-trivial unweighted function space with absolutely convergent Fourier series that exhibits polynomial tractability with an explicit quasi-Monte Carlo rule.

00917 (2/3) : 3D @E507 [Chair: Mario Ullrich]

[04266] Weighted least-squares approximation in expected L^2 norm

Format : Talk at Waseda University
Author(s) : Matthieu Dolbeault (Sorbonne Université)Albert Cohen (Sorbonne Université)Abdellah Chkifa (Mohammed VI Polytechnic University)
Abstract : We investigate the problem of approximating a function in L^2 with a linear space of functions of dimension n, using only evaluations at m chosen points. We improve on earlier results based on the solution to the Kadison-Singer problem, by using a randomized greedy strategy, which allows to reduce the oversampling ratio m/n and provides an algorithm of polynomial complexity.

[05485] On the relation between adaptive and non-adaptive randomized sampling

Format : Talk at Waseda University
Author(s) : Stefan Heinrich (RPTU Kaiserslautern-Landau)
Abstract : Recently the author solved a long-standing problem of Information-Based Complexity: Is there a constant $c > 0$ such that for all linear problems the randomized non-adaptive and adaptive n-th minimal errors can deviate at most by the factor c? The analysis of vector-valued mean computation showed that the answer is negative.
In this talk we give a survey on this and related results concerning further aspects the problem.

[05488] A multivariate Riesz basis of ReLU neural networks

Format : Talk at Waseda University
Author(s) : Cornelia Schneider (Friedrich-Alexander Universität Erlangen)Jan Vybiral (CzechTechnical University)
Abstract : We consider the trigonometric-like system of piecewise linear functions introduced recently by Daubechies, DeVore,
Foucart, Hanin, and Petrova. We provide an alternative proof that this system forms a Riesz basis of $L_2(

[0,1])$

based on the Gershgorin theorem. We also generalize this system to higher dimensions $d > 1$ by a construction, which avoids using (tensor) products. As a consequence, the functions from the new Riesz basis of $L_2(

[0,1]^d)$

can be easily represented by neural networks. Moreover, the Riesz constants of this system are independent of d, making it an attractive building block regarding future multivariate analysis of neural networks.

00917 (3/3) : 3E @E507 [Chair: Mario Ullrich]

[05533] On minimizing the training set fill distance in regression

Format : Talk at Waseda University
Author(s) : Paolo Climaco (Universität Bonn)Jochen Garcke (Universität Bonn & Fraunhofer SCAI)
Abstract : Machine learning regression methods leverage large datasets for training predictive models.However, using large datasets may not be feasible due to computational limitations or high labelling costs. Therefore, sampling small training sets from large pools of unlabelled data is essential to maximize performance while maintaining computational efficiency. In this work, we study a sampling approach aimed to minimize the fill distance of the selected set. We derive an upper bound for the maximum expected prediction error that linearly depends on the training set fill distance, conditional to the knowledge of data features. For empirical validation, we show that selecting a training by farthest point sampling significantly reduces the maximum prediction error, outperforming existing sampling approaches.

[05514] Efficient training of Gaussian processes with tensor product structure

Format : Talk at Waseda University
Author(s) : Max Pfeffer (University of Goettingen)Josie König (Universität Potsdam)Martin Stoll (TU Chemnitz)
Abstract : We consider the special case of Gaussian process kernel learning where the covariance function is given by a sum of products of RBF kernels. For a given dataset, the parameters of the kernel are learned by minimizing the log marginal likelihood. Computing the log-determinant of the covariance matrix is prohibitive for large datasets or in high dimensions unless one exploits its low-rank tensor structure. We employ a stochastic trace estimation together with a Lanczos algorithm for TT-tensors (Tensor Trains). This allows us to break the curse of dimensionality and to perform a gradient-based optimization even in high dimensions.

[05610] Tensor decompositions for high-dimensional kernel regression

Author(s) : Frederiek Wesel (Delft University of Technology)Kim Batselier (Delft University of Technology)
Abstract : Kernel machines provide a nonlinear extension to linear methods by projecting the data in a higher-dimensional feature space. When considering product kernels, the dimensionality of the feature space grows exponentially with the dimensionality of the data, limiting these methods to small-dimensional data. We lift this limitation by constraining the model weights to be a canonical polyadic decomposition of low rank. This allows us to derive a block coordinate descent algorithm which allows for the training of kernel machines under such constraint at a computational complexity which is linear both in the number of samples and in the dimensionality of the data, allowing to tackle both large-sampled and high-dimensional data.

[05481] Optimal sampling for regression: from linear to nonlinear approximation

Format : Online Talk on Zoom
Author(s) : Anthony Nouy (Nantes Université - Centrale Nantes)
Abstract : We consider the approximation of functions in L^2 from point evaluations, using linear or nonlinear approximation tools. For linear approximation, recent results show that weighted least-squares projections allow to obtain quasi-optimal approximations with near to optimal sampling budget.
This can be achieved by drawing i.i.d. samples from suitable distributions (depending on the linear approximation tool) and subsampling methods.
In a first part of this talk, we review different strategies based on i.i.d. sampling and present alternative strategies based on repulsive point processes that allow to achieve the same task with a reduced sampling complexity.
In a second part, we show how these methods can be used to approximate functions with nonlinear approximation tools, in an active learning setting, by coupling iterative algorithms and optimal sampling methods for the projection onto successive linear spaces. We particularly focus on the approximation using tree tensor networks, whose architectures allow for an efficient implementation of optimal sampling procedures within coordinate descent algorithms.

These are joint works with R. Gruhlke, B. Michel, C. Miranda and P. Trunschke

[00919] Recent Advances in Hybridizable Discontinuous Galerkin Methods and Applications

Session Time & Room :

00919 (1/3) : 3E (Aug.23, 17:40-19:20) @E710

00919 (2/3) : 4C (Aug.24, 13:20-15:00) @E710

00919 (3/3) : 4D (Aug.24, 15:30-17:10) @E710

Type : Proposal of Minisymposium

Abstract : This minisymposium concentrates on the recent developments in numerical approximations to partial differential equations by hybridizable discontinuous Galerkin methods and other related schemes such as mixed methods, discontinuous Galerkin methods, and hybrid high-order methods. The scope of the talks is open to mathematical theory and applications of the methods in science and computational engineering, including the development of new hybridizable discontinuous Galerkin methods, Hamiltonian structure-preserving methods, grid adaptivity schemes, linear and nonlinear iterative methods, efficient implementations on emerging computer architectures, and robust shock capturing methods.

[03033] A C0 interior penalty method for mth-Laplace equation

Author(s) : Weifeng Qiu (City University of Hong Kong)Huangxin Chen (Xiamen University)Jingzhi Li (Southern University of Science and Technology)

Abstract : In this paper, we propose a $C0$ interior penalty method for mth-Laplace equation on bounded Lipschitz polyhedral domain in Rd, where m and d can be any positive integers. The standard $H1$-conforming piecewise r-th order polynomial space is used to approximate the exact solution u, where r can be any integer greater than or equal to m. Unlike the interior penalty method in Gudi and Neilan [IMA J. Numer. Anal. 31 (2011) 1734–1753], we avoid computing $D\hat{}m$ of numerical solution on each element and high order normal derivatives of numerical solution along mesh interfaces. Therefore our method can be easily implemented. After proving discrete Hm-norm bounded by the natural energy semi-norm associated with our method, we manage to obtain stability and optimal convergence with respect to discrete Hm-norm.

[03873] Output-Adaptive Hybridized Discontinuous Finite Elements for Efficient Flow Computations

Author(s) : Krzysztof Fidkowski (University of Michigan)

Abstract : Discontinuous Galerkin (DG) methods have enabled accurate computations of complex flowfields, yet their memory footprint and computational costs are large. Hybridized discontinuous Galerkin (HDG/EDG) methods reduce the number of globally-coupled degrees of freedom by decoupling elements and stitching them together through weak flux continuity. However, these methods have not risen to nearly the same level of popularity as DG, and in this work we outline reasons why and demonstrate benefits in an output-based adaptive setting.

[04227] Towards boundary conditions for HDG methods for direct aeroacoustic computations

Author(s) : Philip Lukas Lederer (University of Twente)Jan Ellmenreich (TU Wien)

Abstract : We focus on direct aeroacoustic simulations using hybrid discontinuous Galerkin methods (HDG) for the approximation of the compressible Navier-Stokes equations. A crucial factor for accurate results is the proper handling of artificial boundary conditions, focusing on the reflectivity of the acoustic waves. We discuss various approaches such as LODI relations and extensions of characteristic Navier-Stokes boundary conditions (NSCBC) for HDG methods. Numerical results are presented and discussed in detail.

[04312] Hybrid discontinuous Galerkin methods on multiple levels

Author(s) : Guido Kanschat (Heidelberg University)Peipei Lu (Soochow University)Roland Maier (University of Jena)Andreas Rupp (LUT University)

Abstract : Hybrid finite element schemes approximate the trace of an unknown solution to a partial differential equation on the mesh skeleton (the union of the faces in a mesh). Afterward, these schemes use this trace approximation to recover the primal and dual unknowns. This strategy has several advantages over standard finite elements, such as an enhanced order of convergence, smaller symmetric positive systems of linear equations, and preservation of physically meaningful quantities.

Virtually all of the available multilevel (multigrid and multiscale) techniques for finite elements exploit the fact that their test and trial spaces are nested. However, the test and trial spaces are not nested for hybrid finite elements because their main approximate lives on the mesh's skeleton, which grows with refinement. Thus, the major obstacle that blocks the way to practical multigrid methods comprises the construction of stable mesh transfer operators. Several recent works have addressed this issue by exchanging the hybrid formulation for a non-hybrid formulation in a preliminary step. Afterward, these approaches use the available multilevel strategies for non-hybrid finite elements.

We proceed differently and preserve the advantageous properties of hybrid finite elements on all mesh levels. To this end, we devise stable mesh transfer operators and provide relevant convergence results for our hybrid, multilevel finite elements. This approach allows us to use identical discretizations on all mesh levels (homogeneous strategy) instead of the heterogeneous methods that use different discretizations on different mesh levels.

00919 (2/3) : 4C @E710

[04456] Combining finite element space-discretizations with symplectic time-marching schemes for linear Hamiltonian systems

Author(s) : Manuel Sanchez (Pontificia Universidad Catolica de Chile)Bernardo Cockburn (University of Minnesota)Shukai Du (University of Wisconsin-Madision)
Abstract : We provide a short introduction to the devising of a special type of methods for numerically approximating the solution of Hamiltonian partial differential equations. These methods use Galerkin space-discretizations which result in a system of ODEs displaying a discrete version of the Hamiltonian structure of the original system. The resulting system of ODEs is then discretized by a symplectic time-marching method. This combination results in high-order accurate, fully discrete methods which can preserve the invariants of the Hamiltonian defining the ODE system. We restrict our attention to linear Hamiltonian systems, as the main results can be obtained easily and directly, and are applicable to many Hamiltonian systems of practical interest including acoustics, elastodynamics, and electromagnetism. After a brief description of the Hamiltonian systems of our interest, we provide a brief introduction to symplectic time-marching methods for linear systems of ODEs which does not require any background on the subject. We consider the case of finite-element space discretizations. The emphasis is placed on the conservation properties of the fully discrete schemes.

[04720] Multigrid for HDG

Author(s) : Guosheng Fu (University of Notre Dame)Wenzheng Kuang (University of Notre Dame)
Abstract : We present optimal geometric and algebraic multigrid preconditioners for low-order and high-order HDG schemes for diffusion and Stokes problems. The algebraic multigrid is based on Jinchao Xu's auxiliary space preconditioning framework, while the geometric multigrid is based on the close connection between the lowest-order HDG scheme with the nonconforming Cruzeix-Raviart method. This is a joint work with Wenzheng Kuang from Notre Dame.

[04725] HDG method for elliptic interface problems and industrial application

Author(s) : Masaru Miyashita Norikazu Saito (The University of Tokyo)
Abstract : We propose a hybridized discontinuous Galerkin (HDG) method to solve the interface problem for elliptic equations. We succeed in deriving optimal order error estimates in both the HDG norm and the L2 norm under low regularity assumptions for solutions such as $u|_{\Omega_1} \in H^{1+s}(\Omega_1)$ and $u|_{\Omega_2} \in H^{1+s}(\Omega_2)$ for some $s \in (1/2, 1]$. Numerical examples support our theoretical results. Then, we show an example of developing plasma equipment using the proposed method.

[04892] A C0 interior penalty method for mth-Laplace equation

Author(s) : Weifeng Qiu (City University of Hong Kong)Huangxin Chen (Xiamen University)Jingzhi Li (SUSTech)
Abstract : I will talk about a C0 interior penalty method for the mth-Laplace equation.

00919 (3/3) : 4D @E710

[05082] Discontinuous Galerkin Methods for High Speed Flows

Author(s) : Ngoc Cuong Nguyen (Massachusetts Institute of Technology)Jaime Peraire (Massachusetts Institute of Technology)Jordi Perez (Massachusetts Institute of Technology)Loek Van Heyningen (Massachusetts Institute of Technology)
Abstract : We present discontinuous Galerkin (DG) methods for high-speed flows with particular focus on transition, turbulence, and shock capturing. We describe LDG, HDG, EDG methods and parallel iterative solvers with matrix-free preconditioners. We develop an adaptive viscosity regularization method for capturing shocks by minimizing the artifial viscosity field while enforcing smoothness contraints on the numerical solution. We present numerical results to demonstrate the DG methods and our shock capturing scheme on transonic, supersonic, and hypersonic flows.

[00923] PDEs and variational computational methods in image processing, analysis and classification

Session Time & Room :

00923 (1/3) : 2C (Aug.22, 13:20-15:00) @G602

00923 (2/3) : 2D (Aug.22, 15:30-17:10) @G602

00923 (3/3) : 2E (Aug.22, 17:40-19:20) @G602

Type : Proposal of Minisymposium
Abstract : The minisymposium is devoted to a wide range of novel mathematical models and methods for image reconstruction, segmentation and PDEs based deep-learning classification, applied to time-lapse laser scanning microscopy, medical imagery, airborne and satellite optical and SAR data, arising in various fields of application like developmental and cell biology, medicine, nature protection and Earth biodiversity modelling and monitoring.
Organizer(s) : Karol Mikula, Serena Morigi
Classification : 35K55, 65K10, 65M08, 68U10, 68T05
Minisymposium Program :

00923 (1/3) : 2C @G602 [Chair: Serena Morigi]

[03551] Mathematical models and computational algorithms for 3D and 4D image processing in developmental biology and medicine

Format : Talk at Waseda University
Author(s) : Karol Mikula (Slovak University of Technology in Bratislava)
Abstract : We present mathematical models and numerical algorithms based on nonlinear advection-diffusion equations used for image filtering, segmentation and tracking in 3D+time microscopy images leading to automated reconstruction of the cell lineage tree during the first hours of embryogenesis. To achieve that goal, we discretize the nonlinear partial differential equations by the finite volume method, natural to image processing applications, and develop efficient and stable numerical schemes suitable for massively parallel computer architecture.

[04223] Fractional graph Laplacian for image reconstruction

Format : Talk at Waseda University
Author(s) : Marco Donatelli (University of Insubria)Alessandro Buccini (University of Cagliari)
Abstract : We consider $\ell^2 - \ell^q$ regularization with $0

[03561] Mathematical models for segmentation of Natura 2000 habitats in NaturaSat software

Format : Talk at Waseda University

Author(s) : Michal Kollár (Algoritmy:SK s.r.o. and Slovak University of Technology in Bratislava)Martin Ambroz (Slovak University of Technology in Bratislava)Aneta Alexandra Ozvat (Slovak University of Technology)Karol Mikula (Slovak University of Technology in Bratislava)Lucia Čahojová (Slovak Academy of Sciences)Mária Šibíková (Slovak Academy of Sciences)

Abstract : The contribution presents an overview of numerical methods and mathematical models designed for the NaturaSat software. The application allows botanists, environmentalists and nature conservationists across Europe to explore protected areas of Natura 2000 habitats using the Sentinel-2 optical data. The presented methods are designed for accurate area identification - semi-automatic and automatic segmentation of European protected habitats and monitoring of their spatio-temporal distribution and quality.

[03205] NatNet - forward-backward diffusion classification tool

Format : Talk at Waseda University

Author(s) : Aneta Alexandra Ozvat (Slovak University of Technology)Karol Mikula (Slovak University of Technology in Bratislava)Michal Kollar (Slovak University of Technology)Martin Ambroz (Slovak University of Technology)Maria Sibikova (Slovak Academy of Sciences)Jozef Sibik (Slovak Academy of Sciences)

Abstract : The presentation introduces a novel method for PDE-based data classification using satellite optical data. The Natural Numerical Network (NatNet) is based on the numerical solution of the nonlinear forward-backward diffusion equation on a semi-complete directed graph. Partial differential equations on the directed graph are solved by a finite volume approach considering the balance of diffusion fluxes in the vertices of the graph. The presented natural numerical network is applied to Earth biodiversity modelling.

00923 (2/3) : 2D @G602 [Chair: Karol Mikula]

[02834] Segmentation-based tracking of macrophages in microscopy videos

Format : Talk at Waseda University

Author(s) : Seol Ah Park (Slovak University of Technology in Bratislava)Tamara Sipka (University of Montpellier)Zuzana Kriva (Slovak University of Technology in Bratislava)Georges Lutfalla (University of Montpellier)Mai Nguyen-Chi (University of Montpellier)Karol Mikula (Slovak University of Technology in Bratislava)

Abstract : We propose an algorithm to achieve automatic cell tracking in macrophage videos.
First, we design a segmentation method employing space-time filtering, local Otsu's threshold, and the SUBSURF method.
Then, the partial trajectories are extracted when segmented cells overlap in time. Finally, the extracted trajectories are linked by considering their direction of movement. The automatic tracking achieved 97.4% of accuracy for macrophage data under challenging situations, feeble fluorescent intensity, irregular shapes, and motion of macrophages.

[02927] Model-aware learning for super-resolution in fluorescence microscopy

Format : Talk at Waseda University

Author(s) : Luca Calatroni (CNRS)

Abstract : In this talk, I will present image super-resolution approaches for fluorescence microscopy applications based on the use of combined model-based and data-driven learning methods. Namely, I will show how generative adversarial training and plug-and-play learning methods can be effectively used as new paradigms for obtaining precise reconstructions with guarantees beyond the use of purely model-based approaches. Numerical results on both simulated and challenging real-world data will be presented.

[02833] Macrophages trajectories smoothing by evolving curves

Format : Talk at Waseda University
Author(s) : Giulia Lupi (Slovak University of Technology in Bratislava)Karol Mikula (Slovak University of Technology in Bratislava)Seol Ah Park (Slovak University of Technology in Bratislava)
Abstract : We present a mathematical model and numerical method based on evolving open-plane and 3D curve approach in the Lagrangian formulation. The model contains three terms: the curvature term, the attracting term, and the tangential redistribution. We use the flowing finite volume method to discretize the advection-diffusion partial differential equation. We present results for macrophage trajectory smoothing and define a method to compute the cell velocity for the discrete points on the smoothed curve.

[02718] Limited memory restarted lp-lq minimization methods using generalized Krylov subspaces

Format : Talk at Waseda University
Author(s) : Alessandro Buccini (University of Cagliari)Lothar Reichel (Kent State University)
Abstract : Regularization of certain linear discrete ill-posed problems, as well as of certain regression problems, can be formulated as large-scale, possibly nonconvex, minimization problems, whose objective function is the sum of the p-th power of the lp-norm of a fidelity term and the q-th power of the lq-norm of a regularization term, with $0 < p, q \leq 2$. We describe new restarted iterative solution methods that require less computer storage and execution time than the methods described by [Huang et al.,Majorization-minimization generalized Krylov subspace methods for lp-lq optimization applied to image restoration. BIT (2017)]. The reduction in computer storage and execution time is achieved by periodic restarts of the method. Computed examples illustrate that restarting does not reduce the quality of the computed solutions.

00923 (3/3) : 2E @G602 [Chair: Cancelled]

[00924] Calibration and Validation of Mathematical Models for Biological Systems

Session Time & Room :

00924 (1/2) : 3C (Aug.23, 13:20-15:00) @A512

00924 (2/2) : 3D (Aug.23, 15:30-17:10) @A512

Type : Proposal of Minisymposium
Abstract : The advent of big data in biology offers many new challenges and opportunities. In this minisymposium, we will discuss advances in calibration and validation of biologically-driven mathematical models, spanning biological applications such as cancer, symbiosis, and circadian rhythms. An equally diverse set of mathematical techniques will be discussed such as Bayesian approaches, agent-based parameter estimation, and machine learning approaches. The first session of our minisymposium will focus on challenges specific to cancer modeling such as leveraging population-level data while preserving inter-individual heterogeneity, while the second session of the minisymposium will focus on broader methodology development in inferring mechanisms from data.
Organizer(s) : Lihong Zhao, Tracy Stepien, Erica Rutter
Classification : 92-10, 92B05, 92B20, 92C17, 92C42
Minisymposium Program :

[01710] Multiscale spatiotemporal reconstruction of single-cell genomics data

Format : Talk at Waseda University
Author(s) : Qing Nie (University of California, Irvine)
Abstract : Cells make fate decisions in response to dynamic environments, and multicellular structures emerge from multiscale interplays among cells and genes in space and time. The recent single-cell genomics technology provides an unprecedented opportunity to profile cells. However, those measurements are taken as static snapshots of many individual cells that often lose spatial information. How to obtain temporal relationships among cells from such measurements? How to recover spatial interactions among cells, such as cell-cell communication? In this talk I will present our newly developed computational tools that dissect transition properties of cells and infer cell-cell communication based on nonspatial single-cell genomics data. In addition, I will present methods to derive multicellular spatiotemporal pattern from spatial transcriptomics datasets. Through applications of those methods to systems in development and regeneration, we show the discovery power of such methods and identify areas for further development for spatiotemporal reconstruction of single-cell genomics data.

[01731] Integrating quantitative MRI with computational modeling to predict the response of breast cancers to neoadjuvant therapy

Format : Online Talk on Zoom
Author(s) : Thomas Yankeelov (The University of Texas at Austin)Chase Christenson (The University of Texas at Austin)Casey Stowers (The University of Texas at Austin)Reshmi Patel (The University of Texas at Austin)Chengyue Wu (The University of Texas at Austin)
Abstract : We will discuss how magnetic resonance imaging data (MRI) can initialize and constrain mathematical models describing cancer proliferation, migration/invasion, vascular status, and drug-related growth inhibition and cell death. More specifically, we will focus on 1) incorporating patient-specific MRI data into biology-based mathematical models, and 2) optimizing outcomes via patient-specific digital twins in breast cancer. The long-term goal is to provide a rigorous methodology that allows for optimizing therapeutic interventions on a patient-specific basis.

[04716] Deep Hybrid Modeling of Neuronal Dynamics using Generative Adversarial Networks

Format : Online Talk on Zoom
Author(s) : Casey Diekman (New Jersey Institute of Technology)Soheil Saghafi (New Jersey Institute of Technology)
Abstract : Mechanistic modeling and machine learning methods are powerful techniques for approximating biological systems and making accurate predictions from data. However, when used in isolation these approaches suffer from distinct shortcomings: model and parameter uncertainty limit mechanistic modeling, whereas machine learning methods disregard the underlying biophysical mechanisms. To address these shortcomings, we build Deep Hybrid Models (DeepHMs) that combine deep learning with mechanistic modeling to identify the distributions of mechanistic modeling parameters coherent to the data. We employed DeepHM to identify which ionic conductances are responsible for the altered excitability properties of CA1 pyramidal neurons in mouse models of Alzheimer’s disease.

[03082] Gene regulatory network dynamics in single cells

Format : Online Talk on Zoom
Author(s) : Adam L MacLean (University of Southern California)Megan Rommelfanger (University of Southern California)
Abstract : Single-cell genomics offer unprecedented resolution with which to study cell fate decision-making. We present new tools to infer gene regulatory networks (GRNs) controling cell fate decisions and model their multiscale dynamics. We introduce popInfer, single-cell multi-modal GRN inference via regularized regression, and demonstrate its potential for network discovery. We develop a single-cell resolved multiscale model coupling cell-cell communication with gene regulatory network dynamics, with which we discover a profound role for cell-cell communication in hematopoiesis.

00924 (2/2) : 3D @A512 [Chair: Erica Rutter]

[02727] The role of bacterial chemotaxis in microbial symbiosis

Format : Online Talk on Zoom
Author(s) : Douglas Brumley (The University of Melbourne)
Abstract : Bacterial motility, symbioses, and marine nutrient cycling unfold at the scale of individual microbes, and are inherently dynamic. In this talk, I will outline how iteratively combining video-microscopy, image processing and mathematical modelling can resolve dynamic microscale processes which underpin the ecology of microbes. I will also demonstrate how the highly-resolved processes at the scale of individual cells can be connected to bulk measurements at the population-level through calibrated mathematical models.

[04509] Multi-scale modelling of the uterus and the 12 Labours project

Format : Online Talk on Zoom
Author(s) : Alys Rachel Clark (University of Auckland)Shawn Means (University of Auckland)Claire Miller (University of Auckland)Mathias Roesler (University of Auckland)Amy Garrett (University of Auckland)Leo Cheng (University of Auckland)
Abstract : Uterine contractions contribute to fertility, menstruation, and delivery of babies, and the uterus has unique properties compared to other smooth muscle organs (including extensive stretch in pregnancy without contraction). Here, I present cell-to-tissue models of the uterus which form part of the 12 Labours project. This project takes a data-driven and reproducible approach to modelling physiological systems, which aims to integrate models into clinical workflows and provide feedback to wearable devices that monitor the uterus.

[02752] Bayesian discovery of mechanics and signaling during collective cell migration

Format : Online Talk on Zoom
Author(s) : Simon Martina Perez (Oxford)Ruth E. Baker (University of Oxford)
Abstract : Collective cell migration results from a complex interplay of cell-cell interactions and whole-tissue mechanics. Experimental data enables Bayesian inference to identify the role of mechanics and cell-cell interactions. While mathematical models can be identified with sufficiently detailed data, the relationship between observation noise and uncertainty in the learned models remains unexplored. We explore how to combine data sets to quantify uncertainty, and draw mechanistic conclusions about the underlying biophysical process in morphogenesis and cancer invasion.

[05213] PIEZO1 regulates cellular coordination during collective cell migration

Format : Talk at Waseda University
Author(s) : Jinghao Chen (University of California, Irvine)Jesse Holt (University of California, Irvine)Beth Evans (University of California, Irvine)John Lowengrub (University of California, Irvine)Medha Pathak (University of California, Irvine)
Abstract : The mechanically-activated ion channel PIEZO1 was recently identified to play an inhibitory role during wound healing. Through an integrative experimental and mathematical modeling approach, we elucidate PIEZO1's contributions to keratinocyte collective migration, an essential component of the healing process. Here, through a 2D-multiscale model of wound closure which links observations at both the single and multicell scales, and subsequent experimental validation, we identify cell directionality as being impacted by PIEZO1 activity during wound closure.

[00932] Some recent advances on time-modulated metamaterials

Session Time & Room :

00932 (1/2) : 5B (Aug.25, 10:40-12:20) @D404

00932 (2/2) : 5C (Aug.25, 13:20-15:00) @D404

Type : Proposal of Minisymposium

Abstract : Time-modulated materials constitute the brand new class of metamaterials that is currently raising a huge interest in the mathematics, physics and engineering communities for their ability to achieve extreme wave phenomena. Indeed, by time modulating the properties (acoustic, optical, mechanical, etc.) of materials, one can, for instance, break reciprocity, achieve screening of parts of the domain by wave propagation, and reconfigure materials for optimization. The aim of this minisymposium is to bring together an interdisciplinary group of researchers to discuss the most recent results in the field and to favor interaction between theorists and experimentalists.

[04433] Modeling Plasmons on Graphene with Time- and Space-Dependent Properties

Format : Talk at Waseda University

Author(s) : Fadil Santosa (Johns Hopkins University)Tong Shi (University of Minnesota)

Abstract : Graphene sheets are two-dimensional materials that are known to support plasmonic modes. The latter are electromagnetic waves which are concentrated near a surface and propagate along it. In graphene, these modes can exist on both sides of surfaces of the 2-D material. It has been shown that graphene sheets are effective in its ability to concentrate light, and for this reason, it is a candidate for photonic devices. In this work, we study graphene sheets which have time- and space-dependent properties. They are modeled as a flat conductive sheet with time- and space-dependent Drude weights. We show that in two dimensions, the governing equations can be reduced to a single 1-D time-dependent integro-partial-differential equation. The equation can be discretized and also solved approximately using perturbation arguments. We demonstrate the accuracy of the approximate solution and also show interesting behavior of the plasmons when the Drude weight is modulated temporarily and spatially.

[05163] Analytical and FDTD Modelling of EM Wave Interacting with Time-Varying Media

Format : Talk at Waseda University

Author(s) : Debdeep Sarkar (Indian Institute of Science, Bangalore)

Abstract : First, we will focus on quasi-analytical ODE (ordinary differential equations) based methods to analyze velocity modulation imparted on EM (electromagnetic) waves interacting with infinitely extended time-varying medium. Later, we will examine EM wave interaction with finitely extended time-varying media using in-house Finite Difference Time Domain (FDTD) simulation methods. After critical observations on the generated reflection and transmission spectra of signals, we will comment on possible applications in next generation communication and Radar technologies.

[04583] Using Time-Varying Systems to Challenge Fundamental Limitations in Electromagnetics and Photonics

Format : Online Talk on Zoom

Author(s) : Francesco Monticone (Cornell University)

Abstract : Time-varying systems offer opportunities for efficient electromagnetic and photonic devices, potentially surpassing various well-established theoretical limits, such as the Bode-Fano limit, the Chu limit, the Rozanov bound, delay-bandwidth limits, and others. At the same time, the characteristics of the temporal dimension create challenges and constraints that are unique to time-varying systems. In this talk, I will first review these opportunities and limitations, and will then discuss some of our recent research efforts in this area.

[03155] Energy conserving temporal metasurfaces

Format : Talk at Waseda University

Author(s) : Kshiteej Jayendra Deshmukh (University of Utah)Graeme W Milton (University of Utah)

Abstract : Changing the microstructure properties of a space-time metamaterial while a wave is propagating through it, in general requires addition or removal of energy, which can be of exponential form depending on the type of modulation.
This limits the realization and application of space-time metamaterials. In this work we present non-linear energy conserving temporal interfaces which address this problem.

[00935] Applied mathematics in industry: Success stories of collaboration between academia and industry in Mexico

Session Time & Room :

00935 (1/2) : 3C (Aug.23, 13:20-15:00) @D515

00935 (2/2) : 3D (Aug.23, 15:30-17:10) @D515

Type : Proposal of Industrial Minisymposium
Abstract : The applied collaboration between educational institutions in mathematics and industry is complicated not only from a scientific and technological point of view but also due to intellectual property legislation, organization, response time, and confidentiality. This mini-symposium will present successful real cases of applying mathematics directly to technological development in Mexico and some ideas for achieving greater collaboration.

Organizer(s) : Ivete Sanchez Bravo, Giovana Ortigoza Alvarez, Yasmin Rios Solis
Classification : 90Bxx
Minisymposium Program :

00935 (1/2) : 3C @D515 [Chair: Ivete Sanchez]

[01598] Public Transportation in Mexico

Format : Online Talk on Zoom
Author(s) : Yasmin Rios Solis (Tecnológico de Monterrey)
Abstract : Mexican public transportation planning and operation need different mathematical models than the ones used in developed countries. Indeed, planning stages like timetables and frequency setting should be revisited weekly or even daily. I will present two case studies of companies in Mexico and the main points that differentiate the classical models in the scientific literature from the needed ones. In particular, we will talk about the timetabling problem together with the vehicle scheduling problem to minimize the number of unfulfilled trips. I will present the models, the real case, and computational experimentation.

[01632] Successful cases of mathematical applications for business

Format : Talk at Waseda University
Author(s) : Ivete Sanchez-Bravo (Centro de Investigación en Matemáticas)
Abstract : Science and technology are two key elements for the development of all countries. The industrial sector seeks to apply frontier knowledge to generate value in its processes and products, so it needs a translation to apply it, in addition to having personnel trained in these topics.

This talk will present the results and successful partnerships between some Mexican and multinational companies, as well as some initiatives such as workshops for companies to encourage teamwork, organized by CIMAT with other institutions specifically in areas of Applied Mathematics, such as AI, Optimization, and Data Science.

[01653] Statistical Methods for Natural Disaster Risk Assessment

Format : Online Talk on Zoom
Author(s) : Ramses H Mena (UNAM)
Abstract : The study and risk assessment of natural disasters are of crucial interest for every country. The ability to foresee potencial losses are of paramount importance for emergency policies, prevention, reconstruction and risk transfer mechanisms. Using a case study with the Mexican Natural Disasters Fund (FONDEN), we will discuss the importance of statistical and probabilistic methodologies created to aid the insurance against natural disasters.

[01743] Collaboration between SMM and mathematical professionals in the mexican industry

Format : Talk at Waseda University
Author(s) : Giovana Ortigoza Alvarez (Seguros Monterrey New York Life)
Abstract : The collaboration between mathematics graduates in Mexico and the Mexican Mathematical Society (SMM) has been of vital importance and a topic of interest in recent years.
Since 2016, through special sessions in the national congress that the (SMM) organizes each year, talks, panel discussion and workshops focused on the empowerment of mathematicians and the collaborations that can be developed in the private industry in Mexico are presented.
In this talk we will talk about this project.

00935 (2/2) : 3D @D515 [Chair: Giovana Ortigoza]

[01745] P&L Attribution and Risk Management

Format : Talk at Waseda University
Author(s) : Joyce Vega (Universidad Nacional Autónoma de México)
Abstract : In this session I will talk about the concept of profit and loss attribution in risk management as a predictive and explanatory model of financial market movements in investment portfolios through Taylor expansion, and associated concepts of risk factors as components of a price function of a financial instrument. Finally, I will also present an applied example of this model.

[01753] Building an university-based knowledge transfer network for the financial sector: The case of Fin-ML

Format : Online Talk on Zoom
Author(s) : Manuel Morales (Université de Montréal)
Abstract : In 2017, the Fin-ML Network was created within the Université de Montréal with the goal of training the next generation of applied mathematicians and statisticians working at the intersection of data-science, machine learning, quantitative finance and business intelligence. In the past five years, it has become a knowledge transfer center fostering collaboration between industry and academia around data-centric value creation for businesses in the financial sector. This collaboration is now international as we have started partnering with the innovation ecosystem in two Mexican states. This talk will narrate this success story while showcasing some of the applied projects our researchers have been working on.

[01912] Applied mathematics in industry: Success stories of collaboration between academia and industry in Mexico

Format : Online Talk on Zoom
Author(s) : Cipriano Arturo Santos (Tecnologico de Monterrey)
Abstract : The applied collaboration between educational institutions in mathematics and industry is complicated not only from a scientific and technological point of view but also due to intellectual property legislation, organization, response time, and confidentiality. This mini-symposium will present successful real cases of applying mathematics directly to technological development in Mexico and some ideas for achieving greater collaboration.

[00936] Recent advances in applications for large-scale data assimilation and inverse problems.

Session Time & Room : 4E (Aug.24, 17:40-19:20) @E504

Type : Proposal of Minisymposium

Abstract : The development of algorithms for data assimilation (DA) and inverse problems (IPs) has been traditionally driven by very specific applications in engineering, medicine and the geosciences. However, algorithms that were initially tailored for geophysical data assimilation have now been used for solving tomographic inverse problems in engineering. Similarly, developments on imaging methods have been used for DA. This exchange has not only led to further algorithmic developments but also deeper theoretical insights. In this minisymposium we bring together experts on DA and IPs that work at the interface with applied sciences, with the aim of fostering knowledge transfer across disciplines

Organizer(s) : Svetlana Dubinkina, Marco Iglesias

Classification : 65-XX

Minisymposium Program :

00936 (1/1) : 4E @E504 [Chair: Svetlana Dubinkina]

[05372] Level-set parameterisations for Ensemble Kalman Inversion

Format : Talk at Waseda University

Author(s) : Marco Iglesias (University of Nottingham)

Abstract : We discuss a level-set approach to parameterise unknown interfaces and discontinuous properties with the Ensemble Kalman Inversion (EKI) framework for inverse problems. We demonstrate the applicability of this approach to solve various inverse problems where the unknown is a discontinuous property arising from the presence of an anomalous material/tissue. We will present numerical examples with applications to (i) non-destructive testing of composite materials, (ii) ground penetrating radar and (iii) magnetic resonance elastography.

[05415] Data assimilation for estimating nonlinear dynamics in earthquakes

Format : Online Talk on Zoom

Author(s) : Femke Cathelijne Vossepoel (Delft University of Technology)Hamed Ali Diab-Montero (Delft University of Technology)Arundhuti Banerjee (Delft University of Technology)Celine Marsman (Utrecht University)Ylona van Dinther (Utrecht University)

Abstract : The highly nonlinear dynamics of earthquake sequences and the limited data availability make it very difficult, if not impossible, to forecast earthquakes. State- and parameter estimation with data assimilation can improve estimates and forecasts of earthquake sequences. We illustrate the challenges of data assimilation in earthquake simulation with a range of models using several ensemble data-assimilation methods, including the particle filter, the ensemble Kalman filter, the adaptive Gaussian mixture filter, and the particle flow filter.

[05358] Analysis of a localized ensemble Kalman-Bucy filter with sparse observations

Format : Talk at Waseda University

Author(s) : Gottfried Hastermann (University of Potsdam)Jana de Wiljes (University of Potsdam)

Abstract : With large scale availability of precise real time data, their incorporation into physically based predictive models, became increasingly important. This procedure of combining the prediction and observation is called data assimilation. One especially popular algorithm of the class of Bayesian sequential data assimilation methods is the ensemble Kalman filter which successfully extends the ideas of the Kalman filter to the non-linear situation. However, in case of spatio-temporal models one regularly relies on some version of localization, to avoid spurious oscillations.

In this work we develop a-priori error estimates for a time continuous variant of the ensemble Kalman filter, known as localized ensemble Kalman-Bucy filter. More specifically we aim for the scenario of sparse observations applied to models from fluid dynamics and space weather.

[05397] Edge-preserving inversion with α-stable priors

Format : Talk at Waseda University

Author(s) : Jarkko Suuronen (LUT University)Tomás Soto (LUT University)Neil Chada (Heriot Watt University)Lassi Roininen (LUT University)

Abstract : The α-stable distributions are a family of heavy-tailed and infinitely divisible distributions that are well-suited as prior distributions to edge-preserving inversion in the context of (discretization of) infinite-dimensional

continuous-time statistical inverse problems. In this talk we present a new hybrid approximation method well-suited to the application of such priors.

[00941] Numerical methods for Hamilton-Jacobi equations and their applications

Session Time & Room :

00941 (1/4) : 3D (Aug.23, 15:30-17:10) @F402

00941 (2/4) : 3E (Aug.23, 17:40-19:20) @F402

00941 (3/4) : 4C (Aug.24, 13:20-15:00) @F402

00941 (4/4) : 4D (Aug.24, 15:30-17:10) @F402

Type : Proposal of Minisymposium
Abstract : Hamilton-Jacobi equations arise both in modeling front propagation and in decision-making processes (optimal control & differential games). As a result, they have a broad range of applications including seismic imaging, robotic navigation, photolithography, transportation engineering, optimization of medical treatment policies, and data science. Practical usefulness of HJ-based approaches hinges on efficient and accurate numerical methods, which often need to handle anisotropy, degenerate diffusion, and possible discontinuity of viscosity solutions. High-dimensional problems and HJ-based inverse problems pose additional computational challenges. This mini-symposium will focus on recent advances in numerics for HJ PDEs and their innovative use in a variety of applications.

[01729] HJ equations in optimizing system-level performance objectives of Evolutionary Game Theory models

Format : Talk at Waseda University
Author(s) : Alexander Vladimirsky (Cornell University)
Abstract : Evolutionary Game Theory models time-dependent competitions of "types" or "strategies" in a population. EGT can be used to model the natural selection in biological systems or evolving behavioral patterns among humans. Controlling EGT-models to optimize some system-level performance measures can be accomplished through solving HJ equations. We illustrate this by optimizing drug therapies with an EGT-based model of cancer dynamics. Parts of this talk reflect joint work with Mark Gluzman, MingYi Wang, and Jake Scott.

[02691] Maximizing the probability of desirable outcomes in Hamilton-Jacobi framework

Format : Talk at Waseda University
Author(s) : MingYi Wang (Cornell University)
Abstract : We introduce new tools for robust stochastic control of indefinite-horizon processes. In particular, we maximize the probability of keeping the (random) cumulative cost under any specific threshold. Our approach yields a 2nd-order HJB equation and “threshold-aware” optimal policies recovered for all initial configurations and a range of threshold values. We illustrate this method using examples from drug therapy optimization and sailboat path-planning. Joint work with A. Vladimirsky, J. Scott, and REU students at Cornell University.

[03127] Data assimilation for the eikonal equation on a manifold

Format : Talk at Waseda University
Author(s) : Jerome Fehrenbach (Institut de Mathematiques de Toulouse)Lisl Weynans (University of Bordeaux)
Abstract : We propose a method to determine the source(s) and principal direction of a front propagation on an anisotropic surface, from indirect nonlinear measurements. This model aims at describing the propagation of

electrical waves at the surface of the heart. The framework of variational data assimilation leads to minimize a quadratic cost-function on a manifold. The Gauus-Newton algorithm is implemented using the Exp_x map on this manifold.

[03171] Hamilton-Jacobi equations on graphs with applications to data depth and semi-supervised learning

Format : Talk at Waseda University
Author(s) : Jeff Calder (University of Minnesota)Mahmood Ettehad (Institute for Mathematics and its Applications (IMA))
Abstract : Shortest path graph distances are widely used in data science and machine learning, however, they can be highly sensitive to corruption in graph structures. In this talk we study a family of Hamilton-Jacobi equations on graphs called the p-eikonal equation. We show that p=1 is a provably robust distance-type function on a graph and converges in the continuum limit to a geodesic density weighted distance function. We present applications to data depth and semi-supervised learning.

00941 (2/4) : 3E @F402 [Chair: Hasnaa Zidani]

[03726] Neural networks for first order HJB equations and application to front propagation with obstacle terms

Format : Talk at Waseda University
Author(s) : Olivier Bokanowski (LJLL, University Paris Cité)Olivier Bokanowski (LJLL, University Paris Cité)Averil Prost (Insa Rouen)Xavier Warin (EDF)
Abstract : We propose deep neural network schemes for Bellman's dynamic programming principlefor some deterministic optimal control problems,corresponding also to some first-order Hamilton-Jacobi-Bellman equations with an obstacle term.We give an error analysis in an average norm, which is new in this deterministic context. We give several academic numerical examples on front propagation problems with obstacles in order to show the relevance of the approach.

[03517] A system of of Hamilton-Jacobi equations characterizing geodesic centroidal tessellations

Format : Talk at Waseda University
Author(s) : Adriano Festa (Politecnico di Torino)
Abstract : We introduce a class of systems of Hamilton-Jacobi equations characterizing geodesic centroidal tessellations, i.e. tessellations of domains with respect to geodesic distances where generators and centroids coincide. Typical examples are given by geodesic centroidal Voronoi tessellations and geodesic centroidal power diagrams.
An appropriate version of the Fast Marching method on unstructured grids allows computing the solution of the Hamilton-Jacobi system and therefore the associated tessellations. We propose various numerical examples to illustrate the features of the technique.

[04710] Tropical and multi-level numerical methods for solving optimal control problems

Format : Talk at Waseda University
Author(s) : Marianne Akian (Inria and CMAP, Ecole polytechnique)Stephane Louis Gaubert (INRIA and CMAP, Ecole polytechnique)Shanqing Liu (CMAP, Ecole polytechnique and Inria)
Abstract : We develop and study several numerical approximations and algorithms for computing the solution of Hamilton-Jacobi partial differential equations satisfied by the value function of deterministic optimal control problems over a finite dimensional space.
These algorithms combine tropical numerical method or fast-marching method, with a multi-level discretization in a neighborhood of the optimal trajectories. For regular problems, the complexity as a function of precision, can be as for a one-dimensional problem.

[04939] Exploiting Hamilton-Jacobi-Bellman equations in the representation and evolution of conservative dynamics.

Format : Online Talk on Zoom
Author(s) : Peter Dower (University of Melbourne)William McEneaney (University of California San Diego)
Abstract : Connections between Hamilton's action principle and optimal control are explored in the representation and evolution of conservative dynamics. By associating these dynamics with a Hamilton-Jacobi-Bellman equation or its characteristic system, dynamic programming and verification results are used to construct a fundamental solution and solve inverse problems. On longer time horizons, where the action is not “least”, analogous developments are shown to follow using a notion of “stationary” control. Various applications are highlighted.

00941 (3/4) : 4C @F402 [Chair: Alexander Vladimirsky]

[03669] Sparse-grid WENO fast sweeping methods for Eikonal equations

Format : Online Talk on Zoom
Author(s) : Zachary Miksis (University of Notre Dame)Yong-Tao Zhang (University of Notre Dame)
Abstract : Fixed-point WENO fast sweeping methods are a class of explicit iterative methods for efficiently solving steady-state hyperbolic PDEs. For multidimensional nonlinear problems such as Eikonal equations, high-order fixed-point WENO fast sweeping methods still require quite a large amount of computational costs. In this talk, I shall present our recent work on applying sparse-grid techniques, an effective approximation tool for multidimensional problems, to fixed-point WENO fast sweeping methods for reducing their computational costs.

[03495] Efficient high frequency wave propagation with small sampling density

Format : Online Talk on Zoom
Author(s) : Songting Luo (Iowa State University)Qing Huo Liu (Duke University)
Abstract : In this talk, we will present a few approaches for simulating high frequency wave propagation with low sampling density. One approach is based on WKBJ approximation, which leads to Hamilton-Jacobi type equations for the phase and amplitude. Such equations will be solved efficiently by well-established schemes and their solutions will be used for building the wave. In order to resolve the difficulty of capturing the caustics in the WKBJ approximation, we will further transform the problem into a fixed-point iteration problem that can be solved by operator-splitting based pseudospectral methods, which leads to another approach. Both approaches have low sampling densities that ensure the efficiency, verified by numerical experiments.

[03786] Data-Driven Learning Method for Optimal Feedback Control

Format : Online Talk on Zoom
Author(s) : Qi Gong (University of California, Santa Cruz)
Abstract : Computing optimal feedback controls for nonlinear systems generally requires solving Hamilton-Jacobi-Bellman (HJB) equations, which, in high dimensions, is a well-known challenging problem due to the curse of dimensionality. In this talk, we present a model-based data-driven method to approximate solutions to HJB equations for high dimensional nonlinear systems. To accomplish this, we model solutions to HJB equations with neural networks trained on data generated without any state space discretization. Training is made more effective and efficient by leveraging the known physics of the problem and generating training data in an adaptive fashion. We further develop different neural networks approximation structures to improve robustness during learning and enhance closed-loop stability of the learned controller.

[03577] Leveraging Multi-time Hamilton-Jacobi PDEs for Certain Scientific Machine Learning Problems

Format : Online Talk on Zoom
Author(s) : Jerome Darbon (Brown University)Paula Chen (Brown University)Tingwei Meng (UCLA)Zongren Zou (Brown University)George Em Karniadakis (Brown University)
Abstract : We establish a novel theoretical connection between specific optimization problems arising in machine learning and the multi-time Hopf formula, which corresponds to a representation of the solution to certain multi-time HJ PDEs. Through this connection, we increase the interpretability of the training process of certain machine learning applications by showing that when we solve these learning problems, we also solve a multi-time HJ PDE and, by extension, its corresponding optimal control problem.

00941 (4/4) : 4D @F402

[00949] Optimal and Efficient Algorithms for Inverse Problems

Session Time & Room :

00949 (1/2) : 5C (Aug.25, 13:20-15:00) @E505

00949 (2/2) : 5D (Aug.25, 15:30-17:10) @E505

Type : Proposal of Minisymposium
Abstract : This minisymposium aims at bringing researchers to share their recent progress and to inspire new ideas in the solution of inverse problems and its applications. Talks will address modeling, and theoretical and computational aspects of numerical methods for solving inverse problems.
Organizer(s) : Malena Espanol, Rosemary Renaut

[05576] Geometric Scattering on Measure Spaces

Format : Online Talk on Zoom
Author(s) : Michael Perlmutter (Boise State University)
Abstract : Geometric Deep Learning is an emerging field of research that aims to extend the success of machine learning and, in particular, convolutional neural networks, to data with non-Euclidean geometric structure such as graphs and manifolds. Despite being in its relative infancy, this field has already found great success and is utilized by, e.g., Google Maps and Amazon's recommender systems. In order to improve our understanding of the networks used in this new field, several works have proposed novel versions of the scattering transform, a wavelet-based model of neural networks for graphs, manifolds, and more general measure spaces. In a similar spirit to the original scattering transform, which was designed for Euclidean data such as images, these geometric scattering transforms provide a mathematically rigorous framework for understanding the stability and invariance of the networks used in geometric deep learning. Additionally, they also have many interesting applications such as the analysis of single-cell data

[02094] Variable Projection Methods for Solving Separable Nonlinear Inverse Problems

Format : Talk at Waseda University
Author(s) : Malena Espanol (Arizona State University)
Abstract : Variable projection methods are among the classical and efficient methods to solve separable nonlinear least squares problems. In this talk, I will introduce the variable projection method and its use to solve large-scale blind deconvolution problems.

[03302] Doubly Noisy Kaczmarz

Format : Talk at Waseda University
Author(s) : Anna Ma (UC Irvine)ELHoucine Bergou (Mohamed VI Polytechnic University (UM6P))Aritra Dutta (University of Southern Denmark)Soumia Boucherouite (Mohamed VI Polytechnic University (UM6P))Xin Li (University of Central Florida)
Abstract : Large-scale linear systems, Ax=b, frequently arise in inverse problems. Often, these systems are noisy due to operational errors or faulty data-collection processes. In the past decade, the randomized Kaczmarz algorithm (RK) was studied extensively as an efficient iterative solver for such systems. However, the convergence study of RKA in the noisy regime is limited and considers measurement noise in the right-hand side vector, b. Unfortunately, in practice, that is not always the case; the coefficient matrix A can also be noisy. In this talk, we motivate and discuss the application of RK to doubly noise linear systems, i.e., linear systems with noise in both

the measurements and the measurement matrix. The presented work is a joint collaboration with El Houcine Bergou, Soumia Boucherouite, Aritra Dutta, and Xin Li.

[02096] Geometric Scattering on Measure Spaces

Format : Online Talk on Zoom
Author(s) : Michael Perlmutter (UCLA)
Abstract : Geometric Deep Learning is an emerging field of research that aims to extend the success of machine learning and, in particular, convolutional neural networks, to data with non-Euclidean geometric structure such as graphs and manifolds. Despite being in its relative infancy, this field has already found great success and is utilized by, e.g., Google Maps and Amazon's recommender systems.

In order to improve our understanding of the networks used in this new field, several works have proposed novel versions of the scattering transform, a wavelet-based model of neural networks for graphs, manifolds, and more general measure spaces. In a similar spirit to the original scattering transform, which was designed for Euclidean data such as images, these geometric scattering transforms provide a mathematically rigorous framework for understanding the stability and invariance of the networks used in geometric deep learning. Additionally, they also have many interesting applications such as the analysis of single-cell data

00949 (2/2) : 5D @E505 [Chair: Malena Espanol]

[03055] Conditional sampling via block-triangular transport maps

Format : Talk at Waseda University
Author(s) : Ricardo Baptista (California Institute of Technology)Nikola Kovachki (NVIDIA)Bamdad Hosseini (University of Washington)Youssef Marzouk (MIT)
Abstract : We present an optimal transport framework for conditional sampling of probability measures. Conditional sampling is a fundamental task of solving Bayesian inverse problems and generative modeling. Optimal transport provides a flexible methodology to sample target distributions appearing in these problems by constructing a deterministic coupling that maps samples from a reference distribution (e.g., a standard Gaussian) to the desired target. To extend these tools for conditional sampling, we first develop the theoretical foundations of block triangular transport in a Banach space setting by drawing connections between monotone triangular maps and optimal transport. To learn these block triangular maps, we will then present a computational approach, called monotone generative adversarial networks (MGANs). Our algorithm uses only samples from the underlying joint probability measure and is hence likelihood-free, making it applicable to inverse problems where likelihood evaluations are inaccessible or computationally prohibitive. We will demonstrate the accuracy of MGAN for sampling the posterior distribution in Bayesian inverse problems involving ordinary and partial differential equations, and probabilistic image in-painting.

[02631] Efficient importance sampling for Bayesian inverse problems using tensor-trains

Format : Talk at Waseda University
Author(s) : Tiangang Cui (Monash University)Sergey Dolgov (University of Bath)Robert Scheichl (Heidelberg University)
Abstract : We propose an efficient importance sampling method for rare events in high-dimensional problems, by approximating the optimal importance distribution in a scalable way as the pushforward of a reference distribution under composition of order-preserving transformations based on tensor-train decompositions. By designing a ratio estimator that estimates the normalizing constant using a separate importance distribution, it applies also to Bayesian inverse problems. The efficiency and robustness are demonstrated numerically on high-dimensional problems constrained by differential equations.

[02317] On structured linear measurements for tensor data recovery

Format : Talk at Waseda University
Author(s) : Elizaveta Rebrova (Princeton University)
Abstract : Data-oblivious measurements present an important branch of low-rank data compression and recovery techniques, frequently used in streaming settings and within iterative algorithms. Typically, linear data-oblivious measurements involve some version of a random sketch that preserves the geometric properties of the data. When data is tensorial, a special challenge is to create a sketch with a structure that reflects tensor structure: this way, it can work similarly to a dense random sketch matrix but require much less memory to store and can be applied more efficiently. I will talk about our and others -- including Tropp, Udell et al, De Lathauwer et al -- recently

proposed streaming sketch-based approaches for computing low-rank Tucker approximations of large tensors. I will discuss our new generalized theoretical guarantees for proving their accuracy on full-rank and noisy data with high probability from a wide range of measurements.

[00951] Steps Toward Robust and Stable Artificial Intelligence

Session Time & Room :

00951 (1/2) : 3E (Aug.23, 17:40-19:20) @E818

00951 (2/2) : 4C (Aug.24, 13:20-15:00) @E818

Type : Proposal of Minisymposium
Abstract : Despite significant recent technological advances in Artificial Intelligence (AI), AI systems sometimes make errors and will continue making errors in the future, from time to time. AI errors are usually unexpected; sometimes they are also malicious with the potential to result in dramatic and tragic consequences.

Handling and understanding abstract properties of these errors and developing methods of defence against various attacks and instabilities in modern large-scale high-dimensional AI operating in high-dimensional non-stationary world requires appropriate mathematical methods and techniques. This mini-symposium focuses on discussing relevant mathematical machinery for the analysis and verification of AI robustness and stability.

[03569] Adversarial Ink: Componentwise Backward Error Attacks on Deep Learning

Format : Online Talk on Zoom
Author(s) : Des Higham (University of Edinburgh)Lucas Beerens (University of Edinburgh)
Abstract : Deep neural networks are capable of state-of-the-art performance in many classification tasks. However, they are known to be vulnerable to adversarial attacks---small perturbations to the input that lead to a change in classification. We address this issue from the perspective of backward error and condition number, concepts that have proved useful in numerical analysis. To do this, we build on the work of Beuzeville et al. (2021). In particular, we develop a new class of attack algorithms that use component-wise relative perturbations. Such attacks are highly relevant in the case of handwritten documents or printed texts where, for example, the classification of signatures, postcodes, dates or numerical quantities may be altered by changing only the ink consistency and not the background. This makes the perturbed images look natural to the naked eye. Such "adversarial ink" attacks therefore reveal a weakness that can have a serious impact on safety and security. We illustrate the new attacks on real data and contrast them with existing algorithms. We also study the use of a componentwise condition number to quantify vulnerability.

[05048] On the extended Smale’s 9th problem, phase transitions in optimisation and the limits of AI

Format : Talk at Waseda University
Author(s) : Alexander James Bastounis (Leicester University)
Abstract : Instability is the Achilles’ heel of AI and a paradox, with typical training algorithms unable to recover stable neural networks (NNs). Hence the fundamental question: can one find algorithms that compute stable and accurate NNs? If not, what are the foundational barriers we encounter across machine learning? These questions are linked to recent results on the extended Smale’s 9th problem, which uncovers new phase transitions in optimisation and yields barriers on the computation of NNs.

[04061] Intrinsic dimensionality of real-life datasets in biomedicine and drug discovery

Format : Online Talk on Zoom
Author(s) : Andrey Zinovyev (Evotec)
Abstract : Intrinsic dimensionality (ID) is the most essential characteristic of a multidimensional data point cloud which determines the reliability and stability of the application of all machine learning methods. We provide a toolbox for estimating ID, and we benchmark it using several hundreds of real-life datasets. We demonstrate how data ID affects the results of applying deep classifiers and generative data models in biomedicine and drug discovery domains that allow the user to judge the prediction robustness.

[05037] Generalised hardness of approximation and hallucinations -- On barriers and paradoxes in AI for image reconstruction

Format : Online Talk on Zoom
Author(s) : Anders Hansen (University of Cambridge)
Abstract : AI techniques are transforming medical imaging with striking performance. However, these new methods are susceptible to AI generated hallucinations, the phenomenon where realistically looking artefacts are incorrectly added to the reconstructed image, causing serious concerns in the sciences. The basic question is therefore: can hallucinations be prevented? This question turns out to be linked to a newly discovered phenomenon in the foundations of computational mathematics: generalised hardness of approximation, demonstrating methodological barriers in AI.

00951 (2/2) : 4C @E818 [Chair: Alexander Bastounis]

[03891] Stochastic Separation Theorems for making AI Safe, Adaptive, and Robust

Format : Talk at Waseda University
Author(s) : Ivan Y Tyukin (King's College London)Alexander N Gorban (University of Leicester)
Abstract : In this talk we discuss the issues around stability and robustness of modern AI systems to data and structure perturbations. We show that determining robust generalisation may involve computational costs which are exponential in the dimension of AI feature spaces. As a potential way to mitigate the issue we discuss a set of results, termed stochastic separation theorems, which could be used to efficiently “patch” instances of instabilities as soon as they are identified.

[05438] Advancements in Autodiff

Format : Talk at Waseda University
Author(s) : Elizabeth Cristina Ramirez (Columbia University)
Abstract : The reliance of backpropagation and other gradient-based algorithms on derivative calculations is well-known. Automatic differentiation, a powerful computational tool that often remains overlooked, allows for the efficient computation of gradients, surpassing the limitations of numerical differentiation. In this presentation, we aim to provide a concise overview of the inner workings of autodiff, as implemented in frameworks like TensorFlow, PyTorch, and JAX. Moreover, we will shed light on recent developments that enhance stability and expedite convergence.

[00952] Numerical methods for emerging flow problems in geosciences

Session Time & Room :

00952 (1/2) : 1C (Aug.21, 13:20-15:00) @E702

00952 (2/2) : 1D (Aug.21, 15:30-17:10) @E702

Type : Proposal of Minisymposium

Abstract : In recent years, various flow problems have emerged in geosciences, and they demand development in numerical methods to meet scientific research and industry application needs. Such problems are generally multiscale and multiphysics; they involve various phenomena at different spatial and temporal scales, and our capabilities to simulate the problems remain limited. An example problem is the 2010 Gulf of Mexico oil spill that started from a small-scale effluent jet at the bottom of the ocean and then migrated to water surfaces as floating film patches with huge horizontal sizes. These problems are beyond the reach of conventional approaches, and their simulation is challenging, and new methods have to be developed. This symposium provides researchers with a platform to present their algorithms and simulations for these flow problems, including porous media flows, atmosphere flows, ocean flows, ocean ecosystems, etc. The presenters will discuss encountered difficulties, possible approaches, and future directions. The symposium contains presentations on computational methods and simulation of actual industry problems.

Organizer(s) : Jose E. Castillo, Hansong Tang, Anne-Claire Bennis

[03640] Non-stationary probabilistic tsunami hazard assessments incorporating the influence of tides and sea level rise

Format : Online Talk on Zoom

Author(s) : Ignacio Sepulveda (San Diego State University)

Abstract : Tides are often the largest source of sea levels fluctuations. Two probabilistic-tsunami-hazard-assessments (PTHA) methods are proposed to combine the tidal-phase uncertainty with other tsunami uncertainties. The first method adopts a Stochastic-Reduced Order-Model (SROM) producing sets of tidal phase samples to be used in tsunami simulations. The second method uses tsunami simulations with prescribed collocation-tidal-phases and probability distributions to model the uncertainty. The methods are extended to non-stationary-probabilistic-tsunami-hazard-assessments (nPTHA), combining tsunamis, tides and sea level rise.

[02149] A hybrid numerical method for dispersive multiphase porous media flows

Format : Online Talk on Zoom

Author(s) : Prabir Daripa (Texas A&M University, College Station)

Abstract : We discuss a recently developed model of multiphase multicomponent porous media flows in the context of shear-thinning polymer flooding. This model is based on Darcy’s law, Buckley-Leverett equations and shear-thinning constitutive laws. A multiscale hybrid numerical method based on a combination of discontinuous finite element method, modified method of characteristics, and data driven strategies is developed to solve this model. We study effects of dispersion and shear-thinning on the advective transport of constituents like polymers.

[01968] Ocean canyon dynamics modeled using Mimetic Curvilinear Coastal Ocean Model

Format : Talk at Waseda University

Author(s) : Jared Brzenski (San Diego State University)

Abstract : A 3D case study for Monterey Bay, CA, is performed to validate and demonstrate the capabilities of the Mimetic Coastal Ocean Model (MCCOM) model for simulating non-hydrostatic flows. The MCCOM model can resolve features such as stratified flows, internal bore formation, and strongly nonlinear internal wave processes inside the steep bathymetry of the Monterey Canyon system by implementing the model on a fully 3D curvilinear mesh.

[01610] Hierarchical models for the numerical simulation of shallow water flows

Format : Talk at Waseda University

Author(s) : Julian Koellermeier (University of Groningen)

Abstract : We introduce hierarchical moment models as a flexible way to derive hierarchies of models for shallow flows. The new hierarchical models are based on an expansion of the velocity profile. The equations for the expansion coefficients constitute an hierarchical system. We will exemplify the hierarchical models for 1D and 2D

application cases including their analysis and the extension to complex fluids. We highlight runtime and accuracy improvements with respect to standard shallow water equations.

00952 (2/2) : 1D @E702 [Chair: Jose E. Castillo]

[02375] A stability solver for nonlinear mountain waves

Format : Talk at Waseda University
Author(s) : Craig Epifanio (Texas A&M University)Prabir Daripa (Texas A&M University)Kevin Viner (Naval Research Lab, Monterey)
Abstract : One of the primary sources of clear-air turbulence in the atmosphere is the breaking of internal gravity waves forced by topography, otherwise known as mountain waves. In the present work, the linear stability of nonlinear mountain waves is considered through the application of a steady-state Newton solver combined with a discretized large eigenvalue problem. The results show that mountain waves are subject to instability over a broader range of parameters than previously considered.

[02890] Coupling numerical solutions of NS and GFD equations for ocean flows

Format : Talk at Waseda University
Author(s) : Hansong Tang (City College of New York)
Abstract : This talk discusses the integration of a solver of the Navier Stokes (NS) equations and a solver for the geophysical fluid dynamics (GFD) equations. In the integrated system, the NS solver is applied to local, fully 3D flow phenomena, and the GFD solver is adopted to simulate the background ocean flows. We will discuss the coupling methods and numerical experiments. The presentation will also discuss the difficulties and topics of future study.

[02177] A machine learning approach to phytoplankton productivity across the GoM

Format : Talk at Waseda University
Author(s) : Bailey Armos (Texas A&M University)Shuang Zhang (Texas A&M University)Prabir Daripa (Texas A&M University)
Abstract : Although the hypoxia and algal bloom events seen within the Gulf of Mexico (GoM) have been largely linked to nitrogen loading from the Mississippi River, the nutrient inputs from smaller have been largely unexplored. In this study, we built machine learning models from coupled river-ocean data to better understand and quantify the chlorophyll content on multiple timescales in different regions of the GoM. Our study will help mitigation strategies in a changing coastal environment.

[00955] Incorporating Immune System and Heterogeneous Dynamics into Infectious Disease Modeling

Session Time & Room :

00955 (1/3) : 3E (Aug.23, 17:40-19:20) @A512

00955 (2/3) : 4C (Aug.24, 13:20-15:00) @A512

00955 (3/3) : 4D (Aug.24, 15:30-17:10) @A512

Type : Proposal of Minisymposium
Abstract : Pathogen interactions with immune systems are dynamic. Modeling these nonlinear interactions has traditionally been a separate endeavor from modeling disease spread in a population. In
the current environment of accelerating zoonotic spillovers, in which increasing numbers of pathogens are adapting to new hosts, habitats that include within-host innate and adaptive immune
systems, as well as sequence-level data, should not be ignored. We bring together a diverse group of researchers to

address the resulting multilevel modeling challenges. The three sessions in this minisymposium will focus on:

1. vector-borne pathogens
2. Any Pathogen Transmission Mode
3. air- and water-borne pathogens

Organizer(s) : Julie Allison Spencer, Fabio Milner, Joel C. Miller
Classification : 92-10, Mathematical modeling or simulation for problems pertaining to biology
Minisymposium Program :

[04516] Modelling vector-borne disease dynamics and the impact of new interventions

Format : Online Talk on Zoom
Author(s) : Ilaria Dorigatti (Imperial College London)
Abstract : In this seminar, I will present recent modelling studies developed to analyse the transmission dynamics of vector-borne diseases and to quantify the efficacy of a new dengue antiviral drug (JNJ-1802) from in-vitro and in-vivo experiments and a dengue vaccine candidate (TAK-003) using phase-3 clinical trial data. These models can help assess the population-level impact of novel control interventions across transmission settings. I will discuss current challenges as well as opportunities.

[04353] Hierarchical model of West Nile virus incorporating spatio-temporal environmental effects

Format : Talk at Waseda University
Author(s) : Laura Albrecht (Colorado School of Mines)
Abstract : West Nile virus is primarily transmitted between mosquitoes and birds, with humans as incidental hosts. Climate change may increase the risk of human infections as climatic variables have been shown to accelerate mosquito development, biting rates, and the incubation period of the disease. We developed a spatio-temporal hierarchical SEIR model that incorporates environmental covariates related to climate change. We use a Bayesian paradigm to fit our model and to predict human cases.

[04123] How genomic data can inform contact patterns in epidemiological models

Format : Talk at Waseda University
Author(s) : Julie Allison Spencer (Los Alamos National Laboratory)Emma Goldberg (Los Alamos National Laboratory)Sara Del Valle (Los Alamos National Laboratory)
Abstract : Infectious diseases threaten global health, as illustrated by the COVID-19 pandemic. Population-level models have been essential for understanding and anticipating impacts, but their ability to forecast outcomes accurately has been limited due to the rapid evolution of viruses and limited availability of parameters. Using sequenced SARS-CoV-2 genomes with associated age metadata, we inferred phylogenetic trees and used a birth-death branching model to understand the role of heterogeneous age structure on transmission pathways.

[05574] Capturing heterogeneity: Differential effects of temperature on Culex mosquito vectors

Format : Talk at Waseda University
Author(s) : Sarah Moser (Los Alamos National Laboratory)
Abstract : Culex spp. mosquitoes are the primary transmission vectors for West Nile virus (WNV) worldwide. The differential effects of temperature on mosquito range, distribution, and abundance pose challenges for disease forecasting and mitigation. Current models often assume a single vector species; through our scoping review on thermal response for Culex mosquito life history traits, we show the need to implement real-world species heterogeneity and present a useful data resource for modelers.

00955 (2/3) : 4C @A512 [Chair: Fabio Augusto Milner]

[04150] Immunological variables as structure variables of epidemic models

Format : Talk at Waseda University
Author(s) : Fabio Augusto Milner (Arizona State University)
Abstract : We present some ways to structure epidemic models with infection and immune response as structure variables. The infected class is modeled using a divergence-form partial differential equation with the boundary conditions incorporating the new infections. Some theoretical results are derived, as well as some examples form HIV-infection. Open theoretical and numerical problems will be described.

[01323] Approximations and parameter inference of stochastic models in infectious disease epidemiology

Format : Online Talk on Zoom
Author(s) : Wasiur KhudaBukhsh (University of Nottingham)
Abstract : In this talk, we will consider stochastic compartmental models in infectious disease epidemiology. We will discuss when the stochastic models agree with their deterministic counterparts in some limiting regimes and when one stochastic model can be approximated in some precise mathematical sense by another. We will also consider the problem of parameter inference of such systems using notions of dynamical survival analysis (DSA).

[04927] Intelligent immunity: wet labs, fat data, and machine learning

Format : Online Talk on Zoom
Author(s) : Kaitlyn Martinez (Los Alamos National Laboratory)
Abstract : Developing a universal diagnostic is a long standing challenge. However, the human immune system is able to distinguish pathogens and mounts response quickly, perhaps acting as a guide for design of improved, more general diagnostic development. In collaboration with lab scientists, we use data from hundreds of experiments along with both machine learning and mechanistic models to show the potential for determining the presence of bacteria from markers of a human immune response.

[03423] Why do most sexually transmitted infections not produce long-term immunity?

Format : Talk at Waseda University
Author(s) : Joel C Miller (La Trobe University)
Abstract : Diseases that are classified as "Susceptible-Infected-Recovered" (SIR) are unable to reinfect previously infected individuals. In small communities outbreaks are short-term and the disease is unable to persist. Long-term persistance of an SIR disease requires a large community or many connected small communities, so that new births replenish the susceptible community. The spread of sexually transmitted infections is heavily influenced by the significant heterogeneity of contact rates within the population. We will show that this increases the required "critical community size" for an SIR infection to persist in sexual transmission networks.

00955 (3/3) : 4D @A512 [Chair: Sara Del Valle]

[04157] Basic concepts for the Kermack and McKendrick model with individual heterogeneity

Format : Talk at Waseda University
Author(s) : Hisashi Inaba (Tokyo Gakugei University)
Abstract : The main purpose of my talk is to provide a mathematical basis for the recent arguments and calculations triggered by COVID-19 based on the heterogeneous Kermack-McKendrick model. The basic epidemiological concepts such as basic reproduction number, effective reproduction number, herd immunity threshold and final size are rigorously formulated based on the Kermack-McKendrick model with individual heterogeneity. Furthermore, we discuss a systematic recipe to reduce the infinite-dimensional system to the finite-dimensional ODE system.

[04524] Statistical analysis of global COVID-19 wave dynamics

Format : Talk at Waseda University
Author(s) : Jessica Stockdale (Simon Fraser University)
Abstract : Different countries around the world experienced vastly different COVID-19 pandemics, and in many cases the complex interplay of driving forces behind this remain unclear. Patterns of hybrid and partial immunity affect the ability of new variants to invade, and therefore must be understood to build insightful predictive models. I will present our work in statistically modelling the relative influence of immunity, demographic, social, and other factors on the size and timing of variant-driven COVID-19 waves.

[03113] Will cross-immunity protect the community from COVID-19 variants?

Format : Online Talk on Zoom
Author(s) : Marina Mancuso (Arizona State University)Steffen Eikenberry (Arizona State University)Abba Gumel (University of Maryland, College Park)
Abstract : The emergence of SARS-COV-2 variants threaten the efficacy of COVID-19 vaccines. Not only can variants be potentially more infectious than the wild-type strain, but they may also partially evade existing vaccines. A two-strain, two-group mechanistic mathematical model is designed to assess the impact of vaccine-induced, cross-protective efficacy of COVID-19 transmission in the United States. We present conditions for achieving vaccine-derived herd immunity and results from global sensitivity analysis under different transmissibility and cross-protection scenarios.

[04936] SARS-CoV-2 variant transition dynamics are associated with vaccination rates, number of co-circulating variants, and convalescent immunity

Format : Talk at Waseda University
Author(s) : Sara Del Valle (Los Alamos National Laboratory)
Abstract : I will discuss a retrospective analysis that characterized differences in the speed, timing, and magnitude of 16 SARS-CoV-2 variant waves/transitions for 230 regions, between October 2020 and January 2023. Our results show associations between the behavior of an emerging variant and the number of co-circulating variants as well as demographics and vaccination rates. These results suggest the behavior of a variant may be sensitive to the immunologic and demographic context of its location.

[00957] Mathematics of thin structures

Session Time & Room :

00957 (1/2) : 1C (Aug.21, 13:20-15:00) @G802

00957 (2/2) : 1D (Aug.21, 15:30-17:10) @G802

Type : Proposal of Minisymposium
Abstract : Many models in mechanics, physics and biology invoke thin structures and physical processes therein. With this minisymposium we intend to bring together mathematicians working on the modeling, mathematical analysis and numerics of such models. Topics of particular interest include variational models for mechanical thin films and rods, e.g., featuring wrinkling, prestrain, microstructure, disclocations and their numerical treatment.
Organizer(s) : Patrick Dondl, Stefan Neukamm
Classification : 35Qxx, 74B20

00957 (1/2) : 1C @G802 [Chair: Stefan Neukamm]

[04690] A simple numerical approach for elastic rods

Format : Talk at Waseda University
Author(s) : Patrick Dondl (Albert-Ludwig-University Freiburg)
Abstract : We derive a discrete version of the Kirchhoff elastic energy for rods undergoing bending and torsion and prove Gamma-convergence to the continuous model. This discrete energy is given by the bending and torsion energy of an interpolating conforming polynomial curve and provides a simple formula for the bending energy depending in each discrete segment only on angle and adjacent edge lengths. For the liminf-inequality, we need to introduce penalty terms to ensure arc length parametrization in the limit. For the recovery sequence a discretization with equal euclidean distance between consecutive points is constructed. Particular care is taken to treat the interaction between bending and torsion by employing a discrete version of the Bishop frame. To obtain a local description of the energy without any restrictions on a reference configuration we employ a variant of parallel transport where the singularity for antiparallel directions of current and reference configuration is removed.

[04525] A homogenized bending theory for prestrained plates

Format : Talk at Waseda University
Author(s) : Klaus Böhnlein (TU Dresden)Stefan Neukamm (TU Dresden)David Padilla-Garza (TU Dresden)Oliver Sander (TU Dresden)
Abstract : Nonlinear plate theory described the energy of an incompressible and inextensible thin elastic sheet. In this work, we show a general rigorous derivation of a generalization of such a model for non-euclidean plates with microheterogeneous structures. We also analyze the limiting energy in some examples and discover interesting and counter-intuitive phenomena.

[01825] Variational Modeling of Stress-Driven Rearrangement Instabilities

Format : Talk at Waseda University
Author(s) : Paolo Piovano (Politecnico di Milano)
Abstract : Variational models in the context of the theory of stress-driven rearrangement instabilities are considered to describe the morphology of crystalline materials under stress due to the interaction with other adjacent materials. The existence and regularity of energy minimizers is discussed in various settings, from two to higher dimensions, and in the framework of a two-phase free-boundary problem by letting free also the contact interface with the other materials, both in its coherent and incoherent portions.

00957 (2/2) : 1D @G802 [Chair: Patrick Dondl]

[04480] Numerical approximation of the deformation of thin plates

Format : Talk at Waseda University
Author(s) : Andrea Bonito (Texas A&M University)Diane Guignard (University of Ottawa)Angelique Morvant (Texas A&M University)Ricardo H Nochetto (University of Maryland)Shuo Yang (Yanqi Lake Beijing Institute of Mathematical Sciences and Applications)
Abstract : We study the elastic behavior of prestrained and bilayer plates which can undergo large deformations and achieve nontrivial equilibrium shapes. The mathematical model consists of a fourth order minimization problem subject to a nonlinear and nonconvex metric constraint. We introduce a numerical method based on discontinuous Galerkin finite elements for the space discretization and a discrete gradient flow for the energy minimization. We discuss the properties of the method and present several insightful numerical experiments.

[01792] A reduced model for plates arising as low energy Gamma-limit in nonlinear magnetoelasticity

Format : Talk at Waseda University
Author(s) : Marco Bresciani (University of Erlangen)Martin Kruzik (Czech Academy of Sciences)
Abstract : We investigate the problem of dimension reduction for plates in nonlinear magnetoelasticity. The model features a mixed Eulerian-Lagrangian formulation, as magnetizations are defined on the deformed set in the actual space.
We consider low-energy configurations by rescaling the elastic energy according to the linearized von Kármán regime.
First, we identify a reduced model by computing the Γ-limit of the magnetoelastic energy, as the thickness of the plate goes to zero. Then, we introduce applied loads given by mechanical forces and external magnetic fields and we prove that, under clamped boundary conditions, sequences of almost minimizers of the total energy converge to

minimizers of the corresponding energy in the reduced model.
Subsequently, we study quasistatic evolutions driven by time-dependent applied loads and a rate-independent dissipation. We prove that energetic solutions for the bulk model converge to energetic solutions for the reduced model and we establish a similar result for solutions of the approximate incremental minimization problem. Both these results provide a further justification of the reduced model in the spirit of the evolutionary Γ-convergence.

[04118] A novel dimensional reduction for the equilibrium study of inextensional material surfaces Author links open overlay panel

Format : Talk at Waseda University
Author(s) : Eliot Fried (Okinawa Institute of Science and Technology)Yi-Caho Chen (University of Houston)Roger Fosdick (University of Minnesota)
Abstract : A general framework is developed for finding the equations describing the equilibrium of an inextensional material surface with arbitrary flat reference shape that is deformed by applying tractions or moments to its edge. Euler--Lagrange equations are derived, leading to a complete and definitive set of equilibrium equations, which are a system of ordinary-differential equations for the spatial directrix.

[01343] Mesoscale modeling of systems of planar wedge disclinations and edge dislocations

Format : Talk at Waseda University
Author(s) : pierluigi cesana (kyushu university)
Abstract : Planar wedge disclinations are rotational mismatches at the level of the crystal lattice entailing a violation of rotational symmetry. Alongside dislocations, disclinations are observed in classes of Shape-Memory Alloys undergoing the austenite-to-martensite transformation and in crystal plasticity. In this talk, I will describe some recent results on the modeling of planar wedge disclinations and edge dislocations via an energy minimization principle. We model disclinations and dislocations as the solutions to minimum problems for isotropic elastic energies under the constraint of kinematic incompatibility. Our main result is the analysis of the energetic equivalence of systems of disclination dipoles and edge dislocations in the asymptotics of their singular limit regimes. The material of this talk is mainly based on a collaboration with Prof M. Morandotti & L. De Luca https://arxiv.org/abs/2207.02511

[00959] Numerical modeling and analysis in electromagnetic applications

Session Time & Room : 2C (Aug.22, 13:20-15:00) @E701

Type : Proposal of Minisymposium
Abstract : This mini-symposium presents numerical modeling, analysis and simulation using finite element method in the field of electromagnetism at various scales, from analyzing quantum mechanical effects to calculating the scattering of electromagnetic wave in free space. The Schrodinger-Poisson system of equations to calculate electron states in 3D hetero-structure will be discussed. Numerical modeling of display device will be presented and numerical analysis will be explored for microwave circuits. The electromagnetic vector wave scattering problem is solved to analyze the field characteristics in the presence of stealth platform. This mini-symposium also introduces several challenging issues in these applications and proposes their solutions.
Organizer(s) : Eunjung Lee
Classification : 65N30, 00A71, Numerical Analysis and Simulation
Minisymposium Program :

00959 (1/1) : 2C @E701

[03708] Recent Advances in Finite Element Methods for Electromagnetic Analysis on Integrated Circuits

Author(s) : Woochan Lee (Incheon National University)
Abstract : The finite element method plays a significant role in the electromagnetic analysis of integrated circuits (IC) in electrical engineering. As IC structures constitute a very large-scale problem, the resources required for finite element modeling and analysis increase exponentially, making high-speed electromagnetic analysis an essential factor. This talk reviews recent trends in accelerating electromagnetic analysis, including the fundamental application of time- and frequency-domain finite element methods, high-speed techniques utilizing brick element characteristics, and parallel processing techniques.

[03728] Forced field continuity condition of object interface for the vector wave equation

Author(s) : Hyesun Na (Yonsei University)
Abstract : Electromagnetic wave scattering problem is considered when perfect electric conductor is coated with several dielectric layers. Solving the scattering problem using finite element method requires huge number of degrees of freedom. Insufficient degrees of freedom may not be able to capture the information about abrupt changes in the interface. This work proposes to force a field continuity condition on the functional to overcome the difficulty.

[03748] A three-dimensional NEGF development using finite element method in the presence of heterogeneous quantum dots

Author(s) : URANCHIMEG DORLIGJAV (Yonsei university)
Abstract : In this work, we propose an algorithm to calculate electron density and space charge effect in 3D nanoscale device containing heterogeneous quantum dots. We begin by formulating the nonequilibrium Green’s function (NEGF) approach to calculate electron density and apply a nonlinear solver for Poisson equation using the finite element method.

[04959] A Moving Mesh Method for Nano-Rod Electro-Osmosis

Author(s) : Richard James (Samsung Display)Jahoon Koo (Samsung Display)Sunyoung Oh (Samsung Display)Hyunguk Cho (Samsung Display)Sung-Chan Jo (Samsung Display)
Abstract : Modelling the hydrodynamics of charged colloids within ionic fluids is a challenging multi-physics problem. Rigid body particle motion is resisted by drag due to the viscosity of the fluid. Furthermore, ionic impurities give rise to electrical-double layers that can in turn induce flow of the solvent. In this paper, a moving mesh method for nano-rod electro-osmosis is introduced and applied to analyse particle trajectories in response to external electric fields.

[00960] Hierarchical Low Rank Tensors and DNNs for High-dimensional Approximation

Session Time & Room :

00960 (1/3) : 3C (Aug.23, 13:20-15:00) @E506

00960 (2/3) : 3D (Aug.23, 15:30-17:10) @E506

00960 (3/3) : 3E (Aug.23, 17:40-19:20) @E506

Type : Proposal of Minisymposium
Abstract : The minisymposium aims at bridging the gap between low rank tensors and neural networks for learning
of high-dimensional functions, in particular in the context of uncertainty quantification.
The talks will highlight different aspects ranging from approximation to optimization.

The underlying motivation is to understand strengths and difficulties of network based representations and to identify structures and techniques that can be combined beneficially.
Organizer(s) : Martin Eigel, Lars Grasedyck

Minisymposium Program :

00960 (1/3) : 3C @E506 [Chair: Lars Grasedyck]

[04419] Low-rank tensor approximation of high-dimensional functions

Format : Talk at Waseda University
Author(s) : Helmut Harbrecht (University of Basel)Michael Griebel (University of Bonn)Reinhold Schneider (Technical University of Berlin)
Abstract : In this talk, we analyze tensor approximation schemes for high-dimensional functions in the continuous setting. To this end, we assume that the function to be approximated lies either in an isotropic Sobolev space or an anisotropic Sobolev space. We apply successively the truncated singular value decomposition in order to discuss the cost when approximating the
function under consideration in the continuous analogues of tensor formats such as the Tucker tensor format or the tensor
train format.

[03995] Parameter-dependent multigrid method using low-rank tensor formats

Format : Talk at Waseda University
Author(s) : Tim Andreas Werthmann (RWTH Aachen University)Lars Grasedyck (RWTH Aachen University)
Abstract : We consider a parameter-dependent linear system motivated by a diffusion problem.
The combination of all finitely many parameters leads to an exponential scaling of the computational effort in the number of parameters, the so-called curse of dimensionality.
To break this curse, we use low-rank tensor formats to represent this system.
We introduce the parameter-dependent multigrid method to solve such a high-dimensional system within low-rank tensor formats.

[04205] Alternating nonnegative factorizations for low-rank tensor formats

Format : Talk at Waseda University
Author(s) : Maren Klever (RWTH Aaachen University)Lars Grasedyck (RWTH Aachen)Sebastian Kraemer (RWTH Aachen University)
Abstract : Low-rank tensor formats allow for efficient handling of high-dimensional objects.
If the quantity of interest is nonnegative, we want to preserve this property by constraining all cores to be nonnegative.
Common alternating strategies reduce the high-dimensional problem to a sequence of low-dimensional subproblems, but often suffer from slow convergence and persistence in local minima.
To reduce these inconveniences, we propose a new quasi-orthogonalization strategy as an intermediate step between the alternating minimization steps that preserves nonnegativity.

[04392] Tensor surrogates for sensitivity analysis in the presence of polymorphic uncertainties

Format : Talk at Waseda University
Author(s) : Dieter Moser (RWTH Aachen University)
Abstract : Sensitivity analysis identifies the input parameters that have the greatest influence on model output. However, when input parameters are polymorphic, meaning that epistemic and aleatory uncertainty is present, traditional sensitivity analysis methods based on probabilistic modelling of the uncertainty have to be adapted.
A measurement of distances between polymorphic uncertainties is needed to measure the effect of the input parameters. In this talk, we will discuss how hierarchical tensor surrogates are beneficial for such an adapted sensitivity analysis.

00960 (2/3) : 3D @E506 [Chair: Martin Eigel]

[02980] Weighted sparse and low-rank least squares approximation

Format : Talk at Waseda University
Author(s) : Philipp Trunschke (Nantes Université)Martin Eigel (WIAS Berlin)Anthony Nouy (Nantes Université)
Abstract : Many functions of interest exhibit weighted summability of their coefficients with respect to some dictionary of basis functions.
The resulting best n-term approximations can be estimated efficiently from samples.
We propose to encode the coefficients in a simultaneously sparse and low-rank tensor format to improve the efficiency of the algorithms performing this approximation.
Based on a weighted Stechkin lemma and the restricted isometry property, we provide approximation error and sample complexity bounds.

[04007] Iteratively Reweighted Least Squares Recovery on Tensor Networks

Format : Talk at Waseda University
Author(s) : Sebastian Kraemer (RWTH Aachen University)
Abstract : A fundamental approach to tensor recovery traces back to affine rank minimization. We emphasize that the latter problem is always solved via asymptotic minimization of well-known log-det functions, in practice approachable through iteratively reweighted least squares. Additionally to local convergence properties, in numerical experiments, the theoretical phase transition for generic tensor recoverability becomes observable. Alternating optimization on tensor tree networks in turn allows to apply a relaxed method under minimal, polynomial complexity even in high dimensions.

[04663] Empirical Tensor Train Approximation in Optimal Control

Format : Talk at Waseda University
Author(s) : Mathias Oster (TU Berlin)Reinhold Schneider (TU Berlin)
Abstract : We display two approaches to solve finite horizon optimal control problems. First we solve the Bellman equation numerically by employing the Policy Iteration algorithm. Second, we introduce a semiglobal optimal con-
trol problem and use open loop methods on a feedback level. To overcome computational infeasability we use tensor trains and multi-polynomials, together with high-dimensional quadrature, e.g. Monte-Carlo. By controlling a destabilized version of viscous Burgers and a diffusion equation with unstable reaction term numerical evidence is given.

[05144] Dynamical low-rank approximation of Vlasov-Poisson equations on polygonal spatial domains

Format : Talk at Waseda University
Author(s) : Andreas Zeiser (HTW Berlin)André Uschmajew (University of Augsburg)
Abstract : We consider dynamical low-rank approximation (DLRA) for the numerical simulation of Vlasov-Poisson equations based on separation of space and velocity variables, as proposed in several recent works. A less studied aspect is the incorporation of boundary conditions in the DLRA model. We use a variational formulation of the projector splitting which allows to handle inflow boundary conditions on piecewise polygonal spatial domains. Numerical experiments demonstrate the principle feasibility of this approach.

00960 (3/3) : 3E @E506 [Chair: Dieter Moser]

[04645] Using Low-rank Tensor Formats in Neural Networks

Format : Talk at Waseda University
Author(s) : Thong Pham Hoang Le (RWTH Aachen University)Lars Grasedyck (RWTH Aachen)Janina Enrica Schütte (WIAS Berlin)Martin Eigel (WIAS Berlin)
Abstract : We investigate the use of low-rank tensor decompositions to improve the performance of neural network training. Specifically, we propose an approach that utilizes low-rank tensors to discretize the loss function of the neural network, which allows us to explore a larger parameter space than local methods such as Gradient Descent. Our approach could also facilitate improved weight initialization, further enhancing the network's performance.

[03998] Adaptive Multilevel Neural Networks for parametric PDEs with Error Estimation

Format : Talk at Waseda University
Author(s) : Janina Enrica Schütte (WIAS Berlin)Martin Eigel (WIAS)
Abstract : We focus on efficiently solving high dimensional, parameter-dependent partial differential equations. To approximate the parameter-to-solution map, different model classes have been considered, including low-rank tensor representations and neural network architectures.
In our work, a new multilevel neural network architecture is combined with an adaptive scheme including a solver based on a multilevel decomposition, classical reliable finite element error estimators, and a refinement strategy for the considered finite element grids. We show expressivity results and numerical experiments for the derived networks.

[00961] Reinforcement Learning for Financial Modeling

Session Time & Room : 4C (Aug.24, 13:20-15:00) @A208

Type : Proposal of Minisymposium
Abstract : This minisymposium, sponsored by the SIAM activity group in Financial Mathematics, focuses on the development of novel reinforcement learning paradigms for solving problems in financial mathematics. The RL paradigm aims to approximate solutions to stochastic control problems in discrete time in a manner that is agnostic to the dynamics of environment and its response to agents' actions. The collection of talks covers the incorporation of time-consistent risk-measures into RL, provides explicit error bounds on exploratory control, and develops a new approach to eliciting agents' risk preferences in an novel inverse RL framework.

[03063] Reinforcement learning for mean field games and mean field control problems, with applications to finance

Format : Talk at Waseda University
Author(s) : Mathieu Lauriere (NYU Shanghai)
Abstract : Mean field games have been introduced to study Nash equilibria in large populations of strategic agents, while mean field control problems aim at modeling social optima in large groups of cooperative agents. These frameworks have found a wide range of applications, from economics and finance to social sciences and biology. In the past few years, the question of learning equilibria and social optima in a mean field setting has attracted a growing interest. In this talk, I will discuss several model-free methods based on reinforcement learning. Numerical experiments on stylized examples of financial models will be presented.

[03255] Learning Risk Aversion with Inverse Reinforcement Learning via Interactive Questioning

Format : Talk at Waseda University
Author(s) : Ziteng Cheng (University of Toronto)Anthony Coache (University of Toronto)Sebastian Jaimungal (University of Toronto)
Abstract : This paper proposes a novel framework for identifying an agent's risk aversion using interactive questioning. We assume that the agent's risk aversion is characterized by a spectral risk measure chosen from a finite set of candidates. We show that asking the agent to choose from a finite set of random costs, which may depend on their previous answers, is an effective means of identifying the agent's risk aversion. Specifically, we prove that the agent's risk aversion can be identified as the number of questions tends to infinity, and the questions are randomly designed. We also develop an algorithm for designing optimal questions and provide empirical evidence that our method learns risk aversion significantly faster than randomly designed questions in a simulated

environment. Our framework has important applications in robo-advising and provides a new approach for identifying an agent's risk preferences.

[04804] Fisher-Rao Gradient Descent for Stochastic Control Problems.

Format : Talk at Waseda University
Author(s) : Lukasz Szpruch (University of Edinburgh/The Alan Turing Institute)David Siska (University of Edinburgh)Bekzhan Kerimkulov (University of Edinburgh)
Abstract : We study the convergence of Gradient and Mirror Descent schemes for approximating solutions to stochastic control problems with measure-valued controls in continuous time. By exploiting Pontryagin Optimality Principle, these rely on solving forward and backward (adjoint) equations and performing static optimisation problems regularised with Bregman divergence and can be interpreted as implicit and explicit discretisations of Fisher-Rao gradient flow. In the general (non-convex) case, we show that the objective function decreases along the gradient step. Moreover, in the (strongly) convex case, when Pontryagin Optimality Principle provides a sufficient condition for optimality, we prove that the objective converges at the (exponential) linear rate to its optimal value. The main technical difficulty is to show that stochastic control problem admits suitable relative smoothness and convexity properties. These are obtained by utilising the theory of Bounded Mean Oscillation (BMO) martingales required for estimates on the adjoint Backward Stochastic Differential Equation (BSDE).

[05398] Risk Budgeting Allocation for Dynamic Risk Measures

Format : Talk at Waseda University
Author(s) : Sebastian Jaimungal (University of Toronto)Silvana Manuela Pesenti (University of Toronto)Yuri Saporito (FGV)Rodrigo Targino (FGV)
Abstract : We develop an approach for risk budgeting allocation -- a risk diversification portfolio strategy -- where risk is measured using time-consistent dynamic risk measures. For this, we introduce a notion of dynamic risk contributions that generalise the classical Euler contributions and which allow us to obtain dynamic risk contributions in a recursive manner. Moreover, we prove that, for the class of dynamic coherent distortion risk measures, the risk allocation problem may be recast as a sequence of convex optimisation problems and, leveraging the elicitability of dynamic risk measures, develop an actor-critic approach to solve for risk budgeting strategy using deep learning.

[00963] Nonconvex and nonsmooth optimization

Session Time & Room : 5B (Aug.25, 10:40-12:20) @A206

Type : Proposal of Minisymposium
Abstract : Optimization is a powerful tool to harnesses the power of big data in statistics, machine learning, compressed sensing, etc. Many modern optimization problems involve nonconvexity and nonsmoothness which creates a major gap between the actual solutions being computed and the global optimizers that traditional analysis investigates. Such challenges are new opportunities for researchers to make fundamental contributions to analytical and numerical methods for optimization. This mini-symposium aims to gather researchers with similar interests in optimization and foster in-depth discussions.

[01977] A lifted L1 framework for sparse recovery

Format : Talk at Waseda University
Author(s) : Yifei Lou (University of Texas at Dallas)Yaghoub Rahimi (Georgia Institute of Technology)Sung Ha Kang (Georgia Institute of Technology)
Abstract : Motivated by re-weighted ℓ_1 approaches for sparse recovery, we propose a lifted ℓ_1 (LL1) regularization that can be generalized to several popular regularizations in the literature. During the course of reformulating the existing methods into our framework, we discover two types of lifting functions that can guarantee that the

proposed approach is equivalent to the ℓ_0 minimization. Computationally, we design an efficient algorithm via the alternating direction method of multiplier (ADMM) and establish the convergence for an unconstrained formulation. Experimental results are presented to demonstrate how this generalization improves sparse recovery over the state-of-the-art.

[02344] A generalized formulation for group selection via ADMM

Format : Talk at Waseda University
Author(s) : Sunyoung Shin (Pohang University of Science and Technology)Chengyu Ke (Southern Methodist University)Yifei Lou (University of Texas at Dallas)Miju Ahn (Southern Methodist University)
Abstract : The talk considers a statistical learning model where the model coefficients have a pre-determined group sparsity structure. A loss function is combined with a regularizer to recover the sparsity. We analyze the stationary solution of the formulation, obtaining a sufficient condition for the stationary solution to achieve optimality. We develop an efficient ADMM algorithm, showing the iterates converge to a stationary solution under certain conditions. With the algorithm implemented for GLM, we perform numerical experiments.

[02395] A novel tensor regularization of nuclear over Frobenius norms for low rank tensor recovery

Format : Talk at Waseda University
Author(s) : Huiwen Zheng (Southern University of Science and Technology)Yifei Lou (University of Texas at Dallas)Guoliang Tian (Southern University of Science and Technology)Chao Wang (Southern University of Science and Technology)
Abstract : In this talk, we consider low-rank tensor recovery (LRTR) problems, which include the low-rank tensor completion (LRTC) problem and the tensor robust principal component analysis (TRPCA) problem. Based on tensor singular value decomposition (t-SVD), we use the ratio of the tensor nuclear norm and tensor Frobenius norm as a new nonconvex surrogate of tensor rank in our models. We adopt the alternating direction method of multipliers (ADMM) to tackle the model and analyze the convergence of the models. Extensive experiments demonstrate the superiority of the proposed models.

[02672] Tractable continuous approximations for a constraint selection problem

Format : Online Talk on Zoom
Author(s) : Miju Ahn (Southern Methodist University)Harsha Gangammanavar (Southern Methodist University)David Troxell (Stanford University)
Abstract : This presentation introduces a constraint selection problem where the decision-maker solves an optimization problem with a set of constraints that are preferred to be satisfied. We formulate the problem as a cardinality minimization problem (CMP) that penalizes the number of unsatisfied such soft constraints using an indicator function. Our approach reformulates the discrete CMP as continuous problems. We present an equivalent formulation of a mathematical program with complementarity constraints and an approximation as a difference-of-convex program. The stationary solutions of the alternative formulations are investigated, emphasizing the recovery of the local solutions of the CMP. Our numerical study results demonstrate our method's effectiveness in enforcing desired conditions on several applications.

[00965] New mathematical trends in weather prediction and inverse problems

Session Time & Room :

00965 (1/2) : 5C (Aug.25, 13:20-15:00) @F309

00965 (2/2) : 5D (Aug.25, 15:30-17:10) @F309

Type : Proposal of Minisymposium
Abstract : In applied mathematics including inverse problems, problems are often ill-posed and/or data are limited. Such difficulties have been treated in different subfields of science: medical imaging, data assimilation in numerical weather prediction, etc. In this minisymposium, researchers from data assimilation and inverse problems will gather and discuss different tools and ideas in applied mathematics to handle complicated problems

and incomplete data.

[03741] Gaussian Assimilation of non-Gaussian Image Data via Pre-Processing by Variational Auto-Encoder (VAE)

Author(s) : Daisuke Hotta (Meteorological Research Institute, Japan Meteorological Agency)
Abstract : Assimilation of image data such as satellite images with conventional data assimilation methods is challenging due to non-Gaussian error distribution, dimensional redundancy, and strong inter-pixel correlations. While several techniques have been proposed to address each of these issues, no single method can simultaneously handle them all. Here we propose to use a Variational AutoEncoder to resolve all three difficulties. A preliminary assessment with a toy model shows promising results.

[04216] Implementing local ensemble transform Kalman filter to reservoir computing for improving weather forecast

Author(s) : Mao Ouyang (Chiba University)Shunji Kotsuki (Chiba University)
Abstract : Data assimilation (DA) improves the numerical weather prediction (NWP) by combining the model forecast and observational data. The forecasts were usually obtained from a physical-based model, but recent studies reported that the reservoir computing (RC) could be implemented to surrogate both the small- and intermediate-scale physical models. This study implemented the DA, i.e., local ensemble transform Kalman filter, in both the physic-based and RC-surrogated models and compared their performances in the improvement of forecasts.

[04315] Sparse optimization of inverse problems regularized with infimal-convolution-type functionals

Author(s) : Marcello Carioni (University of Twente)
Abstract : The infimal convolution of functionals is a convex-preserving operation that have been used to construct regularizers for inverse problems by optimally combining features of two or more functionals. In this talk, we analyze the infimal convolution regularization from a sparse optimization point of view. First, we discuss optimal transport-type energies. Then, we consider the infimal convolution of a parametrized family of functionals and we develop optimization methods taking advantage of the sparsity in the parameters.

[04562] Efficient data-driven regularization for ill-posed inverse problems in imaging

Author(s) : Subhadip Mukherjee (University of Bath, UK)Marcello Carioni (University of Twente)Ozan Öktem (KTH Royal Institute of Technology)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : In recent years, data-driven regularization has led to impressive performance for image reconstruction problems in various scientific applications, e.g., medical imaging. We propose a new adversarial learning approach for imaging inverse problems by combining an iteratively unrolled network with a deep regularizer using ideas from optimal transport. The resulting unrolled adversarial regularization approach is shown to be provably stable, efficient in terms of image reconstruction time, and competitive with supervised methods in empirical performance.

00965 (2/2) : 5D @F309

[05386] Inverse problems for nonlocal PDEs with applications to quantum optics

Author(s) : John Schotland (Yale University)
Abstract : I will discuss recent work with Jeremy Hoskins and Howard Levinson on reconstruction methods for inverse problems for nonlocal PDEs. Applications to quantum optics will be discussed.

[05472] Implicit Ensemble Tangent Linear Models (IETLMs) for model differentiation

Author(s) : Craig H Bishop (University of Melbourne)Nathan W Eizenberg (University of Melbourne)

Abstract : Ideally, Tangent Linear Models (TLMs) predict the difference between perturbed and unperturbed non-linear forecasts of interest. The adjoint of a TLM gives the gradient of the non-linear model and is used in 4DVar data assimilation and in adjoint-based Forecast Sensitivity to Observation Impact (FSOI). The Local Ensemble Tangent Linear Model's (LETLM) accuracy has been shown to be limited by its inability to account for implicit time stepping. Here we derive Implicit Ensemble TLMs (IETLMs) that, at most, require the number of independent ensemble members to be equal to the number of variables in the implicit computational stencil. The accuracy of the IETLM in the linear regime is confirmed using an implicitly time stepped Lorenz 96 model and a 9-member ensemble. IETLMs feature two sparse matrices: matrix N that operates on an initially unknown future time perturbation, and matrix L that operates on the current time perturbation. For ensemble perturbations in the non-linear regime, we develop a Diagonally Robust (DR) IETLM that reduces the chances of N becoming ill-conditioned. The performance of the DR IETLM was compared with traditional TLM performance using IETLM ensemble perturbations whose "Gilmour et al., 2001" measure of non-linearity ranged up to the non-linearity of operational 32 hr ensemble forecast perturbations. Over a wide range of non-linearity, the DR IETLM performance was found to match that of the traditional TLM provided the initial standard deviation of the ensemble perturbations was   times the standard deviation of the test perturbations. Ideal FSOI requires the adjoint of a TLM that accurately predicts the known difference between   corrected and uncorrected non-linear forecasts. The DR IETLM was found to meet this FSOI accuracy requirement much more closely than the traditional TLM when the ensemble perturbations were created by subtracting the corrected forecast from ensemble members that were centred on the uncorrected forecast. Finally, if time permits, a method for reducing the size of the ensemble required to produce accurate TLMs will be described.

[05482] Advances in Integrating AI and Machine Learning with Data Assimilation for Weather Prediction

Author(s) : Stephen G Penny (Sofar Ocean)

Abstract : Capabilities of AI/ML methods necessary for online data assimilation (DA), such as accounting for accurate model response to perturbations in initial conditions, will be discussed in the context of a variety of increasing complexity dynamical systems ranging from Lorenz-96, to quasi-geostrophic (QG) dynamics, to surface QG turbulence. In this context, the success of recurrent neural networks for achieving this goal will be demonstrated by integrating with conventional DA methods such as the Ensemble Kalman Filter (EnKF) and 4D-Var. Dynamical invariants such as the Lyapunov spectrum will also be explored both as a useful diagnostic and as tool to accelerate the training of ML models. Caveats regarding training on simulated datasets and reanalysis datasets will also be discussed.

[05497] Learned weakly convex regularisers in inverse problems

Author(s) : Zakhar Shumaylov (University of Cambridge)Jeremy Budd (University of Bonn)Carola-Bibiane Schönlieb (University of Cambridge)

Abstract : In this talk, we consider the problem of learned regularisation in the area of imaging inverse problems. By showing limitations of existing methods arising in adversarial regularisation, we propose usage of weakly convex regularisers to address the problems. We provide a construction of weakly convex input neural networks and discuss convergence guarantees for the variational problem. We provide numerical evidence to exemplify their usage in the settings of sparse and limited angle computed tomography reconstruction.

[00966] Theoretical and computational advances in measure transport

Session Time & Room :

00966 (1/3) : 1C (Aug.21, 13:20-15:00) @F411

00966 (2/3) : 1D (Aug.21, 15:30-17:10) @F411

00966 (3/3) : 1E (Aug.21, 17:40-19:20) @F411

Type : Proposal of Minisymposium

Abstract : Transportation of measures is an important topic in applied mathematics based on constructing invertible transformations between random variables. These transformations can include deterministic maps, plans and stochastic processes. In recent years, this broad topic has seen wide applications for generative modeling, inference, and comparing probability distributions. Despite these successes, efficiently constructing these transformations remains challenging, especially in high-dimensional problems with complex data manifolds. This minisymposium will present novel statistical analysis and computational methods that widen the breadth of transport methods in statistics and scientific computing applications.

[05226] Optimal transport map estimation in general function spaces

Format : Talk at Waseda University

Author(s) : Vincent Divol (Université PSL)Jonathan Niles-Weed (New York University)Aram Pooladian (New York University)

Abstract : We consider the problem of estimating the optimal transport map between a (fixed) source distribution P and an unknown target distribution Q, based on samples from Q. The estimation of such optimal transport maps has become increasingly relevant in modern statistical applications, such as generative modeling. At present, estimation rates are only known in a few settings (e.g. when P and Q have densities bounded above and below and when the transport map lies in a Hölder class), which are often not reflected in practice. We present a unified methodology for obtaining rates of estimation of optimal transport maps in general function spaces. Our assumptions are significantly weaker than those appearing in the literature: we require only that the source measure P satisfies a Poincaré inequality and that the optimal map be the gradient of a smooth convex function that lies in a space whose metric entropy can be controlled. As a special case, we recover known estimation rates for bounded densities and Hölder transport maps, but also obtain nearly sharp results in many settings not covered by prior work. For example, we provide the first statistical rates of estimation when P is the normal distribution and the transport map is given by an infinite-width shallow neural network.

Abstract : TBA

[04165] Efficient subspace modeling via transport transforms

Format : Talk at Waseda University

Author(s) : Shiying Li (University of North Carolina - Chapel Hill)Gustavo Rohde (University of Virginia)Akram Aldroubi (Vanderbilt University)Abu Hasnat Rubaiyat (University of Virginia)Yan Zhuang (NIH)Mohammad Shifat-E-Rabbi (University of Virginia)Xuwang Yin (Center for AI Safety)

Abstract : When data is generated though deformations of certain template distributions, transport-based transforms often linearize data clusters which are nonlinear in the original domain. We will describe convexification properties of several transport transforms under various generative modeling assumptions, enabling efficient modeling of data classes as subspaces in the transform domain. Such subspace representations also give rise to accurate machine learning algorithms with low computational cost. We will show applications for image and signal classification.

[04063] Conditional simulation through the data-driven optimal transport barycenter problem

Format : Talk at Waseda University

Author(s) : Esteban Gregorio Tabak (New York University, Courant Institute)

Abstract : A methodology is proposed to generate samples from a conditional probability distribution, with factors that are either known explicitly, up to discovery or only by association.The procedure pushes forward the conditional distribution to its barycenter through particle flows, whose inverse provides the simulation sought. Idiosyncratic factors are included through subsampling. The methodology serves as a conditional generator, to eliminate batch effects, to uncover hidden factors and to predict and optimize trajectories under treatment.

00966 (2/3) : 1D @F411 [Chair: Tiangang Cui]

[04311] On the Monge gap and the MBO feature-sparse transport estimator.

Format : Talk at Waseda University
Author(s) : marco cuturi (Apple)
Abstract : This talk will cover two recent works aimed at estimating Monge maps from samples. In the first part (in collaboration with Théo Uscidda) I will present a novel approach to train neural networks so that they mimic Monge maps for the squared-Euclidean cost. In that field, a popular approach has been to parameterize dual potentials using input convex neural networks, and estimate their parameters using SGD and a convex conjugate approximation. We present in this work a regularizer for that task that is conceptually simpler (as it does not require any assumption on the architecture) and which extends to non-Euclidean costs. In the second part (in collaboration with Michal Klein and Pierre Ablin), I will show that when adding to the squared-Euclidean distance an extra translation-invariant cost, the Brenier theorem translates into the application of the proximal mapping of that extra term to the derivative of the dual potential. Using an entropic map to parameterize that potential, we obtain the Monge-Bregman-Occam (MBO) estimator, which has the definOn the Monge gap and the MBO feature-sparse transport estimator.ing property that its displacement vectors $T(x) - x$ are sparse, resulting in interpretable OT maps in high dimensions.

[05300] Simulation-Free Generative Modeling with Neural ODEs

Format : Talk at Waseda University
Author(s) : Ricky Tian Qi Chen (Meta AI)
Abstract : Standard diffusion models offer a simulation-free method of training continuous-time transport maps but are typically restricted to linear stochastic processes. In this talk, I will discuss Flow Matching, a training objective that allows regressing onto the generating vector field instead of the score vector field. This allows more flexibility in the design of probability paths, extends seamlessly to general manifolds, and brings the model closer to optimal transport solutions.

[04077] Diffusion Schrödinger Bridge Matching

Format : Talk at Waseda University
Author(s) : Yuyang Shi (Oxford university)Valentin De Bortoli (ENS Ulm)Andrew Campbell (Oxford University)Arnaud Doucet (Oxford University)
Abstract : Solving transport problems, i.e. finding a map transporting one given distribution to another, has numerous applications in machine learning. Novel mass transport methods motivated by generative modeling have recently been proposed, e.g. Denoising Diffusion Models (DDMs) and Flow Matching Models (FMMs) implement such a transport through a Stochastic Differential Equation (SDE) or an Ordinary Differential Equation (ODE). However, while it is desirable in many applications to approximate the deterministic dynamic Optimal Transport (OT) map which admits attractive properties, DDMs and FMMs are not guaranteed to provide transports close to the OT map. In contrast, Schrödinger bridges (SBs) compute stochastic dynamic mappings which recover entropy-regularized versions of OT. Unfortunately, existing numerical methods approximating SBs either scale poorly with dimension or accumulate errors across iterations. In this work, we introduce Iterative Markovian Fitting, a new methodology for solving SB problems, and Diffusion Schrödinger Bridge Matching (DSBM), a novel numerical algorithm for computing IMF iterates. DSBM significantly improves over previous SB numerics and recovers as special/limiting cases various recent transport methods. We demonstrate the performance of DSBM on a variety of problems.

[05473] Diffusion Bridge Mixture Transports, Schrödinger Bridge Problems and Generative Modeling

Format : Talk at Waseda University
Author(s) : Stefano Peluchetti (Cogent Labs)
Abstract : The dynamic Schrödinger bridge problem seeks a stochastic process that defines a transport between two target probability measures, while optimally satisfying the criteria of being closest, in terms of Kullback-Leibler divergence, to a reference process.
We propose a novel sampling-based iterative algorithm, the iterated diffusion bridge mixture (IDBM) procedure, aimed at solving the dynamic Schrödinger bridge problem.
The IDBM procedure exhibits the attractive property of realizing a valid transport between the target probability measures at each iteration.

We perform an initial theoretical investigation of the IDBM procedure, and carry out numerical experiments illustrating the competitive performance of the IDBM procedure.
Recent advancements in generative modeling employ the time-reversal of a diffusion process to define a generative process that approximately transports a simple distribution to the data distribution.
As an alternative, we propose utilizing the first iteration of the IDBM procedure as an approximation-free method for realizing this transport.
This approach offers greater flexibility in selecting the generative process dynamics and exhibits accelerated training and superior sample quality over larger discretization intervals.

00966 (3/3) : 1E @F411 [Chair: Youssef Marzouk]

[05484] Neural Optimal Transport for Single-Cell Biology

Format : Online Talk on Zoom
Author(s) : Charlotte Bunne (ETH Zurich)
Abstract : To accurately predict the responses of a patient’s tumor cells to a cancer drug, it is vital to recover the underlying population dynamics and fate decisions of single cells. However, measuring molecular properties of single cells requires destroying them. As a result, a cell population can only be monitored with sequential snapshots, obtained by sampling a few particles that are sacrificed in exchange for measurements. In order to reconstruct individual cell fate trajectories, as well as the overall dynamics, one needs to re-align these unpaired snapshots, in order to guess for each cell what it might have become at the next step. Optimal transport theory can provide such maps, and reconstruct these incremental changes in cell states over time. This celebrated theory provides the mathematical link that unifies the several contributions to model cellular dynamics that we present here: Inference from data of an energy potential best able to describe the evolution of differentiation processes (Bunne et al., 2022), building on the Jordan-Kinderlehrer-Otto (JKO) flow; recovery of differential equations modeling the stochastic transitions between cell fates in developmental processes (Bunne et al., 2023) through Schrödinger bridges; as well as zero-sum game theory models parameterizing distribution shifts upon interventions, which we employ to model heterogeneous responses of tumor cells to cancer drugs (Bunne et al., 2022, 2023).

[04231] Tensor-train methods for sequential state and parameter learning in state-space models

Format : Talk at Waseda University
Author(s) : Tiangang Cui (Monash University)Yiran Zhao (Monash University)
Abstract : We consider sequential state and parameter learning in state-space models with intractable state transition and observation processes. By exploiting low-rank tensor-train (TT) decompositions, we propose new sequential learning methods for joint parameter and state estimation under the Bayesian framework. Our key innovation is the introduction of scalable function approximation tools such as TT for recursively learning the sequentially updated posterior distributions. The function approximation perspective of our methods offers tractable error analysis and potentially alleviates the particle degeneracy faced by many particle-based methods. In addition to the new insights into algorithmic design, our methods complement conventional particle-based methods. Our TT-based approximations naturally define conditional Knothe-Rosenblatt (KR) rearrangements that lead to filtering, smoothing, and path estimation accompanying our sequential learning algorithms, which open the door to removing potential approximation bias. We also explore several preconditioning techniques based on either linear or nonlinear KR rearrangements to enhance the approximation power of TT for practical problems. We demonstrate the efficacy and efficiency of our proposed methods on several state-space models, in which our methods achieve state-of-the-art estimation accuracy and computational performance.

[04473] Tensor train approximation of deep transport maps for Bayesian inverse problems.

Format : Talk at Waseda University
Author(s) : Tiangang Cui (Monash University)Sergey Dolgov (University of Bath)Robert Scheichl (Heidelberg University)Olivier Zahm (Universite Grenoble Alpes, Inria)
Abstract : We develop a deep transport map for sampling concentrated distributions defined by an unnormalised density function. We approximate the target distribution as the pushforward of a reference distribution under a composition of transport maps formed by tensor-train approximations of bridging densities. We propose two bridging strategies: tempering the target density, and smoothing of an indicator function with a sigmoids. The latter opens the door to efficient computation of rare event probabilities in Bayesian inference problems.

[05065] Accelerated Interacting Particle Transport for Bayesian Inversion

Format : Talk at Waseda University
Author(s) : Martin Eigel (WIAS)Robert Gruhlke (FU Berlin)David Sommer (WIAS)
Abstract : Ensemble methods have become ubiquitous for solving Bayesian inference problems. State-of-the-art Langevin samplers such as the Ensemble Kalman Sampler (EKS) and Affine Invariant Langevin Dynamics (ALDI) rely on many evaluations of the forward model, which we try to improve. First, adaptive ensemble enrichment strategies are discussed. Second, analytical consistency guarantees of the ensemble enrichment for linear forward models are presented. Third, a homotopy formalism for involved distributions is introduced.

[00967] Stochastic Dynamical Systems and Applications in Data Science

Session Time & Room :

00967 (1/3) : 1D (Aug.21, 15:30-17:10) @E502

00967 (2/3) : 1E (Aug.21, 17:40-19:20) @E502

00967 (3/3) : 2C (Aug.22, 13:20-15:00) @E502

Type : Proposal of Minisymposium
Abstract : The theory of Dynamical Systems has helped us to analyze models in various quantitative and qualitative ways, but when considering noisy data with tools in stochastic analysis, there are still challenges in many applications to get precise models for different kinds of processes. On the other hand, lots of innovative methods in data science are now opening up new research directions and broadening the range of research fields where conventional dynamical systems can play a role. Therefore, it is important to consider interplanetary research fields between stochastic dynamics and machine learning: how to analyze stochastic dynamic systems based on observation data instead of studying models analytically? And how to analyze Machine Learning algorithms using tools from the theory of stochastic dynamical systems? In this minisymposium, we seek to find a deeper understanding of the mathematical foundations of the state-of-the-art ideas and techniques in data science as well as its applications in understanding stochastic dynamics, through algorithm development, theoretical analysis, and/or computational implementation. Fields can be covered by but are not limited to Stochastic Analysis, Inverse Problems, Stochastic Optimal Control, Numerical Analysis, Optimization, Topological Data Analysis, Nonparametric Statistics, Uncertainty Quantification, Meta Learning and Deep Reinforcement Learning, etc.

[02120] Föllmer flows: contraction, sampling and generative learning

Author(s) : Ting Gao (Huazhong University of Science and Technology)Yuling Jiao (Wuhan University)
Abstract : We construct a unit-time flow on the Euclidean space, termed the F{"o}llmer flow, whose flow map at time 1 pushes forward a standard Gaussian measure onto a general target measure. We study the well-posedness of the F{"o}llmer flow and establish the Lipschitz property of the flow map at time 1. We apply the Lipschitz mapping to several rich classes of probability measures on deriving functional inequalities with dimension-free constants, sampling and generative learning.

[02122] Stochastic systems via rough path theory: theory and numerics

Author(s) : Ting Gao (Huazhong University of Science and Technology)Hoang Duc Luu (MPI MIS & IMH-VAST)
Abstract : This talk presents stochastic differential equations driven by Hoelder noises, which can be solved in the pathwise sense using rough path theory. The asymptotic dynamics of the system can be studied under random dynamical systems, and results on existence of random pullback attractors can be derived for dissipative systems. The numerical attractor of the discrete system is proved to converge to the one of the continuous system as the time step tends to zero.

[02124] Data-driven method to learn polymer dynamics

Author(s) : Xiaoli Chen (National University of Singapore)

Abstract : We propose a machine learning approach where we construct reduced thermodynamic coordinates and interpret the dynamics of these coordinates directly from microscopic stochastic trajectory data. Our approach allows the creation of custom thermodynamics that elucidates macroscopic dynamical landscapes and facilitates subsequent analysis and control. We demonstrate our method on a long polymer chain in an externally applied field by showing that only three learnt thermodynamic coordinates are sufficient to build a dynamical landscape of unfolding.

[02123] Transition Phenomena in Non-Gaussian Stochastic Dynamical Systems

Author(s) : Ting Gao (Huazhong University of Science and Technology)Jinqiao Duan (Illinois Institute of Technology and Great Bay University)

Abstract : Dynamical systems under non-Gaussian Levy fluctuations manifest as nonlocality at a certain “macroscopic” level. Transition phenomena are special events for evolution from one metastable state to another. Examples for such events are phase transition, pattern change, gene transcription, climate change, abrupt shifts, extreme transition, and other rare events. The most probable transition pathways are the maximal likely trajectory (in the sense of optimizing a probability or an action functional) between metastable states.

[02126] Understanding the diffusion models by conditional expectations

Author(s) : Ting Gao (Huazhong University of Science and Technology)Yubin Lu (Illinois Institute of Technology)

Abstract : We provide several mathematical analyses of the diffusion model in machine learning. The drift term of the backwards sampling process is represented as a conditional expectation involving the data distribution and the forward diffusion. The training process aims to find such a drift function by minimizing the mean-squared residue related to the conditional expectation. We derive a new target function and associated loss and illustrate the theoretical findings with several numerical examples.

[02127] Early-warning indicator of transition time for noise-induced critical transition of Atlantic Meridional Overturning Circulatio n

Author(s) : Ting Gao (Huazhong University of Science and Technology)Yayun Zheng (Jiangsu University)

Abstract : We develop an effective and general early-warning indicator for critical transition. The indicator of most probable transition time based on the critical tube is proposed by Onsager-Machlup method based on a critical tube probability. The approach is applied to investigate the abrupt transition from the strong to the weak mode in a thermohaline circulation model. The indicator of the most probable transition time can provide important insights for predicting future abrupt climate transitions.

[02128] Solving the Non-local Fokker-Planck Equations by Physics-informed Neural Networks

Author(s) : Ting Gao (Huazhong University of Science and Technology)Senbao Jiang (Illinois Institute of Technology)Xiaofan Li (Illinois Institute of Technology)

Abstract : We present trapz-PiNNs, incorporated with a modified trapezoidal rule recently developed for accurately evaluating fractional Laplacian and solve the space-fractional Fokker-Planck equations in 2D/3D. We demonstrate trapz-PiNNs have high expressive power through predicting solution with low L^2 relative error by a variety of numerical examples. The trapz-PiNN is able to solve PDEs with fractional Laplacian with arbitrary $0<\alpha<(0,2)$ and on rectangular domains. It could be generalized into higher dimensions or other bounded domains.

[02129] Emergent Short-range Memory in Stochastic Gradient Noise and Its Implications on Generalization

Author(s) : Ting Gao (Huazhong University of Science and Technology)Jiangshe Zhang (Xi'an Jiaotong University)
Abstract : Investigating stochastic gradient descent (SGD) from the perspective of stochastic differential equations (SDEs) is quite popular in the deep learning community. In this talk, I will present an analytical result on modeling SGD with SDEs driven by fractional Brownian motion, which reveals the escaping efficiency when trapped in local minima. From the optimization point of view, I will further show how we can relate the smoothness of the optimization pathway to the generalization ability.

00967 (3/3) : 2C @E502

[03377] Modeling and learning methods applied to collective motion in biology

Author(s) : James Greene (Clarkson University)Ming Zhong (Illinois Institute of Technology)
Abstract : From groups of cells to groups of humans, collective motion is ubiquitous in biological systems . Inspired by phototaxis, we develop minimal mathematical models that exhibit the emergence of social structure in Cucker-Smale type pairwise interaction models. Numerical and analytical results are provided, which show the emergence of linear spatial structures. We also present methods by which local interaction rules may be learned from trajectory data, and apply these techniques to cancer migration models.

[03399] Neural architectures for identifying stochastic differential equations

Author(s) : Ali Hasan (Duke University)Joao Pereira (Instituto Nacional de Matemática Pura e Aplicada)Haoming Yang (Duke University)Sina Farsiu (Duke University)Vahid Tarokh (Duke University)
Abstract : In this work, we will describe a variational framework to recover the parameters of a latent stochastic differential equation (SDE) from high dimensional observations. We prove that, in the limit of infinite data, the true parameters can be recovered up to an isometry and numerically illustrate the efficacy of the method. We finally discuss connections to McKean-Vlasov SDEs when using neural network parameterizations of SDEs and present numerical examples in machine learning applications.

[03687] Deep learning framework for solving Fokker-Planck equations with low-rank separation representation

Author(s) : Yong Xu (Northwestern polytechnical university)
Abstract : An insightful deep learning framework is proposed in this study for solving the well-known Fokker-Planck (FP) equations that quantify the evolution of the probability density function. It e�ciently reduces the demand of training data in acquiring precise integrations of special normalizing conditions when using neural network (NN). While it also avoids the exponential increase in training data as dimension increases. Instead of all hypercubic discrete points, the inputs of each NN only require one-dimensional discrete data. Without loss of generality, to solve a d-dimensional FP equation, d NNs are employed and assembled into a low-rank separation representation. The FP, boundary, and integral operators are then re-expressed in separation representation. It enables the constructed loss function performs simple vector operations, because the complicated d-dimensional operators are replaced by a set of onedimensional operators. A tractable strategy is presented for the selection of separation rank inspired by the system's potential function, although selecting an appropriate separation rank is still an open issue. Typical numerical examples reveal that the proposed algorithm is e�ective and superior for solving the FP equations. The suggested framework is applicable and has considerable potential in various areas of engineering and applied sciences.

[00969] Eigenvalue Problems in Electronic Structure Calculations

Session Time & Room :

00969 (1/3) : 4C (Aug.24, 13:20-15:00) @G709

00969 (2/3) : 4D (Aug.24, 15:30-17:10) @G709

00969 (3/3) : 4E (Aug.24, 17:40-19:20) @G709

Type : Proposal of Minisymposium
Abstract : The first principles electronic structure calculations have become important tools for studying the material mechanism, understanding and predicting the material properties, and have achieved great success. The key mathematical models for electronic structure calculations are eigenvalue problems or equivalent forms. There are still many challenges on the design of highly efficient and highly accurate computational methods for dealing these eigenvalue problems or equivalent forms, especially for larger system. The purpose of this mini-symposium is to provide a platform for exchanging the recent developments on the numerical methods and theories for eigenvalue problems or equivalent forms arising in electronic structure calculations, and exploring the topic of further research and collaborations.
Organizer(s) : Huajie Chen (Beijing Normal University), Xiaoying Dai (Academy of Mathematics and Systems Science, CAS), Xin Liu (Academy of Mathematics and Systems Science, CAS), Yuzhi Zhou (Institute of Applied Physics and Computational Mathematics)
Classification : 35Q55, 65N25, 81Q05,
Minisymposium Program :

00969 (1/3) : 4C @G709 [Chair: Xiaoying Dai]

[04472] Recent Advances in Self-Consistent-Field Iterations for Solving Eigenvector-Dependent Nonlinear Eigenvalue Problems

Format : Talk at Waseda University
Author(s) : Zhaojun Bai (University of California, Davis)
Abstract : Much like the power method for solving linear eigenvalue problems,
self-Consistent-Field (SCF) iteration is a gateway algorithm to
solve eigenvector-dependent nonlinear eigenvalue problems such as
ones arising from electronic structure calculations. The SCF was
introduced in computational physics back in the 1950s. In this talk,
from numerical linear algebra perspective, we present recent advances
in the SCF, such as sharp estimation of convergence rate and
geometry interpretation of the SCF for a class of NEPv.

[04337] Kohn-Sham GGA Models and Their Approximations

Format : Talk at Waseda University
Author(s) : Aihui Zhou (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this presentation, I will talk about the finite dimensional approximations of Kohn-Sham GGA models, which are often used in electronic structure calculations. I will show the convergence of the finite dimensional approximations and present the a priori error estimates for ground state energy and solution approximations.

[04173] Model and data driven electromagnetic inverse problems with optimal transport

Format : Online Talk on Zoom
Author(s) : Yanfei Wang (Institute of Geology and Geophysics, Chinese Academy of Sciences)
Abstract : Electromagnetic inverse problems have important applications in non-destructive testing and evaluation of materials. By using electromagnetic measurements to probe the properties of materials like metals and composites, researchers can gain insight into the structural integrity, conductivity, and other important

properties of these materials. In this study, we consider application of electromagnetic inverse problems is in geophysics, i.e., using electromagnetic measurements to study the composition and structure of the Earth's subsurface. We propose a new attempt to use the probability metric (Wasserstein metric) for electromagnetic inversion. This lays the foundation for the future application of probability metric type of methods to large-scale electromagnetic inversion. In addition, data driven electromagnetic inverse problems will be also addressed.

[05566] Porting Quantum ESPRESSO Eigensolvers on GPUS

Format : Talk at Waseda University
Author(s) : Stefano de Gironcoli (SISSA - Trieste)
Abstract : I will report on the effort by the Quantum ESPRESSO developing team regarding the porting of the main iterative eigensolvers employed in the solution the Kohn-Sham self-consistent equations in electronic structure applications to new hybrid hardware architectures including both CPUS and GPUS chips. Directions for future developments will be briefly outlined.

00969 (2/3) : 4D @G709 [Chair: Huajie Chen]

[05006] An efficient LOBPCG solver for Kohn-Sham solution

Format : Talk at Waseda University
Author(s) : Guanghui Hu (University of Macau)
Abstract : In this talk, an efficient implementation of the LOBPCG solver in the self-consistent field iteration for the Kohn-Sham solution is introduced. It is found that in an h-adaptive finite element framework, the precondition in the LOBPCG method plays an important role to guarantee the fast convergence of the solver. Several choices are introduced, and the comparison of the performance among those choices will be demonstrated in detail.

[03997] Sampling-based approaches for multimarginal optimal transport problems with Coulomb cost

Format : Talk at Waseda University
Author(s) : Yukuan Hu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Mengyu Li (Renmin University of China)Xin Liu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Cheng Meng (Renmin University of China)
Abstract : The multimarginal optimal transport problem with Coulomb cost find applications in understanding strongly correlated systems. We develop for its Monge-like reformulation novel methods that favor highly scalable subiteration schemes and avoid the full matrix multiplications in the existing ones. Convergence properties are built on the random matrix theory. For large-scale global resolution, we embed the proposed methods into a grid refinements-based framework. The numerical results corroborate the effectiveness and better scalability of our approach.

[03145] A mixed precision LOBPCG algorithm

Format : Online Talk on Zoom
Author(s) : Daniel Kressner (EPF Lausanne)Yuxin Ma (Fudan University)Meiyue Shao (Fudan University)
Abstract : The LOBPCG algorithm is a popular approach for computing a few smallest eigenvalues of a large Hermitian positive definite matrix. We propose a mixed precision variant of LOBPCG that uses a (sparse) Cholesky factorization computed in lower precision as the preconditioner. We carry out a rounding error and convergence analysis of PINVIT, a simplified variant of LOBPCG. Our theoretical results predict and our numerical experiments confirm that the impact on convergence remains marginal.

[04317] An extended plane wave framework for the electronic structure calculations of twisted bilayer material systems

Format : Online Talk on Zoom
Author(s) : Yuzhi Zhou Xiaoying Dai (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Aihui Zhou (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk, we introduce extensions of our PW framework for the practical electronic calculations of twisted bilayer material systems in the following aspects: (1) a tensor-producted basis set with PWs in the incommensurate dimensions and localized functions in z direction, (2) the practical application of our newly developed cutoff techniques, and (3) a quasi-band structure picture under the small twisted angles and weak interlayer coupling limits. With (1) and (2), we have remarkably reduced the dimensions of hamiltonian matrix,

which makes the electronic structure calculations of twisted bilayer 2D material systems affordable to most modern computers. And (3) helps us better organize the calculations as well as understand results. We further use the linear TGB system with magic twisted angles as numerical examples. We have reproduced the famous flat bands with key features in good quantitative with other theoretical and experimental results. In terms of efficiency, our framework has much less computational cost compared to the commensurate cell approximations. While it is also more extendable compared to the traditional model hamiltonians and tight binding calculations. Lastly, nonlinear terms like Hartree energy and exchange-correlation energy can be readily included in the framework thus more effective and accurate DFT calculations of incommensurate 2D material systems can be expected in the near future.

00969 (3/3) : 4E @G709 [Chair: Yuzhi Zhou]

[04226] Grassmann Extrapolation of Density Matrices for Born–Oppenheimer Molecular Dynamics

Format : Online Talk on Zoom
Author(s) : Benjamin Stamm (University of Stuttgart)
Abstract : Born–Oppenheimer molecular dynamics (BOMD) is a powerful but expensive technique. We show how converged densities from previous DFT-calculations in the trajectory can be used to extrapolate a new guess for the SCF-iterations. We apply the method to real-life, multiscale, polarizable QM/MM BOMD simulations, showing that sizeable performance gains can be achieved. This is joint-work with É. Polack, G. Dusson and F. Lipparini.

[04929] Applications of Atomic Cluster Expansion in Electronic Structure Calculations

Format : Online Talk on Zoom
Author(s) : Liwei Zhang (University of British Columbia)
Abstract : Nonlinear eigenvalue problems are quite typical in the field of electronic structure calculations. For decades, people tended to solve them by the so-called self-consistent field iterations method, which suffers from both convergence and numerical efficiency. In this talk, we will introduce a generalized Atomic Cluster Expansion (ACE) framework, which provides a complete and symmetry-preserving basis for approximating equivariant properties, to give rise to a way to skip the self-consistent procedure. We will also cover some potential applications of ACE in the context of post-DFT electronic structure calculation models.

[04280] Numerical Analysis of the Operator Modification Approach for the Calculation of Band Diagrams of Crystalline Materials

Format : Online Talk on Zoom
Author(s) : Eric Cancès (CERMICS, École des Ponts and Inria Paris) Muhammad Hassan (Laboratoire Jacques-Louis Lions, Sorbonne Université)Laurent Vidal (CERMICS, École des Ponts and Inria Paris)
Abstract : In solid-state physics, electronic properties of crystalline materials are often described by the spectrum of periodic Schrödinger operators. Due to Bloch's theorem, the numerical computation of quantities of interest involves computing integrals over the Brillouin zone of energy bands, which are piecewise smooth, periodic functions obtained by solving a parametrized elliptic eigenvalue problem. Classic discretization strategies for resolving these eigenvalue problems produce approximate energy bands that are either non-periodic or discontinuous, both of which cause difficulties when employing numerical quadrature.

We present here an alternative discretization strategy based on an ad hoc operator modification approach. We derive a priori error estimates for the resulting energy bands and we show that these bands are periodic and can be made arbitrarily smooth (away from band crossings) by adjusting suitable parameters in the operator modification approach. We also present numerical experiments involving a toy model in 1D, graphene in 2D, and silicon in 3D to validate our theoretical results and showcase the efficiency of the operator modification approach.

[00970] High Performance Linear Algebra Software toward Extreme Heterogeneity

Session Time & Room :

00970 (1/2) : 4C (Aug.24, 13:20-15:00) @G305

00970 (2/2) : 4D (Aug.24, 15:30-17:10) @G305

Type : Proposal of Minisymposium
Abstract : Today, the leadership High Performance Computing (HPC) systems accommodates exa-flops capability through massive parallelism from thousands of heterogeneous compute nodes. This poses a huge challenge for math library developers to derive scalable performance. This heterogeneity trend is likely to continue and it is anticipated that future computing systems could have multiple of accelerators or special processing options to accommodate a variety of application needs. This poses a new challenge for handling multiple types of computing node architectures. In this session, we will discuss the latest research on implementing linear algebra libraries for extreme scale heterogeneous computing systems.
Organizer(s) : Keita Teranishi and Pedro Valero Lara
Classification : 15-04, 68-04, 68VXX
Minisymposium Program :

00970 (1/2) : 4C @G305 [Chair: Keita Teranishi]

[03921] Using the StarPU task-based runtime system for heterogeneous platforms as the core engine for a linear algebra software stack.

Format : Talk at Waseda University
Author(s) : Olivier Aumage (Inria)
Abstract : StarPU is a runtime system developed by Team STORM at Inria in Bordeaux, France, to support computing platforms based on heterogeneous architectures composed of combination of CPUs, GPUs and FPGAs. This talk will present how the Sequential Task Flow programming model offered by StarPU is being used to build a scalable, comprehensive linear algebra software stack for heterogeneous supercomputers.

[04285] A Look at the Future of High-Performance Linear Algebra with DPLASMA and PaRSEC

Format : Online Talk on Zoom
Author(s) : george bosilca (The University of Tennessee)
Abstract : This talk will focus on the dataflow programming to address some of the linear algebra challenges. I will focus in particular on two open-source projects, the PaRSEC runtime and the DPLASMA dense linear algebra library, and discuss the programming approach, the handling of heterogeneity and the opportunities to cover a large spectrum of linear algebra needs.

[04413] Multiple- and Mixed-Precision BLAS with C++ Template

Format : Talk at Waseda University
Author(s) : Toshiyuki Imamura (RIKEN Center for Computational Science)Daichi Mukunoki (RIKEN Center for Computational Science)Atsushi Suzuki (RIKEN Center for Computational Science)
Abstract : We propose a new design for BLAS that can handle multiple- and mixed-precision computations. Our templated mixed-precision BLAS (tmBLAS) addresses weaknesses in existing BLAS by decoupling the data types of each operand and operator using C++ generic programming, with explicit descriptions of operators and type-castings. We demonstrate a prototype implementation that instantiates routines with FP{16, 32, 64, 128}, and DD data types with those operations in one level with higher precision than the data precision.

[05194] MatRIS: A Scalable and Performance Portable Math Library for Heterogeneous and Multi-Device Systems based on the IRIS Runtime

Format : Talk at Waseda University
Author(s) : Keita Teranishi (Oak Ridge National Laboratory)Pedro Valero-Lara (Oak Ridge National Laboratory)
Abstract : Vendor libraries are tuned for one architecture and are not portable to others. Moreover, these lack support for heterogeneity and multi-device computation orchestration. We introduce MatRIS, a scalable and performance portable library for sparse/dense BLAS/LaPACK operations to address these challenges. MatRIS separates linear algebra algorithms and vendor libraries by using IRIS runtime. Such abstraction makes the implementation completely agnostic to the vendor libraries/architectures, providing high programming productivity. We demonstrate that MatRIS can fully utilize different multi-device heterogeneous systems, achieving high performance and scalability on three heterogeneous systems, Summit (#5 TOP500), Frontier (#1 TOP500), and CADES with four NVIDIA A100 GPUs and four AMD MI100 GPUs. A detailed performance study is presented for sparse and dense LU factorization where MatRIS provides a speedup of up to 8× from the previous version of the library (LaRIS). Along with better scalability, MatRIS provides competitive and even better performance than vendor libraries.

00970 (2/2) : 4D @G305 [Chair: Keita Teranishi]

[05190] Responsibly Reckless Matrix Algorithms for HPC Scientific Applications

Format : Talk at Waseda University
Author(s) : Hatem Ltaief (KAUST)
Abstract : Referred to by Jack Dongarra, the 2021 ACM Turing Award Laureate, as “responsibly reckless” matrix algorithms, we highlight the implications of mixed-precision (MP) computations for HPC applications. Reducing precision comes at the price of trading away some accuracy for performance (reckless) but in noncritical segments of the workflow (responsible) so that the accuracy requirements of the application can still be satisfied. We illustrate the MP impact on seismic imaging, climate/environment geospatial predictions, and computational astronomy.

[04598] A scalable multi-GPU approach for solving H2-approximated dense linear systems

Format : Talk at Waseda University
Author(s) : Qianxiang Ma (Tokyo Institute of Technolgy)Rio Yokota (Global Scientific Information and Computing Center, Tokyo Institute of Technology)
Abstract : In this talk, we present a novel approach for directly solving a dense linear system emerged from 3-D geometry approximated using $\mathcal{H}^2$-matrices. From the pre-compressing the fill-ins, we are able to ULV-factorize and apply forward and backward substitution in an entirely parallel manner by batched BLAS/LAPACK operations on GPUs. Using 512 NVIDIA V100 GPUs, we are able to factorize a matrix of N=29,242,368 under 1 second, utilizing 0.808 PFLOPS/s of performance.

[05233] Towards a Unified Micro-kernel Abstraction for GPU Linear Algebra

Format : Talk at Waseda University
Author(s) : Vijay Thakkar (NVIDIA | Georgia Tech)Richard Vuduc (Georgia Tech)
Abstract : We have created a micro-kernel abstraction for GPUs robust enough to represent the tensor core and data movement operations from NVIDIA GPU architectures spanning Maxwell all the way to Hopper. In this talk, we discuss how CuTe layouts and layout algebra allow us to uniformly represent GPU architecture specific operations in a consistent programming model regardless of the threads and data they operate upon to build CUTLASS 3.x’s core abstractions.

[00974] Finite element complexes and multivariate splines

Session Time & Room :

00974 (1/3) : 3D (Aug.23, 15:30-17:10) @E703

00974 (2/3) : 3E (Aug.23, 17:40-19:20) @E703

00974 (3/3) : 4C (Aug.24, 13:20-15:00) @E703

Type : Proposal of Minisymposium
Abstract : Differential complexes encode important structures in a wide range of problems, and there has been a surge of interest in discretizing these complexes. Examples include the de-Rham complex, the elasticity complex, and, more recently, other BGG complexes. Algebraic and differential geometric structures play an important role in the construction of finite elements and multivariate splines. This mini-symposium aims to bring together researchers to discuss recent progress in the construction of discrete complexes and the emerging connections between algebra, geometry and discretization.
Organizer(s) : Kaibo Hu, Nelly Villamizar
Classification : 65M60, 65D07, 65M70, 14Q99, 14F40, finite elements, splines, exterior calculus, applied algebraic geometry

00974 (1/3) : 3D @E703 [Chair: Kaibo Hu]

[02331] A polytopal exterior calculus framework

Format : Online Talk on Zoom
Author(s) : Francesco Bonaldi (University of Perpignan)Daniele Antonio Di Pietro (University of Montpellier)Jerome Droniou (Monash University)Kaibo Hu (University of Oxford)
Abstract : For $\Omega \subset \mathbf{R}^n$, the de Rham complex of differential forms

$$0 \to H\Lambda^0(\Omega) \xrightarrow{d} H\Lambda^1(\Omega) \xrightarrow{d} \cdots \xrightarrow{d} H\Lambda^n(\Omega) \xrightarrow{d} 0 \tag{1}$$

is essential to establish the well-posedness of certain PDE models; developing discrete versions of this complex is a key for designing robust schemes for these models. We will present two such discrete complexes, inspired by the DDR and VEM approaches, of arbitrary order, and applicable on generic meshes. Compared to FEEC, these complexes benefit from the flexibility and high-level construction of polytopal methods.

[05349] Finite Element Complex

Format : Talk at Waseda University
Author(s) : Long Chen (University of California at Irvine)Xuehai Huang (Shanghai University of Finance and Economics)
Abstract : This presentation provides an overview of finite element complex construction, showcasing the finite element de Rham complex through a geometric decomposition method. The construction is extended to additional finite element complexes, such as the Hessian complex, elasticity complex, and divdiv complex, using the Bernstein-Gelfand-Gelfand (BGG) framework.

The resulting finite element complexes hold potential applications in numerical simulations for the biharmonic equation, linear elasticity, general relativity, and other geometry-related PDEs.

[05423] Diagram chases yielding discrete elasticity complexes

Format : Talk at Waseda University
Author(s) : Jay Gopalakrishnan (Portland State University)
Abstract : Differential complexes have shed new insight into the finite elements in recent years. This talk is devoted to the elasticity complex, which provides an example of how complicated exact sequences of spaces can be built from simple ones. Lining up two simpler complexes, we start by performing a "diagram chase", which often goes

by the name of Bernstein-Gelfand-Gelfand resolution. The purpose of
this talk is to outline a few cases where this process can be
perfectly mimicked at the discrete level. The earliest example in
three-dimensions is on mesh of macroelements of Alfeld splits,
facilitated by the understanding of supersmoothness from research into
splines. Other emerging constructions will also be touched upon.
(Parts of the talk contain results obtained jointly with
S. Christiansen, S. Gong, J. Guzman, K. Hu, and M. Nielan.)

[03116] Nonconforming finite element exterior calculus

Format : Talk at Waseda University
Author(s) : Shuo Zhang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : A family of nonconforming finite element complexes are presented for n-dimensional de Rham complexes, $n \geq 2$. Particularly, the n-dimensional Crouzeix-Raviart elements are used to discretize the space of 0 forms. These finite element spaces are generally not constructed by Ciarlet's triples, and can be viewed as nonconforming splines. New theories are presented so that many basic properties of the finite element spaces and complexes can be established.

00974 (2/3) : 3E @E703 [Chair: Nelly Villamizar]

[05444] Bounds on smooth spline spaces

Format : Online Talk on Zoom
Author(s) : Henry Schenck (Auburn University)Michael Stillman (Cornell University)Beihui Yuan (Swansea University)
Abstract : For a planar simplicial complex Delta contained in R^2, Schumaker proved that a lower bound on the dimension of the space C^r_k(Delta) of planar splines of smoothness r and polynomial degree at most k on Delta is given by a polynomial P_Delta(r,k), and Alfeld-Schumaker showed this polynomial gives the correct dimension when k >= 4r+1. We prove that the equality dim C^r_k(Delta)= P_Delta(r,k) cannot hold in general for k <= (22r+7)/10.

[04982] Conforming Finite Element Methods with Arbitrary Smoothness in Any Dimension

Format : Talk at Waseda University
Author(s) : Jun Hu (Peking University)Ting Lin (Peking University)Qingyu Wu (Peking University)
Abstract : This talk proposes a construction of C^r conforming finite element spaces with arbitrary r in any dimension. It is shown that if $k \geq 2^d r+1$ the space P_k of polynomials of degree $\leq k$ can be taken as the shape function space of C^r finite element spaces in d dimensions. This is the first work on constructing such C^r conforming finite elements in any dimension in a unified way.

[03133] An algebraic framework for geometrically continuous splines

Format : Talk at Waseda University
Author(s) : Angelos Mantzaflaris (Inria at Universite Cote d'Azur, Sophia Antipolis, France)Bernard Mourrain (Inria at Universite Cote d'Azur, Sophia Antipolis, France)Nelly Villamizar (Swansea University)Beihui Yuan (Swansea University)
Abstract : Geometrically continuous splines are piecewise polynomials defined on a collection of patches stitched together through transition maps. In this talk, we introduce an algebraic framework to study geometrically continuous splines. This framework enables us to use algebraic tools to analysis the dimension of spline spaces, and to present a new algorithm to construct bases using algebraic methods. This talk is based on a joint work with Angelos Mantzaflaris, Bernard Mourrain and Nelly Villamizar.

[05200] Multivariate spline functions on "oranges"

Format : Talk at Waseda University
Author(s) : Nelly Villamizar (Swansea University)Maritza Sirvent (The Ohio State University)Tatyana Sorokina (Towson University)Beihui Yuan (Swansea University)Michael DiPasquale (University of South Alabama)
Abstract : A spline is a piecewise polynomial function defined on a partition of a real domain. Splines play an important role in many areas such as finite elements, computer-aided design, and data fitting.

In the talk, we will focus on splines defined on "oranges" which are partitions composed of a finite number of simplices of the same dimension that share one common lower dimensional face. For any fixed maximal polynomial degree and minimum order of global smoothness, we prove that the dimension of the spline space on an orange can be computed as a sum of the dimension of spline spaces on simpler lower-dimensional partitions. The examples and results in the atalk combine both Bernstein-Bézier methods for splines and algebraic tools.

00974 (3/3) : 4C @E703 [Chair: Kaibo Hu]

[05202] The strain Hodge Laplacian and discretisation of the incompatibility operator

Format : Talk at Waseda University
Author(s) : Francis Raul Anthony Aznaran (University of Oxford)Kaibo Hu (University of Oxford)
Abstract : Motivated by the physical relevance of many Hodge Laplace PDEs from the FEEC, we analyse the Hodge Laplacian arising from the strain space $H(\mathrm{inc}; \mathbb{R}^{d\times d}_{\mathrm{sym}})$, $\mathrm{inc} := \mathrm{rot} \circ \mathrm{rot}$, in the elasticity complex. We propose an adaptation of C^0-interior penalisation for the incompatibility, using the Regge element to discretise the strain. Building on pioneering work by van Goethem, we discuss promising connections between functional analysis of the inc operator and Kröner's intrinsic theory of defect elasticity.

[02874] Nonconforming finite elements for the Brinkman Problems and Quad-curl Problems on Cubical Meshes

Format : Talk at Waseda University
Author(s) : Qian Zhang (Michigan Technological University)
Abstract : In this talk, I will present two families of nonconforming elements on cubical meshes: one for the quad-curl problem and the other for the Brinkman problem. The element for the quad-curl problem is the first nonconforming element on cubical meshes. The element for the Brinkman problem can yield a uniformly stable finite element method with respect to the parameter nu. The lowest-order elements for the quad-curl and the Brinkman problems have 48 and 30 degrees of freedom, respectively. The two families of elements, as a nonconforming approximation to H((gradcurl)) and H1, can form a discrete Stokes complex together with the Lagrange element and the DG element.

[05642] Distributional finite element BGG complexes

Format : Talk at Waseda University
Author(s) : Jay Gopalakrishnan (Portland State University)Kaibo Hu (University of Oxford)Ting Lin (Peking University)Joachim Schöberl (TU Wien)Qian Zhang (Michigan Technological University)
Abstract : Distributional finite elements generalize classical concepts by allowing measures (Dirac deltas) as shape functions. Distributional elements were used to derive equilibrated residual error estimators (Braess, Schöberl 2008) and discretization of the stress-displacement formulation of linear elasticity (Pechstein, Schöberl 2011, TDNNS). Regge calculus from discrete relativity can be interpreted as a finite element version of metric with distributional curvature (Christiansen 2008). In this talk, we review the concept of distributional elements and discuss progress in discretizing Bernstein-Gelfand-Gelfand (BGG) diagrams and sequences.

[00975] Data-driven methods for learning mathematical models

Session Time & Room : 5D (Aug.25, 15:30-17:10) @G703

Type : Proposal of Minisymposium
Abstract : Mathematical models are important tools helping people understand scientific phenomena in many disciplines. Recent advances in technologies make it easier to collect huge amounts of data, which offers new opportunities on data-driven methods for the identification of mathematical models behind a phenomenon. This minisymposium focuses on learning mathematical models from an observed data set. Topics in this field include identification of governing equations, reconstruction of certain functions in an equation, and learning operators between input and output spaces. Recently, there have been interesting developments in this field, varying from problem formulations, efficient solvers, techniques on improving robustness to theoretical analysis. This minisymposium brings together researchers to discuss recent advances, challenges and applications in this field.

[05503] Recent Advances in Weak Form-Based System Identification

Format : Online Talk on Zoom
Author(s) : David Bortz (University of Colorado - Boulder)Daniel Messenger (University of Colorado - Boulder)
Abstract : Recent advances in data-driven modeling approaches have proven highly successful in a wide range of fields in science and engineering. In this talk, I will present our weak form methodology which has proven to have surprising performance properties. After describing our equation learning (WSINDy) and parameter estimation (WENDy) algorithms, I will discuss applications to several benchmark problems to illustrate the computational efficiency, noise robustness, and modest data needs.

[05502] Identification of variable coefficient PDEs using group projected subspace pursuit

Format : Online Talk on Zoom
Author(s) : Yuchen He (Shanghai Jiao Tong University)Sung Ha Kang (Georgia Institute of Techonology)Wenjing Liao (Georgia Institute of Technology)Hao Liu (Hong Kong Baptist University)Yingjie Liu (Georgia Institute of Technology)
Abstract : We propose a novel scheme, GP-IDENT, for identifying variable coefficient PDEs from noisy observations of single solution trajectories. To effectively solve the associated feature selection problems, we designed a group projected subspace pursuit (GPSP) algorithm, which is also suitable for general feature selection problems with group structure. We will provide examples to show that GP-IDENT can successively identify many non-linear high-order PDEs, and its effectiveness is also justified via comparisons with state-of-the-art methods.

[05509] How much can one learn a PDE from its solution?

Format : Talk at Waseda University
Author(s) : Yimin Zhong (Auburn University)Hongkai Zhao (Duke University)Yuchen He (Shanghai Jiao Tong University)
Abstract : In this work we study a few basic questions for PDE learning from observed solution data. Using various types of PDEs, we show 1) how the approximate dimension (richness) of the data space spanned by all snapshots along a solution trajectory depends on the differential operator and initial data, and 2) identifiability of a differential operator from solution data on local patches. Then we propose a consistent and sparse local regression method (CaSLR) for general PDE identification. Our method is data driven and requires minimal amount of local measurements in space and time from a single solution trajectory by enforcing global consistency and sparsity.

[05246] Learning Koopman Operators that Generalize Well

Format : Online Talk on Zoom
Author(s) : Bethany Lusch (Argonne National Laboratory)
Abstract : The Koopman operator is a way to represent a nonlinear dynamical system as a globally linear system. However, the linear system is infinite-dimensional, and the representation is difficult to find. Much recent research is on data-driven methods to approximate the Koopman operator. However, finding an approximation that generalizes well for a large region without finely sampling the space can be challenging. We explore learning a Koopman operator that can generalize well given limited data.

[00977] Recent advances on sparse optimization: algorithms and applications

Session Time & Room : 5C (Aug.25, 13:20-15:00) @A206

Type : Proposal of Minisymposium

Abstract : Sparse optimization arises from various application problems in statistics and machine learning. In the past decades, the well-known Lasso model and its variants have been extensively studied, and many efficient methods have been well explored correspondingly. Nevertheless, efficient methods for solving more and more difficult models involving sparse structures are still under explored. Considering the high dimension of the application problems, it is important to highly utilize their structures thus to obtain efficient algorithms. In this minisymposium, we focus on recent development of the algorithms and applications of the modern sparse optimization.

[02162] Asymptotically Consistent Linear Convergence Rate of the Randomized Sparse Kaczmarz Method

Format : Talk at Waseda University

Author(s) : Liang Chen (Hunan University)

Abstract : The sparse Kaczmarz method has drawn much attention from researchers in recent years. This is mainly due to its capability of producing sparse solutions to linear systems, which is a core problem of many applications in the big-data era, such as sparse signal recovery and image processing. This method was shown to be linearly convergent in 2019. However, the convergence rate is not consistent with the well-known convergence rate of the randomized Kaczmarz method. In this work, we try to fix this gap by proposing an asymptotically consistent linear convergence rate for the former.

[02234] A difference-of-convex algorithm for sparse support vector machines in high dimensions

Format : Talk at Waseda University

Author(s) : Ning Zhang (Dongguan University of Technology)

Abstract : The support vector machine（SVM）is a popular and powerful technique for binary classification. We consider the penalized SVM with a class of difference-of-convex penalties. We show that the difference-of-convex algorithm is guaranteed to produce an oracle estimator in two iterations if the solution to L1-norm SVM is selected as the initial estimator. We further prove that the d.c. algorithm for SCAD/MCP penalized SVM converges to a d-stationary point with local linear convergence rate.

[01567] Frank-Wolfe type methods for a class of nonconvex inequality-constrained problems

Author(s) : Liaoyuan Zeng (Zhejiang University of Technology)Yongle Zhang (Sichuan Normal University)Guoyin Li (University of New South Wales)Ting Kei Pong (The Hong Kong Polytechnic University)

Abstract : The Frank-Wolfe method and its variants, which implement efficient linear oracles for minimizing smooth functions over compact convex sets, form a prominent class of projection-free first-order methods. In this talk, we extend the Frank-Wolfe method and its away-step variant for minimizing a smooth function over a possibly nonconvex compact set, based on our new generalized linear oracles. We discuss convergence and present numerical performance of our nonconvex Frank-Wolfe type methods for solving matrix completion problems.

[00980] Recent Advances in Applied Mathematics including adopting machine learning and deep learning

Session Time & Room : 1D (Aug.21, 15:30-17:10) @E504

Type : Proposal of Minisymposium

Abstract : Applied mathematics is the field of mathematical methods and statistical reasoning to solve practical problems of a scientific or decision-making nature in a variety of subjects, engineering, medicine, physical and biological sciences. In particular, Industrial mathematics is one of the fastest-growing branches in applied mathematics and plays a growing role in developing robotics and automation systems, mechanical engineering, medicine, and others. It is concerned with developing and finding the most efficient mathematical methods to solve problems arising in recent.

This session consists of recent research trends on applied mathematics, numerical analysis to find optimal solutions, and statistical methodology for uncertainty inference including machine learning (deep learning) applications.

[01658] A hybrid difference method and its postprocessings for second order elliptic problems

Format : Talk at Waseda University

Author(s) : Dongwook Shin (Ajou University)Youngmok Jeon (Ajou University)Eun-Jae Park (Yonsei University)

Abstract : In this talk, we investigate a new method, the hybrid difference method, proposed by S., Jeon, and Park (Appl. Math. Comput., 2022), for second order elliptic problems. The hybrid difference method is a finite difference method that is based on the hybrid discontinuous Galerkin method introduced by Jeon and Park (SINUM, 2010). The HD method allows arbitrarily high-order approximations, and the local conservation property holds. The HD method allows arbitrarily high-order approximations, and satisfies the local conservation property. Additionally, it can significantly reduce the global degrees of freedom by the static condensation via Schur complement similar to the HDG method. In the recent work, we have extended and improved the HD method by introducing additional conditions. This new generalized method can be seen as the method introduced by Jeon, Park, and S. (Comput. Methods Appl. Math., 2017) with the addition of a simple postprocessing. To increase computational efficiency, we also introduce a residual type error estimator that allows for the use of adaptive algorithms. The proposed method can be extended to more complex domain geometries through simple modifications, although the local conservation property may not hold in these cases and thus requires further postprocessing. Several numerical experiments are presented to show the performance of the proposed method, which support our theoretical findings.

[05287] Predicting Thermoelectric Material Properties using Machine Learning

Format : Talk at Waseda University

Author(s) : YunKyong Hyon (National Institute for Mathematical Sciences)

Abstract : According to the development of machine learning technologies, the application of machine learning is already very active in all research areas. Material design requires a lot of calculation and computer resources in its classical process, but the process and period of material development can be shortened by using machine learning methodologies. We present a machine learning model that predicts the properties of materials required for the development of thermoelectric materials and its performance.

[05338] Classification of respiratory sounds using deep learning methods

Format : Talk at Waseda University

Author(s) : Sunju Lee (National Institute for Mathematical Sciences (NIMS))

Abstract : Auscultation with a stethoscope has been an essential part of diagnosing patients with respiratory diseases and providing first aid. However, accurate interpretation and diagnosis of auscultation sounds relies on the expertise of clinicians, so it is important to develop an artificial intelligence-based diagnosis support system using respiratory sounds. In this talk, we propose a deep-learning based classification model for respiratory sounds recorded in the clinical setting.

[05339] Interpretable Classification for Multivariate Gait Analysis

Format : Talk at Waseda University
Author(s) : Soon-Sun Kwon (Department of Mathematics/Artificial Intelligence, Ajou University, South Korea)
Abstract : Motivated by gait data from both the normal and the cerebral palsy (CP) patients group with various gross motor function classification system (GMFCS) levels, we propose a multivariate functional classification method to investigate the relationship between kinematic gait measures and GMFCS levels. A sparse linear functional discrimination framework is utilized to achieve an interpretable prediction model. The method is generalized to handle multivariate functional data and multi-class classification. The method yields superior prediction accuracy and provides easily interpretable discriminant functions. And it will help clinicians to diagnose CP and assign an appropriate GMFCS level in a more consistent and mathematical evidence.

[00981] Various Methods for the Analysis of PDEs

Session Time & Room : 5B (Aug.25, 10:40-12:20) @G709

Type : Proposal of Minisymposium
Abstract : There has been a strong interaction between classical analysis (theory of function spaces, harmonic analysis, geometric analysis, asymptotic analysis, real analysis, functional analysis, etc) and nonlinear partial differential equations.
This minisymposium provides a forum to discuss the latest methods for the analysis of nonlinear partial differential equations arising in Mathematical Physics and to exchange ideas for further developments.
Organizer(s) : Vladimir Georgiev (University of Pisa, Waseda University), Tohru Ozawa (Waseda University)
Classification : 35Q55, 35L10, 46E35, 26D10, 42B37
Minisymposium Program :

00981 (1/1) : 5B @G709 [Chair: Vladimir Georgiev]

[03982] Carleson's problem for infinitely many fermions

Format : Talk at Waseda University
Author(s) : Neal Bez (Saitama University)
Abstract : Carleson's problem for the free Schrodinger equation is concerned with the minimal level of regularity that guarantees the solution converges to the initial data in an almost everywhere sense as time goes to zero. Here we consider a version of this problem for infinitely many particles.

[05489] Stabilité results for the Sobolev inequality with computable constants and optimal behaviour

Format : Talk at Waseda University
Author(s) : Maria J. Esteban (CNRS and University Paris-Dauphine)
Abstract : In this talk I will present recent results concerning optimal quantitative stability properties for the Sobolev and logarithmic-Sobolev inequalities with computable constants. The result for the Gaussian version of the logarithmic Sobolev inequality is actually a corollary of the one for Sobolev. This is done, in an optimal manner, by a limiting argument in high dimensions.

This work is the result of a collaboration with J. Dolbeault, A. Figalli, R. Frank and M. Loss.

[05451] Lifespan estimate for classical damped wave equations with some initial data

Format : Talk at Waseda University
Author(s) : Kazumasa FUJIWARA (Ryukoku university)Vladimir Georgiev (Pisa University)
Abstract : The lifespan estimate for the Cauchy problem of the semilinear classical damped wave equation is estimated when the Fourier 0th mode of the initial data is 0. In earlier works, the lifespan was estimated based on the magnitude of the Fourier 0th mode of the initial data. We will explore the lifespan estimate by considering the magnitude of the Fourier 1st and 2nd modes of the initial data instead of the 0th mode.

[05511] Blow-up for the 1d cubic NLS

Format : Talk at Waseda University
Author(s) : Luis Vega (BCAM-UPV/EHU)
Abstract : We consider the 1D cubic NLS on R and prove a blow-up result for functions that are of borderline regularity, i.e. Hs for any s<−1/2 for the Sobolev scale and FL∞ for the Fourier-Lebesgue scale. This is done by identifying at this regularity a certain functional framework from which solutions exit in finite time. This functional framework allows, after using a pseudo-conformal transformation, to reduce the problem to a large-time study of a periodic Schrödinger equation with non-autonomous cubic nonlinearity. The blow-up result corresponds to an asymptotic completeness result for the new equation. We prove it using Bourgain's method and exploiting the oscillatory nature of the coefficients involved in the time-evolution of the Fourier modes. Finally, as an application we exhibit singular solutions of the binormal flow. More precisely, we give conditions on the curvature and the torsion of an initial smooth curve such that the constructed solutions generate several singularities in finite time. This is a joint work with V. Banica, R. Luca, and N. Tzvetkov

[00982] Partial Differential Equations in Fluid Dynamics

Session Time & Room :

00982 (1/3) : 1C (Aug.21, 13:20-15:00) @G405

00982 (2/3) : 1D (Aug.21, 15:30-17:10) @G405

00982 (3/3) : 1E (Aug.21, 17:40-19:20) @G405

Type : Proposal of Minisymposium
Abstract : This mini-symposium is aimed to bring together the leading experts as well as promising young researchers to present their recent results in partial differential equations with applications in fluid dynamics. Key topics focus on the most challenging open problems in the area such as global regularity, uniqueness of solutions, singular limits, boundary layers behavior, and free boundary problems, etc. It also provides a premier interdisciplinary forum for senior and junior researchers to exchange their experiences in the study of partial differential equations. The talks will span from analysis through modeling and computation to applications of partial differential equations.
Organizer(s) : Yachun Li, Ming Mei, Shinya Nishibata, Ronghua Pan
Classification : 35-xx, 76-xx, partial differential equations, fluid mechanics
Minisymposium Program :

00982 (1/3) : 1C @G405 [Chair: Shinya Nishibata]

[04512] Two-Dimensional Riemann Problems: Transonic Shocks and Free Boundary Problems

Format : Online Talk on Zoom
Author(s) : Gui-Qiang George Chen (University of Oxford)
Abstract : We are concerned with global solutions of multidimensional Riemann problems for nonlinear hyperbolic systems of conservation laws, focusing on their global configurations and structures. We present some recent developments in the rigorous analysis of two-dimensional Riemann problems involving transonic shock waves and free boundary problems through several prototypes of hyperbolic systems of conservation laws and discuss some further M-D Riemann problems and related problems for nonlinear partial differential equations.

[05347] Global stability of steady supersonic flow for 1D Compressible Euler system

Format : Talk at Waseda University
Author(s) : Jianli Liu (Shanghai University)
Abstract : It is more important to consider the stability of compressible flow with some phyical effects. In this talk, we will give the global nonlinear stability of steady supersonic flows for one dimensional unsteady compressible

Euler systems with physical effect, such as a nonlinear damping representing frictions, heat transfer term or mass addition.

[04192] Scaling limit of vortex dynamics on the filtered-Euler flow

Format : Talk at Waseda University
Author(s) : Takeshi Gotoda (Tokyo Institute of Technology)
Abstract : We consider weak solutions of the 2D filtered-Euler equations, which describe a regularized Euler flow. We show that, in the limit of the filtering scale, filtered weak solutions converge to weak solutions of the 2D Euler equations and an energy dissipation rate for the filtered weak solution converges to zero for initial vorticity in a certain class.

[05331] Characteristic Decomposition for Hyperbolic System

Format : Talk at Waseda University
Author(s) : Wancheng Sheng (Shanghai University)
Abstract : In this talk, we show the method of characteristic decompositions for hyperbolic conservation laws. By this methods, we give some results on the multidimensional Riemann problems of compressible Euler equations.

00982 (2/3) : 1D @G405 [Chair: Ronghua Pan]

[04072] Global Finite-Energy Solutions of the Compressible Euler-Poisson Equations for General Pressure Laws with Spherical Symmetry

Format : Talk at Waseda University
Author(s) : Feimin Huang (Academy of Mathematics and Systems Science, Chinese Academy of Science)
Abstract : We are concerned with global finite-energy solutions of the three-dimensional compressible Euler-Poisson equations with gravitational potential and general pressure law,
especially including the constitutive equation of white dwarf stars. In this paper, we construct a global finite-energy solution with spherical symmetry of the Cauchy problem for the Euler-Poisson
equations as the vanishing viscosity limit of the corresponding compressible Navier-Stokes-Poisson equations. The strong convergence of the vanishing viscosity solutions is achieved through
the compensated compactness analysis and uniform estimates in L^p via several new main ingredients. A new key estimate is first established for the integrability of the density over unbounded domains independent of the vanishing viscosity coefficient. Then a special entropy pair is carefully designed via solving a Goursat problem for the entropy equation such that a higher integrability of the velocity is established, which is a crucial step. Moreover, the weak entropy kernel for the general pressure law and its fractional derivatives of the required order near vacuum ($\rho = 0$) and far-field ($\rho = \infty$) are carefully analyzed. Owing to the generality of the pressure law, only the $W^{-1,p}_{\mathrm{loc}}$-compactness of weak entropy dissipation measures
with $p \in [1, 2)$ can be obtained; this is rescued by the equi-integrability of weak entropy pairs
which can be established by the estimates obtained above, so that the div-curl lemma still applies.
Finally, based on the above analysis of weak entropy pairs, the L^p compensated compactness framework for the compressible Euler equations with general pressure law is established.
This new compensated compactness framework and the techniques developed in this paper
should be useful for solving further nonlinear problems with similar features.

[04789] Global-in-time quasi-neutral limit for a two-fluid Euler-Poisson system

Format : Talk at Waseda University
Author(s) : Yue-Jun Peng (Université Clermont Auvergne)
Abstract : We consider Cauchy problem for a two-fluid Euler-Poisson system where
the single parameter is the Debye length.
When the initial data are sufficiently close to constant
equilibrium states, we show the uniform global existence of smooth solutions
and justify the convergence of the system to compressible Euler equations
with damping as the Debye length tends to zero. We also establish global
error estimates of the solutions. A key step of the proof is to control
the quasi-neutrality of the velocities by using a projection operator.

[03623] A compressible two-fluid model with unequal velocities: existence and uniqueness

Format : Talk at Waseda University
Author(s) : Huanyao Wen (South China University of Technology)
Abstract : In this talk, we will introduce our recent works on the existence and uniqueness theory of a compressible two-fluid model with unequal velocities. The viscosity coefficients depend on the density functions, which can be degenerate.

[04539] On the Stability of Outflowing Compressible Viscous Gas

Format : Talk at Waseda University
Author(s) : Yucong Huang (University of Edinburgh)Shinya Nishibata (Tokyo Institute of Technology)
Abstract : I will discuss the long-time stability of a spherically symmetric motion of outflowing isentropic and compressible viscous gas. The fluid occupies unbounded exterior domain, and it is flowing out from an inner sphere centred at the origin. In this talk, I will show that, for a large initial data, the solution will converge to the stationary solution as time goes to infinity. This is a joint work with S. Nishibata.

00982 (3/3) : 1E @G405 [Chair: Ming Mei]

[04434] Hyperbolic Cattaneo-Approximation of the compressible Navier-Stokes-Fourier system

Format : Talk at Waseda University
Author(s) : Jiang Xu (Nanjing University of Aeronautics and Astronautics)
Abstract : We will talk about the Cattaneo-Chistov approximation of the compressible non-isentropic Navier-Stokes system in whole space. First, we establish a global well-posedness of the Navier-Stokes-Cattaneo-Christov system uniformly with respect to the relaxation parameter. Then we justify the strong convergence of the solution toward that of the compressible Navier-Stokes system, and the explicit convergence rates are also exhibited.

[04767] Local regularity conditions on initial data for local energy solutions of the incompressible Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Hideyuki Miura (Tokyo institute of technology)Kyungkeun Kang (Yonsei university)Tai-Peng Tsai (University of British Columbia)
Abstract : We study the regular sets of local energy solutions to the Navier-Stokes equations in terms of conditions on the initial data. It is shown that if a weighted L2 norm of the initial data is finite, then all local energy solutions are regular in a region confined by space-time hypersurfaces determined by the weight. This result refines and generalizes Theorems C and D of Caffarelli, Kohn and Nirenberg (1982).

[04554] Sharp non-uniqueness of weak solutions to viscous fluids

Format : Talk at Waseda University
Author(s) : Yachun Li (Shanghai Jiao Tong University) Zirong Zeng (Shanghai Jiao Tong University)Deng Zhang (Shanghai Jiao Tong University)Peng Qu (Fudan University)
Abstract : In this talk, I will present our recent results about non-uniqueness of weak solutions to some viscous fluid models. For incompressible Navier-Stokes equations , we proved the sharp non-uniqueness of weak solutions at two endpoints of the Ladyženskaya-Prodi-Serrin (LPS) criteria even in hyper-viscous regime. For MHD equations, we prove the sharp non-uniqueness near one endpoint of the LPS condition. Furthermore, the strong vanishing viscosity and resistivity result is obtained, it yields the failure of Taylor’s conjecture along some sequence of weak solutions. For hypo-viscous compressible Navier-Stokes equations, we prove that there exist infinitely many different weak solutions with the same initial data. This provides the first non-uniqueness result of weak solutions to viscous compressible fluid. Our proof are based on the spatial-temporal intermittent convex integration scheme. These are joint works with Yachun Li, Peng Qu and Deng Zhang.

[05340] On controllability of the incompressible MHD system

Format : Talk at Waseda University
Author(s) : Yaguang Wang (Shanghai Jiao Tong University)
Abstract : In this talk, we shall introduce our recent study on the controllability of the initial boundary value problem for the incompressible magnetohydrodynamic systems. For the two-dimensional ideal incompressible MHD system, we obtained the global exact controllability by using the return method, and for the two- and three-dimensional viscous MHD systems with coupled Navier slip boundary condition, we deduced the global approximate controllability. This is a joint work with Manuel Rissel.

[00988] Treatment of infinity and finite-time singularities in differential equations

Session Time & Room :

00988 (1/2) : 1C (Aug.21, 13:20-15:00) @G402

00988 (2/2) : 1D (Aug.21, 15:30-17:10) @G402

Type : Proposal of Minisymposium
Abstract : Finite-time singularities arise in various problems in differential equations and have been ones of the most important issues towards the comprehensive understanding of the global nature of systems for decades.
In recent years, various universal machineries from geometry, dynamical systems and numerical analysis have been proposed and applied to unraveling wide variety of finite-time singularities, as well as appropriate treatments of infinity, and the common nature among them.
This symposium aims at sharing state-of-the-art topics of singularity, instability and unboundedness manifesting in finite times in differential equations towards new foundations of these complex and rich characteristics.

[01480] Finite-time singularity and dynamics at infinity: characterization and asymptotic expansions

Format : Talk at Waseda University
Author(s) : Kaname Matsue (Kyushu University)
Abstract : Finite-time singularities in differential equations, in particular finite-time blow-up, from the viewpoint of dynamical systems are discussed in this talk.
Using compactifications of phase spaces and time-scale desingularization naturally introduced by the quasi-homogeneity of vector fields in an asymptotic sense, blow-up characterization is reduced to dynamics at infinity.
We also discuss a systematic calculations of multi-order asymptotic expansion of blow-up solutions with a natural correspondence to dynamical properties of invariant sets at infinity.

[01461] Compactification for Asymptotically Autonomous Dynamical Systems with Applications to Tipping Points.

Format : Talk at Waseda University
Author(s) : Sebastian Wieczorek (University College Cork)Christopher K.R.T. Jones (University of North Carolina)
Abstract : We develop a general compactification framework for non-autonomous ODEs, where non-autonomous terms decay asymptotically. The aim is to use compact invariant sets of the autonomous limit systems from infinity to analyse non-autonomous instabilities in the original problem, in the spirit of dynamical systems theory. We illustrate our framework using rate-induced tipping instability that occurs in natural systems when external inputs, such as climatic conditions, vary faster than some critical rate.

[01512] Rate-induced tipping in heterogeneous reaction-diffusion systems

Format : Talk at Waseda University

Author(s) : Cris Hasan (University of Glasgow)Sebastian Wieczorek (University College Cork)Ruaidhrí Mac Cárthaigh (University College Cork)

Abstract : We propose a framework to study nonlinear waves in reaction-diffusion equations (RDEs) based on a compactification technique and Lin's method for constructing heteroclinic orbits. We identify generic instabilities of travelling pulses in an RDE with a fold of heteroclinic orbits in the compactified system. In an illustrative model of a habitat patch that is geographically shrinking or shifting due to climate change, we combine our framework with numerical continuation to study tipping points to extinction.

[01527] Using Geometric Singular Perturbation Theory to Understand Singular Shocks

Format : Talk at Waseda University

Author(s) : Barbara Lee Keyfitz (The Ohio State University)

Abstract : Solutions to hyperbolic conservation laws (quasilinear hyperbolic partial differential equations) typically satisfy the equations in the sense of distributions. But there are examples of systems whose solutions have even lower regularity, solutions known as singular shocks or delta shocks. In some of these examples, candidates for solutions that exhibit singular shocks have been found as limits of approximations.

An unusual model in two-component chromatography, discovered by Marco Mazzotti, provides the first physically significant example of a system where singular shocks appear. This model does not fit into the existing theory.

Here, I present new approach. Singular perturbation theory (SPT), long a mainstay of classical applied mathematics, has been put on a new footing by an approach developed by Fenichel in the 1970's and since then extended by many other researchers. This approach uses manifold and dynamical systems theory to replace the formal constructions of SPT. It was first applied to singular shocks by Stephen Schecter. Using geometric singular perturbation theory, Ting-Hao Hsu, Martin Krupa, Charis Tsikkou and I can give a singular shock structure to Mazzotti's unusual chromatography equations.

00988 (2/2) : 1D @G402 [Chair: Kaname Matsue]

[01810] Traveling wave solutions for certain 1D degenerate parabolic equation

Format : Talk at Waseda University

Author(s) : Yu Ichida (Meiji University)

Abstract : In this talk, the speaker will report results on the classification of the traveling wave solutions of the 1D degenerate parabolic equation and porous medium equation, and give observations and suggestions on phenomena corresponding to bifurcations of equilibria at infinity. These are obtained through dynamical systems theory and Poincar'e compactification. This talk includes a collaborative work with Professor Takashi Sakamoto at Meiji University.

[02005] Blow-up Rates for Solutions of a Quasi-Linear Parabolic Equation

Format : Talk at Waseda University

Author(s) : Koichi Anada (Waseda University)Tetsuya Ishiwata (Shibaura Institute of Technology)Takeo Ushijima (Tokyo University of Science)

Abstract : The motion of curves by the power of their curvatures with positive exponent has been studied. The motion is described by a parabolic equation and some solutions blow up with Type II singularity. In this talk, we discuss the blow-up rates of solutions with Type II singularity. Precisely, we derive an asymptotic expansion of the traveling wave which plays a significant role and then we provide an upper estimate for the blow-up rates.

[02492] Computation of collision and near-collision orbits in Celestial Mechanics problems.

Format : Talk at Waseda University

Author(s) : Shane Kepley (Vrije Universiteit)Jason Desmond Mireles James (Florida Atlantic University)Maciej Capinski (AGH University of Science and Technology)

Abstract :

Understanding connecting and collision/ejection orbits is central to the study of transport in Celestial Mechanics.

Finding and validating connecting orbits can be difficult in general, and is complicated even more by the presence of ejection/collisions which are singularities of the flow. We present a rigorous Levi-Cevita regularization algorithm which, combined with existing analytic continuation techniques, allows us to overcome this obstruction. This regularization is performed dynamically allowing invariant manifolds to be parameterized dynamically and globally, even near singularities.

[04119] Rigorous numerics for finding the monodromy of Picard-Fuchs differential equations for a family of K3 toric hypersurfaces

Format : Talk at Waseda University
Author(s) : Akitoshi Takayasu (University of Tsukuba)Toshimasa Ishige (Chiba University)
Abstract : In this talk, we present a method for finding monodromy matrices of linear differential equations with finite-dimensional solution spaces via rigorous numerics. We also provide a computational result that gives monodromy matrices, which represent the fundamental group of the differential equation, of Picard-Fuchs differential equations for a certain family of K3 toric hypersurfaces.

[00989] Structure and dynamics in complex biological systems

Session Time & Room :

00989 (1/2) : 2C (Aug.22, 13:20-15:00) @D515

00989 (2/2) : 2D (Aug.22, 15:30-17:10) @D515

Type : Proposal of Minisymposium
Abstract : Biological systems have been identified as complex networks consisting of many biomolecules and interactions between them. The dynamics of molecular activities based on such networks are considered to be the origin of biological functions. In the recent progress of mathematical sciences, various methods have been developed to determine important aspects of dynamical properties based on network topologies. Such theories may become breakthroughs to solve the dynamics of complex biological systems. In this symposium, we introduce a wide variety of topological approaches and discuss their future perspectives from both mathematical and biological points of view.

[01956] Controlling cell fate specification system based on network structure

Format : Talk at Waseda University
Author(s) : Atsushi Mochizuki (Institute for Life and Medical Sciences, Kyoto University)Kenji Kobayashi (Department of Zoology, Graduate School of Science, Kyoto University)Kazuki Maeda (Faculty of Informatics, The University of Fukuchiyama)Miki Tokuoka (Department of Zoology, Graduate School of Science, Kyoto University)Yutaka Satou (Department of Zoology, Graduate School of Science, Kyoto University)
Abstract : Modern biology provided large networks describing regulatory interactions between biomolecules. We developed Linkage Logic theory, which ensures observability and controllability of any long-term dynamics of the whole system by a subset of nodes, that is identified from the network alone as a feedback vertex set (FVS). We applied the theory to gene network for cell-fate specification in ascidian, including 92 genes. By manipulating 6 genes in FVS, all the seven tissues could be induced experimentally.

[01938] An extension of the Fiedler-Mochizuki theory to time-delay systems

Format : Talk at Waseda University
Author(s) : Atsushi Kondo (Department of Mathematics, Kyoto University)
Abstract : We consider the dynamics of a system of differential equations called a Regulatory Network, which represents complex regulatory relationships such as gene regulatory networks. The paper by Fiedler-Mochizuki et al. (JDDE 2013) showed that it is possible to identify a set of determining nodes that determines the asymptotic dynamics of the Regulatory Network from its network structure alone. We extend this theory to the case where the regulatory network contains time delays.

[01727] Structure-based and dynamics-based control of biological network models

Format : Talk at Waseda University
Author(s) : Jorge Gomez Tejeda Zanudo (Harvard Medical School)Reka Albert (Pennsylvania State University)Eli Newby (Pennsylvania State University)
Abstract : A task of interest when analyzing mathematical models of intracellular networks is to identify nodes that can provide attractor control in these systems. I will introduce stable motif control and feedback vertex set (FVS) control, two methods we have used to provide control strategies in multiple systems. I will discuss how we used FVS control and structure-based metrics based on signal propagation to identify high-ranking manipulations involving only 1-3 nodes that can provide attractor control.

[01991] Universal structural requirements for maximal robust perfect-adaptation in biomolecular networks

Format : Talk at Waseda University
Author(s) : Ankit Gupta (ETH Zürich)Mustafa Khammash (ETH Zürich)
Abstract : Living systems survive in unpredictable environments by maintaining key physiological variables at their desired levels through tight regulation. This property is called robust perfect adaptation (RPA) and the aim of this talk is to mathematically characterize the structural requirements for biomolecular networks to attain a form of maximal RPA, whereby the network is simultaneously robust to the largest set of disturbances. These results provide a new Internal Model Principle for biomolecular RPA networks.

00989 (2/2) : 2D @D515 [Chair: Atsushi Mochizuki]

[01961] Network topology determines robustness and flexibility in chemical reaction systems

Format : Talk at Waseda University
Author(s) : TAKASHI OKADA (Kyoto Univ)
Abstract : In living cells, biochemical reactions form complex networks. Conventional sensitivity analysis is limited by the need for detailed reaction kinetics and parameters, which are often not available for living systems. Our new method, structural sensitivity analysis, determines qualitative sensitivity solely from network structures. Based on this framework, we established a topological theorem that determines the extent to which the perturbation of a parameter affects chemical concentrations and fluxes within the network.

[01937] Simplifying complex chemical reaction networks

Format : Talk at Waseda University
Author(s) : Yuji Hirono (Asia Pacific Center for Theoretical Physics)
Abstract : Understanding the behavior of complex biochemical reaction networks is an important and challenging problem. To ease the analysis, it is desirable if we can simplify a complex reaction network while preserving its important features. In this talk, we discuss a method for the reduction of chemical reaction networks. We identify topological conditions on its subnetworks, reduction of which preserves the original steady state exactly.

[01907] Multistationarity conditions for polynomial systems in biology

Format : Talk at Waseda University
Author(s) : Carsten Conradi (HTW Berlin)
Abstract : Polynomial Ordinary Differential Equations are an important tool in quantitative biology. Often parameters vary in large intervals. Consequently one is interested in parameter conditions that guarantee multistationarity and further constrain parameter values. The focus of this talk are mass action ODEs that admit a monomial parameterization of positive steady states. For such systems it is straightforward to derive a parameterization of rate constants where multistationarity exists. Multisite phosphorylation systems are of this type.

[02165] Global Attractor Conjecture, Persistence Conjecture, and Toric Differential Inclusions

Format : Talk at Waseda University
Author(s) : Gheorghe Craciun (University of Wisconsin-Madison)
Abstract : The Global Attractor Conjecture can be regarded as a far-reaching generalization of Boltzmann's H-theorem for finite dimensional systems. The related Persistence Conjecture is even more general, and essentially says that solutions of weakly reversible systems cannot go extinct. We will discuss some of these connections, and we focus especially on introducing Toric Differential Inclusions as a tool for proving these conjectures. We also describe implications for biochemical mechanisms for noise filtering and cellular homeostasis.

[00994] Mathematical modeling approach in pharmacokinetics/pharmacodynamics

Session Time & Room : 1D (Aug.21, 15:30-17:10) @D515

Type : Proposal of Minisymposium
Abstract : Pharmacokinetics/pharmacodynamics (PK/PD) modeling is an essential component of drug discovery and development. PK modeling describes the relationship between dose and drug concentration while PD modeling quantifies the relationship between drug concentration and therapeutic effects. A model-based simulation could provide a scientific decision-making information in new drug development process and the prediction power for the success of clinical trial. The session is dedicated to discuss recent advances and challenges in PK/PD modeling and simulation to overcome fundamental limitation and conventional approaches.

[05562] Principles and applications of clinical pharmacology and pharmacometrics in the drug development

Format : Talk at Waseda University
Author(s) : Sungpil Han (The Catholic University of Korea)
Abstract : In the rapidly evolving landscape of pharmaceutical research, clinical pharmacology and pharmacometrics have emerged as pivotal disciplines in the drug development process. This presentation will delve into the principles and applications of these disciplines, particularly focusing on the integration of mathematical modeling in pharmacokinetics/pharmacodynamics (PK/PD) to accelerate and optimize drug development.

Clinical pharmacology plays a crucial role in understanding the effects of a drug and the mechanisms of its actions in humans, while pharmacometrics aids in quantifying drug, disease, and trial information to aid efficient drug development and regulatory decisions. This presentation will discuss the synergy between these two disciplines, highlighting how they can form the bedrock for creating more effective, safer drugs.

A key element in this context is the employment of mathematical models in PK/PD studies. The presentation will demonstrate the use of such models to predict the time course of drug concentration and its consequent effects, thereby guiding optimal dosage and timing strategies. Special emphasis will be placed on the role of mathematical modeling in minimizing adverse drug reactions and predicting drug-drug interactions.

[05550] Pharmacokinetic Model of Tacrolimus based on Stochastic Simulation and Estimation in Korean Adult Transplant Recipients

Format : Talk at Waseda University
Author(s) : Suein Choi (Catholic university of Korea)Seunghoon Han (Catholic university of Korea)
Abstract : Therapeutic drug monitoring (TDM) is a crucial clinical procedure that involves measuring drug concentrations in a patient's blood or other biological fluids to ensure optimal dosing. To achieve targeted exposure and improve dosing precision, the Bayesian estimation method is utilized, which optimizes individual pharmacokinetic (PK) parameters based on previous TDM data and a population PK model. The development of an accurate PK model is essential, as it integrates clinically relevant covariates and appropriate random effect parameters.

However, the nature of TDM data poses certain limitations for PK model development. Although it provides a wealth of real-world data reflecting a wide range of covariates, it primarily consists of trough concentrations, which restricts the information available for model building. To overcome these limitations, we employed the stochastic simulation and estimation (SSE) method, enabling the integration of published PK models with acquired real-world TDM data, even in the absence of raw data from the published models. This approach also allowed us to evaluate clinically meaningful covariates.

Using the SSE method, we successfully developed a population PK model for tacrolimus that encompasses both published PK models and newly collected TDM data from the Korean population. This model serves as a robust framework for practical TDM procedures, as it incorporates clinically relevant covariates and reflects real-world settings. Despite the inherent limitations associated with TDM data, the SSE method proved invaluable in leveraging the information contained within TDM data by integrating published PK models while accounting for model variability.

Overall, the developed population PK model for tacrolimus, utilizing the SSE method, represents a significant advancement in TDM practices. It enhances dosing precision, incorporates relevant covariates, and provides a solid foundation for guiding therapeutic strategies in clinical settings. By addressing the challenges posed by TDM data limitations, this research contributes to the refinement and optimization of pharmacokinetic modeling for improved patient outcomes.

[01369] Distributional approaches expressing tumor delay of the transit compartment model

Format : Talk at Waseda University
Author(s) : Jong Hyuk Byun (Pusan National University)Il Hyo Jung (Pusan National University)
Abstract : Transit compartment model describes the way in which drugs inhibit the growth of tumors, based on a system of ODEs describing damaged cells' transition under the influence of the drug, using Erlang distribution. In our approach, Coxian distribution is used to model the various delays when the number of delay compartments is fixed. In the other approach, the delay compartments are combined into a single form using Mittag-Leffler distribution, without pre-specifying the number of compartments.

[01975] Accurate Prediction of Drug Interactions Through Cytochrome P450 Induction

Format : Talk at Waseda University
Author(s) : Yun Min Song (KAIST)Ngoc-Anh Thi Vu (Chungnam National University)Quyen Thi Tran (Chungnam National University)Hwi-yeol Yun (Chungnam National University)Jung-woo Chae (Chungnam National University)Sang Kyum Kim (Chungnam National University)Jae Kyoung Kim (KAIST)
Abstract : FDA guidance has recommended several model-based predictions to determine potential drug-drug interactions (DDIs). In particular, the ratio of substrate AUCs under and not under the effect of enzyme inducers is predicted by the Michaelis-Menten model, which is valid only in low-enzyme-concentration conditions. We found that such DDI predictions lead to severe errors. To resolve this, we derived a new equation that significantly improves clinical DDI prediction, which is critical to preventing drug toxicity and failure.

[01000] Advances in random dynamical systems and ergodic theory

Session Time & Room :

01000 (1/3) : 2D (Aug.22, 15:30-17:10) @F309

01000 (2/3) : 2E (Aug.22, 17:40-19:20) @F309

01000 (3/3) : 3C (Aug.23, 13:20-15:00) @F309

Type : Proposal of Minisymposium
Abstract : Random or non-autonomous dynamical systems provide useful and flexible models to investigate systems whose evolution depends on external factors, such as noise or seasonal forcing. In recent years, there have been significant advances in the ergodic-theoretic investigation of random dynamical systems, allowing for an enhanced understanding of statistical properties, coherent structures, and the complicated interplay between noise and chaotic dynamics. This minisymposium presents the work of experts and emerging mathematicians working in this vibrant and evolving field, featuring both general-audience lectures giving an overview of the field, and expert-level talks on cutting-edge advances.

[01338] Random dynamical systems and multiplicative ergodic theorems

Format : Talk at Waseda University
Author(s) : Cecilia Gonzalez Tokman (University of Queensland)
Abstract : Random dynamical systems are flexible mathematical models for the study of complicated systems whose evolution is affected by external factors, such as seasonal cycles and random effects. This talk will start with a broad introduction to the area, with an emphasis on multiplicative ergodic theory. Then, we will review recent advances in the field, which provide fundamental information for the study of transport phenomena in such systems.

[05504] Compound Poisson Statistics for Random Dynamical Systems via Spectral Perturbation

Format : Talk at Waseda University
Author(s) : Jason Atnip (University of Queensland)Gary Froyland (UNSW Sydney)Cecilia Gonzalez Tokman (University of Queensland)Sandro Vaienti (Aix Marseille Universite)
Abstract : In this talk we discuss recent results concerning the return time statistics for deterministic and random dynamical systems. Taking a perturbative approach, we consider a decreasing sequence of holes in phase space which shrink to a point. For systems satisfying a spectral gap, we show that limiting distribution of return times to these shrinking holes is a compound Poisson distribution. We provide specific examples of classes of transformations for which the limiting distribution is Polya-Aeppli.

[01905] Entropy and pressure formulas for conditioned random dynamical systems

Format : Talk at Waseda University
Author(s) : Maximilian Engel (Free University of Berlin)Tobias Hurth (Free University of Berlin)
Abstract : Building upon recent results on Lyapunov eponents for memoryless random dynamical systems with absorption --- see Castro et al. 2022 ---, we establish the notion of metric entropy for this setting. We further discuss the relation between entropy, positive Lyapunov exponents and escape rates for such conditioned RDS, where the main example concerns the local dynamics of stochastic differential equations on bounded domains with escape through the boundary. This is joint work with Tobias Hurth.

01000 (2/3) : 2E @F309 [Chair: Cecilia Gonzalez Tokman]

[01767] Lyapunov exponents for random perturbations of coupled standard maps

Format : Talk at Waseda University

Author(s) : Alex Blumenthal (Georgia Tech)Jinxin Xue (Tsinghua University)Yun Yang (Virginia Tech)

Abstract : In this talk, we show how to give a quantitative estimate for the sum of the first N Lyapunov exponents for random perturbations of a natural class 2N-dimensional volume-preserving systems exhibiting strong hyperbolicity on a large but non invariant subset of phase space. Concrete models covered by our setting include systems of coupled standard maps, in both `weak' and`strong' coupling regimes. This is a joint work with Alex Blumenthal and Yun Yang.

[05620] Shear-induced effects Random Dynamical Systems

Format : Talk at Waseda University

Author(s) : Dennis Chemnitz (Freie Universität Berlin)Maximilian Engel (Freie Universität Berlin)

Abstract : The mechanism of shear-induced chaos was first demonstrated by Wang and Young for periodic orbits perturbed by deterministic periodic kicking. In this talk I will present recent results on shear-induced chaos, as well as shear-induced blow-up, in random dynamical systems generated by stochastic differential equations with additive noise.

[02045] Horseshoes for a class of non-uniformly expanding random circle maps

Format : Online Talk on Zoom

Author(s) : Giuseppe Tenaglia (Imperial College London)

Abstract : We prove the abundance of horseshoe-like behavior in random circle endomorphisms with a positive Lyapunov exponent under large IID noise conditions. By satisfying a transitivity requirement towards an expanding full branch and effectively controlling the tails of hyperbolic times, our results prove that any two disjoint intervals almost surely exhibit horseshoe-like behavior with full probability.

01000 (3/3) : 3C @F309 [Chair: Maximilian Engel]

[05540] Continuation of attractors of random dynamical systems with bounded noise

Format : Talk at Waseda University

Author(s) : Jeroen Lamb (Imperial College London)Martin Rasmussen (Imperial College London)Konstantinos Kourliouros (Imperial College London)Dmitry Turaev (Imperial College London)Wei Hao Tey (IRCN, The University of Tokyo)Kalle Timperi (Oulu University)

Abstract : We study the problem of persistence of minimal invariant sets with smooth boundary for a class of discrete-time set-valued dynamical systems, naturally arising in the context of random dynamical systems with bounded noise. In particular, we introduce a single-valued map, the so-called boundary map, which has the property that a certain class of invariant submanifolds for this map is in one-to-one correspondence with invariant sets for the corresponding set-valued map. We show that minimal invariant sets with smooth boundary persist under small perturbations of the set-valued map, provided that the associated boundary map is normally hyperbolic at the unit normal bundle of the boundary.

[05055] Noise-induced chaos and conditioned Lyapunov exponents in a random logistic map

Format : Talk at Waseda University

Author(s) : Bernat Bassols Cornudella (Imperial College London)Jeroen SW Lamb (Imperial College London)

Abstract : We consider a random logistic map with bounded additive noise, in the parameter regime where the deterministic logistic map has a stable period three cycle. We demonstrate how the transition from noise-induced synchronisation (negative Lyapunov exponent) to noise-induced chaos (positive Lyapunov exponent), arising as a result of growing noise amplitude, can be understood through a two-compartment approximation, effectively modelling the competition between contracting and expanding behaviour. Relevant characteristic exit times and conditioned Lyapunov exponents for the predominantly contracting and expanding compartments are obtained through quasi-stationary and quasi-ergodic invariant measures.

[01453] On the quasi-ergodicity of absorbing Markov chains with unbounded transition densities, including random logistic maps with escape

Format : Online Talk on Zoom
Author(s) : Matheus Manzatto de Castro (Imperial College London)Jeroen S. W. Lamb (Imperial College London)Martin Rasmussen (Imperial College London)Vincent P. H. Goverse (Imperial College London)
Abstract : In this paper, we consider absorbing Markov chains X_n admitting a quasi-stationary measure μ on M where the transition kernel $\mathcal{P}$ admits an eigenfunction $0 \leq \eta \in L^1(M, \mu)$. We find conditions on the transition densities of $\mathcal{P}$ with respect to μ, which ensure that $\eta(x)\mu(\mathrm{d}x)$ is a quasi-ergodic measure for X_n and that the Yaglom limit converges to the quasi-stationary measure μ-almost surely. We apply this result to the random logistic map $X_{n+1} = \omega_n X_n(1 - X_n)$ absorbed at $\mathrm{R}\setminus

[0,1], *where***omega_n**
*isani.i.dsequenceofrandomvariablesuniformlydistributedin***[a,b]**, *for*

[01003] Mathematical Modeling and Simulation in Land-Ocean Transition Zones

Session Time & Room :

01003 (1/3) : 4E (Aug.24, 17:40-19:20) @D402

01003 (2/3) : 5B (Aug.25, 10:40-12:20) @D402

01003 (3/3) : 5C (Aug.25, 13:20-15:00) @D402

Type : Proposal of Minisymposium
Abstract : Around 30% of global populations live in coastal zones, which are facing increasing threatens from both land and ocean. These include saltwater intrusion, storm surge, ecosystem degeneration and coastal erosion, to name a few. Mathematical modeling and simulation on multiple processes in the land-ocean transition zones are essential to understand intrinsic mechanisms and make reliable predictions for the future. This symposium aims to exchange new advances on mathematical modeling, numerical simulation, operational applications, and other relevant topics in hydrodynamic, ecological, and other processes in the land-ocean transition zones, thus to promote interdisciplinary collaborations in applied mathematics and earth science.

[05505] Analytical solution to the elliptic PDE of shelf wave with the relaxation of semi-geostrophic approximation

Format : Talk at Waseda University
Author(s) : Hui Wu (East China Normal University)
Abstract : The response of a wide shelf to sub-inertial and barotropic offshore pressure signals from the shelf edge was investigated. By relaxing the semi-geostrophic approximation, an elliptical wave structure equation was formulated and solved with the integral transform method. It was found that when the imposed offshore signal has an along-shelf length scale similar to the shelf width, it can efficiently break the potential vorticity barrier and propagate towards the coast, producing a significant coastal sea-level set-up. Thereafter, the pressure signal reflects from the coast or the sloping topography, producing a transient eddy and propagates to the downshelf. The intensities of the coastal set-up and the eddy increase as the along-shelf scale of the sub-inertial signal decreases or when its timescale is close to the inertial period. For a signal with longer timescale, the eddy is insignificant. The

nature of the shelf response is controlled by the shelf conductivity κ≡r/((fsB)), in which r is the Rayleigh friction coefficient, f is the Coriolis parameter, s is the shelf slope, and B is the shelf width, respectively. For a given offshore signal, coastal set-up increases with κ. For large κ, the eddy energy is concentrated at low modes, producing a large eddy, whereas a small κ produces a small eddy. The proposed theory can explain coastal sea-level fluctuations under eddy impingement in the Mid-Atlantic Bight or other similar areas.

[05568] Boundary layer dynamics of wave-current flows over cylindrical canopies

Format : Talk at Waseda University
Author(s) : Jun Ao Kan (Shanghai Jiao Tong University)Rui Wang (Shanghai Jiao Tong University)Hui Xu (Shanghai Jiao Tong University)
Abstract : Interactions of waves and currents with large roughness elements in the coastal ocean play a crucial role in drag generation and energy dissipation, which are quite different from the extensively-investigated smooth wall boundary layer or small-scale roughness. In the framework of high-order spectral/hp element method, the present study focuses on the analysis of implicit large eddy simulations of the combined current-wave flows over arrays of staggered circular cylinders with a diameter and a height of 0.5D. Unlike previous studies, our research examines array units that go beyond individual obstacles, enabling us to explore a wider range of physical mechanisms in turbulence, which consequently increases the computational complexity. By manipulating the wave amplitude, three distinct scenarios were obtained (i.e. pure current, weak wave and strong wave conditions, respectively) to analyze the effects of waves on currents or vice versa. The primary objective of current work is to investigate the energy transport mechanisms between the canopy and non-canopy layers, as well as the characteristics of the population of coherent structures. The dependences of energy budget, large-scale structures, sweeps and ejections are analyzed in detail.

[05325] On discrete shape gradients of boundary type for PDE-constrained shape optimizations

Format : Talk at Waseda University
Author(s) : Wei Gong (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Shape gradients have been widely used in numerical shape gradient descent algorithms for shape optimization. The two types of shape gradients, i.e., the distributed one and the boundary type, are equivalent at the continuous level but exhibit different numerical behaviors after finite element discretization. To be more specific, the boundary type shape gradient is more popular in practice due to its concise formulation and convenience in combining with shape optimization algorithms but has lower numerical accuracy. In this talk we provide a simple yet useful boundary correction for the normal derivatives of the state and adjoint equations, motivated by their continuous variational forms, to increase the accuracy and possible effectiveness of the boundary shape gradient in PDE-constrained shape optimization. We consider particularly the state equation with Dirichlet boundary conditions and provide a preliminary error estimate for the correction. Numerical results show that the corrected boundary type shape gradient has comparable accuracy to that of the distributed one. Extensions to other type of PDE-constrained shape optimizations are also considered, including the interface identification problems, the eigenvalue problems, the Stokes and Navier-Stokes problems. Moreover, we give a theoretical explanation for the comparable numerical accuracy of the boundary type shape gradient with that of the distributed shape gradient for Neumann boundary value problems.

[05596] An incremental SVD method for integro-differential equations: addressing storage and computational challenges

Format : Online Talk on Zoom
Author(s) : Yangwen Zhang (University of Louisiana at Lafayette)Gang Chen (Sichuan University)
Abstract : At the current stage, it is widely recognized that the numerical solution of integro-differential equations with a memory term depends on all previous time instances. Consequently, the storage requirement increases linearly, while the computational complexity grows quadratically with the number of time steps. This presents a significant challenge for numerical simulations, and to the best of our knowledge, it remains an unresolved issue. In this paper, we present a memory-free algorithm, based on the incremental SVD technique, that exhibits only linear growth in computational complexity as the number of time steps increases. Rigorous error analysis and numerical experiments will be presented to validate our approach.

01003 (2/3) : 5B @D402

[05546] Causal AI Ocean Learning and Prediction

Author(s) : X. San Liang (Fudan University)

Abstract : Ocean-atmosphere forecasting is faced with many challenges such as open boundary condition specification, unresolved process parameterization, unknown physics modeling, etc. Even if all these are fixed, a more challenging issue that ever exists is the unpredictability intrinsically embedded in chaotic systems. The recent fast development of AI seems to be promising for a partial solution to these problems. But AI is also faced with the problem of interpretability. Due to the black-box nature, it is difficult for one to decide whether a forecast is acceptable or not. In this presentation, I will show how interpretability will be enhanced for AI algorithms with the aid of a recently developed causality analysis which has been rigorously established from first principles during the past 18 years (e.g., Liang, Information flow and causality as rigorous physical notions ab initio. Phys Rev E 94:052201, 2016). In the oceanographic context, this is easily understood as the tracing of predictability sources to make the maximal usage of information. Also the quantitative nature of the causality analysis allows for an adjustment of the neural network to remove spurious correlations toward an optimal performance. Demonstrated here will be an operational forecast of the surface circulation of a region in the South China Sea, and a decadal forecast of the Central Pacific-type El Niño.

[02217] Parameterizing the baroclinic instability with an artificial potential energy term

Format : Online Talk on Zoom

Author(s) : Qingshan Chen (Clemson University)

Abstract : In a numerical model that is under-resolved in the horizontal and/or vertical directions, baroclinic instability is often
suppressed, leading to a build-up of layer interface slopes and potential energy that can not be released. In this work, we demonstrate, within the multilayer shallow water model and the Hamiltonian framework, how the baroclinic
instability can be parameterized by adding an artificial potential energy term based on the slope of the interior layer
interfaces.

[05534] Two-grid Finite Element Decoupling Scheme for the Mixed Navier-Stokes/Darcy Model

Author(s) : Yanren Hou (Xi'an Jiaotong University)

Abstract : For the mixed steady-state Navier-Stokes/Darcy model with BJS interface condition, a two-grid FEM based decoupling scheme is analyzed in the talk. The well-posedness of the discrete system and its optimal error estimation are obtained.

01003 (3/3) : 5C @D402

[05525] Shape Optimization of Incompressible Navier-Stokes flows with Shape Gradients

Format : Talk at Waseda University

Author(s) : Shengfeng Zhu (East China Normal University)Jiajie Li (East China Normal University)

Abstract : Shape design of fluid flows has applications in engineering. We consider shape optimization of incompressible flows with shape gradients. Traditional boundary shape gradients have high smoothness requirement on the boundary and is less general than the distributed shape gradient. We consider numerically finite element approximations to the distributed and boundary corrected shape gradients. A prior error estimates are shown. Numerical results are reported to verify theory and show effectiveness of shape gradient algorithms.

[03963] Simulation of Droplet-laden Turbulent Channel flow by LBM and Phase field method

Format : Online Talk on Zoom
Author(s) : Dingyi Pan (Zhejiang University)Yuqing Lin (Zhejiang University)
Abstract : Direct numerical simulation of droplet-laden turbulent channel flow is studied by coupled lattice Boltzmann method and phase field modeling with Cahn-Hilliard (CH) equation. The weighted essentially non-oscillatory (WENO) scheme is applied for the discretization of CH equation. The simulated friction Reynolds number is up to 180, and the mass conservation of droplet phase is well fulfilled. The results show that the existence of droplets contribute to the drag reduction of the turbulent channel flow.

[01011] Analysis and Design of Dynamical Circuits, Systems and Networks

Session Time & Room : 5D (Aug.25, 15:30-17:10) @A207

Type : Proposal of Minisymposium
Abstract : In order to properly design electric circuits and other dynamical systems and networks, it is important to understand their structures and dynamics through mathematical analysis. This minisymposium brings together four engineering researchers working on dynamical circuits, systems and networks to present their recent research results on analysis and design from various perspectives such as discrete harmonic analysis, bifurcation analysis, model order reduction, mathematical programming and contraction mapping principle, with applications to metamaterials, communications, control and signal processing. Through their talks, the importance of mathematics in engineering will be demonstrated.

[01717] Network dynamics on electric circuits and Maxwell's equations

Format : Talk at Waseda University
Author(s) : Takashi Hisakado (Kyoto University)
Abstract : Electric circuits are the network dynamics of voltages and currents, and electromagnetic phenomena described by Maxwell's equations can be appropriately modeled and designed on the network. In the presentation, we will summarize the properties of electric circuits as discrete harmonic analysis and show that by considering the relationship between Maxwell's equations and electric circuits, a new type of electric circuit can be used to design metamaterials, antennas, etc.

[01871] Design of a delayed feedback controller based on bifurcation analysis

Format : Talk at Waseda University
Author(s) : Koki Yoshida (National Institute of Technology, Toyama College)Keiji Konishi (Osaka Metropolitan University)Naoyuki Hara (Osaka Metropolitan University)
Abstract : In addition to stabilizing an operating point, increasing the basin size is required to construct a robust system against disturbances. However, the time delays in the system or control dynamics make it difficult to estimate the basin size analytically. This presentation will show how to design a delayed feedback controller that expands the basin size of the operating point in a DC bus system with the help of a numerical bifurcation analysis tool.

[02715] Nonlinear Model Order Reduction for CT Image Reconstruction

Format : Talk at Waseda University
Author(s) : Yuichi Tanji (Kagawa University)Ken'ichi Fujimoto (Kagawa University)
Abstract : X-ray computed tomography apparatus is widely used in clinics to determine whether there is a tumor inside
the human body. In this study, we present how to generate a prediction model for image reconstruction using nonlinear
model order reduction of the nonlinear dynamical system. For the model reduction, we use proper orthogonal decomposition. We improve the computational techniques so that many observed data can be considered,
which provides effective orthogonal vectors for model reduction.

[02712] Analysis and Design of Recurrent Neural Networks Generating Desired Sequences of Bipolar Vectors

Format : Talk at Waseda University
Author(s) : Norikazu Takahashi (Okayama University)Tsuyoshi Yamakawa (Kyushu University)Yasuhiro Minetoma (Kyushu University)Tetsuo Nishi (Kyushu University)Tsuyoshi Migita (Okayama University)
Abstract : Recurrent neural networks or RNNs can generate a variety of pattern sequences by the time evolution of each neuron's output. We derive sufficient conditions under which an RNN described by a system of piecewise linear differential equations can generate a desired pattern sequence, and present mathematical programming problems to find its parameter values that satisfy those conditions. Furthermore, we analyze the convergence of state trajectories of an RNN to a limit cycle using a fixed-point theorem and the contraction mapping principle.

[01024] Multiscale modeling and simulation methods of inhomogeneity in defected systems

Session Time & Room :

01024 (1/3) : 3E (Aug.23, 17:40-19:20) @D102

01024 (3/3) : 4D (Aug.24, 15:30-17:10) @D102

Type : Proposal of Minisymposium
Abstract : Inhomogeneity, as the source of various multiscale effects in systems such as materials and data, play essential roles in the material properties and the data structure of these defected systems with multiple scales. The complexity of modeling defects and their impact to the properties of the systems present new challenges for mathematical modeling and analysis. Multi-scale, multi-physics and multi-fidelity models are required to accurately describe the complicated phenomena associated with the inhomogeneity. Speakers in this minisymposium will discuss recent advances in modeling approaches and simulation methods, and new findings obtained in analysis and simulations.
Organizer(s) : Shuyang Dai, Luchan Zhang

[04025] Recent progress on multiscale coupling for crystalline defects

Format : Talk at Waseda University
Author(s) : Lei Zhang (Shanghai Jiao Tong University)Yangshuai Wang (University of British Columbia)
Abstract : In this talk, we present some recent progress on the multiscale coupling methods for crystalline defects, which include: 1) MeshAC, a three-dimensional mesh package designed for atomistic-to-continuum; 2) (a/c) coupling with higher order far-field boundary conditions; 3) Adaptive QM/MM coupling with machine-learned interatomic potentials (MLIP).

[02228] Mathematical perspectives in modeling microstructures in metallic materials

Format : Online Talk on Zoom
Author(s) : Yejun Gu (Agency for Science Technology and Research)
Abstract : The mechanical properties of metallic materials are strongly dependent on their microstructural features (e.g. morphology and distribution of dislocations, grains, and other defects). Thus it necessitates a comprehensive understanding of the microstructure evolutions in materails during deformation. I will present some attempts of applying mathematical methods to address this problem. The presentation consists of two parts: one is the fast algorithms for solving partial differential equations, in order to precisely describe the microstructure evolutions; the other is the probabilistic description and statistical analysis, which are employed to quantify the relationship between the microstructures and mechanical properties.

[04547] A Three-Dimensional Continuum Simulation Method for Grain Boundary Motion Incorporating Dislocation Structure

Format : Talk at Waseda University
Author(s) : Xiaoxue Qin (Shanghai University)
Abstract : We develop a continuum model for the dynamics of grain boundaries in three dimensions that incorporates the motion and reaction of the constituent dislocations. The continuum model is based on a simple representation of densities of curved dislocations on the grain boundary. Illposedness due to nonconvexity of the total energy is fixed by a numerical treatment based on a projection method that maintains the connectivity of the constituent dislocations. An efficient simulation method is developed, in which the critical but computationally expensive long-range interaction of dislocations is replaced by another projection formulation that maintains the constraint of equilibrium of the dislocation structure described by the Frank’s formula. This continuum model is able to describe the grain boundary motion and grain rotation due to both coupling and sliding effects, to which the classical motion by mean curvature model does not apply. Comparisons with atomistic simulation results show that our continuum model is able to give excellent predictions of evolutions of low angle grain boundaries and their dislocation structures.

[04727] A nonlocal elasiticity model for simulating the static and dynamic problems of crystalline defects in materials

Format : Talk at Waseda University
Author(s) : Xiaoyin Wang (Wuhan University)
Abstract : In this work, we present a nonlocal elasticity model in order to solve the static and dynamic problems related to crystalline defects such as dislocations, interfaces, etc. In our model, a superposition framework based on nonlocal description is used to solve the stress and displacement field due to defects. The interaction of dislocation with other types of defects such as cracks can be modeled with higher accuracy due to the consideration of nonlocal effects. The model is solved by optimization based numerical techniques in order to accelerate the simulations. We also apply this model to problems related to crystal interfaces.

01024 (2/3) : 4C @D102 [Chair: Shuyang Dai]

[05384] An IBVP of a model for motion of grain boundaries

Format : Talk at Waseda University
Author(s) : Peicheng Zhu (Shanghai University)
Abstract : We shall prove global existence of weak solutions to an initial-boundary value problem for a novel phase-field model which is proposed as an attempt to describe the motion of grain boundaries, a type of interface motion by interface diffusion driven by bulk free energy in elastically deformable solids. Its applications include important processes arising in Materials science, e.g., Sintering. In this model the evolution equation for an order parameter is a non-uniformly, degenerate parabolic equation of fourth order, which differs from the Cahn-Hilliard equation by a non-smooth term of the gradient of the unknown.

[04942] Stochastic Continuum Models for High–Entropy Alloys with Short-range Order

Format : Talk at Waseda University
Author(s) : Luchan Zhang (Shenzhen University)Yahong Yang (Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)
Abstract : High entropy alloys (HEAs) are a class of novel materials that exhibit superb engineering properties. It has been demonstrated by extensive experiments and first principles/atomistic simulations that short-range order in the atomic level randomness strongly influences the properties of HEAs. In this talk, we present stochastic continuum models for HEAs with short-range order from atomistic models. A proper continuum limit is obtained such that the mean and variance of the atomic level randomness together with the short-range order described by a characteristic length are kept in the process from the atomistic interaction model to the continuum equation. The obtained continuum model with short range order is in the form of an Ornstein–Uhlenbeck (OU) process, which validates our previous continuum model adopting the OU process phenomenologically for HEAs with short range order. We derive such stochastic continuum models with short-range order for both elasticity in HEAs without defects and HEAs with dislocations (line defects). The obtained stochastic continuum models are based on the energy formulations, whose variations lead to stochastic partial differential equations.

[03918] GAS: A Gaussian Mixture Distribution-Based Adaptive Sampling Method for PINNs

Format : Talk at Waseda University
Author(s) : Cheng Yuan (Wuhan University)
Abstract : With the recent study of deep learning in scientific computation, the Physics-Informed Neural Networks (PINNs) method has drawn widespread attention for solving Partial Differential Equations (PDEs). Compared to traditional methods, PINNs can efficiently handle high-dimensional problems, but the accuracy is relatively low, especially for highly irregular problems. Inspired by the idea of adaptive finite element methods and incremental learning, we propose GAS, a Gaussian mixture distribution-based adaptive sampling method for PINNs. During the training procedure, GAS uses the current residual information to generate a Gaussian mixture distribution for the sampling of additional points, which are then trained together with historical data to speed up the convergence of the loss and achieve higher accuracy. Several numerical simulations on 2D and 10D problems show that GAS is a promising method that achieves state-of-the-art accuracy among deep solvers, while being comparable with traditional numerical solvers.

[05016] An Elastic Interaction-Based Loss Function in Image Segmentation and Detection

Format : Talk at Waseda University
Author(s) : Yaxin FENG (Hong Kong University of Science and Technology)Yuan Lan (Huawei Theory Lab)Yang Xiang (Hong Kong University of Science and Technology)Luchan Zhang (Shenzhen University)
Abstract : Deep learning techniques have shown their success in image processing since they are easy to manipulate and robust to various types of datasets. The commonly used pixel-wise loss functions result in a bottleneck to achieve high precision for complicated structures in biomedical and autonomous driving science images. For example, the predicted small blood vessels in retinal images are often disconnected or even missed under the supervision of the pixel-wise losses, and the existence of lanes needed to be inferred even when they are occluded by cars or human. This long-range elastic interaction-based training strategy addresses these problem. In this strategy, convolutional neural network (CNN) learns the target region under the guidance of the elastic interaction energy between the boundary of the predicted region and that of the actual object. Under the supervision of the proposed loss, the boundary of the predicted region is attracted strongly by the object boundary and tends to stay connected.

01024 (3/3) : 4D @D102 [Chair: Luchan Zhang]

[03366] Phase field model for self-climb of prismatic dislocation loops by vacancy pipe diffusion

Format : Online Talk on Zoom
Author(s) : Xiaohua NIU (Xiamen University of Technology)
Abstract : In this talk, we present a phase field model for the self-climb motion of prismatic dislocation loops via vacancy pipe diffusion driven by elastic interactions. This conserved dynamics model is developed under the

framework of the Cahn-Hilliard equation with incorporation of the climb force on dislocations, and is based on the dislocation self-climb velocity formulation established in Ref. (Niu et al., 2017). Asymptotic analysis shows that the proposed phase field model gives the dislocation self-climb velocity accurately in the sharp interface limit. Numerical simulations of evolution, translation, coalescence and repelling of prismatic loops by self-climb show excellent agreement with discrete dislocation dynamics simulation results and the experimental observation. Also a phase field model for the motion of prismatic dislocation loops by both conservative climb and non-conservative climb is also developed. The simulations will be shown to illustrate the influence of the self-climb in the dislocation climb process.

[05129] Global weak solutions to an initial-boundary value problem of a phase-field model for motion of grain boundaries

Author(s) : Luchan Zhang (Shenzhen University)Peicheng Zhu (Shanghai University)
Abstract : We shall prove global existence of weak solutions to an initial-boundary value problem for a novel phase-field model which is proposed as an attempt to describe the motion of grain boundaries, a type of interface motion by interface diffusion driven by bulk free energy in elastically deformable solids. Its applications include important processes arising in Materials science, e.g., Sintering. In this model the evolution equation for an order parameter is a non-uniformly, degenerate parabolic equation of fourth order, which differs from the Cahn-Hilliard equation by a non-smooth term of the gradient of the unknown.

[01028] High-order numerical methods for nonlinear PDEs

Session Time & Room :

01028 (1/3) : 2E (Aug.22, 17:40-19:20) @E708

01028 (2/3) : 3C (Aug.23, 13:20-15:00) @E708

01028 (3/3) : 3D (Aug.23, 15:30-17:10) @E708

Type : Proposal of Minisymposium
Abstract : Nonlinear partial differential equations (PDEs) have been widely used in various fields, such as thermodynamics, biology, material science, electromagnetism, to name just a few. Even though the history of the study on numerical PDEs is quite long, there are still many open and important questions. In this mini-symposium, we aim at gathering researchers working on the topic to discuss recent advances on the development and numerical analysis of high-order numerical methods for approximately solving nonlinear PDEs, in order to further promote the developments of the topic.

[05134] Error Analysis of IMEX and Time-Splitting Schemes for the Logarithmic Schrodinger's Equation

Author(s) : Li-Lian Wang (Division of Mathematical Sciences, Nanyang Technological University)
Abstract : The Schrodinger's equation with a logarithmic nonlinear term (LogSE): f(u)=u log(|u|^2) exhibits rich dynamics, but such a nonlinearity presents significant challenges in both numerical solution and error analysis. Compared with usual cubic case, f(u) is non-differentiable at u=0 but possesses certain Holder continuity. In this talk, we shall report our recent attempts in numerical study of LogSE with a focus on time discretization via implicit-explicit scheme and time-splitting scheme and on the introduction of new tools for the error analysis. This talk is based on joint works with Jingye Yan (Jiangsu University, China) and Xiaolong Zhang (Hunan Normal University, China).

[02750] Constructing structure-preserving schemes via Lagrange multiplier approach

Author(s) : Qing Cheng (Tongji University)Jie Shen (Purdue University)

Abstract : In the talk, I will introduce a new Lagrange multiplier approach to construct efficient and accurate structure-preserving schemes for a class of semi-linear and quasi-linear parabolic equations. To be more specific, I will introduce how to construct positivity/bound-preserving, length-preserving, energy-dissipative schemes for a large class of PDEs. I will establish stability results under a general setting, and carry out an error analysis for second-order structure-preserving schemes. Finally, I will apply our approach to several typical PDEs which preserve structures described above. Some numerical results will be presented to validate our approach.

[04415] Optimal L^2 error estimates of unconditionally stable FE schemes for the Cahn-Hilliard-Navier-Stokes system

Author(s) : Wentao Cai (Beijing Computational Science Research Center)Weiwei Sun (BNU-HKBU United International College)Jilu Wang (Harbin Institute of Technology (Shenzhen))Zongze Yang (The Hong Kong Polytechnic University)

Abstract : The paper is concerned with the analysis of a popular convex-splitting finite element method for the Cahn-Hilliard-Navier-Stokes system, which has been widely used in practice. Since the method is based on a combined approximation to multiple variables involved in the system, the approximation to one of the variables may seriously affect the accuracy for others. Optimal-order error analysis for such combined approximations is challenging. The previous works failed to present optimal error analysis in L^2-norm due to the weakness of the traditional approach. Here we first present an optimal error estimate in L^2-norm for the convex-splitting FEMs. We also show that optimal error estimates in the traditional (interpolation) sense may not always hold for all components in the coupled system due to the nature of the pollution/influence from lower-order approximations. Our analysis is based on two newly introduced elliptic quasi-projections and the superconvergence of negative norm estimates for the corresponding projection errors. Numerical examples are also presented to illustrate our theoretical results. More important is that our approach can be extended to many other FEMs and other strongly coupled phase field models to obtain optimal error estimates.

01028 (2/3) : 3C @E708 [Chair: Zhi Zhou]

[05392] Pointwise-in-time a posteriori error control for higher-order discretizations of time-fractional parabolic equations

Author(s) : Natalia Kopteva Sebastian Franz (Technical University Dresden)

Abstract : Time-fractional parabolic equations with a Caputo time derivative are considered. For such equations, we explore and further develop the new methodology of the a-posteriori error estimation and adaptive time stepping proposed in [N. Kopteva, Pointwise-in-time a posteriori error control for time-fractional parabolic equations, Appl. Math. Lett., 123 (2022)]. We improve the earlier time stepping algorithm based on this theory, and specifically address its stable and efficient implementation in the context of high-order methods. The considered methods include an L1-2 method and continuous collocation methods of arbitrary order, for which adaptive temporal meshes are shown to yield optimal convergence rates in the presence of solution singularities.

[05204] An L^1 mixed DG method for second-order Elliptic Equations in the Non-divergence Form

Author(s) : Weifeng Qiu (City University of Hong Kong)Jin Ren (Old Dominion University)Ke Shi (Old Dominion University)Yuesheng Xu (Old Dominion University)

Abstract : In this talk we present an L^1 mixed DG method for second-order elliptic equations in the non-divergence form. The elliptic PDE in nondivergence form arises in the linearization of fully nonlinear PDEs. Due to the nature of the equations, classical finite element methods based on variational forms can not be employed directly. In this work, we propose a new optimization based finite element method which combines the classical DG framework with recently developed L^1 optimization technique. Convergence analysis in both energy norm and L^∞ norm are obtained under weak regularity assumption of the PDE (H^1). Such L^1 optimization problems are nondifferentiable and invalidate traditional graidnet methods. To overcome this difficulty, we characterize solutions of L^1 optimization as fixed-points of proximity equations and utilize matrix splitting technique to obtain a class of fixed-point proximity algorithms with convergence analysis. In addition, various numerical examples will be displayed to validate the analysis in the end.

[02310] New analysis of a mixed FEM for Ginzburg-Landau Equations

Author(s) : Huadong Gao (Huazhong University of Science and Technology)
Abstract : This talk is concerned with new error analysis of a lowest-order backward Euler Galerkin-mixed finite element method for the time-dependent Ginzburg-Landau equations. The method is based on a commonly-used non-uniform approximations $(P_1, ND_1 \times RT_0)$, which has been widely used. We establish the second-order accuracy for the order parameter in spatial direction, although the accuracy for $(\mathbf{curl A}, \mathbf{A})$ is in the first order only. Our numerical experiments confirm the optimal convergence of ψ_h.

[01989] Spectral analysis of a mixed method for linear elasticity

Author(s) : Xiang Zhong (City University of Hong Kong)Weifeng Qiu (City University of Hong Kong)
Abstract : We consider a mixed method for linear elasticity eigenvalue problem,
which approximates numerically the stress, displacement, and rotation, by piecewise (k+1),
k and (k+1)-th degree polynomials (k>=1) on Hseih-Clough-Toucher grids. The numerical eigenfunction
of stress is symmetric. By the discrete H^1-stability of numerical displacement, we prove an O(h^(k+2)) approximation
to the L^2-orthogonal projection of the eigenspace of exact displacement for the
eigenvalue problem, with proper regularity assumption. We also prove that numerical approximation to the
eigenfunction of stress is locking free with respect to Poisson ratio. We introduce a hybridization to reduce
the mixed method to a condensed eigenproblem and prove an O(h^2) initial approximation of the eigenvalue by using the discrete H^1-stability of numerical displacement.

01028 (3/3) : 3D @E708 [Chair: Zhi Zhou]

[05520] A convergent algorithm for the interaction of mean curvature flow and surface diffusion

Author(s) : Charles M. Elliott (University of Warwick)Harald Garcke (University of Regensburg)Balázs Kovács (Paderborn University)
Abstract : In this talk we will discuss a numerical approach for the interaction of mean curvature flow and a diffusion process on the surface.
The evolving surface finite element discretisation is analysed for a coupled geometric PDE system.
We will present an algorithm based on a system coupling the diffusion equation to evolution equations for geometric quantities in the velocity law for the surface; give insight into the stability estimates; which lead to optimal-order H^1-norm error estimates.
We will present numerical experiments reporting on: convergemce, preservation of mean convexity, loss of convexity, weak maximum principles, and the occurrence of self-intersections.
Based on a joint work with C. M. Elliott (Warwick) and H. Garcke (Regensburg).

[02942] Optimal convergence of the arbitrary Lagrangian-Eulerian second-order projection method for the Navier-Stokes equations on an evolving domain

Author(s) : Buyang Li (The Hong Kong Polytechnic University)Qiqi Rao (The Hong Kong Polytechnic University)Yupei Xie (The Hong Kong Polytechnic University)
Abstract : In this talk, we introduce how to prove the optimal convergence of the arbitrary Lagrangian-Eulerian second-order projection method for the Navier-Stokes equations on an evolving domain.

[03545] Exponential Spactral Method for Semilinear Subdiffusion Equations with Rough Data

Author(s) : Qiqi RAO (PolyU)
Abstract : A new spectral method is constructed for the linear and semilinear subdiffusion equations with possibly discontinuous rough initial data. The new method effectively combines several computational techniques, including the contour integral representation of the solutions, the quadrature approximation of contour integrals, the exponential integrator using the de la Valĺee Poussin means of the source function, and a decomposition of the time interval geometrically refined towards the singularity of the solution and the source function. Rigorous error analysis shows that the proposed method has spectral convergence for the linear and semilinear subdiffusion

equations with bounded measurable initial data and possibly singular source functions under the natural regularity of the solutions.

[01029] Extremal Combinatorics and Probabilistic Combinatorics

Session Time & Room :

01029 (1/3) : 4C (Aug.24, 13:20-15:00) @G304

01029 (2/3) : 4D (Aug.24, 15:30-17:10) @G304

01029 (3/3) : 4E (Aug.24, 17:40-19:20) @G304

Type : Proposal of Minisymposium
Abstract : Combinatorics studies discrete objects and their properties, which has striking applications in statistical physics, biology, computer science and so on. This minisymposium we propose will focus on Extremal Combinatorics and Probabilistic Combinatorics, which are two of the most central branches of modern combinatorial theory. We aim to attract the top researchers to the minisymposium, where they will present their recent results, discuss open problems, exchange research ideas, and initiate new collaborations. We expect the minisymposium will have a lasting impact in this area.

[03243] Turan problem for graphs from geometric shapes

Format : Talk at Waseda University
Author(s) : Hong Liu (Institute for Basic Science)
Abstract : While Tur'{a}n type problem is the most studied topic in extremal combinatorics, some of the most basic bipartite degenerate Tur'{a}n problems remain elusive. In this talk, I will discuss some recent advancements on this topic and new results on bipartite graphs arising from geometric shapes and periodic tilings commonly found in nature, including even prisms, planar hexagonal tiling and quadrangulations of plane, cylinder and torus. This is joint work with Jun Gao, Oliver Janzer, Zixiang Xu.

[03233] Robust linear algebra methods and some applications

Format : Talk at Waseda University
Author(s) : Jun Gao (Institute for Basic Science)Hong Liu (Institute for Basic Science)Zixiang Xu (Institute for Basic Science)
Abstract : Given a set $L \subseteq [n]$, what can we say about the size or structure of a set system $\mathcal{F} \subseteq 2^{[n]}$ if $A \star B \in L$ for $A, B \in \mathcal{F}$, where $\star \in \{\cap, \cup, \setminus, \triangle\}$. Many important results have been produced around the above questions, and several far-reaching methods have been developed. In this talk, I will explain how to apply the linear algebra methods in the above problems, and introduce an algebraic proof of the stability result for Kleitman's theorem.

[03332] Optimal bisections of directed graphs

Format : Talk at Waseda University
Author(s) : Guanwu Liu (University of Science and Technology of China)Jie Ma (University of Science and Technology of China)Chunlei Zu (Shanghai Jiaotong Univerisity)
Abstract : In this paper, motivated by a problem of Scott and a conjecture of Lee, Loh and Sudakov we consider bisections of directed graphs. We prove that every directed graph with m arcs and minimum semidegree at least d admits a bisection in which at least $\left(\frac{d}{2(2d+1)} + o(1)\right)m$ arcs cross in each direction. This provides an optimal bound as well as a positive answer to a question of Hou and Wu in a stronger form.

[03231] Hypergraphs with infinitely many extremal constructions

Format : Online Talk on Zoom
Author(s) : JIANFENG HOU (Fuzhou University)
Abstract : We give the first exact and stability
results for a hypergraph Tur'{a}n problem with infinitely many extremal constructions
that are far from each other in edit-distance.
This includes an example of triple systems with Tur'{a}n density $2/9$,
thus answering some questions posed by the third and fourth authors and Reiher about the feasible region of hypergraphs. Our results also provide extremal constructions whose shadow density is a transcendental number.

Our novel approach is to construct certain multilinear polynomials that attain
their maximum (in the standard simplex) on a line segment and then to use these polynomials to define an operation on hypergraphs that gives extremal constructions.

01029 (2/3) : 4D @G304

[04610] Embeddings in “random like” hypergraphs

Format : Talk at Waseda University
Author(s) : Guanghui Wang (Shandong University)
Abstract : An archetype problem in extremal combinatorics is to study the structure of subgraphs appearing in different classes of (hyper)graphs. We will focus on such embedding problems in “random like” hypergraphs. In precise, we will mention Turan problems in quasi-random hypergraphs.

[03333] Spectral extremal graphs for disjoint cliques

Format : Talk at Waseda University
Author(s) : Liying Kang (Shanghai University)
Abstract : Let kK_{r+1} be the graph consisting of k vertex-disjoint copies of the complete graph K_{r+1}.
Moon [Canad. J. Math. 20 (1968) 95--102] and Simonovits [Theory of Graphs (Proc. colloq., Tihany, 1996)] independently showed that if n is sufficiently large, then the join of a complete graph K_{k-1} and an r-partite Tur'{a}n graph $T_{n-k+1,r}$ is the unique extremal graph for kK_{r+1}. In this talk we consider the graph which has the maximum spectral radius among all graphs without k disjoint cliques. We show that if G attains the maximum spectral radius over all n-vertex kK_{r+1}-free graphs for sufficiently large n, then G is isomorphic to the join of a complete graph K_{k-1} and an r-partite Tur'{a}n graph $T_{n-k+1,r}$. This is a joint work with Zhenyu Ni, Jing wang.

[03579] Co-degree threshold for rainbow perfect matchings in uniform hypergraphs

Format : Talk at Waseda University
Author(s) : Hongliang Lu (Xi'an Jiaotong University)Yan Wang (Shanghai Jiao Tong University)Xingxing Yu (Georgia Institute of Technology)
Abstract : Let k and n be two integers, with $k \geq 3$, $n \equiv 0 \pmod{k}$, and n sufficiently large. We determine the $(k-1)$-degree threshold for the existence of a rainbow perfect matchings in n-vertex k-uniform hypergraph. This implies the result of R"odl, Ruci'nski, and Szemer'edi on the $(k-1)$-degree threshold for the existence of perfect matchings in n-vertex k-uniform hypergraphs. In our proof, we identify the extremal configurations of closeness, and consider whether or not the hypergraph is close to the extremal configuration. In addition, we also develop a novel absorbing device and generalize the absorbing lemma of R"odl, Ruci'nski, and Szemer'edi.

[03715] Recent progress on non-separating subgraphs in highly connected graphs

Format : Talk at Waseda University
Author(s) : Shinya Fujita (Yokohama City University)
Abstract : Let k be a positive integer. A connected graph G is said to be k-connected, if for any vertex subset S of $V(G)$ such that $|S|

01029 (3/3) : 4E @G304

[04621] Spanning trees with bounded number of leaves in $K_{1,p}$-free graphs

Format : Talk at Waseda University
Author(s) : Kenta Ozeki (Yokohama National University)
Abstract : Matthews and Sumner proved that a connected $K_{1,3}$-free graph contains a Hamiltonian path if the graph satisfies a certain minimum degree condition.
Extending this result, it has been widely studied about the existence of a spanning k-ended tree in $K_{1,3}$-free or $K_{1,4}$ -free graphs with $k \geq 2$, and in $K_{1,5}$-free graphs with $k = 4, 6$, where a k-ended tree is a tree with at most k leaves.
With this situation in mind, in this talk, we pose a conjecture on a spanning k-ended tree in $K_{1,p}$-free graphs, and show two partial answers to the conjecture:
One solves the case $p = 5$ completely, and the other proves the conjecture asymptotically for all $p \geq 6$.
This is a joint work with Masao Tsugaki (Tokyo University of Science) and partially with Masahiro Kimura (Yokohama National University).

[04636] Hadwiger's conjecture for some graphs with independence number two

Format : Talk at Waseda University
Author(s) : Guiying YAN (Academy of Mathematics and Systems Science'Chinese Academy of Sciences)Qiang Zhou (Academy of Mathematics and Systems Science'Chinese Academy of Sciences)
Abstract : Hadwiger's conjecture is difficult to prove even for graphs with independence number two. Recently, Daniel Carter
found the conjecture is true for H-free graphs if H is some particular graphs of 6, 7, 8 or 9 vertices with the help of computers. In this talk, we will introduce this conjecture is true if H is one of four special graphs with 6 or 7 vertices
mathematically.

[05371] On Connectivities of Edge-Colored Graphs

Format : Talk at Waseda University
Author(s) : Kiyoshi Yoshimoto (Nihon University)
Abstract : In this talk, we consider two kind of color-connectivities of edge-colored graphs which are generalizing strong connectivity of directed graphs and also the relation is given.
Furthremore we show structures of edge-colored complete graphs using the color-connectivities.

[01036] Progress in Mathematical Programming Methods and Applications

Session Time & Room :

01036 (1/2) : 3C (Aug.23, 13:20-15:00) @A208

01036 (2/2) : 3D (Aug.23, 15:30-17:10) @A208

Type : Proposal of Industrial Minisymposium
Abstract : (Mixed-)integer (non-)linear optimization has been one of the biggest successes in transferring mathematical insight into real-world impact. Due to the generality of the integer programming model combined with continuous improvement in solving capability, the list of industrial applications is virtually endless. While the problems are usually NP-hard in theory, in practice, an incredible number of real-world instances can be solved within seconds. The algorithmic progress outpaced the increase in computer performance by far; combined, the solver speed has exponentially grown over the last 40 years. We present the latest state-of-the-art and a glimpse into the future.

[05521] An efficient solver for multi-objective onshore wind farm siting and network integration

Author(s) : Thorsten Koch (Technische Universität Berlin / Zuse Institute Berlin)Jaap Pedersen (Zuse Institute Berlin)
Abstract : Existing planning approaches for onshore wind farm siting and network integration often do not meet minimum cost solutions or social and environmental considerations. In this talk, we present an approach for the multi-objective optimization of turbine locations and their network connection using the Quota Steiner tree problem. We design an exact solver that makes large problem instances solvable and outperforms generic MIP solvers. Although our case studies in selected regions of Germany show large trade-offs between the objective criteria of cost and landscape impact, small burdens on one criterion can significantly improve the other. In addition, we demonstrate that contrary to many approaches for exclusive turbine siting, network integration must be simultaneously optimized in order to avoid excessive costs or landscape impacts in the course of a wind farm project. Our novel problem formulation and the developed solver can assist planners in decision making and help optimize wind farms in large regions in the future.

[02270] Steepest-Edge Simplex Algorithms for Quadratic Programming

Format : Talk at Waseda University
Author(s) : Shoji Shimizu (NTT DATA Mathematical Systems Inc.)Koichi Fujii (NTT DATA Mathematical Systems Inc.)Julian Hall (University of Edinburgh)
Abstract : We present steepest-edge simplex algorithms for quadratic programming problems. It is well known that in linear programming problems, the steepest-edge rule or Devex rule greatly reduces the total number of iterations in the simplex method. We extend these rules to the simplex method for quadratic programming and show their effectiveness through numerical experiments.

[02259] Techniques and advances for solving MINLPs

Author(s) : Robert Luce (Gurobi)
Abstract : We consider solving mixed-integer nonlinear optimization problems to global optimality. Our solver is based on the common branch-and-bound paradigm, but includes a number of specialized techniques to deal with nonconvex constraints and nonconvex objective functions. In this talk we will outline a few of these components from a theoretical and computational point of view.

[02296] New MIP presolving techniques in the Cardinal Optimizer

Format : Online Talk on Zoom
Author(s) : Gerald Gamrath (COPT GmbH)
Abstract : Presolving is an essential component of modern MIP solvers. Besides model cleanup, it identifies structures in the problem and tightens the formulation before the branch-and-cut search starts.
In this talk, we discuss common structures in real-world instances and show how a mathematical analysis of those structures resulted in new presolving reductions implemented in the Cardinal Optimizer (COPT). The impact of the new techniques is demonstrated in computational experiments.

01036 (2/2) : 3D @A208 [Chair: Thorsten Koch]

[05523] News from the FICO Xpress MIP Solver and Global MINLP Solver

Author(s) : Thorsten Koch (Technische Universität Berlin / Zuse Institute Berlin)Timo Berthold (Fair Isaac Germany GmbH)
Abstract : We will present the latest algorithmic advances and new features of the FICO Xpress Solver family.
Next to enhanced MIP performance, a focus will be on recent new technologies like the ability to solve multi-objective optimization problems and mixed-integer nonlinear optimization problems to proven global optimality.

[03882] Realization of smart factories using MIP

Format : Talk at Waseda University
Author(s) : Hiroki Ishikura (Kyushu University)
Abstract : Smart factories have become widely used for more efficient production activities recently. In collaboration with Rohto Pharmaceutical Co. (Rohto), we have conducted research to realize smart factories. In

this talk, we will introduce mobility optimization related to automated warehouses. Rohto uses an automated warehouse to manage a large volume of various items. By optimizing the mobility of automated warehouses, production activities can be streamlined, and factory operations can be made more efficient.

[02009] Benders' decomposition approach for the integrated long-haul and local VRP

Format : Talk at Waseda University
Author(s) : Junko Hosoda (Hitachi, Ltd.)Stephen J. Maher (Quantagonia GmbH)Yuji Shinano (Zuse Institute Berlin)Christoffer Villumsen (Hitachi, Ltd.)
Abstract : A supply chain management problem that integrates the determination of consolidation locations with the coordination of long-haul and local vehicle routing is a complicated problem. A Benders' decomposition approach is used to solve this problem. The delivery area and consolidation locations are computed in the master problem, and the long-haul and local vehicle routes are computed in the subproblems. The effectiveness of the decomposition is discussed in the presentation.

[05524] Progress in Mathematical Programming Solvers from 2001 to 2020 and future Challenges

Format : Talk at Waseda University
Author(s) : Thorsten Koch (Technische Universität Berlin / Zuse Institute Berlin)
Abstract : We investigate the progress made in LP and MILP solver performance during the last two decades. On average, we found that for solving LP/MILP, the total speed-up was about 180 and 1,000 times, respectively.
However, these numbers considerably underestimate the progress made on the algorithmic side: many problem instances can nowadays be solved within seconds, which the old codes are not able to solve within any reasonable time.
Finally, we will comment on future developments.

[01037] From interacting particles to social dynamics: modelling and analysis of agent-based systems

Session Time & Room : 1E (Aug.21, 17:40-19:20) @G802

Type : Proposal of Minisymposium
Abstract : Modelling of social dynamics, including social media or epidemics, has a long tradition.
Recently, stochastic modelling has become more relevant, touching upon such diverse aspects as
uncertainty quantification or robust control. Despite recent advances,
there is still a gap between the theoretical analysis of models and the model calibration based on empirial
data. In this minisymposium, we aim at bringing together researchers from dynamical systems, scientific computing and empirical research to discuss connections between agent-based models, particle systems and social simulation, with particular focus on the numerical analysis of agent-based models, reduced-order models and the role of random forcing.
Organizer(s) : Ana Djurdjevac, Carsten Hartmann
Classification : 35Qxx, 91Dxx, 37Hxx
Minisymposium Program :

01037 (1/1) : 1E @G802 [Chair: Ana Djurdjevac]

[04502] Feedback loops in opinion dynamics of agent-based and mean-field models

Format : Talk at Waseda University
Author(s) : Natasa Conrad (Zuse Institute Berlin)Ana Djurdjevac (Freie Universität Berlin)Jonas Koeppl (Weierstraß-Institut Berlin)
Abstract : We present a new mathematical model for co-evolving opinion and social dynamics within a group of

mobile,
interacting agents. Agents' movements are governed by their social position and opinions of others, and opinion dynamics are affected by their proximity and opinion similarity. We investigate the behaviour of this ABM in different
regimes, study the empirical distribution, and, in the limit of infinite number of agents, we derive a corresponding reduced model given by a PDE.

[03486] Bounded Confidence Models of Opinion Dynamics

Format : Talk at Waseda University
Author(s) : Benjamin Goddard (University of Edinburgh)Grigorios Pavliotis (Imperial College London)
Abstract : Bounded confidence models postulate that people only take into account the opinions of others if they are already sufficiently close in 'opinion space' (i.e., they somewhat agree). I will introduce agent-based, ODE, SDE, and PDE models, before focusing on the (nonlocal, nonlinear) PDE case. The main results concern the complex dynamics that arise; the presence of 'phase transitions' under varying parameters; the importance of boundary conditions; and the introduction of 'radicals' with unchanging opinions.

[04255] Open systems of interacting particles: a probabilistic and multiscale framework

Format : Talk at Waseda University
Author(s) : Mauricio del Razo (Freie Universität Berlin)
Abstract : Open systems are ubiquitous in nature and can be found in a variety of applications, such as chemical reactions, biological processes and even social dynamics. In this talk, we will introduce a comprehensive probabilistic framework for open systems of interacting particles. We will further discuss how our framework can be used to systematically construct consistent multiscale models and simulation schemes by examining how the framework scales up in different limiting regimes, such as system size and large population.

[04762] Branching and coalescing particles in a singular environemnt

Format : Talk at Waseda University
Author(s) : Tommaso-Cornelis Rosati (University of Warwick)
Abstract : In this talk we analyse how the presence of a random, highly irregular, environment can influence the evolution of particle systems. We study the fluctuations of branching particles in a white-in-space environment, leading to a rough super-process. Further, we describe the scaling limit of a system of Brownian motions driven by a singular drift by means of the so-called Brownian castle. Joint works with N. Perkowski and (in progress) M. Hairer and G. Cannizzaro.

[01040] Optimization and its Applications

Session Time & Room :

01040 (1/2) : 3D (Aug.23, 15:30-17:10) @F312

01040 (2/2) : 3E (Aug.23, 17:40-19:20) @F312

Type : Proposal of Minisymposium
Abstract : This minisymposium focuses on recent advances in mathematical optimization with versatile subjects such as optimal control, variational analysis, dynamical systems, nonlinear functional analysis, network systems, fixed point theory, and so forth. Application topics discussed here mainly lie in mathematical economics and engineering, in particular, optimal economic growth, general equilibrium analysis, utility theory, and Marxian economics as well as generative adversarial networks, but possible applications are not necessarily restricted to such problems. The minisymposium serves for a communication with applied mathematics in different areas.
Organizer(s) : Nobusumi Sagara, Alexander Zaslavski, Yuhki Hosoya
Classification : 49J27, 68M01, 91A27, 91B50, 91B62
Minisymposium Program :

01040 (1/2) : 3D @F312 [Chair: Yuhki Hosoya]

[01444] Non-Smooth Integrability Theory

Format : Talk at Waseda University
Author(s) : Yuhki Hosoya (Chuo University)
Abstract : We study a method of calculating the utility function from a candidate of a demand function that is not differentiable but is locally Lipschitz. Using this method, we obtain two new necessary and sufficient conditions for a candidate of a demand function to be a demand function. The first is conditions for the Slutsky matrix, and the second is the existence of a concave solution to a partial differential equation. Moreover, we show that the upper semi-continuous weak order that corresponds to the demand function is unique, and this weak order is represented by our calculated utility function. We provide applications of these results to econometric theory. First, we show that, under several requirements, if a sequence of demand functions converges to some function with respect to the metric of compact convergence, then the limit is also a demand function. Second, the space of demand functions that have uniform Lipschitz constants on any compact set is complete under the above metric. Third, the mapping from a demand function to the calculated utility function becomes continuous. This implies that a consistent estimation method for the demand function immediately defines a consistent estimation method for the utility function using our calculation method.

[01446] Theoretical analysis of two time-scale update rule for training GANs

Format : Talk at Waseda University
Author(s) : Naoki Sato Hideaki Iiduka (Meiji University)
Abstract : A theoretical analysis of a two time-scale update rule (TTUR) for training generative adversarial networks (GANs) has been given using decaying learning rates. In this talk, we give a theoretical analysis of TTUR using constant learning rates and show that, for TTUR using constant learning rates, the number of steps needed to train GAN decreases as the batch size increases. We also provide numerical results to support our theoretical analyses.

[01450] Production Prices and Walrasian Intertemporal Competitive Equilibrium Prices in a Generalized Neoclassical Production Economy

Format : Talk at Waseda University
Author(s) : Naoki Yoshihara (University of Massachusetts Amherst)
Abstract : We examine a general correspondence between production prices in classical and Marxian economics and the Walrasian competitive equilibrium prices in the standard general equilibrium theory by considering a standard intertemporal economy with a discounted lifetime utility function and a set of general neo-classical production technologies. This work resembles Duménil and Levy (1985) and Dana et. al (1989), but unlike these, a path of intertemporal Walrasian equilibrium prices is characterized by the Euler equation, derived from the economic model in this paper. In addition, equilibrium factor prices are endogenously determined and can vary across periods. Therefore, our intertemporal Walrasian equilibrium is much closer to the standard neoclassical type, compared to the intertemporal competitive equilibrium defined by Dana et. al (1989). However, we will show that any intertemporal Walrasian equilibrium prices converge to a system of production prices in the long term.

[01982] Optimal Growth in the Two-Sector Robinson-Shinkai-Leontief Model

Format : Talk at Waseda University
Author(s) : Minako Fujio (Yokohama National University)Ali M. Khan (The Johns Hopkins University)Liuchun Deng (Yale-NUS College)
Abstract : In this talk we synthesize the findings on the two-sector Robinson-Shinkai-Leontief model of optimal growth with and without discounting and demonstrate a variety of optimal dynamics. We provide a taxonomy of the optimal policy and the dynamics it yields for the entire parameter space of the model. At the same time, we shall focus on the two approaches we rely on to delineate those results, the value-loss minimization and the dynamic programming.

01040 (2/2) : 3E @F312 [Chair: Yuhki Hosoya]

[02153] On the approximate purification of mixed strategies in games with infinite action sets

Format : Talk at Waseda University
Author(s) : Chaowen Yu (Rissho University)Yuhki Hosoya (Chuo University)
Abstract : We consider a game in which the action set of each player is uncountable, and show that, from weak assumptions on the common prior, any mixed strategy has an approximately equivalent pure strategy. The assumption of this result can be further weakened if we consider the purification of a Nash equilibrium. Combined with the existence theorem for a Nash equilibrium, we derive an existence theorem for a pure strategy approximated Nash equilibrium under sufficiently weak assumptions. All of the pure strategies we derive in this paper can take a finite number of possible actions.

[03646] Numerical aspects of finding nonlinear production – consumption equilibrium

Format : Talk at Waseda University
Author(s) : Igor Griva (George Mason University)Roman A Polyak (George Mason University)
Abstract : We present and analyze numerical results obtained by using extra pseudo-gradient (EPG) method on a set of randomly generated nonlinear production – consumption equilibrium (NPCE) problems. The obtained results show that the number of EPG steps required for finding NPCE grows linearly with the number of products of a given economy. The number of arithmetic operations or time required for finding NPCE grows as a cube of the number of products.

[04476] Envelope theorems in Optimization

Author(s) : Joël Blot (Université PParis 1 Panthéon-SorbonneUniversi)
Abstract : We present recent results on the Envelope theorems in three chapters of Optimization. First in Static Optimization, secondly in Calculus of Variations and thirdly in Optimal Control Theory. To do that, we provide new results on the continuous dependence of coordiates in a moving frame, on the Hadamard di�erentiability of functionals under the integral form, and on the proof of the Pontryagin principle.
Date: November 13, 2022.

[01043] Applications of applied mathematics towards ocean engineering and related technologies

Session Time & Room :

01043 (1/4) : 3C (Aug.23, 13:20-15:00) @G605

01043 (2/4) : 3D (Aug.23, 15:30-17:10) @G605

01043 (3/4) : 3E (Aug.23, 17:40-19:20) @G605

01043 (4/4) : 4C (Aug.24, 13:20-15:00) @G605

Type : Proposal of Industrial Minisymposium
Abstract : A reasonable knowledge about the response of nonlinear offshore dynamical systems under environmental loads is necessary but challenging. This is due to the coupling of internal forces along with external excitations. In this mini symposium, mathematical model of nonlinear offshore systems will be considered with the intention of keeping the response close to the desired one. This can be achieved using sub-optimal control mechanism derived from nonlinear quadratic regulator theory and also its associated data can be visualized via ensemble statistical sense.

[01637] Robust control design for an autonomous underwater vehicle with uncertain dynamics

Format : Online Talk on Zoom
Author(s) : Antony Crispin Sweety Charles Selvaraj (Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore)
Abstract : In this talk, we consider the robust control problem for autonomous underwater vehicles in the presence of nonlinearities and uncertainties. The aim is to obtain a robust controller in order to maneuver to any given point and track a moving target in the presence of parametric uncertainty and external disturbances. Specifically, the proposed state feedback robust controller guarantees the closed-loop system stability in the sense of the Lyapunov stability theory. Finally, simulation results are provided to verify the effectiveness of the control design.

[01719] Particle swarm optimization based robust controller for autonomous underwater vehicle

Format : Online Talk on Zoom
Author(s) : Pankajavalli Palanisamy Balamani (Bharathiar University)Abinandhitha Radhakrishnan (Bharathiar University)
Abstract : The purpose of this work is to design a Particle Swarm Optimization (PSO) based controller in a systematic way to get the superior performance and robustness of the considered autonomous underwater vehicle model. Further, simulation results demonstrated the effectiveness of the proposed controller. The developed controller provides faster convergence to the change of parameters as compared to the conventional state feedback controller, for the stabilization of the closed-loop systems with external disturbances.

[01959] Applications of applied mathematics towards dynamic control of multi-dimensional structures

Format : Online Talk on Zoom
Author(s) : Payel Chaudhuri (IIT KHARAGPUR)
Abstract : This work addresses an evolutionary optimal dynamic inversion algorithm-based semi-active controller for vibration reduction. The proposed inverse control algorithm is established on robust mathematical conceptualization and is ideal with semi-active magnetorheological dampers. The optimum voltage estimated from the proposed controller aid in generating the required control force from the MR dampers to the structures under dynamic loading. The resilience of the proposed inverse control algorithm is evaluated employing various seismic time histories on a multi-dimensional structure.

[01807] Ship maneuvering in waves

Format : Talk at Waseda University
Author(s) : Rameesha T V (Scientist B)Krishnankutty P (Professor (Retired))
Abstract : Poor controllability of a surface ship is considered as a major cause for most of the marine accidents, which may result in loss of life and property. The present proposal is focused on the prediction of ship maneuvering in waves. Mathematical model for maneuvering prediction is modified for wave condition. The steering and turning characteristics of a container ship in still water and wave condition are compared experimentally and numerically.

01043 (2/4) : 3D @G605 [Chair: Dr.Alankrita Singh]

[01761] AuX (X = Cu, Ag) monolayers promising Thermoelectric materials

Format : Online Talk on Zoom
Author(s) : Kulwinder Kaur (Mehr Chand Mahajan DAV College for Women, Chandigarh)
Abstract : Under the application of strain, the electronic and thermoelectric properties of AuX (X = Cu, Ag) monolayers are investigated using density functional theory with the help of Boltzmann transport equations. At 6% strain, ultralow lattice thermal conductivity is observed. The maximum value of ZT is 2.20 and 1.40 for unstrained

case and enhances to 3.61 and 2.91 at 6% strain for AuCu and AuAg monolayers, respectively, which compare favorably to several promising thermoelectric materials.

[01770] One-Dimensional Hetero-Nanothread Fibres for high mechanical energy storage Applications

Format : Online Talk on Zoom
Author(s) : Marutheeswaran Srinivasan (Amrita Vishwa Vidyapeetham)Ramesh Sivasamy (Amrita Vishwa Vidyapeetham)
Abstract : Searching for high density energy materials is a key challenge for the engineering sciences. Recently discovered carbon nanothread bundles (CNB) exhibit higher mechanical strengths than carbon nanotube bundles. MD simulation and continuum elastic theory show that CNB exhibits a high mechanical energy storage density of up to 1.76 MJ kg−1. The results suggest CNB is an ideal candidate for fiber applications. We look at how mechanical behavior changes with heteroatom doping in the pristine state.

[01763] The Li-based quaternary Heusler compound LiYPdSn: A promising thermoelectric material

Format : Online Talk on Zoom
Author(s) : Jaspal Singh Dhillon (Mata Sundri University Girls College)
Abstract : A newly discovered Li-based quaternary Heusler compound LiYPdSn is investigated which is the 18 Valence Electron Count (VEC) rule follower, non-magnetic, stabilized in FCC cubic structure of F-43m space group, possessing a melting point of 1700K. The Boltzmann transport equations and the Density Functional Theory is employed to investigate its dynamic stability, electronic band structure, thermodynamic response, motivating mechanical and elastic properties, thermodynamic response, which finally results in favorable thermoelectric performances and safe environmental opportunities.

[02187] Mathematical modeling and Environmental Impact of COVID 19 pandemic

Format : Online Talk on Zoom
Author(s) : Satarupa Dey (Shyampur Siddheswari Mahavidyalaya)
Abstract : The corona virus disease was declared as a global pandemic on the year 2020 due to its rapid spread and complex impact on human health. By the end of the pandemic in 2021, there has been numerous impacts on environment. The prolonged lockdown enhanced the quality of air and water in urban areas on the other hand use of personal protective equipment and mask have increased plastic pollution in water bodies due to its improper disposal. In this study the positive as well as negative impact of corona virus pandemic on environment is discussed.

01043 (3/4) : 3E @G605 [Chair: Dr. Satarupa Dey]

[01894] Highly Stable Lead-Free Magnetic Perovskite semiconductors

Format : Online Talk on Zoom
Author(s) : Shakeel Ahmad Khandy (Zhejiang University)
Abstract : Lead Free Halide Perovskites play a key role in Solar cell, LED, nondestructive bioimaging, long-wave communications, and medical care applications as they emit in the broader regions of spectrum from near-infrared region to visible range. Cs2MoX6 (X=Cl,Br) as key members of the luminescent family, have been reported to emit light in ultraviolet and visible regions. Both these systems grow in cubic phase and are stable under thermal, mechanical and dynamical constraints of density functional theory. In addition, the ferromagnetic interactions of Mo with halide p-states create a total magnetic moment of 2 mB, thus enabling another degree of freedom to play with

[02416] CFD of impingement over a curved surface by equilaterally staggered jets

Format : Online Talk on Zoom
Author(s) : Alankrita Singh (Indian Institute of Technology Roorkee)
Abstract : The equilateral staggered arrangement of jets constitutes of a central jet surrounded by four neighboring jets. The concave plate is uniformly heated at constant heat flux of 3 kW/m2. SIMPLE is incorporated

for pressure velocity coupling.SST k-ω is used as the turbulence model. The solution is assumed to be converged when sum of the normalized
residuals drop to e-5 for momentum, continuity and turbulence equations and e-7 for energy equations. Similar to lampblack visualization results, the CFD results show stretching of flow along the corners of the concave target surface.

[02634] An application of the Fuzzy inference system to Seismic Damage Prediction

Format : Online Talk on Zoom
Author(s) : Dr. Champakali Das (Nims University)Dr. Narendra Kumar (Nims University)Dr. Amit Kumar Singh (RBS Engineering College)
Abstract : A damage prediction form has been developed by using fuzzy logic techniques. An earthquake caused significant damage to any building. The results of damage prediction must be used as the basis for a disaster preparedness plan if loss of life and property is to be reduced. Fuzzy logic offers a more unified strategy for addressing earthquake damage prediction difficulties because of the interconnectedness of the key components and the ambiguity of the ideas at play.

01043 (4/4) : 4C @G605 [Chair: Dr Payel Chaudhuri]

[03120] The Li-based quaternary Heusler compound LiYPdSn: A promising thermoelectric material

Format : Online Talk on Zoom
Author(s) : Jaspal Singh Dhillon (Mata Sundri University Girls College)
Abstract : A newly discovered Li-based quaternary Heusler compound LiYPdSn is investigated which is the 18 Valence Electron Count (VEC) rule follower, non-magnetic, stabilized in FCC cubic structure of F-43m space group, possessing a melting point of 1700K. The Boltzmann transport equations and the Density Functional Theory is employed to investigate its dynamic stability, electronic band structure, thermodynamic response, motivating mechanical and elastic properties, thermodynamic response, which finally results in favorable thermoelectric performances and safe environmental opportunities.

[03204] Structural, electronic, dynamical and thermoelectric performance of LaCoTiSn Heusler alloy

Format : Online Talk on Zoom
Author(s) : Yuhit Gupta (GSSS Badbar, Department of School Education, Punjab, India)
Abstract : In the present report, the physical properties of LaCoTiSn have been investigated by employing density functional theory. The calculated electronic band structure revealed the half-metallic character and 100% spin-polarization ratio suggest the ferromagnetic nature of the alloy. The evaluated value of Poisson's ratio '0.34' revealed the metallic bonding. To examine lattice dynamical stability, the phonon frequencies have been computed for first time. To measure the efficiency, the figure of merit is achieved to be 0.35.

[01050] Delay equations in mathematical biology

Session Time & Room : 4E (Aug.24, 17:40-19:20) @G402

Type : Proposal of Minisymposium
Abstract : The mathematical modelling of many biological systems require the application of delay differential equations, since the future evolution of such systems depend of the duration of various processes. Examples range from cell cycle length in cell biology, maturation delay in population dynamics, and latency period in epidemiology . Time delays naturally occur in the control of biological systems as well. On the other hand, delay differential equations pose great challenges from the modelling, analysis, and numerical points of view, especially if nonlinearities are present and the delay is defined in a more involved way, such as state dependent delays. The goal of this minisymposium is to highlight recent advances and novel applications of delay equations in the field of mathematical biology.

[04514] An approach to model the bird migration

Format : Talk at Waseda University
Author(s) : Rongsong Liu (University of Wyoming)Stephen Gourley (Surrey University)
Abstract : An approach to modelling bird migration is proposed, in which there is a region where birds do not move but spend time breeding. Birds leave this breeding region and enter a migration flyway. Mathematically, the flyway is a curve parametrised by arc-length. Per-capita mortality along the flyway is both position and age-dependent.

[05022] Infectious disease dynamics with delayed control on the reproduction number

Format : Talk at Waseda University
Author(s) : Ferenc A Bartha (Bolyai Institute, University of Szeged)
Abstract : We attempt to mitigate an epidemic governed by a compartmental transmission model by introducing an adaptive control based on the effective reproduction number $\mathcal{R}_t$. The control aims to keep $\mathcal{R}_t$ within the prescribed interval $\mathcal{I}$ containing 1 by triggering or lifting non-pharmaceutical interventions affecting the transmission rate. The inherent delay in measuring the control output, i.e. $\mathcal{R}_t$, results in involved dynamics. We analyze the effects of both the choice of $\mathcal{I}$ and of the delay.

[04371] A delayed epidemic model for behavior change

Format : Talk at Waseda University
Author(s) : Toshikazu Kuniya (Kobe University)
Abstract : In the period of COVID-19, the on/off of strict interventions such as lockdown caused oscillations of reported infected population in many countries. In this study, we formulate a delayed epidemic model with psychological effect that people change their contact frequency according to the recent information on the reported cases. We perform the Hopf bifurcation analysis, and show that time delay and behavior change play an important role in the occurrence of the recurrent epidemic waves.

[04511] Evolution of maturation delay

Format : Talk at Waseda University
Author(s) : Gergely Röst (University of Szeged, Hungary)
Abstract : We propose a new mathematical model to address the evolution of maturation period, building on the well-studied Nicholson's blowfly equation, formulated as a system of delay differential equations with two delays. We identify the optimal maturation delay, depending on the quality and suitability of the habitat, which is both a globally evolutionary stable and convergence stable strategy. Mathematically interesting questions raised by the invasibility of oscillatory insect populations. Joint work with Xingfu Zou.

[01054] Scalable Solvers for Multiphysics Problems

Session Time & Room :

01054 (1/3) : 4D (Aug.24, 15:30-17:10) @E507

01054 (2/3) : 4E (Aug.24, 17:40-19:20) @E507

01054 (3/3) : 5B (Aug.25, 10:40-12:20) @E507

Type : Proposal of Minisymposium

Abstract : Many applications in computational sciences and engineering involve multiple physical quantities. Accurate simulations of multiphysics problems involve the solution of large sparse linear equation systems consisting of blocks that correspond to the different physics and their coupling. This has to be taken into account when designing scalable and efficient solvers for such kind of problems.

This minisymposium addresses the development and implementation of the solution strategies for large-scale complex multiphysics systems as well as the presentation of results on modern supercomputers.

Organizer(s) : Alexander Heinlein, Matthias Mayr

01054 (1/3) : 4D @E507 [Chair: Alexander Heinlein]

[01909] On the Use of Algebraic Multigrid in Various Applications on High Performance Computers

Format : Talk at Waseda University

Author(s) : Ulrike Meier Yang (Lawrence Livermore National Laboratory)

Abstract : The hypre software library provides a variety of parallel linear solvers implemented for high performance computers. Its focus is on algebraic multigrid methods (AMG), which provide excellent scalability. With the increasing inclusion of accelerators into current and future high-performance computers, various new programming models have been added to take advantage of the increased performance potential of GPUs. This talk will discuss porting challenges and present results of use of hypre's GPU-enabled multigrid solvers within several application codes.

[03924] Implications of multiphysics problems in multigrid methods from a linear algebra view point

Format : Talk at Waseda University

Author(s) : Matthias Bolten (University of Wuppertal)

Abstract : Multiphysics problems require special attention in multigrid methods, as standards methods often do not converge. To overcome this, different approaches have been considered, e.g, special smoothers and special grid transfer and coarse grid selection. We are studying methods for block matrices, as they arise when systems of PDEs are considered. Different approaches for block matrices are presented, including block smoothers as well as analysis of multigrid methods resulting in requirements on grid transfer operators.

[03818] Parallel scalable solvers for Helmholtz problems

Format : Talk at Waseda University

Author(s) : Cornelis Vuik (Delft University of Technology)Jinqiang Chen (Delft University of Technology)Vandana Dwarka (Delft University of Technology)

Abstract : A matrix-free, parallel multi-level deflation preconditioning method is proposed for Helmholtz problems. The method integrates the geometric multi-grid-based Complex Shifted Laplace Preconditioner (CSLP) and higher-order deflation, employing re-discretization schemes derived from Galerkin coarsening approach for a matrix-free parallel implementation. The method shows close to wavenumber-independent convergence and satisfactory strong, and weak parallel scalability. Numerical experiments demonstrate the effectiveness of our approach for complex mo problems, solving large-scale heterogeneous Helmholtz problems with minimized pollution error.

[02018] Reynolds-robust preconditioners for the stationary incompressible viscoresistive MHD equations

Format : Talk at Waseda University

Author(s) : Patrick Emmet Farrell (University of Oxford)Fabian Laakmann (University of Oxford)

Abstract : We present an augmented Lagrangian preconditioner for the incompressible viscoresistive equations of magnetohydrodynamics. For stationary problems, our solver achieves robust performance with respect to the Reynolds and coupling numbers. We extend our method to fully implicit methods for time-dependent problems. Our approach relies on specialized parameter-robust multigrid methods for the hydrodynamic and electromagnetic blocks. The scheme ensures exactly divergence-free approximations of both the velocity and the magnetic field up to solver tolerances.

01054 (2/3) : 4E @E507 [Chair: Alexander Heinlein]

[04232] Robust nonlinear domain decomposition methods for problems with micro-heterogeneous structures

Format : Talk at Waseda University

Author(s) : Alexander Heinlein (Delft University of Technology (TU Delft))Axel Klawonn (University of Cologne)Martin Lanser (University of Cologne)

Abstract : Nonlinear domain decomposition methods (DDMs) are efficient alternatives to classical Newton-Krylov-DDMs.
In contrast to the latter ones, in nonlinear DDMs, the nonlinear partial differential equation is decomposed into subdomains before linearization, which often improves the nonlinear convergence behavior. To obtain robustness applying nonlinear DDMs to heterogeneous multiscale or multiphysics problems, a global and coarse second level should be included. In this talk, several two-level nonlinear Schwarz methods for heterogeneous problems are discussed and compared.

[05039] Immersed Mesh Methods for Coupled Multiphysics Problems

Format : Talk at Waseda University

Author(s) : Rolf Krause (Euler Institute, USI, Lugano)Patrick Zulian (Euler Institute, USI, Lugano)Maria Nestola (Euler Institute, USI, Lugano)

Abstract : We present overlapping domain domain decomposition methods coupling different discretizations in the volume, along surfaces, or between surfaces and volumes. Central element of our approach is a massively parallel discrete L^2 projection, which allows for stable variational transfer between different physical models. Examples from fluid structure interaction (FSI), i.e. artificial heart valves, or flow in fracture networks, as well as from contact mechanics coupled with FSI illustrate our approach.

[04600] Towards a scalable multilevel domain decomposition solver for immersed boundary finite element method

Format : Talk at Waseda University

Author(s) : Jakub Sistek (Institute of Mathematics of the Czech Academy of Sciences)

Abstract : We develop multilevel balancing domain decomposition by constraints (BDDC) method tailored to the solution of the linear systems arising in the context of immersed boundary FEM with parallel adaptive grid refinement. A crucial challenge is presented by fragmenting of subdomains. We present these concepts, the challenges, our implementation, and numerical results for the Poisson problem on complex geometries from engineering. This is joint work with Fehmi Cirak, Eky Febrianto, Matija Kecman, and Pavel Kus.

[03836] Co-Design of Modelling and Monolithic Overlapping Schwarz Solvers in Chemo-Mechanics

Format : Talk at Waseda University

Author(s) : Friederike Röver (TU Bergakademie Freiberg)Bjoern Kiefer (TU Bergakademie Freiberg)Stefan Prüger (TU Bergakademie Freiberg)Oliver Rheinbach (TU Bergakademie Freiberg)

Abstract : The focus of this talk is the co-design of the variational formulations arising from model problems in chemo-mechanics and parallel iterative solvers from domain decomposition.
We choose the FROSch framework of the Trilinos Software library as a parallel solver. It contains a parallel implementation of the GDSW preconditioner, which allows an algebraic construction.
We present results applying FROSch to a fully coupled deformation-diffusion boundary value problem of a swelling hydrogel. For the FE-implementation, we use the deal.II software library and incorporate FROSch as a solver framework.

01054 (3/3) : 5B @E507 [Chair: Alexander Heinlein]

[03397] A tensor-preserving domain decomposition preconditioner for high-order implicit methods

Format : Talk at Waseda University
Author(s) : Jing-Yuan Wang (University of Macau)Yingzhi Liu (University of Macau)Xiao-Chuan Cai (University of Macau)
Abstract : We investigate high-order block implicit methods for solving parabolic and unsteady Stokes problems, including the fully implicit Runge-Kutta method as a special case. These methods provide high accuracy with relatively large time step size, but the large, often nonsymmetric, and highly ill-conditioned stiffness matrix limits its practical use. To overcome this, we propose one- and two-level tensor-preserving domain decomposition preconditioners. Numerical experiments show the effectiveness and scalability of this approach for parabolic and Stokes flows.

[01058] Recent advances in stochastic nonlinear dynamics: modeling, data analysis

Session Time & Room :

01058 (1/3) : 2D (Aug.22, 15:30-17:10) @E502

01058 (2/3) : 2E (Aug.22, 17:40-19:20) @E502

01058 (3/3) : 3C (Aug.23, 13:20-15:00) @E502

Type : Proposal of Minisymposium
Abstract : Stochasticity, nonlinearity and complexity can be found and used in many different fields, including the natural sciences such as mechanics, physics, biology, neuroscience as well as technology and engineering fields such as aeronautics, astronautics, information theory and computer science. The symposium focuses on the stochastic modeling and data analysis in nonlinear dynamical system. The contributions cover various fields such as Brownian motion, Levy process, and fractional Brownian motion et al and applications, data analysis methods and techniques combining complex systems science and machine learning. This symposium provides a forum to discuss science, strengthen relationships, create new contacts and gain a direct experience of new progresses in stochastic modeling and data analysis.

[02085] Almost sure averaging for fast-slow stochastic differential equations via controlled rough path

Format : Talk at Waseda University
Author(s) : Bin PEI (Northwestern Polytechnical University)Yong Xu (Northwestern polytechnical university)
Abstract : We apply the averaging method to a coupled system consisting of two differential equations which has a slow component driven by fractional Brownian motion (FBM) with the Hurst parameter $\frac{1}{3} < H_1 \leq \frac{1}{2}$ and a fast component driven by additive FBM with the Hurst parameter $\frac{1}{3} < H_2 \leq \frac{1}{2}$. The main purpose is to show that the slow component of such a couple system can be described by a stochastic differential equation with averaged coefficients. Our main result deals with an averaging procedure which proves that the slow component converges almost surely to the solution of the corresponding averaged equation using the approach of time discretization and controlled rough path. To do this we generate a stationary solution by a exponentially attracting random fixed point of the random dynamical system generated by the fast component.

[01488] Discrete-time Approximation of Partially Observed Stochastic Optimal Control Problem

Format : Talk at Waseda University
Author(s) : Yunzhang Li (Fudan University)
Abstract : In this talk, we study a class of stochastic optimal control problems under partial observation by discrete-time control problems. To establish a convergence result, we adapt the weak convergence technique together with the notion of relaxed control rule. With a well chosen discrete-time control system, we provide an implementable numerical algorithm to approximate the value. We illustrate our convergence result by numerical experiments on a partially observed control problem in a linear quadratic setting.

[03981] Large deviations for a slow-fast McKean-Vlasov model with jumps

Format : Talk at Waseda University
Author(s) : Xiaoyu YANG (Northwestern Polytechnical University)Yong Xu (Northwestern polytechnical university)
Abstract : We aim to investigate large deviations for a slow-fast McKean-Vlasov system with jumps. Based on the variational framework of the McKean-Vlasov system with jumps, it is turned into weak convergence for the controlled system. Different from the general case, the controlled system is related to the distribution of the original system, which causes difficulties. To solve it, the combination of asymptotic of original system and averaging principle is employed efficiently.

[02182] Recent advances in stochastic nonlinear dynamics: modeling, data analysis

Format : Online Talk on Zoom
Author(s) : Zi-Fei Lin (Xi 'an University of Finance and Economics)Yan-Ming liang (Xi 'an University of Finance and Economics)Jia-Li Zhao (Xi 'an University of Finance and Economics)Jiao-Rui Li (Xi 'an University of Finance and Economics)Kapitaniak Tomasz (Lodz University of Technology)
Abstract : Predicting strongly noise-driven dynamic systems has always been a difficult problem due to their chaotic properties. In this study, we investigated the prediction of dynamic systems driven by strong noise intensities, which proves that deep learning can be applied in diverse fields. This is the first study that uses deep learning algorithms to predict dynamic systems driven by strong noise intensities. We examined the effect of hyperparameters in deep learning and introduced an improved algorithm for prediction. Several numerical examples are presented to illustrate the performance of the proposed algorithm, including the Lorenz system and the Rossler system driven by noise intensities of 0.1, 0.5, 1, and 1.25. All the results suggest that the proposed improved algorithm is feasible and effective for predicting strongly noise-driven dynamic systems. Furthermore, the influences of the number of Neurons, the Spectral Radius, and the Regularization Parameters are discussed in detail. These results indicate that the performances of the machine learning techniques can be improved by appropriately constructing the neural networks.

01058 (2/3) : 2E @E502 [Chair: Bin Pei]

[02193] Response prediction of dynamical systems with the GCM-DL method

Format : Talk at Waseda University
Author(s) : Xiaole Yue (Northwestern Polytechnical University)Yong Xu (Northwestern polytechnical university)Xiaocong Liu (Northwestern Polytechnical University)Yue Zhao (Northwestern Polytechnical University)
Abstract : Generalized cell mapping method based on deep learning is proposed which can predict responses of dynamical systems from experimental data with part of information about physical model. This method trains the neural network model from a small amount of experimental data and obtains the potential dynamic model. The global characteristics of system are analyzed by GCM method. By introducing deconvolution layer and image super-resolution, the probability density function of stochastic dynamic system response is estimated.

[02190] Complex dynamics of a conceptual airfoil structure with consideration of extreme flight conditions

Format : Talk at Waseda University
Author(s) : Qi Liu (Tokyo Institute of Technology)
Abstract : An aircraft in practice serves under extreme flight conditions, that will have a substantial impact on its flight safety. Understanding dynamics of airfoil structure of an aircraft subjected to severe load conditions is thus extremely valuable and necessary. In this study, we will explore the complicated dynamical behaviors of a conceptual airfoil excited by an external harmonic force and an extreme random load. Importantly, such an extreme random load is portrayed by a non-Gaussian Lévy noise with a heavy-tailed feature. We theoretically deduce amplitude-frequency equations associated with the deterministic airfoil system. We observe excellent agreements between the analytical solutions and the numerical ones, as well as bistable behaviors. Besides, the effects of the extreme random load on the airfoil system are thoroughly investigated. Interestingly, within the bistable regime, the extreme random load can lead to stochastic transition and stochastic resonance. Due to its heavy-tailed nature, the Lévy noise would increase the possibility of a highly unexpected stochastic transition behavior between desirable low-amplitude and catastrophic high-amplitude oscillations compared with the Gaussian scenario. Such vibration patterns might damage or destroy the airfoil structure, which will put an aircraft in great danger. All the findings would be helpful in ensuring the flight safety and enhancing the strength and reliability of airfoil structure operating at extreme flight conditions.

[02205] Pattern Dynamics of Higher Order Reaction-Diffusion network

Format : Talk at Waseda University
Author(s) : Jianwei Shen (North China University of Water Resources and Electric Power)
Abstract : In this paper, we will investigate the pattern dynamics of higher order reaction-diffusion network by group interactions and prove the interplay between different orders of interaction can affact the emergence of turing patterns. Our results try to the mechanism of many body interaction on complex network.

[02243] Three occurrence mechanisms of extreme events in stochastic dynamical systems

Format : Online Talk on Zoom
Author(s) : Yongge Li (Northwestern Polytechnical University)Dan Zhao (Northwestern Polytechnical University)Yong Xu (Northwestern polytechnical university)
Abstract : In this work, three mechanisms for the occurrence of extreme events in stochastic dynamical systems are given. Firstly, for systems with a bifurcation structure, if the difference of the branches at the bifurcation point is large, then a time-varying amplitude of the external periodic excitation is able to induce an extreme event. This is verified in the rolling motion of a ship system. Secondly, for systems with rare attractors, a random pulse excitation, such as Poisson white noise, is able to drive the system to escape from the basin of general attractor to that of rare attractor. However, the basin of rare attractor is so small that the system will go back to the general state immediately. Such a kind of transition is also extreme event. Finally, an extreme excitation can also generate extreme event, such as the Lévy noise. In such cases, it does not require much about the systems, but the extreme excitations work. These results provide theoretical guidance for further prediction and avoidance of extreme events.

01058 (3/3) : 3C @E502 [Chair: Qi Liu]

[02092] Homogenization of the two dimensional singular polymer measure

Format : Online Talk on Zoom
Author(s) : Huanyu Yang (Free University of Berlin)
Abstract : We consider the SDE on $

[0,n]$:

\begin{equation}
\left{
\begin{aligned}
dZ^n_t&=\nabla h(n-t,Z^n_t)dt+dB_t,\

Z_0^n&=x,
\end{aligned}
\right.
\end{equation}
where B is the standard Brownian motion and h is the solution to KPZ equation driven by space-white noise ξ on $\mathbb{T}^2$.
The law of Z^n is the same as the law of the coordinate process under the sigular polymer measure Q^n constructed by Cannizzaro and Chouk:
\begin{equation}
Q^n(d\omega)=\frac{1}{U(n)}\exp\left(\int_0^n\left(\xi\left(\omega\left(s\right)\right)-\infty\right)\right)\mathbb{W}(d\omega),
\end{equation}
where $\mathbb{W}$ is the Wiener measure on $C(

[0,\infty),\mathbb{R}). *Bydecomposingthedriftterm* **h** *intoasingulartime − homogenioustermandasmoothtime − dependentterm, weproveth*
\left(\frac{1}{\sqrt{n}}Z^n*nt}\right)***{t\in**

[0,1]}$ converges to a Brownian motion.

This is the joint work with Nicolas Perkowski.

[01060] Exploring Arithmetic and Data Representation Beyond the Standard in HPC

Session Time & Room :

01060 (1/3) : 1C (Aug.21, 13:20-15:00) @E803

01060 (2/3) : 1D (Aug.21, 15:30-17:10) @E803

01060 (3/3) : 1E (Aug.21, 17:40-19:20) @E803

Type : Proposal of Minisymposium
Abstract : This mini-symposium explores the potential of utilizing arithmetic operations and data representations other than FP32 (single-precision) and FP64 (double-precision) in numerical computations with HPC. Such attempts include not only higher or lower floating-point precision, but also integer representation, error handling, rounding, etc., and are intended not only for performance but also for quality and reliability of computations. We explore various angles of this challenge, from low-level implementations to applications.

[01783] FP-ANR: A representation format to handle floating-point cancellation at run- time

Author(s) : David DEFOUR (Universite de Perpignan)
Abstract : When dealing with floating-point numbers there are several sources of error which can drastically reduce the numerical quality of computed results. Among those errors, the loss of significance, or cancellation, occurs during for example the subtraction of two nearly equal numbers. In this article, we propose a representation format named Floating-Point Adaptive Noise Reduction (FP-ANR). This format embeds cancellation information directly into the floating-point representation format thanks to a dedicated pattern. With this format, unsignificant trailing bit lost during cancellation are removed from every manipulated floating-point number. The immediate consequence is that it increases the numerical confidence of computed values. The proposed representation format

corresponds to a simple and efficient implementation of significance arithmetic based and compatible with the IEEE-754 standard.

[01812] Precision autotuning using stochastic arithmetic

Author(s) : Quentin Ferro (Sorbonne University)Stef Graillat (Sorbonne University)Thibault Hilaire (Sorbonne University)Fabienne Jezequel (Sorbonne University)
Abstract : We present PROMISE, a tool that makes it possible to provide a mixed precision version of a program by taking into account the requested accuracy on the computed results. With PROMISE the numerical quality of results is verified using Discrete Stochastic Arithmetic that enables one to estimate round-off errors. PROMISE has been used for floating point auto-tuning on neural networks to lower their precision while keeping an accurate output.

[01839] Implementation of highly optimized multiple precision BLAS: Strassen vs. Ozaki scheme

Author(s) : Tomonori Kouya (Shizuoka Institute of Science and Technology)
Abstract : We have already developed a highly optimized extended multiple precision basic linear algebra subprogram library using various technologies such as AVX2 and OpenMP. In particular, Strassen algorithm and Ozaki scheme we employed are distinctive methods for accelerating matrix multiplication. In this talk, we describe the software structure of our library and highlight the advantages and disadvantages of Strassen algorithm and Ozaki scheme through benchmark tests using fixed- and arbitrary-precision floating-point arithmetic.

[03869] Accelerating 128-bit Matrix Multiplication for Applications using FPGAs

Author(s) : Fumiya Kono (Shizuoka Institute of Science and Technology)
Abstract : General Matrix Multiplication (GEMM) is a core of various scientific applications. Since the requirement for the number of bits representing floating-point numbers depends on individual applications, the precision of GEMM is critical. Particularly, Semidefinite Programming requires higher precision, such as binary128. We researched methods of accelerating GEMM in binary128 using FPGAs because arithmetic in binary128 was very slow without hardware unit support. This talk presents an evaluation of our designs on several Intel FPGAs.

01060 (2/3) : 1D @E803 [Chair: Naohito Nakasato]

[04191] Multiple Integer Divisions with an Invariant Dividend

Author(s) : Daisuke Takahashi (University of Tsukuba)
Abstract : In this talk, we propose an algorithm for multiple integer divisions with an invariant dividend and monotonically increasing or decreasing divisors.
In such multiple integer divisions, we show that if the dividend and divisors satisfy a certain condition, then if only one quotient is calculated by division first, the remaining quotients can be obtained by correcting the previously calculated quotients at most once.

[04628] Reduced-Precision Data Representation on Sparse Matrix-Vector Multiplications

Author(s) : Daichi Mukunoki (RIKEN Center for Computational Science)Masatoshi Kawai (Nagoya University)Toshiyuki Imamura (RIKEN Center for Computational Science)
Abstract : In sparse iterative solvers, data and arithmetic precision affect convergence and solution accuracy, and their precision can be optimized. There is a demand for its kernel, sparse matrix vector multiplication (SpMV), with different precision. Due to its memory-intensive nature, SpMV could benefit from low-precision floating-point formats to improve performance. In this talk, we demonstrate the performance of our SpMV implementations on CPU and GPU, allowing precision adjustment in 8-bit increments from 16 to 64 bits.

[04862] High-performance multidimensional integration

Author(s) : Elise Helene de Doncker (Western Michigan University)
Abstract : Techniques for parallel multidimensional integration will be presented, with applications to Feynman loop integrals
in high energy physics. Integrand singularities are addressed with adaptive region partitioning, transformations, and convergence acceleration via linear or nonlinear extrapolation.
Parallel implementations are commonly layered over a platform that interfaces with the underlying computer architecture, including MPI (Message Passing Interface), OpenMP for iterated multi-threaded integration, and CUDA kernels supporting integrand evaluation for lattice type rules on thousands of GPU CUDA cores.

[04875] Introducing MPLAPACK 2.0.1: An Extension of BLAS and LAPACK for Multiple Precision Computation

Author(s) : Maho Nakata (RIKEN)
Abstract : MPLAPACK, a multiple-precision extension of LAPACK, offers enhanced numerical linear algebra capabilities. Translated from Fortran 90 to C++ using FABLE, MPLAPACK 2.0.1 supports MPBLAS, real and complex versions, and all LAPACK features except mixed-precision routines. Porting legacy C/C++ numerical codes is straightforward, and it supports various numerical libraries for diverse precision levels. MPLAPACK offers OpenMP acceleration for some routines and CUDA support for specific double-double versions. Achieving impressive performance, MPLAPACK is available under the 2-clause BSD license on GitHub.

01060 (3/3) : 1E @E803 [Chair: Tomonori Kouya]

[04912] Evaluation of various arithmetic for linear algebra on GPU and FPGA

Author(s) : Naohito Nakasato (University of Aizu)
Abstract : We present the evaluation of various non-standard floating-point (FP) arithmetic for linear algebra. We accelerate matrix multiplication in 128-bit FP arithmetic on both GPU and FPGA. Also we evaluate other FP format such as POSIT and reduced precision FP arithmetic. We discuss the energy efficiency and the numerica accuracy of the non-standard FP arithmetic on GPUs and FPGA accelerators for dense matrices.

[05094] Using quad-precision numbers for preconditioner of domain decomposition method

Author(s) : Hiroshi Kawai (Toyo University)Masao Ogino (Daido University)Ryuji Shioya (Toyo University)
Abstract : Domain decomposition method with BDD preconditioner is one of the effective parallelization methods for the finite element method. Coarse grid correction in BDD handles a medium-sized linear system, which could be bottleneck in parallel environment. To accelerate this step, the inverse approach is adopted. It replaces foward and back substitution to parallel matrix vector multiplication. Double-double is utilized to preserve the accuracy of the inverse matrix.

[01063] Challenges in biomathematical modeling and control

Session Time & Room :

01063 (1/3) : 1C (Aug.21, 13:20-15:00) @A206

01063 (2/3) : 1D (Aug.21, 15:30-17:10) @A206

01063 (3/3) : 1E (Aug.21, 17:40-19:20) @A206

Type : Proposal of Minisymposium
Abstract : In biomathematics, theoretical and data modeling showed to be big challenges, both at the macroscopic and microscopic levels. Complex networks are proved to be a rather powerful theoretical tools in epidemics, neuroscience, protein functions, ecology and cancer. When considering space-time analysis of big data, we have at

our disposal a variety of methods, wavelets, Bayesian, Topological Data Analysis, Cross-entropy, Fuzzy logic, among others. The choice of a method is linked to the kind of questions we want to target.
The emergency experienced with pandemics showed also the importance of being able to make predictions and to develop methods of control.

Minisymposium Program :

01063 (1/3) : 1C @A206

[05271] Analyzing infectious disease dynamics: the challenge of non-stationarity

Author(s) : Bernard Cazelles (IBENS CNRS INSERM)
Abstract : The spread of disease through human populations is complex. The characteristics of disease propagation evolve with time, as a result of a multitude of environmental and anthropic factors, including social distancing. This non-stationarity is a key factor in the complexity of disease propagation.
In the absence of appropriate external data sources, to correctly describe disease propagation, I propose a flexible methodology, based on stochastic models for disease dynamics, and on Brownian processes for parameter evolution. Using such a diffusion process has the advantage of not requiring a specific mathematical function for the parameter dynamics. Coupled with Bayesian inference using particle MCMC, this approach allows us to reconstruct both the time evolution of some key parameters of an epidemiological dynamic and its incidence.
I will demonstrate the efficiency of this methodology on toy epidemiological models where the parameters and the observation process are known, and also on more complex epidemics, such as flu, dengue and COVID-19.

[05319] Models of mosquito population control strategies for fighting against arboviruse

Author(s) : Michel Duprez (Inria)Luis Almeida (Inria)Yves Dumont (CIRAD - University of Pretoria)yannick Privat (Université de Strasbourg)Nicolas Vauchelet (Université Paris 13)
Abstract : In the fight against vector-borne arboviruses, an important strategy of control of epidemic consists in controlling the population of the vector, Aedes mosquitoes in this case. Among possible actions, a technique consist in releasing sterile mosquitoes to reduce the size of the population (Sterile Insect Technique). This talk is devoted to studying the issue of optimizing the dissemination protocol for each of these strategies, in order to get as close as possible to these objectives. Starting from a mathematical model describing the dynamic of a mosquitoes population, we will study the control problem and introduce the cost function standing for sterile insect technique. In a second step, we will consider a model with several patchs modeling the spatial repartition of the population. Then, we will establish some properties of these two optimal control problems. Finally, we will illustrate our results with numerical simulations.

01064 (2/3) : 3E (Aug.23, 17:40-19:20) @E605

01064 (3/3) : 4C (Aug.24, 13:20-15:00) @E605

Type : Proposal of Minisymposium

Abstract : Manifold optimization has been developing remarkably with its rich theory and a wide variety of applications. This minisymposium aims to pioneer state-of-the-art in the field. The talks include optimization algorithms on manifolds, e.g., Riemannian adaptive and interior point methods, ADMM, local stochastic algorithms, a CG method for multiobjective optimization, and an augmented Lagrangian method based on sequential optimality conditions. Furthermore, efficient optimization on specific manifolds such as Grassmann and Stiefel manifolds and the manifold of fixed-rank positive-semidefinite matrices, and applications to practical problems, e.g., problems under differential privacy, low-rank matrix optimization problems, and design of tight minimum-sidelobe windows, are addressed.

[04372] Sequential optimality conditions for nonlinear optimization on Riemannian manifolds and a globally convergent augmented Lagrangian method

Format : Talk at Waseda University

Author(s) : Yuya Yamakawa (Kyoto University)Hiroyuki Sato (Kyoto University)

Abstract : Recently, the approximate Karush--Kuhn--Tucker (AKKT) conditions, also called the sequential optimality conditions, have been proposed for nonlinear optimization in Euclidean spaces, and several methods to find points satisfying such conditions have been developed by researchers. These conditions are known as genuine necessary optimality conditions because all local optima satisfy them with no constraint qualification (CQ). In this paper, we extend the AKKT conditions to nonlinear optimization on Riemannian manifolds and propose an augmented Lagrangian (AL) method that globally converges to points satisfying such conditions. In addition, we prove that the AKKT and KKT conditions are indeed equivalent under a certain CQ. Finally, we examine the effectiveness of the proposed AL method via several numerical experiments.

[04682] Nonlinear conjugate gradient method for vector optimization on Riemannian manifolds

Format : Talk at Waseda University

Author(s) : Kangming Chen (Kyoto University)Hiroyuki Sato (Kyoto University)Ellen Hidemi Fukuda (Kyoto University)

Abstract : In this research, we propose a conjugate gradient descent algorithm for vector optimization on Riemannian manifolds. We extend the concepts of Wolfe conditions and Zoutendjik conditions to Riemannian manifolds. The convergence of the proposed method is proved for different choices of the parameter beta, including the Riemannian extension of Fletcher-Reeves, Conjugate Descent, and Dai-Yuan. Numerical experiments are conducted to validate the proposed method.

[04852] Gauss-Southwell type descent methods for low-rank matrix optimization

Format : Talk at Waseda University

Author(s) : Guillaume Olikier (Université Catholique de Louvain)André Uschmajew (University of Augsburg)Bart Vandereycken (University of Geneva)

Abstract : We consider gradient-related methods for low-rank matrix optimization with a smooth strongly convex cost function. The methods operate on single factors and share aspects of both alternating and Riemannian optimization. We compare two possible choices for the search directions based on Gauss-Southwell type selection rules: one using the gradient of a factorized non-convex formulation, the other using the Riemannian gradient. Both methods provide convergence guarantees for the gradient that are analogous to the unconstrained case.

[03269] Min-max optimization on manifolds

Format : Online Talk on Zoom

Author(s) : Bamdev Mishra (Microsoft)

Abstract : In this talk, we discuss some recent algorithms on min-max optimization problems over Riemannian manifolds.

01064 (2/3) : 3E @E605 [Chair: Hiroyuki Sato]

[03743] Design of Tight Minimum-Sidelobe Windows via Optimization on Oblique Manifolds

Format : Online Talk on Zoom
Author(s) : Daichi Kitahara (Osaka University)Kohei Yatabe (Tokyo University of Agriculture and Technology)
Abstract : The short-time Fourier transform (STFT), or the discrete Gabor transform (DGT), has been widely utilized in signal analysis and processing. For noise-robust STFT/DGT domain signal processing, windows used in STFT/DGT are desired to be tight. In this talk, we propose to design tight windows minimizing the sidelobe energy. It is expressed as the maximization of Rayleigh quotients on oblique manifolds. We apply the Riemannian Newton's method to obtain the optimal tight windows by several iterations.

[04008] The Bures-Wasserstein geometry of the manifold of fixed-rank positive-semidefinite matrices

Format : Online Talk on Zoom
Author(s) : Estelle Massart (UCLouvain)Pierre-Antoine Absil (UCLouvain)
Abstract : We explore the well-known identification of the manifold of rank p positive-semidefinite matrices of size n with the quotient of the set of full-rank n-by-p matrices by the orthogonal group in dimension p. The induced metric corresponds to the Wasserstein metric between centered degenerate Gaussian distributions, and is a generalization of the Bures–Wasserstein metric on the manifold of positive-definite matrices.

[02861] Cayley parametrization strategy for optimization over the Stiefel manifold

Format : Talk at Waseda University
Author(s) : Keita Kume (Tokyo Institute of Technology)Isao Yamada (Tokyo Institute of Technology)
Abstract : We introduce the basic idea behind the adaptive localized Cayley parametrization strategy for optimization over the Stiefel manifold. The proposed adaptive strategy can mitigate slow convergence caused by singular-points of the naive Cayley parametrization. Unlike the so-called retraction-based strategy, the proposed strategy can utilize directly many powerful Euclidean optimization algorithms. For a certain class of optimization algorithms combined with the proposed parametrization strategy, we also explain briefly an idea for their unified convergence analyses.

[02851] Accelerated gradient methods on the Grassmann and Stiefel manifolds

Format : Talk at Waseda University
Author(s) : Xiaojing Zhu (Shanghai University of Electric Power)
Abstract : In this talk we extend a nonconvex version of Nesterov's accelerated gradient method to optimization over the Grassmann and Stiefel manifolds. We propose an exponential-based AG algorithm for the Grassmann manifold and a retraction-based AG algorithm that exploits the Cayley transform for both of the Grassmann and Stiefel manifolds. Global rates of convergence of our algorithms are analyzed under reasonable assumptions. Details of computing some geometric objects as ingredients of our algorithms are also discussed.

01064 (3/3) : 4C @E605 [Chair: Xiaojing Zhu]

[04571] A Riemannian ADMM

Format : Online Talk on Zoom
Author(s) : Shiqian Ma (Rice University)
Abstract : We consider a class of Riemannian optimization problems where the objective is the sum of a smooth function and a nonsmooth function, considered in the ambient space. This class of problems finds important applications in machine learning and statistics such as the K-means clustering, sparse spectral clustering, and orthogonal dictionary learning. We propose a Riemannian alternating direction method of multipliers to solve this class of problems. Our algorithm adopts easily solvable subproblems in each iteration. The iteration complexity of the proposed algorithm for obtaining an ϵ-stationary point is analyzed under mild assumptions. Numerical experiments are conducted to demonstrate the advantage of the proposed method.

[04455] Local stochastic algorithms for Riemannian optimization

Format : Online Talk on Zoom
Author(s) : Sam Davanloo Tajbakhsh (The Ohio State University)
Abstract : We consider optimizing a function available through its first-order stochastic oracle over a Riemannian manifold in a distributed setting with the coordination of a central server. We develop local stochastic approximation methods that perform multiple local stochastic updates in parallel on different clients and merge them in some intervals. Theoretical convergence results in different optimization and communication settings will be presented.

[03649] Riemannian Interior Point Methods for Constrained Optimization on Manifolds

Format : Talk at Waseda University
Author(s) : Zhijian Lai (University of Tsukuba)Akiko Yoshise (University of Tsukuba)
Abstract : We extend the classical primal-dual interior point method from the Euclidean setting to the Riemannian one. Our method, named the Riemannian interior point method (RIPM), is for solving Riemannian constrained optimization problems. We establish its locally superlinear and quadratic convergence under the standard assumptions. Moreover, we show its global convergence when it is combined with a classical line search. Numerical experiments show the stability and efficiency of our method.

[03887] Riemannian Adaptive Optimization Algorithms and Their Applications

Format : Talk at Waseda University
Author(s) : Hiroyuki Sakai (Meiji University)Hideaki Iiduka (Meiji University)
Abstract : We will talk about Riemannian adaptive optimization algorithms to solve the Riemannian stochastic optimization problems. In Euclidean space, adaptive optimization algorithms, such as AdaGrad, Adam, Adadelta, and AMSGrad, are widely used. However, adaptive optimization algorithms cannot be naturally extended to general Riemannian manifolds, due to the absence of a canonical coordinate system.
We introduce the ways to generalize adaptive optimization algorithms to Riemannian manifolds and consider their applications.

[01065] Mathematics and its Applications of Risk and Decision

Session Time & Room : 4E (Aug.24, 17:40-19:20) @D501

Type : Proposal of Minisymposium
Abstract : In the age of uncertainty highlighted by events such as the financial crisis and the outbreak of COVID-19, policy makers need to acquire a holistic yet rigorous understanding of decision making under risk. This symposium aims to bring together academic researchers of diverse background to showcase the latest development of the mathematical theories and applications for risk and decision. The covered topics include stochastic control, optimal decision-making, model uncertainty and their applications in fields like economics and insurance. The collective effort of the expert speakers from this symposium will constitute impactful decision protocols and policy implications.
Organizer(s) : Alex S.L. Tse, Andrea Macrina
Classification : 91B06, 93E20, 91B05, 91G15, 91G05
Minisymposium Program :

01065 (1/1) : 4E @D501 [Chair: Alex S.L. Tse]

[04299] Optimal reinsurance with multivariate risks and dependence uncertainty

Format : Talk at Waseda University
Author(s) : Tolulope Rhoda Fadina (University of Essex)Tolulope Fadina (University of Essex)
Abstract : We study the optimal reinsurance design from the perspective of an insurer with multiple lines of business, where the
reinsurance is purchased by the insurer for each line of business respectively. For the risk vector generated by the multiple lines of business, we suppose that the marginal distributions are fixed, but the dependence structure between
these risks is unknown. Due to the unknown dependence structure, the optimal strategy is investigated for the worst-case scenario. We consider two types of risk measures: Value-at-Risk (VaR) and Range-Value-at-Risk including Expected Shortfall as a special case, and general premium principles satisfying certain conditions. To be more
practical, the minimization of the total risk is conducted with both budget constraints and expected profit constraints.
For the VaR-based model with only two risks, it turns out that the limited stop-loss reinsurance treaty is optimal for each line of business. For the model with more than two risks, we obtain two types of optimal reinsurance strategies if the marginals have convex or concave distributions on their tail parts by constraining the ceded loss functions to be
convex or concave.

[04329] Irreversible consumption habit under ambiguity: Singular control and optimal G-stopping time

Format : Talk at Waseda University
Author(s) : HOI YING WONG (The Chinese University of Hong Kong)Kyunghyun Park (Nanyang Technological University)Kexin Chen (The Hong Kong Polytechnic University)
Abstract : Consider robust utility maximization with an irreversible consumption habit, where an agent concerned about model ambiguity is unwilling to decrease consumption and must simultaneously contend with a disutility (i.e., an adjustment cost) due to a consumption increase. While the optimization is a robust analog of singular control problems over a class of consumption-investment strategies and a set of probability measures, it is a new formulation that involves non-dominated probability measures of the diffusion process for the underlying assets in addition to singular controls with an adjustment cost. This paper provides a novel connection between the singular controls in the optimization and the optimal G-stopping times in a G-expectation space, using a duality theory. This connection enables to derive the robust consumption strategy as a running maximum of the stochastic boundary, which is characterized by a free boundary arising from the optimal G-stopping times. The duality, which relies on arguments based on reflected G-BSDEs, is achieved by verifying the first-order optimality conditions for the singular control, the budget constraint equation for the robust strategies, and the worst-case realization under the non-dominated measures.

[05330] On/Off Shore Currency Rate Discrepancy

Format : Talk at Waseda University
Author(s) : Samuel Drapeau (Shanghai jiao Tong university)Xuan Tao (Shanghai Jiao Tong University)
Abstract : Most developing countries (especially in Asia) adopted a tight control of foreign capital in order to protect their economy from abrupt capital outflows in period of crisis.
As those economies developed and opened up to foreign financial investment, they often set up off shore currency exchange markets to facilitate the transfer of capital.
This is for instance the case of China where the on shore rmb (CNY) was complemented with an off shore market for trading this currency (CNH).
Theoretically, the face value from a domestic viewpoint of the currency is the same regardless of on/off shore origin.
And indeed, when observing the spot rate, the CNY and the CNH rate only differ marginally.
However, when looking at the price of futures for longer maturity, there is a significant discrepancy (in the CNY/CNY case, up to 4% when corrected for maturity).
This is puzzling as the future face value follows the same principle as the present one.
In the present work we propose a continuous time equilibrium in two similar market which are scholastically coupled.
This solution of which is given by a coupled quadratic jump diffusion FBDE that provide an equilibrium price on both markets.

We then use a second equilibrium to price futures and therefore provide some interpretations as for the price discrepancy observed on the market.

This is a joint work with Xuan Tao, Peng Luo, Wang Tan and Wang Tao

[04244] Portfolio Selection, Periodic Evaluations and Risk Taking

Format : Talk at Waseda University
Author(s) : Alex Sing-lam Tse (University College London)Harry Zheng (Imperial College London)
Abstract : We present a continuous-time portfolio selection problem faced by an agent with S-shaped preference who maximizes the utilities derived from the portfolio's periodic performance over an infinite horizon. The periodic reward structure creates subtle incentive distortion. In some cases, local risk aversion is induced which discourages the agent from risk taking in the extreme bad states of the world. In some other cases, eventual ruin of the portfolio is inevitable and the agent underinvests in the good states of the world to manipulate the basis of subsequent performance evaluations. We outline several important elements of incentive design to contain the long-term portfolio risk.

[01070] PDE Based Image Processing

Session Time & Room :

01070 (1/2) : 4D (Aug.24, 15:30-17:10) @G502

01070 (2/2) : 4E (Aug.24, 17:40-19:20) @G502

Type : Proposal of Minisymposium
Abstract : Partial differential equation (PDE) method shows better performance than traditional image processing methods, and some new ideas have never been considered in traditional image processing, such as affine invariant feature extraction, image structure and texture decomposition, etc. This method aims to establish the mathematical model of a partial differential equation, and then make the image change according to the PDE, and finally achieve the desired effect. PDE models are mathematically robust and also provide insights in developing new algorithms. Fusion of AI/ML methods and PDE models makes it even more effective.

[01942] A new PDE model for Image Inpainting

Format : Online Talk on Zoom
Author(s) : Abdul Halim (King Abdullah University of Science and Technology)B.V. Rathish Kumar (IIT Kanpur)
Abstract : In this talk, I will present a fourth-order PDE model with a multi-well potential function for grayscale image inpainting. Convexity splitting in time and Fourier spectral method in space has been used to derive an unconditional scheme on time. The stable scheme is both consistent and convergent. Also, I present the fractional variant of the time discretized scheme by replacing the Laplacian with its fractional counterpart. Numerical results for some standard test images will be presented and will be compared with the results of other existing models in the literature. To quantify the quality of the recovered image, we calculate the image quality metric such as PSNR, SNR, and SSIM.

[01962] Fractional Calculus Based Approach for Retinal Blood Vessel Segmentation

Format : Online Talk on Zoom
Author(s) : Rajesh Kumar Pandey (Indian Institute of Technology (BHU) Varanasi)Varun Makkar (Indian Institute of Technology (BHU) Varanasi)Rathish Kumar Venkatesulu Bayya (Indian Institute of Technology Kanpur)
Abstract : We will discuss a new fractional filter and an algorithm for retinal blood vessel segmentation. The proposed fractional filter is designed with the help of a weighted fractional derivative and an exponential weight factor. Firstly, the image is denoised using developed fractional. Then, multi-scale line detector is used to compute

the line responses at multiple lengths using a punctured window of fixed dimensions. The final response is the computed as the arithematic mean of all responses at different scales and the underlying image intensity. This enhances the retinal blood vessels and suppresses rest of the background. Finally, hysteresis thresholding is applied to obtain the segmented vessels. Experiments are performed on two well-studied evaluation databases named STARE and DRIVE and the simulation results are discussed.

[02860] Game theoretic Approach for Image segmentation and Image restoration by using Fractional PDE

Format : Online Talk on Zoom

Author(s) : Kedarnath Buda (Indian Institute of Technology Kanpur, India)Rathish Kumar Venkatesulu Bayya (Indian Institute of Technology Kanpur)

Abstract : In this study, a game theoretic algorithm through which a noisy image is both restored and segmented simultaneously is proposed. We define a two cost functions for two players of a Game. One player is Image restoration and another one is Image segmentation. Both of them are further constrained by fractional PDEs.The establish the Nash equilibrium for this game, which is an ideal strategy for deciding the amount of image restoration and image segmentation that can be done through the optimization of the bi-objective cost functions. We then numerically compute this with some real images.

[02862] Higher Order PDE Model for Effective Image Denoising

Format : Talk at Waseda University

Author(s) : Rathish Kumar Venkatesulu Bayya (Indian Institute of Technology Kanpur)Abdul Halim (KAUST)

Abstract : In this talk we will introduce a new higher order nonlinear PDE model for image denoising and demonstrate its ability to denoise without any staircase effect as routinely noticed with lower order PDE models. We use convexity splitting based Fourier Spectral scheme for the computation of the denoised version of a given noisy image. Fourier spectral method is both accurate and faster than many standard approaches. Performance of the model and the method will be discussed based on the benchmark test images and the related computational metrics.

01070 (2/2) : 4E @G502 [Chair: Prof. BVR Kumar]

[02870] A Framework for Motion Estimation with Physics-Based Constraints in Image Sequences

Format : Online Talk on Zoom

Author(s) : Hirak Doshi (Doctoral Research Scholar)Uday Kiran Nori (Associate Professor)

Abstract : Motion estimation using variational models has been a central topic in mathematical image processing for many years. The Horn and Schunck model's variational approach to optical flow motion estimation is a seminal work that has been studied in-depth to develop different variational models for motion estimation. However, the Horn and Schunck model's constancy assumption cannot reflect the reality of actual motion, as deformation effects of fluid, illumination variations, perspective changes, poor contrast, etc., directly affect the important motion parameters. Therefore, physics-dependent motion estimation algorithms have been extensively investigated in the literature.

In this paper, we propose a generic framework that captures physics-based constraints for motion estimation as perceived at the smallest intensity level (pixel) of an image sequence. These constraints are introduced as non-conservative terms that capture the loss of particles at the pixel-level, in the minimizing energy functional. We demonstrate our framework with two physics-based constraints, the continuity constraint for fluid motion and the harmonic constraint for capturing rotation in the images. Furthermore, we theoretically justify the effectiveness of our model through the techniques of Augmented Lagrangian and maximal monotone operators.

We establish the mathematical well-posedness of the associated PDE in the Hilbert space setting. For the linear case, we perform a decoupling of the associated PDE into diffusion equations on the curl and divergence of the flow field through a diagonalization with the Cauchy-Riemann operator. This decoupling process suggests that our approach preserves the spatial characteristics of the divergence and the vorticities of the flow field.

We adapt the first-order primal-dual Chambolle-Pock algorithm to obtain the minimization of our variational problem. We demonstrate the robustness of our approach through velocity plots and use the Average Angular Error (AAE) and End-Point Error (EPE) as performance metrics. We test our algorithm on several relevant datasets and show good results. In particular, for the Middlebury dataset, we show that our algorithm outperforms some of the state-of-the-art Horn and Schunk based flow models.

Moreover, for the fluid motion estimation case, a primal-dual implementation of our two-phase refinement model has a faster convergence rate of $O(1/N)$ compared to the $O(1/\sqrt{N})$ convergence rate of a direct primal-dual implementation of the Liu-Shen continuity-based model, where N is the number of iterations. Although we do not have a theoretical proof for this observed efficiency, we provide substantial empirical evidence.

[03393] On the convergence analysis of DNN for vorticity stream function formulation and application

Format : Online Talk on Zoom
Author(s) : Rajendra Kumar (Student)Rathish Kumar Venkatesulu Bayya (Indian Institute of Technology Kanpur)Ming-Chih Lai (National Yang Ming Chiao Tung University, Taiwan)
Abstract : The physics-informed neural network is a completely mesh-free method for partial differential equations. In this paper, We introduce a Physics-informed neural network for the two dimensions Navier-stokes equation in the vorticity-stream function form with boundary conditions. We estimate the error of the physics-informed neural network for vorticity stream function formulation and theoretically establish the convergence of the computational procedure. In Deep neural network representation imposing the boundary condition is one of the main issues. We successfully incorporate periodic boundary conditions in the vorticity stream function formulation which is known for its difficulty in training the model. We have successfully applied PINNS on applications such as the Double shear layer and Taylor vortex problem

[01071] Recent Advances on Groebner Bases and Their Applications

Session Time & Room :

01071 (1/2) : 2C (Aug.22, 13:20-15:00) @G305

01071 (2/2) : 2D (Aug.22, 15:30-17:10) @G305

Type : Proposal of Minisymposium
Abstract : The purpose of this mini-symposium is to share recent developments in the theory of Gr"obner bases and their applications. Gr"obner bases have been studied by many researchers and have been used in various fields including commutative algebra, algebraic geometry, and engineering. Solving interesting open problems and devising efficient algorithms are still highly desired. In this mini-symposium, we will discuss, in particular, the complexity of Gr"obner basis computation, applications of Gr"obner bases, and algorithms for Gr"obner bases in parametric, non-commutative, or valuation polynomial rings.

[01758] Parametric Ideal Operations

Format : Talk at Waseda University
Author(s) : Yuki Ishihara (Tokyo University of Science)
Abstract : We present several algorithms for parametric ideal operations of polynomial ideals. Let $K[X]=K[x_1,\ldots,x_n]$ be the polynomial ring over a filed K and $K[A,X]$ the parametric polynomial ring with parameters $A=\{a_1,\ldots,a_m\}$. Let φ_α be the homomorphism from $K[A,X]$ to $K[X]$ by $\varphi_\alpha(f(A,X))=f(\alpha,X)$ for $\alpha\in K^m$. For an ideal operation F and parametric ideals $I_1,\ldots,I_r$, we compute a set of pairs $\{(A_i,G_i)\}_{i=1}^s$ s.t. $\bigcup_{i=1}^s A_i=K^m$ and $\varphi_\alpha(G_i)$ is a Groebner basis of $F(\varphi_\alpha(I_1),\ldots,\varphi_\alpha(l_r))$ for any $\alpha\in A_i$.

[01892] On the complexity of Groebner basis computation

Format : Talk at Waseda University
Author(s) : Kazuhiro Yokoyama (Rikkyo University)
Abstract : The complexity of computation of Groebner basis is heavily related to the syzygy of given generating set. We will discuss this relation for generic case, where coefficients of generating set can be considered as parameters.

[01851] On Parametric Border Basis and Comprehensive Gröbner System

Format : Talk at Waseda University
Author(s) : Yosuke Sato (Tokyo University of Science)
Abstract : A border basis is an alternative tool to a Gröbner basis
for handling a polynomial ideal.
One of the most important properties of a border basis is its stability.
Though this property is cited by many researchers,
its precise definition has not been given anywhere yet.
We give its rigorous definition in terms of a parametric
polynomial ideal and introduce several properties which enable
us to have a simple representation of a parametric polynomial ideal.

[01843] Universal Analytic Gröbner bases, Tate Algebras and toward Tropical Analytic Geometry

Format : Talk at Waseda University
Author(s) : Tristan Vaccon (Limoges University)Thibaut Verron (Johannes Kepler University)
Abstract : Tate algebras are defined as multivariate formal power series over a p-adic field, with a convergence condition.
We will present the concept of Universal Analytic Gröbner Basis for a polynomial ideal:
a finite polynomial basis of an ideal such that it is a Gröbner basis in any of the completions into Tate algebras
for any (rational) convergence radius.
We will present how to compute it and its relation with tropical varieties.

01071 (2/2) : 2D @G305 [Chair: Yuki Ishihara]

[01891] Criteria for Grobner bases and degenerations by structure of signatures

Format : Talk at Waseda University
Author(s) : Yuta Kambe (Mitsubishi Electric Corporation)
Abstract : The F5 algorithm was presented by Faugere in 2002 and variants of the F5 algorithm have been proposed by various researchers called signature based algorithms (SBAs). The concept of signatures was revised by Arri-Perry in 2011 as normal monomials for syzygies and Vaccon-Yokoyama presented an implementable SBA in 2017 with the concept of guessed signatures. The speaker will talk about these new concepts and his new criterion theorem for Grobner bases and degenerations.

[01876] On signature-based algorithm for tropical Groebner bases on Weyl algebra

Format : Talk at Waseda University
Author(s) : Ari Dwi Hartanto (Department of Mathematics, Universitas Gadjah Mada)Katsuyoshi Ohara (Faculty of Mathematics and Physics, Kanazawa University)
Abstract : The computational aspect of tropical Groebner basis for polynomial rings introduced by A.W.Chan is extended to the Weyl algebras over fields with valuations. A term order with valuation is designed to be a generalization of the tropical term orders studied by A.W.Chan and by T.Vaccon. Although it is not well-ordering, a signature-based algorithm can still be developed. The minimal natural signature of a polynomial exists. The F5 criterion is then adopted for this context.

[01898] Algorithms for bivariate lexicographic Groebner bases

Format : Talk at Waseda University
Author(s) : Xavier DAHAN (Tohoku UniversityTohoku University)
Abstract : The lexicographic monomial order for Groebner bases is fundamental since it holds the elimination property. This also implies strong structural properties, as shown by Lazard in 1985 in the case of two variables. Yet these properties have not been fully exploited. I will explain how they allow to perform Chinese Remainder Theorem like operations in several situations, as well as the difficulties in remaining cases. I will also discuss extensions to more than two variables.

[01885] An algebraic approach to factor analysis

Format : Talk at Waseda University
Author(s) : Ryoya Fukasaku (Kyushu University)Kei Hirose (Kyushu University)Yutaro Kabata (Nagasaki University)Keisuke Teramoto (Hiroshima University)
Abstract : When the maximum likelihood method is used in factor analysis, it is not uncommon for an unique variance less than or equal to zero to be generated, which is known as the improper solution problem. Although numerical approaches have been made to this problem, algebraic approaches have not. Therefore, we aim to exactly describe the solution space associated with the maximum likelihood method in factor analysis by making use of computational algebraic methods such as Gröbner bases and cylindrical algebraic decomposition.

[01072] Data-Driven Methods in Scientific Machine Learning

Session Time & Room :

01072 (1/2) : 4D (Aug.24, 15:30-17:10) @E803

01072 (2/2) : 4E (Aug.24, 17:40-19:20) @E803

Type : Proposal of Minisymposium
Abstract : The ample availability of data for scientific problems, in addition to developments in hardware and software for machine and deep learning have changed the way mathematicians approach problems, particularly those in numerical analysis and scientific computing. Rather than relying strictly on the physics of the problem at hand for modeling and computing, data-driven methods incorporate observational data to inform their solutions. This session focuses on significant advances in data-driven methods and machine learning for a variety of problems in scientific computing, including but not limited to: function approximation, inverse problems, dynamical systems, dimensionality reduction, and generally scientific machine learning.

[05116] Acceleration of multiscale solvers via adjoint operator learning

Format : Talk at Waseda University
Author(s) : Emanuel Eld Ström (KTH Royal Institute of Technology)Ozan Öktem (KTH Royal Institute of Technology)Anna-Karin Tornberg (KTH Royal Institute of Technology)
Abstract : We leverage recent advances in operator learning to accelerate multiscale solvers for laminar fluid flow over a rough boundary. We focus on the HMM method, which involves formulating the problem through a coupled system of microscopic and macroscopic subproblems. Solving microscopic problems can be viewed as a nonlinear operator mapping from the space of micro domains to the solution space. Our main contribution is to use an FNO-type architecture to perform this mapping.

[05635] A Stochastic MaxiIn this work, we introduce a stochastic maximum principle (SMP) approach for solving the reinforcement learning problem with the assumption that the unknmum Principle Approach for Reinforcement Learning with Parameterized Environment

Format : Talk at Waseda University

Author(s) : Feng Bao (Florida State University)Richard Archibald (Oak Ridge National Lab)Jiongmin Yong (University of Central Florida)

Abstract : In this work, we introduce a stochastic maximum principle (SMP) approach for solving the reinforcement learning problem with the assumption that the unknowns in the environment can be parameterized based on physics knowledge. For the development of numerical algorithms, we apply an effective online parameter estimation method as our exploration technique to estimate the environment parameter during the training procedure, and the exploitation for the optimal policy is achieved by an efficient backward action learning method for policy improvement under the SMP framework. Numerical experiments are presented to demonstrate that the SMP approach for reinforcement learning can produce reliable control policy, and the gradient descent type optimization in the SMP solver requires less training episodes compared with the standard dynamic programming principle based methods.

[05649] A pseudo-reversible normalizing flow for stochastic dynamical systems with various initial distributions

Format : Talk at Waseda University

Author(s) : Guannan Zhang (Oak Ridge National Laboratory)

Abstract : We present a pseudo-reversible normalizing flow method for efficiently generating samples of the state of a stochastic differential equation (SDE) with various initial distributions. The primary objective is to construct an accurate and efficient sampler that can be used as a surrogate model for computationally expensive numerical integration of SDE, such as those employed in particle simulation. After training, the normalizing flow model can directly generate samples of the SDE's final state without simulating trajectories. Existing normalizing flow model for SDEs depend on the initial distribution, meaning the model needs to be re-trained when the initial distribution changes. The main novelty of our normalizing flow model is that it can learn the conditional distribution of the state, i.e., the distribution of the final state conditional on any initial state, such that the model only needs to be trained once and the trained model can be used to handle various initial distributions. This feature can provide a significant computational saving in studies of how the final state varies with the initial distribution. Additionally, we propose to use a pseudo-reversible network architecture to define the normalizing flow model, which has sufficient expressive power and training efficiency for a variety of SDEs in science and engineering, e.g., in particle physics. We provide a rigorous convergence analysis of the pseudo-reversible normalizing flow model to the target probability density function in the Kullback–Leibler divergence metric. Numerical experiments are provided to demonstrate the effectiveness of the proposed normalizing flow model.

01072 (2/2) : 4E @E803 [Chair: Victor Churchill]

[05632] Flow Map Learning for Unknown Dynamical Systems: Overview, Implementation, and Benchmarks

Format : Talk at Waseda University

Author(s) : Victor Churchill (Trinity College)Dongbin Xiu (The Ohio State University)

Abstract : Flow map learning has shown promise for data-driven modeling of unknown dynamical systems. A remarkable feature is the capability of producing accurate predictive models for partially observed systems, even when their exact mathematical models do not exist. We present an overview of the framework, as well as the important computational details for its successful implementation. A set of well defined benchmark problems are presented in full numerical detail to ensure accessibility for cross-examination and reproducibility.

[01074] Approximation Theory, Approximation Methods and Applications (ATAMA)

Session Time & Room :

01074 (1/3) : 5B (Aug.25, 10:40-12:20) @F310

01074 (2/3) : 5C (Aug.25, 13:20-15:00) @F310

01074 (3/3) : 5D (Aug.25, 15:30-17:10) @F310

Type : Proposal of Minisymposium
Abstract : Approximation theory is a subject that serves as an important bridge between pure and applied mathematics. It has become a very important branch of mathematics and is of fundamental support of many new disciplines and research areas.

The proposed minisymposium aims to merge together active researchers in the following topics:
polynomial inequalities in the multivariate real and complex fields, pluripotential numerics, kernel-based approximation, generalized sampling type operators and exponential sampling.
Special attention will be given to applications, modeling, as well as computational and numerical aspects in approximation.

[04256] Approximation Theory, Approximation Methods and Applications: an introduction

Format : Online Talk on Zoom
Author(s) : Stefano De Marchi (University of Padova)
Abstract : In this initial talk, I will briefly summarize why we have proposed such a mini-symposium, why approximation theory is still an important research subject for numerical and analytical analysts, and why approximation theory can help industrial applications. I will also outline the main contributions provided by all the speakers invited to this mini-symposium.

[04857] On the quality of adaptive methods for numerical approximation

Format : Talk at Waseda University
Author(s) : Leszek Plaskota (University of Warsaw)
Abstract : Methods for numerical approximation generally fall into two categories:
nonadaptive algorithms and adaptive algorithms. By ‘adaptive’ we mean that
in its successive steps the algorithm uses information about the underlying function
obtained from the previous steps. If the function possesses some singularities and
is otherwise smooth, then adaption is necessary to restore the right convergence rate.
For globally smooth functions adaptive algorithms can essentially lower asymptotic constants.
We present recent quantitative results on the subject.

[05019] Monte Carlo approximation of non-autonomous Julia sets

Format : Online Talk on Zoom
Author(s) : Maciej Klimek (Uppsala University)
Abstract : In the the metric space of compact, pluriregular and polynomially convex subsets of $\mathbb{C}^N$, both finite and infinite families of proper polynomial mappings generate a
variety of Julia type compact sets, known also as the composite Julia sets.

These sets can be interpreted as attractors of generalized iterated function systems. Since stochastic approximation of composite Julia sets is viable, some of
those sets can be visualized with the help of Monte Carlo methods.

01074 (2/3) : 5C @F310 [Chair: Elisabeth Larsson]

[05151] Projection Constants for Spaces of Multivariate Polynomials

Format : Online Talk on Zoom
Author(s) : Mieczysław Mastyło (Adam Mickiewicz University, Poznań)
Abstract : We study the projection constant of spaces of polynomials with the supremum norm over the unit ball of finite dimensional Banach sequence space including the Hilbert space. We consider the action of topological groups over these spaces of polynomials and provide some integral formulas for their projection constants. This cycle of ideas leads to the asymptotic behaviour of the projection constants of spaces of Dirichlet polynomials and the space of nuclear operators on ℓ_2^n.

[05170] Stable high-order randomized cubatures for integration in arbitrary dimension

Format : Online Talk on Zoom
Author(s) : Giovanni Migliorati (Sorbonne Université)
Abstract : We present cubature formulae for the integration of functions in arbitrary dimension and arbitrary domain. These cubatures are exact on a given finite-dimensional subpace V_n of L^2 of dimension n, they are stable with high probability and are constructed using m pointwise evaluations of the integrand function with m proportional to $n \log n$. For these cubatures we provide a convergence analysis showing that the expected cubature error decays as $m^{-1/2}$ times the L^2 best approximation of the integrand function in V_n.

[05108] On empirical adequacy of approximations within mathematical models

Format : Online Talk on Zoom
Author(s) : Michael A Slawinski (Memorial University)
Abstract : We discuss a phenomenological model formulated to study the power applied by a cyclist on a velodrome.
The dissipative forces we consider are air resistance, rolling resistance, lateral friction and drivetrain resistance.
Also, the power is used to increase the kinetic and potential energy.
Following derivations and justifications of expressions that constitute this mathematical model, we discuss them in the context of measurements.

[05186] On technical considerations of velodrome track design

Format : Online Talk on Zoom
Author(s) : Theodore Stanoev (Memorial University of Newfoundland)
Abstract : We present a novel approach to velodrome track design. The mathematical model uses differential geometry to form a three-dimensional ruled surface. The track is comprised of straight lines, the arcs of circles, and connecting transition curves, whose features are derived from the Frenet-Serret relations. Symmetric and asymmetric designs are obtained using least-squares optimization. The formulation may be used to design velodrome tracks of a wide variety of track geometry specifications.

01074 (3/3) : 5D @F310 [Chair: Stefano De Marchi]

[05085] Optimal scaling of radial basis function approximations

Format : Talk at Waseda University
Author(s) : Elisabeth Larsson (Uppsala University)Boštjan Mavrič (Institute of Metals and Technology)Andreas Michael (Uppsala University)Ulrika Sundin (Uppsala University)
Abstract : We revisit the question about which shape parameter to use in radial basis function approximations. We compute the flat shape parameter limit of a Gaussian interpolant as an expansion in even powers of the shape parameter and illustrate how the correction terms cancel the dominant part of the error for smooth solution

functions. We also provide a closed form expression that explains the shape of the error curves in terms of the shape parameter.

[04984] Interpolation on the sphere using series kernels

Format : Online Talk on Zoom
Author(s) : Janin Jäger (KU Eichstätt-Ingolstadt)Simon Hubbert (Birkbeck University of London)
Abstract : We study the use of series kernels for interpolation and approximation of data on a d- dimensional sphere. Kernels in series representation allow us to easily deduce geometric properties of the kernel, strict positive definiteness of the kernel, smoothness of the approximant and approximation error estimates. We will show how series representations can be derived for restrictions of radial basis functions from the surrounding Euclidean space to the sphere and state the explicit expansion for the generalised Wendland functions.

[05064] (β,γ)-Chebyshev functions and points

Format : Online Talk on Zoom
Author(s) : Francesco Marchetti (University of Padova)
Abstract : (β,γ)-Chebyshev functions are a generalization of classical Chebyshev polynomials of the first kind. They consist of a family of orthogonal functions on a subset of $[-1,1]$, which indeed satisfies a three-term recurrence formula and complies with various properties of classical families of orthogonal polynomials. Moreover, for certain configurations of parameters β and γ, the roots of (β,γ)-Chebyshev functions contained in the corresponding orthogonality interval lead to a stable polynomial interpolation process.

[01077] Recent Advances on Spectral Methods and Applications

Session Time & Room :

01077 (1/2) : 5B (Aug.25, 10:40-12:20) @E709

01077 (2/2) : 5C (Aug.25, 13:20-15:00) @E709

Type : Proposal of Minisymposium
Abstract : During the past several years, significant progress has been made in spectral methods and applications, especially in challenge problems such as numerical approximations for non-local and high-dimensional partial differential equations, where spectral and high-order methods are often preferred to low-order methods due to high-accuracy and lower memory request. This minisymposium aims to bring together active researchers in related areas to present and discuss their newest advances in both mathematical theory and numerical algorithms of efficient spectral numerical approximations for challenge scientific and engineering applications.
Organizer(s) : Hui-Yuan Li (Institute of Software Chinese Academy of Sciences), Li-Lian Wang (Nanyang Technological University), Haijun Yu
Classification : 65N35, 65M70
Minisymposium Program :

01077 (1/2) : 5B @E709 [Chair: Li-Lian Wang]

[04186] A positive and moment-preserving Fourier spectral method

Format : Talk at Waseda University
Author(s) : Zhenning Cai (National University of Singapore)Bo Lin (National University of Singapore)
Abstract : We present a novel Fourier spectral method that utilizes optimization techniques to ensure the positivity and conservation of moments in the space of trigonometric polynomials. We rigorously analyze the accuracy of the new method and prove that it maintains spectral accuracy. To solve the optimization problem, we propose an efficient Newton solver that has quadratic convergence rate. Applications to the Boltzmann equation are considered in our numerical tests.

[03237] Efficient structure-preserving spectral methods for plasma simulations

Format : Talk at Waseda University
Author(s) : Zhiguo Yang (Shanghai Jiao Tong University)
Abstract : In this talk, we present H^1-, H(div) and H(curl)-conforming spectral method with exact preservation of the curl/divergence-free constraints for two typical PDEs arising from plasma simulations. One is the incompressible visco-resistive MHD system and the other one is the Vlasov-Ampere system. Two key ingredients, i.e. exact de Rham complexes and their commuting diagram, and the derivative property of the generalized Jacobi polynomials, are essential for the derivation of the desired basis functions. Besides, we propose a novel efficient solution algorithm based on simultaneous multiple-matrices diagonalisation technique. Ample 2D and 3D numerical examples illustrate both the accuracy and efficiency of the proposed methods.

[04790] A deep adaptive sampling method for the approximation of PDEs

Format : Talk at Waseda University
Author(s) : Kejun Tang (Changsha Institute for Computing and Digital Economy, Peking University)Jiayu Zhai (ShanghaiTech University)Xiaoliang Wan (Louisiana State University)
Abstract : In this work, we develop an adaptive sampling strategy when approximating the PDE solution with a neural network. Two neural networks will be trained simultaneously through a min-max optimization problem, which is formulated by coupling PINN and the optimal transport. One neural network is used as a surrogate model of the true solution and the other neural network is used to optimize the collocation points in the training set. Numerical experiments will be presented.

[04098] A variable time-step scheme for Navier-Stokes equations

Format : Talk at Waseda University
Author(s) : Yana DI (Beijing Normal University)
Abstract : In the talk, the implicit-explicit (IMEX) second-order backward difference (BDF2) scalar auxiliary variable (SAV) scheme for Navier-Stokes equation with periodic boundary conditions ($Huang\ and\ Shen, SIAM\ J.Numer.Anal.$, 2021) has been generalized to a variable time-step IMEX-BDF2 SAV scheme. We derive global and local optimal H^1 error estimates in 2D and 3D, respectively. An adaptive time-stepping strategy has also been designed and numerical examples will confirm the effectiveness and efficiency of our proposed methods.

01077 (2/2) : 5C @E709 [Chair: Hui-Yuan Li]

[03896] Barycentric Interpolation Based on Equilibrium Potential

Format : Talk at Waseda University
Author(s) : Shuhuang Xiang (Central South University)Kelong Zhao (Central South University)
Abstract : A novel barycentric interpolation algorithm with specific exponential convergence rate is designed for analytic functions defined on the complex plane, with singularities located near the interpolation region, where the region is compact and can be disconnected or multiconnected. The core of the method is the efficient computation of the interpolation nodes and poles using discrete distributions that approximate the equilibrium logarithmic potential, achieved by solving a Symm's integral equation. It takes different strategies to distribute the poles for isolated singularities and branch points, respectively. In particular, if poles are not considered, it derives a polynomial interpolation with exponential convergence. Numerical experiments illustrate the superior performance of the proposed method.

[04757] Log orthogonal functions in semi-infinite intervals: approximation results and applications

Format : Talk at Waseda University
Author(s) : Sheng Chen (Beijing Normal University at Zhuhai)
Abstract : We construct two new classes of log orthogonal functions in semi-infinite intervals, log orthogonal functions (LOFs-II) and generalized log orthogonal functions (GLOFs-II), by applying a suitable log mapping to Laguerre polynomials. We develop a basic approximation theory for these new orthogonal functions and show that they can provide uniformly good exponential convergence rates for problems in semi-infinite intervals with slow decay at infinity. We apply them to solve several linear and nonlinear differential equations whose solutions decay

algebraically or exponentially with very slow rates and present ample numerical results to show the effectiveness of the approximations by LOFs-II and GLOFs-II.

[05466] A class of efficient spectral methods and error analysis for nonlinear Hamiltonian systems

Format : Online Talk on Zoom
Author(s) : Waixiang Cao (Beijing Normal University)Jing An (Guizhou Normal university)Zhimin Zhimin Zhang (Wayne state University)
Abstract : In this talk, we investigate efficient numerical methods for nonlinear Hamiltonian systems. Three polynomial spectral methods (including spectral Galerkin, Petrov-Galerkin, and collocation methods) coupled with domain decomposition are presented and analyzed. Our main results include the energy and symplectic structure-preserving properties and error estimates. We prove that the spectral Petrov-Galerkin method preserves the energy exactly while both the spectral Gauss collocation and spectral Galerkin methods are energy conserving up to spectral accuracy. While it is well known that collocation at Gauss points preserves symplectic structure, we prove that the Petrov-Galerkin method preserves the symplectic structure up to a Gauss numerical quadrature error and the spectral Galerkin method preserves the symplectic structure up to spectral accuracy error. Finally, we show that all three methods converge exponentially, which makes it possible to simulate the long time behavior of the system. Numerical experiments indicate that our algorithms are efficient.

[01081] New Trends in Education of Applied Mathematics, Industry, Technology and Knowledge Transfer

Session Time & Room : 1E (Aug.21, 17:40-19:20) @A208

Type : Proposal of Minisymposium
Abstract : The field of applied mathematics is constantly evolving and it is important for professionals in the industry amd academics to stay up-to-date with the latest trends and developments. This minisymposium is aimed at discussing how the recent technology developments are changing both how and what we need to teach in undergraduate applied mathematics programs. We will provide a platform for experts to share their insights and experiences on the current and future trends in the education of Applied Mathematics and its applications in industry and technology.
Organizer(s) : Dae-Jin Lee (IE University), David Gómez-Ullate (IE University), Luis Vega (UPV/EHU-BCAM)
Classification : 97M10, 97M20, 97D99, Mathematics and Education
Minisymposium Program :

01081 (1/1) : 1E @A208

[02936] Applied Mathematics curriculum in the 21 st century

Author(s) : Beatriz Rumbos (Instituto Tecnológico Autónomo de México)
Abstract : Throughout history, Mathematics has made it possible for humans to cope and understand their surroundings and to make our lives more predictable. In the 20th century, mathematical models became indispensable tools for the development of almost every discipline; thus, promoting the creation of Applied Mathematics degrees at universities worldwide. The essence of an Applied Mathematics undergraduate program is to endow the student with the knowledge and analytical skills, needed to model and solve problems arising in a diversity of fields. The complexity of modern societies, the boom of the knowledge economy, the pace of technological change and the increasing social responsibility of modern youth, call for a major overhaul in the Applied Mathematics curricula and its teaching methods. In this talk I shall address the actions that we have taken at ITAM in order to address these challenges.

[01931] An innovative experience in a Computer Engineering programme

Author(s) : M. Teresa T. Monteiro (Centre Algoritmi, Systems and Production Department,University of Minho)Gabriel Hornink (Educational Media Laboratory, Department of Biochemistry, Institute of Biomedical Sciences, Federal University of Alfenas)Flávia Vieira (Centro de Investigação em Educação (CIEd), Institute of Education, University of Minho, Braga)
Abstract : The talk reports an innovative learner-centred experience developed with 146 graduate students in the course “Numerical Methods and NonLinear Optimization” in a Computer Engineering programme at the University of Minho, Portugal. Students developed collaborative MATLAB projects by applying a course topic to a real-world phenomenon. Project analysis and students’ perceptions collected through a survey showed that they became pro-active learners and developed their ability to formulate, analyse and solve problems from a multidisciplinary perspective.

[04341] How the last few years have reshaped teaching First-Year mathematics

Author(s) : Joshua Jordan Capel (UNSW, School of Mathematics and Statistics)
Abstract : In this talk we will discuss how the past few years have reshaped the teaching of mathematics in the School of Mathematics and Statistics, UNSW (University of New South Wales) Sydney, Australia. We will discuss how the in-term and end-of-term assessment have been re-designed to scaffold student learning throughout term and test understanding instead of just rewarding rote learning and computing. We will also discuss how this style has been embraced or challenged by university administrators and accreditation bodies, and speculate on what future challenges await us.

[04591] Experiencing Mathematics: Compute. Intuit. Imagine. Create.

Author(s) : Amrik Sen (Plaksha University)
Abstract : If the next generation of engineering and science students are to be trained with the skills required to address contemporary societal and environmental challenges then both the curriculum and pedagogy of mathematics needs to be re-visited. I propose that training students to use computer technology to do mathematics and incorporating experiential projects as an immersive learning technique will foster intuition and imagination necessary to anchor abstract conceptual learnings to practical applications.

[01088] Differential Equations meet Data: Scientific Machine Learning for Cardiovascular Applications

Session Time & Room :

01088 (1/4) : 3E (Aug.23, 17:40-19:20) @E708

01088 (2/4) : 4C (Aug.24, 13:20-15:00) @E708

01088 (3/4) : 4D (Aug.24, 15:30-17:10) @E708

01088 (4/4) : 4E (Aug.24, 17:40-19:20) @E708

Type : Proposal of Minisymposium
Abstract : In silico models offer effective tools to address cardiovascular diseases and quantitatively analyze clinical data. Recently, many methods have been proposed to blend numerical solvers with machine learning techniques. These approaches hold promise for the patient-specific personalization of models and for the acceleration of their numerical resolution. This minisymposium will offer a forum to discuss the state-of-the-art and future lines of research toward an increasingly effective integration between clinical data and numerical simulations
Organizer(s) : Francesco Regazzoni, Stefano Pagani, Francisco Sahli Costabal, Simone Pezzuto
Classification : 65Mxx, 65Zxx
Minisymposium Program :

01088 (1/4) : 3E @E708 [Chair: Simone Pezzuto]

[04634] Scientific machine learning approaches for many-query problems in cardiovascular applications

Format : Online Talk on Zoom
Author(s) : Stefano Pagani (MOX, Department of Mathematics, Politecnico di Milano)Francesco Regazzoni (MOX, Dipartimento di Matematica, Politecnico di Milano)Luca Dede' (Politecnico di Milano)Alfio Quarteroni (Politecnico di Milano, EPFL)
Abstract : In many cardiovascular applications, only partial and (possibly) noisy measurements of the phenomenon are available, limiting data-driven techniques in robustly reconstructing quantities of interest. Scientific machine learning approaches compensate for this partial information by integrating physics-based parametric differential models into machine/deep learning models, enabling efficient and accurate solutions to inverse or parameter estimation problems. In this talk, we present some numerical examples of scientific machine learning strategies in computational medicine.

[04639] GPU-Parallel Cardiac Simulation

Format : Talk at Waseda University
Author(s) : Toby Simpson (Università della Svizzera italiana)Rolf Krause (Università della Svizzera italiana)
Abstract : The computational cost of current approaches to whole heart simulation make them impractical for research or clinical application.

We compute a complete description of a human heartbeat, including electrophysiology, solid mechanics and fluid dynamics, on a single Graphics Processing Unit (GPU) within a few minutes.

The implementation via a matrix- and mesh-free Finite Volume discretisation, is simple enough to allow patient-specific fitting or provide ground truth data to machine learning algorithms.

[05161] In-silico perivascular flow and transport

Format : Online Talk on Zoom
Author(s) : Marie Elisabeth Rognes (Simula Research Laboratory)
Abstract : Your brain has its own waterscape: whether you are reading, thinking or sleeping, fluid flows through or around the brain tissue, clearing waste in the process. These biophysical processes are crucial for the well-being and function of the brain. In spite of their importance we understand them but little. In this talk, I will give an overview of mathematical, mechanical and numerical approaches to gain new insight into mechanisms underlying brain clearance.

[04430] Lipschitz Stabilised Autoencoders in Parameter Identification of Dynamical Systems

Format : Talk at Waseda University
Author(s) : Haibo Liu (Inria Paris)Damiano Lombardi (Inria Paris)Muriel Boulakia (Université de Versailles et Saint-Quentin en Yveline)
Abstract : The present work deals with data-driven modelling. Given a set of partial noisy observations of a dynamical system, we investigate using the Lipschitz stabilised auto-encoder to perform an intrinsic dimension estimation to understand how many parameters are responsible for the observed variability. By incorporating the information of the intrinsic dimensionality, we investigate a data-driven model that can complement the classical parameter identification method with the help of data.

01088 (2/4) : 4C @E708 [Chair: Francesco Regazzoni]

[05201] Accelerating hemodynamic predictions via machine learning

Format : Online Talk on Zoom
Author(s) : Noelia Grande Gutierrez (Carnegie Mellon University)
Abstract : Image-based computational blood flow simulations allow quantifying patient-specific hemodynamics with applications for personalized diagnosis, risk stratification, and treatment selection. However, the clinical translation of these methods is limited due to their high computational cost. We propose machine learning super-resolution to accelerate hemodynamic predictions. For upsampling simulation results, we combine physics-based

simulations on a coarse mesh with a graph neural network. Unstructured data (mesh) can be directly transformed into a graph representation, minimizing information loss.

[04443] The fibrotic kernel signature: simulation-free prediction of atrial fibrillation

Format : Online Talk on Zoom
Author(s) : Francisco Sahli Costabal (Pontificia Universidad Católica de Chile)Simone Pezzuto (Università di Trento)Lia Gander (Università della Svizzera Italiana)Tomás Banduc (Pontificia Universidad Católica de Chile)
Abstract : We propose a fast classifier that is able to predict atrial fibrillation inducibility in patient-specific cardiac models. This is achieved by training the classifier on a variant of the Heat Kernel Signature, which includes information about the fibrosis. These features are fast to compute, when compared to standard cardiac models. The classifier is able to predict the inducibility of single points and also the overall inducibility of the model.

[05176] Learning Reduced-Order Models for Blood Flow Simulations Using Graph Neural Networks

Format : Talk at Waseda University
Author(s) : Luca Pegolotti (Stanford University)Martin Pfaller (Stanford University)Natalia Rubio (Stanford University)Rita Brugarolas Brufau (Intel)Ke Ding (Intel)Eric Darve (Stanford University)Alison Marsden (Stanford University)
Abstract : We develop one-dimensional reduced-order models for simulating blood flow dynamics in complex cardiovascular geometries using a graph neural network trained on 3D hemodynamic data. Our method, which is a modified version of MeshGraphNet, accurately and efficiently predicts pressure and flow rate with errors below 2% and 3%, respectively, outperforming traditional physics-based models while maintaining high inference efficiency. Our findings demonstrate the potential of this approach in handling diverse anatomies and boundary conditions in physiological settings.

01088 (3/4) : 4D @E708 [Chair: Stefano Pagani]

[04920] Fast and accurate reduced order modelling techniques for the simulation of blood flow dynamics

Format : Talk at Waseda University
Author(s) : Gianluigi Rozza (SISSA Trieste)
Abstract : Heart disease is one of the main cause of death worldwide, therefore in the last years the medical profession
has shown a growing attention for simulating blood flow dynamics through numerical methods.
The main purpose is to build a support for surgical procedure and to predict the progression of a disorder.
Full order mathematical models can be adopted for patient-specific cases, varying physical and geometrical parameters, however the complexity of the computational domain requires a fine discretization and as a result a considerable amount of time. Our works focus on the study of Reduced Order Models (ROMs), which are specifically formulated to reduce the computational cost of complex dynamics such as biomedical ones. A complete decoupling between an offline and an online stage is adopted to speed up high fidelity simulations, by splitting what can be done only once and what need to be evaluated for every new parameter to obtain e good ROM solution. Both intrusive and data-driven approaches are tested for patient-specific applications to investigate both the efficiency and the accuracy of the ROM framework.

[04420] Parameter estimation in cardiac biomechanical models based on physics-informed neural networks

Format : Online Talk on Zoom
Author(s) : Federica Caforio (Institute of Mathematics and Scientific Computing, NAWI Graz, University of Graz)Francesco Regazzoni (MOX, Dipartimento di Matematica, Politecnico di Milan)Stefano Pagani (MOX, Department of Mathematics, Politecnico di Milano)Alfio Maria Quarteroni (MOX, Department of Mathematics, Politecnico di Milano)Gernot Plank (Gottfried Schatz Research Center: Division of Biophysics, Medical University of Graz)Gundolf Haase (Institute of Mathematics and Scientific Computing, NAWI Graz, University of Graz)
Abstract : In this talk a novel methodology is proposed, based on the integration of physics-informed neural networks methodologies with biophysically detailed three-dimensional cardiac biomechanical models, to generate robust and effective surrogate reduced-order models that are able to reconstruct displacement fields and locally

estimate heterogeneous passive mechanical properties. The accuracy and robustness of the proposed method are demonstrated in several benchmarks. This methodology potentially paves the way for the robust and effective identification of patient-specific physical properties.

[03697] Super-resolution and denoising of 4D flow MRI via implicit neural representations

Format : Talk at Waseda University
Author(s) : Simone Saitta (Politecnico di Milano)Marcello Carioni (University of Twente)Subhadip Mukherjee (University of Bath)Carola-Bibiane Schönlieb (University of Cambridge)Alberto Redaelli (Politecnico di Milano)
Abstract : We trained sinusoidal representation networks (SIRENs) for denoising and super-resolution of time-varying 3-directional velocity fields measured in the aorta by 4D flow MRI. The performance of different SIREN architectures was evaluated on synthetic measurements and then we applied the best architecture to real 4D flow data of an aortic aneurysm. Our method provides a continuous representation of 4D velocity fields (super-resolution) and achieves denoising thanks to SIREN's spectral bias, outperforming state-of-the-art techniques.

01088 (4/4) : 4E @E708

[01098] Elucidating theoretical biology and deep learning by algebraic statistics and topology

Session Time & Room : 1E (Aug.21, 17:40-19:20) @E504

Type : Proposal of Minisymposium
Abstract : Nonlinear algebra and topology are gaining popularity as a tool for studying theoretical biology including phylogenetics and mathematical neuroscience. Applying these modern mathematical fields can lead to a breakthrough in the important fields. However, there can be rather a limited access to the practical resources for the sophisticated mathematical methods. Thus, it is important to introduce the modern algebraic and topological methods and exchange their hands-on skills in person. In this minisymposium, each speaker will talk about the combinations of modern mathematical methods with statistical machine learning and their applications.
Organizer(s) : Keiji Miura
Classification : 62R01, 55-08, 68T07, 92D15
Minisymposium Program :

01098 (1/1) : 1E @E504 [Chair: Keiji Miura]

[04921] Judging unlearnability from structures of deep neural networks for low dimensional inputs

Format : Talk at Waseda University
Author(s) : Keiji Miura (Kwansei Gakuin University)
Abstract : Zhang, Naitzat and Lim (2019) showed that a feedforward ReLU neural network is equivalent to a tropical rational map. Here we visualize the shapes of deep neural network functions by using the tropical algebra and judge its unlearnability of complicated boundaries. Especially, the limitation can be naturally interpreted by the tropical factorization of polynomials for the cases of one-dimensional input.

[04805] Hit and Run Sampling from the Space of Phylogenetic Trees

Format : Talk at Waseda University
Author(s) : David Barnhill (Naval Postgraduate School)Ruriko Yoshida (Naval Postgraduate School)Keiji Miura (Kwansei Gakuin University)
Abstract : In this presentation we introduce a Markov Chain Monte Carlo (MCMC) Hit and Run (HAR) uniform sampler over a tropically convex space of ultrametrics. This is particularly important because by sampling from the space of ultrametrics, we are sampling from the space of phylogenetic trees, or tree space. This has wide ranging implications to statistical inference relating to drawing inference about the tree space. Specifically, we show how

this HAR sampler can be employed to sample over the space of ultrametrics in order to non-parametrically estimate the phylogenetic tree distribution using what we call tropical density estimator (TDE) with the tropical metric. We compare the results of the TDE using the tropical metric against often used density estimation methods using the Billera-Holmes-Vogtman metric to show that TDE is more accurate and computationally less expensive.

[04960] Approximate Computation of Vanishing Ideals

Format : Talk at Waseda University
Author(s) : Hiroshi Kera (Chiba University)
Abstract : The vanishing ideal of points is the set of all polynomials that vanish over the points. The approximate computation of generators has been developed at the intersection of computer algebra and machine learning in the last decade. Computer-algebraic algorithms have a rich theoretical background, whereas machine learning-oriented algorithms are designed for applications such as classification at the cost of some theoretical properties. This talk reviews the development of approximate computation of vanishing ideals.

[01099] Physics-based and data-driven modeling for digital twins

Session Time & Room :

01099 (1/3) : 2C (Aug.22, 13:20-15:00) @A206

01099 (2/3) : 2D (Aug.22, 15:30-17:10) @A206

01099 (3/3) : 2E (Aug.22, 17:40-19:20) @A206

Type : Proposal of Minisymposium
Abstract : Digital twins have emerged in recent years as a paradigm for the lifetime operation of physical assets. A digital twin is an exact virtual representation of a physical asset that uses real-time data. The construction of a digital twin requires the use and sometimes union of different modeling methods that include physics-based modeling, data assimilation, data-driven modeling, and model reduction. This minisymposium has the goal to bring together researchers working on the theory and practice of modeling in the context of digital twins with a particular focus on industrial applications.

[03242] Towards smart city digital twins

Format : Talk at Waseda University
Author(s) : Francisco Chinesta (ENSAM)Daniele Di Lorenzo (ESI)Victor Champaney (ENSAM)Angelo Pasquale (ENSAM)Amine Ammar (ENSAM)Elias Cueto (I3A)Dominique Baillargeat (CNRS@CREATE)
Abstract : Smart cities are composed of a number of coupled complex system of systems. Modelling them needs enhancing the traditional physics-based modelling approaches as well as speeding-up the predictions. Artificial intelligence and data-driven models obtained by using physics-informed and physics-augmented learning represents a valuable approach where accuracy and rapidity met. In this presentation advanced methodologies will be used for addressing complex scenarios, enabling real-time diagnosis and prognosis.

[05203] Digital twins for green carbon processes

Format : Talk at Waseda University
Author(s) : Peter Benner (MPI for Dynamics of Complex Technical Systems, Magdeburg)Ion Victor Gosea (Max Planck Institute for Dynamics of Complex Technical Systems)
Abstract : Recent advances in scientific computing have made digital twins (DTs) increasingly popular in various fields,
including process engineering (ProcEng). DTs have the potential to transform ProcEng by enabling real-time monitoring or process optimization. However, their full potential in this area has yet to be realized. We provide an

overview of computational tools required for developing DTs in ProcEng. It characterizes models used to develop DTs and discusses the challenges and requirements associated with their implementation. We particularly focus on the development of sustainable chemical production processes in the context of a green carbon society.

[01503] Hierarchical modeling of electrical machines in the context of digital twins

Format : Talk at Waseda University
Author(s) : Karim Cherifi (TU Berlin)Volker Mehrmann (TU Berlin)Philipp Schulze (TU Berlin)
Abstract : Digital twins of electrical machines require mathematical models that are accurate enough for the design and fast enough to be used for condition monitoring. This leads to a hierarchy of models that are used within the digital twin. These models must in addition incorporate the physical coupling between electrical, mechanical, and thermal phenomena for more accurate computations. In this talk, we present how one can construct this model hierarchy by incorporating physics-based and data-driven modeling.

[04060] From physics to machine learning and back: Applications to fault diagnostics and prognostics

Format : Online Talk on Zoom
Author(s) : Olga Fink (EPFL)
Abstract : Deep learning requires representative data, but condition monitoring data for complex systems lack labels and representativeness. Integrating physics can help to overcome this.
The talk will give some insights into various techniques that combine physics-based and deep learning algorithms, as well as incorporate structural inductive bias for fault diagnostics and prognostics. The focus will be in particular on calibration-based hybrid approaches, physics-enhanced graph neural networks and on transformer-based architectures combined with transfer learning.

01099 (2/3) : 2D @A206 [Chair: Karim Cherifi]

[02141] Machine Learning for Scientific Discovery, with Examples in Fluid Mechanics

Format : Talk at Waseda University
Author(s) : Steven Brunton (University of Washington)
Abstract : This work describes how machine learning may be used to develop accurate and efficient nonlinear dynamical systems models for complex natural and engineered systems. We explore the sparse identification of nonlinear dynamics (SINDy) algorithm, which identifies a minimal dynamical system model that balances model complexity with accuracy, avoiding overfitting. This approach tends to promote models that are interpretable and generalizable, capturing the essential “physics” of the system.

[02075] Hamiltonian structure-preserving non-intrusive operator inference for predictive digital twins

Format : Talk at Waseda University
Author(s) : Anthony Gruber (Sandia National Laboratories)Irina Tezaur (Sandia National Laboratories)Max Gunzburger (University of Texas at Austin)
Abstract : To serve as reliable predictive tools, digital twins require dimensionality-reduction techniques that preserve key properties of the underlying equations. This talk presents a novel non-intrusive structure-preserving model reduction technique for canonical and non-canonical Hamiltonian systems based on operator inference. The method reduces to a straightforward linear solve given snapshot data and “gray-box” knowledge of the underlying problem. We demonstrate that, unlike traditional reduction methods, the proposed approach delivers stable, accurate, energy-conserving and robust reduced-order models.

[01631] Weakly supervised learning for power grid state estimation

Format : Talk at Waseda University
Author(s) : Jochen Lorenz Cremer (TU Delft)Elvin Isufi (TU Delft)Benjamin Habib (TU Delft)
Abstract : In this talk, I present a novel approach for Distribution System State Estimation (DSSE) called the Deep Statistical Solver for Distribution System State Estimation (DSS^2). This approach, based on graph neural networks (GNNs) and weakly-supervised learning, addresses the challenges of lack of observability and high density in the

distribution system. DSS^2 uses hypergraphs to represent the heterogeneous components of the distribution system and updates their latent representations via a node-centric message-passing scheme. Our approach allows for the training of DSS^2 using noisy and corrupted measurements, alleviating the need for ideal labelled data. The results of our experiments on various sizes of power networks showed DSS2 outperforms the conventional Weighted Least Squares algorithm in terms of accuracy, convergence, and computational time and is more robust to noisy, erroneous, and missing measurements. Our approach demonstrates the potential of weakly-supervised learning in DSSE and the ability to respect the physical constraints of the distribution system while learning from noisy measurements.

[03438] Data-driven Balancing for Acoustical Systems

Format : Talk at Waseda University
Author(s) : Art J.R. Pelling (TU Berlin)Ennes Sarradj (TU Berlin)
Abstract : Constructively modelling acoustical systems is difficult due to unknown material and domain properties and complexity of dynamics. Although measurement data is abundantly available, reduced order modelling is not well-established in the field.
We showcase recent system identification methods from the mathematical community and analyze their aptitude and performance in real applications that involve high-dimensional measurement data. Amongst others, we consider head-related transfer functions that are used for auralization in virtual reality applications.

01099 (3/3) : 2E @A206 [Chair: Ion Victor Gosea]

[04485] Constrained Optimal Sensing for Nuclear Digital Twins

Format : Talk at Waseda University
Author(s) : Krithika Manohar (University of Washington)
Abstract : We develop a constrained optimization for sensor placement in nuclear digital twins where sensing capability may be severely constrained or limited. These constraints may arise in certain areas of a reactor due to hostile operating conditions, accessibility issues, and physical limitations on sensing capability. Our data-driven method optimizes sensor placement with constraints for full flow field reconstruction, leveraging reduced order models of flow physics. We demonstrate the technique is near optimal using empirical and theoretical validation and provide uncertainty analyses for noisy sensor measurements. The method is demonstrated on a nuclear fuel rod prototype which is heated to mimic the neutronics effect of nuclear fuel within the Transient Reactor Test facility (TREAT) at Idaho National Laboratory.

[03365] Exploring security challenges in enhancing Digital Twins capabilities with ChatGPT

Format : Talk at Waseda University
Author(s) : Xingheng Liu (NTNU)Shen Yin (NTNU)Jie Liu (NTNU)Jørn Vatn (NTNU)Asmae Bni (NTNU)
Abstract : Digital twins offer valuable insights for monitoring and managing physical systems. With the upsurge of ChatGPT, integrating it with digital twins during the design or operation phase could unlock new capabilities. However, this integration may introduce new security challenges and vulnerabilities. In this talk, we will briefly discuss the potential of enhancing digital twins with ChatGPT and the associated security concerns, emphasizing the importance of addressing these issues to ensure robust, secure DTs.

[04925] Reduced order modelling for large-scale CFD

Format : Talk at Waseda University
Author(s) : Zoltán Horváth (Széchenyi István University)Mátyás Yves Constans (Széchenyi István University)
Abstract : The RedSim in-house reduced-order modeling (ROM) software for the 3D compressible Euler and Navier-Stokes equations is introduced. RedSim’s core consists of a finite volume code running on GPUs and the proper orthogonal decomposition-based ROM-module. The application of RedSim to digital twinning for urban air pollution (in HiDALGO2 EuroHPC Centre of Excellence) and an acoustics problem in the automotive industry are presented. Numerical experiments raise mathematical challenges, which will be presented and some of them solved.

[04687] Comparison of physics-based and data-driven surrogate models of a gas-bearings supported rotor

Format : Online Talk on Zoom
Author(s) : Dimitri Goutaudier (EPFL)Jürg Schiffmann (EPFL)Fabio Nobile (EPFL)
Abstract : Gas bearings use pressurized gas as a lubricant to support and guide rotating machinery. These bearings have several advantages over traditional lubricated bearings but they more complex to operate and exhibit nonlinear behaviors. In this contribution, we present physics-based and data-driven frameworks to compute the dynamics of a gas-bearings supported rotor operating at very high rotation speeds. We compare the numerical performances of the two approaches, and we propose research directions to improve the models.

[01107] Efficient methods for Isogeometric Analysis

Session Time & Room :

01107 (1/2) : 2D (Aug.22, 15:30-17:10) @G301

01107 (2/2) : 2E (Aug.22, 17:40-19:20) @G301

Type : Proposal of Minisymposium
Abstract : Isogeometric Analysis is a relatively novel technique used to solve PDEs. The same functions that are used to describe the computational domain (typically B-Splines or NURBs) are used also to approximate the solution of the considered PDE. This approach brings several advantages with respect to the classical finite element method, but it also leads to new challenges, in particular from the computational point of view. This mini-symposium aims at gathering researchers that contribute to the improvement of the efficiency for isogeometric methods.
Organizer(s) : Mattia Tani, John Evans, Angelos Mantzaflaris, Stefan Takacs
Classification : 65N30, 65Y20, 65N38
Minisymposium Program :

01107 (1/2) : 2D @G301

[04261] Matrix free weighted quadrature IgA applied to heat transfer problems

Author(s) : Joaquin Eduardo Cornejo Fuentes (INSA Lyon)Thomas Elguedj (Lamcos)Arnaud Duval (Lamcos)David Dureisseix (Lamcos)
Abstract : IsoGeometric Analysis was introduced as an extension of Finite Element Method to represent the geometry and the solution field. However, the algorithms commonly used in FEM represented a major challenge from a computational point of view in IgA. This communication focuses on novel techniques applied to heat transfer problems which take advantage of the tensor structure of the shape functions, improve computation time of matrix-vector products and enhance the convergence rate of the iterative solver.

[04410] Solving boundary value problems via the Nystrom method using spline Gauss rules

Author(s) : Michael Barton Ali Hashemian (BCAM)Hanna Sliusarenko (BCAM)Sara Remogna (University of Torino)Domingo Barrera (University of Granada)
Abstract : We propose to use spline Gauss quadrature rules for solving boundary value problems~(BVPs) using the Nystrom method. When solving BVPs, one converts the corresponding partial differential equation inside a domain into the
Fredholm integral equation of the second kind on the boundary in the sense of boundary integral equation (BIE).
The Fredholm integral equation is then solved using the Nystrom method, which involves the use of a particular quadrature rule, thus, converting the BIE problem to a linear system. We demonstrate this concept on the 2D Laplace problem over domains with smooth boundary as well as domains containing corners. We validate our approach on benchmark examples and the results indicate that, for a fixed number of quadrature points (i.e., the

same computational effort), the spline Gauss quadratures return an approximation that is by one to two orders of magnitude more accurate compared to the solution obtained by traditional polynomial Gauss counterparts.

[04643] Fast computation of electromagnetic wave propagation with spline differential forms

Author(s) : Bernard Kapidani (Ecole Polytechnique Fédérale Lausanne)Rafael Vazquez (Ecole Polytechnique Fédérale Lausanne)
Abstract : We present a new structure-preserving numerical method for hyperbolic problems which does not rely on the geometric realisation of any dual mesh. We use B-spline based de Rham complexes to construct two exact sequences of discrete differential forms and apply them to solving Maxwell's equations. The method exhibits high order convergence and energy conservation, with computational effort much lower than standard Galerkin. We will also present preliminary results towards extension to multi-patch geometries.

[04698] Isogeometric Coupling Methods for H(curl) Problems

Author(s) : Melina Merkel (Technische Universität Darmstadt)Sebastian Schöps (Technische Universität Darmstadt)
Abstract : In this work, we present a method for the efficient simulation of electric motors using isogeometric analysis. As these machines include moving parts, conformity of the patches cannot be guaranteed for all rotation angles without modification of the geometry. We therefore use domain decomposition methods, e.g., mortaring or Nitsche-type coupling, for the coupling of stator and rotor. These methods can also be applied to all patches to facilitate patch-parallel computations.

01107 (2/2) : 2E @G301

[05111] Efficient reduced order models for unfitted spline discretizations

Author(s) : Margarita Chasapi (EPFL)Pablo Antolin (EPFL)Annalisa Buffa (EPFL)
Abstract : This talk presents a methodology for efficient reduced order modelling of PDEs on unfitted spline discretizations. We are interested in problems formulated on parameterized unfitted geometries and aim to construct efficient reduced basisapproximations. The presented methodology is based on extension of solution snapshots on the background mesh and localization strategies to confine the number of reduced basis functions. Numerical experiments on trimmed spline discretizations show the accuracy and efficiency of the method.

[05187] Singularity extraction and efficient numerical integration for isogeometric BEM

Author(s) : Tadej Kanduc (University of Ljubljana)
Abstract : Quadrature rules to evaluate governing (weakly singular) integrals that appear in boundary integral equations for 3D potential problems are presented. The rules are described by two main features: a higher order isoparametric singularity extraction technique and a spline-based quasi-interpolation technique. Uniform distribution of quadrature nodes is preferable to improve the implementation efficiency. The integration scheme has high order converge rates and since it is tailored for spline integrands, it perfectly fits in the isogeometric framework.

[05212] Low-rank Tensor Train Methods for IGA with Multiple Patches

Author(s) : Alexandra Bünger (University of British Columbia)Martin Stoll (Technical University of Chemnitz)Tom Christian Riemer (Technical University of Chemnitz)
Abstract : In IGA, the equation systems for, e.g., optimization problems may quickly become very costly to assemble and solve. We developed a method exploit the underlying tensor structure with low-rank tensor train approximations. This low-rank formulation can be efficiently used in a block-structured iterative solver to solve challenging PDE problems in a compact format.
We recently extended this for multi-patch domains and show how the resulting systems can be treated effectively in the tensor train framework.

[05302] An efficient solver for space–time isogeometric Galerkin methods for parabolic problems

Author(s) : Gabriele Loli (Università di Pavia)Monica Montardini (Università di Pavia)Giancarlo Sangalli (Università di Pavia)Mattia Tani (University of Pavia)

Abstract : We present an efficient solver for a Galerkin space–time isogeometric discretization of the heat equation. In particular, we propose a preconditioner that is the sum of Kronecker products of matrices and that can be efficiently applied thanks to an extension of the classical Fast Diagonalization method.

The preconditioner is robust w.r.t. the polynomial degree of the spline space and the time required for the application is almost proportional to the number of degrees-of-freedom.

[01111] Mathematical and numerical analysis on blow-up phenomena

Session Time & Room :

01111 (1/2) : 4C (Aug.24, 13:20-15:00) @G501

01111 (2/2) : 4D (Aug.24, 15:30-17:10) @G501

Type : Proposal of Minisymposium

Abstract : Blow-up phenomena appear in various science fields. They are described by partial differential equations. It is difficult to construct a general theory for the blow-up phenomena of partial differential equations. Therefore, we need to approach them from both mathematical and numerical aspects. In this mini-symposium, we discuss blow-up time and blow-up profile from the perspectives of mathematical and numerical analysis. The purpose of this minisymposium is to bring together researchers from both mathematical and numerical analysis to discuss recent advances on blow-up phenomena.

Organizer(s) : Takiko Sasaki

Classification : 35B44, 35A35, 35K05, 35L71

Minisymposium Program :

01111 (1/2) : 4C @G501 [Chair: Takiko Sasaki]

[01625] On the convergence order of the numerical blow-up time

Author(s) : Chien-Hong Cho (National Sun Yat-sen University)

Abstract : It is quite often that the solutions of initial-value problems become unbounded in a finite time. Such a phenomenon is called blow-up and the finite time is called the blow-up time. In this talk, we put our attention on the computation of an approximate blow-up time and its convergence order.

[01957] The blow-up curve for systems of semilinear wave equations

Author(s) : Takiko Sasaki (Department of Mathematical Engineering, Faculty of Engineering, Musashino University and Mathematical Institute, Tohoku University)

Abstract : In this talk, we consider a blow-up curve for systems of semilinear wave equations with different propagation speeds in one space dimension. The blow-up curve has been studied from the view point of its differentiability and singularity. We show that the blow-up curve has a singular point under suitable initial conditions. We also show some numerical examples of blow-up curves.

[01774] Lifespan estimates of semilinear wave equations of derivative type with characteristic weights in one space dimension

Author(s) : Shunsuke Kitamura (Tohoku University, Graduate School of Science)

Abstract : In this talk, I discuss the initial value problems for semilinear wave equations of derivative type with characteristic weights in one space dimension. Such equations provide basic principles on extending the general theory for nonlinear wave equations to the non-autonomous case. The results are quite different from the results of a series of joint work with Takamura, Wakasa and Morisawa about the nonlinear terms of unknown function itself.

[01740] On degenerate blow-up profiles for the semilinear heat equation

Author(s) : Hatem Zaag (CNRS and Université Sorbonne Paris Nord)
Abstract : We consider the semilinear heat equation with a superlinear power nonlinearity in the Sobolev subcritical range. We construct a solution which blows up in finite time only at the origin, with a completely new blow-up profile, which is cross-shaped. Our method is general and extends to the construction of other solutions blowing up only at the origin, with a large variety of blow-up profiles, degenerate or not.

01111 (2/2) : 4D @G501 [Chair: Takiko Sasaki]

[03241] Collapse Versus Blowup and Global Existence in Generalized Constantin–Lax–Majda Equation with dissipation

Format : Online Talk on Zoom
Author(s) : Pavel M Lushnikov (University of New Mexico)David M Ambrose (Drexel University)Michael Siegel (Department of Mathematical Sciences and Center for Applied Mathematics and Statistics, New Jersey Institute of Technology,)Denis A Silantyev (Department of Mathematics, University of Colorado, Colorado Springs,)
Abstract : We analyze dynamics of singularities and finite time blowup of
generalized Constantin-Lax-Majda equation for
non-potential effective motion of fluid with competing convection,
vorticity stretching and dissipation. Multiple exact solutions are found with blowups. Global existence of solutions is proven for small data in periodic case. The analytical solutions on real line allow finite-time singularity formation for
arbitrarily small data illustrating critical difference between real line and periodic
cases. Analysis is complemented by accurate numerical
simulations.

[01136] Advances in Variational Models and PDEs for Images

Session Time & Room :

01136 (1/3) : 4C (Aug.24, 13:20-15:00) @E819

01136 (2/3) : 4D (Aug.24, 15:30-17:10) @E819

01136 (3/3) : 4E (Aug.24, 17:40-19:20) @E819

Type : Proposal of Minisymposium
Abstract : Variational models and partial differential equations have been used to model various aspects of images, and this has led to many effective approaches to solve diverse image processing problems, such as image denoising, segmentation, reconstruction. This minisymposium will provide a venue for the latest advances in analysis and algorithm design for variational models and PDEs, and we will showcase state-of-the-art applications in image processing.

Organizer(s) : Gunay Dogan, Ronald Lok Min Lui
Classification : 68U10, 65D18, 62H35, 94A08, 68T45
Minisymposium Program :

01136 (1/3) : 4C @E819 [Chair: Gunay Dogan]

[03732] Algorithms for Variational Segmentation of Regions and Boundaries

Format : Talk at Waseda University
Author(s) : Gunay Dogan (National Institute of Standards and Technology)
Abstract : We propose several algorithms for variational segmentation of regions and boundaries in images. The algorithms come in Lagrangian and Eulerian flavors, and optimize variational models incorporating boundaries

and region statistics, as well as various geometric regularizers. We demonstrate the advantages of each algorithm on several examples. Our algorithms are available in the open-source Python package scikit-shape.

[04275] Individual Tooth Segmentation in Human Teeth Images Using Pseudo Edge-Region Obtained by Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Chang-Ock Lee (KAIST)Seongeun Kim (KAIST)
Abstract : In human teeth images taken outside the oral cavity with a general optical camera, it is difficult to segment individual tooth due to common obstacles such as weak edges, intensity inhomogeneities and strong light reflections. In this talk, we propose a method for segmenting individual tooth in human teeth images. The key to this method is to obtain pseudo edge-region using deep neural networks.

[05117] Joint solution of multi-task problems in imaging

Format : Talk at Waseda University
Author(s) : Doga Gursoy (Argonne National Laboratory)
Abstract : Imaging in challenging conditions, such as with limited and uncertain data, typically involves solving multiple tasks, including image denoising, registration, segmentation, and various other reconstruction tasks. While the traditional approach has been to address these problems one at a time, solving them jointly with minimal manual hyperparameter setting can provide significant benefits in terms of image quality and acquisition time. In this presentation, I will explore the use of distributed optimization techniques to tackle these challenges and offer examples from my experience in the field of x-ray imaging.

[01799] Counting Objects by Diffused Index: geometry-free and training-free approach

Format : Talk at Waseda University
Author(s) : Maryam Yashtini (Georgetown University)
Abstract : Counting objects is a fundamental but challenging problem. In this talk, I propose diffusion-based, geometry-free, and learning-free methodologies to count the number of objects in images. The main idea is to represent each object by a unique index value regardless of its intensity or size, and to simply count the number of index values. First, I place different vectors, referred to as seed vectors, uniformly throughout the mask image. The mask image has boundary information of the objects to be counted. Secondly, the seeds are diffused using an edge-weighted harmonic variational optimization model within each object. I propose an efficient algorithm based on an operator splitting approach and alternating direction minimization method, and theoretical analysis of this algorithm is given. An optimal solution of the model is obtained when the distributed seeds are completely diffused such that there is a unique intensity within each object, which I refer to as an index. For computational efficiency, I stop the diffusion process before a full convergence, and propose to cluster these diffused index values. I refer to this approach as Counting Objects by Diffused Index (CODI). I explore scalar and multi-dimensional seed vectors. For Scalar seeds, I use Gaussian fitting in histogram to count, while for vector seeds, I exploit a high-dimensional clustering method for the final step of counting via clustering. The proposed method is flexible even if the boundary of the object is not clear nor fully enclosed. I present counting results in various applications such as biological cells, agriculture, concert crowd, and transportation. Some comparisons with existing methods are presented.

01136 (2/3) : 4D @E819 [Chair: Gunay Dogan]

[04373] A deep quasiconformal approach for topological preserving image segmentation

Format : Online Talk on Zoom
Author(s) : Ronald Lok Ming LUI (The Chinese University of Hong Kong)
Abstract : In this talk, we address the problem of topology-preserving image segmentation based on quasiconformal (QC) theories. We introduce a variational model to obtain an optimal QC map that deforms a template mask to the segmentation mask while preserving the topology of the template mask. The bijectivity of the mapping is controlled by the Beltrami coefficient, which measures the QC distortion. We demonstrate that the proposed QC segmentation model can be effectively incorporated into a deep neural network architecture. The resulting deep QC segmentation network takes an image and a template mask with a prescribed topological prior as inputs and outputs the optimal QC map. The QC map is further used to deform the template mask to obtain the segmentation result. Experimental results show that the proposed approach outperforms existing state-of-the-art

methods, making it a promising approach for topological preserving image segmentation. This work is supported by HKRGC GRF (Project IDs: 14306721,14307622).

[02523] Geodesic Models with Curvature Penalization for Image Analysis

Format : Talk at Waseda University
Author(s) : Da CHEN (Shandong Artificial Intelligence Institute)
Abstract : Geodesic models establish the connection between the minimization of a weighted curve length and the viscosity solutions to the HJB PDEs. In contrast to globally minimizing a simplified first-order energy, as done by the classical geodesic models, we have recently extended the geodesic models to cover different curvature regularization terms, in conjunction with convexity shape prior and curvature prior constraint. We also show their applications in tubular structure tracking and image segmentation.

[02808] Texture edge detection via Patch consensus

Format : Talk at Waseda University
Author(s) : Guangyu Cui (Georgia Institute of Technology)Sung Ha Kang (Georgia Institute of Techonology)
Abstract : While well-known segmentation method are often based on homogeneity of regions, we focus on finding boundaries between different textured regions. We propose a training-free method to detect the boundary of texture by considering consensus of patch responses away from the boundary. We derive the necessary condition for textures to be distinguished, and analyze the size of the patch with respect to the scale of textures. Various experiments are presented to validate our model.

[04153] Density-equalizing map with applications

Format : Talk at Waseda University
Author(s) : Gary Choi (The Chinese University of Hong Kong)
Abstract : We present surface and volumetric mapping methods based on a natural principle of density diffusion. Specifically, we start with a prescribed density distribution in a surface or volumetric domain, and then create shape deformations with different regions enlarged or shrunk based on the density gradient. By changing the density distribution, we can achieve different mappings including area-preserving parameterizations. Applications of the methods to medical shape analysis, data visualization, remeshing and shape morphing will be presented.

01136 (3/3) : 4E @E819 [Chair: Gunay Dogan]

[01712] Application of weighted TV flow to material science problems

Format : Online Talk on Zoom
Author(s) : Prashant Athavale (Clarkson University)Emmanuel Atindama (Clarkson University)Peter Lef (Clarkson University)Gunay Dogan (National Institute of Standards and Technology)
Abstract : Several variational and partial differential equation (PDE)-based image processing methods can restore noisy crystallographic orientation data.
We discuss restoration approaches, such as the classical total variation-based methods to diffusion PDEs.
However, such methods are parameter-dependent, making them challenging in practice.
Our work discusses an algorithm to restore noisy orientation data and circumvent the parameter selection problem by using weighted total variation flow, a nonlinear diffusion applied to the noisy orientation map.

[04202] Rank-One Prior: Real-Time Scene Recovery

Format : Talk at Waseda University
Author(s) : Tieyong Zeng (The Chinese University of Hong Kong)
Abstract : Scene recovery is a fundamental imaging task with several practical applications, including video surveillance and autonomous vehicles, etc. In this talk, we provide a new real-time scene recovery framework to restore degraded images under different weather/imaging conditions, such as underwater, sand dust and haze. A degraded image can actually be seen as a superimposition of a clear image with the same color imaging environment (underwater, sand or haze, etc.). Mathematically, we can introduce a rank-one matrix to characterize this phenomenon, i.e., rank-one prior (ROP). Using the prior, a direct method with the complexity is derived for real-time recovery. For general cases, we develop ROP to further improve the recovery performance. Comprehensive experiments of the scene recovery illustrate that our method outperforms competitively several state-of-the-art imaging methods.

[02233] Multispectral Image Restoration by Structured Eigendecomposition

Format : Talk at Waseda University
Author(s) : Zhantao MA (The University of Hong Kong)Michael Kwok-Po NG (The University of Hong Kong)
Abstract : We propose and study the opponent transformation for multispectral images. We generalize the well-known opponent transformation for color images and use it to bring the generalized opponent transformation total variation (GOTTV) multispectral image restoration model. By inheriting the crucial properties of the opponent transformation, the minimization formula of the GOTTV can be simplified and solved by the ADMM. Numerical examples are presented to demonstrate that the performance of the new GOTTV is well.

[01138] Advances in embedded and Eulerian methods for fluid-structure interaction

Session Time & Room : 4C (Aug.24, 13:20-15:00) @E820

Type : Proposal of Minisymposium
Abstract : This mini-symposium brings together young researchers and experts working on numerical modeling of fluid-structure interaction problems. To avoid the remeshing step involved in ALE method, other approaches based on non-body fitted grids have become more and more attractive. One is the embedded approach where a Lagrangian structure solver interacts with an Eulerian fluid solver to enforce appropriate conditions on the immersed interface. Another one is the fully Eulerian approach where both the fluid and the elastic structure are discretized on the same grid. This mini-symposium welcomes contributions to embedded and fully Eulerian numerical modelling for both compressible and incompressible FSI.
Organizer(s) : Michel Bergmann, Thomas Milcent
Classification : 76-XX, 74-XX, 65-XX, 68-XX, fluid structure interaction, embedded methods, fully Eulerian models
Minisymposium Program :

01138 (1/1) : 4C @E820 [Chair: Bergmann Michel]

[05651] A fully Eulerian FSI framework: introduction

Format : Talk at Waseda University
Author(s) : Thomas Milcent (I2M Bordeaux)Michel Bergmann (Inria - centre de l'université de Bordeaux)
Abstract : In the fully Eulerian framework, both the fluid and the solid are described by an Eulerian approach. The fluid-structure problem is recast as a complex flow: the fluid equations with an elastic source term is coupled with a transport equation on the Eulerian interface and deformation. In this presentation we will present this approach in the case where the elastic media (bulk or/and membrane) is immersed in an incompressible or compressible flow.

[05652] A fully Eulerian FSI framework: numerical approach and applications

Format : Talk at Waseda University
Author(s) : Michel Bergmann (Inria - centre de l'université de Bordeaux)Thomas Milcent (I2M Bordeaux)Antoine Fondaneche (NUREA)
Abstract : A quadtree-based fully Eulerian finite volume approach for the simulation of fluid-structure interaction problems is presented. The discretization stencils are limited to the first layer of neighbors thus enhancing the efficiency of the parallel computations while limiting the numerical order of the finite volume discretizations that can be reached. To illustrate the versatility of the numerical model presented, a biomedical application, the axisymmetric simulation of a blood flow in a cardiac pump, is presented.

[02558] Embedded Methods for Floating Offshore Structures

Format : Talk at Waseda University
Author(s) : Jan Modderman (Delft University of Technology)Oriol Colomés (Delft University of Technology)
Abstract : In this talk we will present a single-phase FE approach for free surface flows, where only the wave-structure interaction is accounted for, in combination with an unfitted floating structure with arbitrary geometry. In this work we propose a monolithic coupling with block preconditioning, ensuring robustness and efficiency of the solution. We will demonstrate the capabilities of the proposed framework with a series of tests for wave-structure interaction problems, assessing accuracy and conservation properties.

[03927] FULLY EULERIAN MODELS FOR FLUID-STRUCTURE INTERACTION: APPLICATION TO CAPSULES

Format : Talk at Waseda University
Author(s) : Mirco Ciallella (ENSAM - I2M)Thomas Milcent (ENSAM - I2M)
Abstract : Capsules have an important potential in the fields of biotechnologies but many scientific aspects, related to their modeling and simulation, are still challenging. In this context, eulerian models for fluid-structure interaction are a very promising tool to understand their behavior when interacting with complex geometries. In this talk, we will present a novel numerical tool to analyze complex applications of deformable capsules by introducing a solid bulk within the membrane.

[01140] Modelling and simulation of electro-chemo-mechanical processes in batteries and fuel cells

Session Time & Room :

01140 (1/3) : 5B (Aug.25, 10:40-12:20) @G404

01140 (2/3) : 5C (Aug.25, 13:20-15:00) @G404

01140 (3/3) : 5D (Aug.25, 15:30-17:10) @G404

Type : Proposal of Minisymposium
Abstract : The mini-symposium addresses various aspects of modelling and simulation of electro-chemo-mechanical processes in batteries and fuel cells. It is aimed at scientists from academia and industry and focuses on the physical and mathematical fundamentals of the processes rather than the system level. Aspects such as model derivation at the microscopic level and its upscaling, model validation and model reduction are the focus of this mini-symposium. It covers contributions on lithium and sodium ion and redox flow batteries, solid oxide and polymer electrolyte fuel cells, among others.

Minisymposium Program :

01140 (1/3) : 5B @G404 [Chair: Thomas Carraro]

[01934] Li-Ion battery kinetics model validation of NMC 111 and Graphite

Format : Talk at Waseda University
Author(s) : Robert Morasch (Technical University of Munich)Bharatkumar Suthar (Indian Institute of Technology Bombay)Hubert Gasteiger (Technical University of Munich)
Abstract : Understanding Li-Ion battery fundamentals is an important aspect when modelling Li-Ion batteries. The Doyle-Fuller-Newman model is often used as mathematical basis for such models, but rarely validated. Here we present an in-depth analysis of the kinetic behavior of NMC 111 and graphite using Electrochemical Impedance Spectroscopy. Measurements on thin electrodes allow an easy distinction of the kinetic resistance for either electrode without the influence of transport resistances.

[04354] Fluid–electrochemical-stress-coupled Simulation Method for SOFC Degradation Prediction

Format : Talk at Waseda University
Author(s) : Mayu Muramatsu (Keio University)Masami Sato (Tohoku University)Reika Nomura (Tohoku University)Kenjiro Terada (Tohoku University)Yashiro Keiji (Tohoku University)Tatsuya Kawada (Tohoku University)Harumi Yokokawa (The University of Tokyo)
Abstract : To predict the mechanical degradation of solid oxide fuel cells (SOFCs) during operation, we have developed an analysis system for their electro-chemo-mechanical phenomena by incorporating general-purpose finite element analysis software. This simulation system also takes into account the effects of gas and heat distributions, also calculated by commercial software.

[02306] Modeling and State Estimation of Lithium-Ion Batteries under Long-Term Degradation Conditions in Aerospace Application

Format : Talk at Waseda University
Author(s) : Linda Juliane Bolay (German Aerospace Center (DLR))Tobias Schmitt (German Aerospace Center (DLR))Simon Hein (German Aerospace Center (DLR))Omar Mendoza-Hernandez (Japan Aerospace Exploration Agency (JAXA))Eiji Hosono (National Institute of Advanced Industrial Science and Technology (AIST))Daisuke Asakura (, National Institute of Advanced Industrial Science and Technology (AIST))Koichi Kinoshita (, National Institute of Advanced Industrial Science and Technology (AIST))Hirofumi Matsuda (, National Institute of Advanced Industrial Science and Technology (AIST))Minoru Umeda (Nagaoka University of Technology)Yoshitsugu Sone (Japan Aerospace Exploration Agency (JAXA))Arnulf Latz (German Aerospace Center (DLR))Birger Horstmann (German Aerospace Center (DLR))
Abstract : The performance and durability of Li-ion batteries is impacted by various degradation mechanisms such as SEI growth. Here, we address the modeling and simulation of the batteries of the Japanese satellite REIMEI. We simulate SEI growth in a P2D and microstructure-resolved framework. The simulations are validated with in-flight data from JAXA. Furthermore, a multi-time-scale filter algorithm is applied to estimate the inner states of the battery by making use of the battery in-flight data.

[02922] Simulation of Chemo-Mechanically Coupled Battery Active Particles with Mechanical Constraints

Format : Talk at Waseda University
Author(s) : Raphael Schoof (Karlsruhe Institute of Technology)Giuseppe Fabian Castelli (Karlsruhe Institute of Technology)Willy Dörfler (Karlsruhe Institute of Technology)
Abstract : During charging and discharging of lithium-ion batteries, large mechanical stresses can occur due to phase-separation or limited swelling area. A chemo-mechanically coupled model for cycling battery active particles with mechanical constraints is used to investigate the stress development within representative active particles. The combination of the primal-dual active set algorithm, interpreted as semismooth Newton method, and a spatial and temporal adaptive algorithm allows the efficient two- and three-dimensional numerical simulation and computationally intensive parameter regimes.

01140 (2/3) : 5C @G404 [Chair: Thomas Carraro]

[04773] Electro-chemical based modelling of battery cells for automotive applications.

Format : Online Talk on Zoom
Author(s) : Edwin Knobbe (BMW AG)
Abstract : This contribution presents challenges with respect to modelling and (numerical) simulations of the interaction of mechanics and electro-chemistry for applications in battery cell development. Some of the challenges will be explained by examples relevant for automotive applications. For instance: solid mechanics to model the swelling behavior of battery cells during cycling, fluid mechanics with detailed chemistry during a thermal event and modelling electro-chemical phenomena at the interface between an electrode and a solid electrolyte.

[02597] Analytical solution to a multilayer particle model for Li-ion cells under generic high current profiles

Format : Online Talk on Zoom

Author(s) : Javid Piruzjam (Mercedes-Benz AG)Lukas Rubacek (Mercedes-Benz AG)Thomas Carraro (Helmut Schmidt University / UniBw Hamburg)

Abstract : Reduced order Li-ion battery models are widely used in applications such as state of charge estimation by electric vehicles' battery management systems, or cell characterization. Among those models, Single Particle Model is a computationally inexpensive physics-based solution. However, neglecting the effect of the electrolyte dynamics on the cell performance, SPM can lead to large errors especially at high current applications. In this work, we propose an analytical solution to a single particle model including electrolyte dynamics (SPMe) which is applicable for a wide range of currents. The boundary conditions and source terms in all differential equations are time-varying, and a spherical multilayer diffusion scenario is also considered which allows modelling particles coating and degradation effect.

[03013] Exploring non-isothermal effects in all-vanadium redox flow batteries through advanced numerical models

Format : Online Talk on Zoom

Author(s) : Marcos Vera (Universidad Carlos III de Madrid)Vanesa Muñoz-Perales (Universidad Carlos III de Madrid)Santiago E. Ibáñez (Repsol)Enrique García-Quismondo (IMDEA Energy)Sabrina Berling (IMDEA Energy)Jesús Palma (IMDEA Energy)

Abstract : Redox flow batteries are a promising electrochemical technology for large-scale stationary energy storage that still requires further development to increase its profitability and energy market penetration. Continuous macroscopic models enable the optimization of new architectures and operational strategies without extensive fabrication and experimental procedures. This work presents a non-isothermal two-dimensional steady-state model of a unit-cell all-vanadium redox flow battery. The model integrates state-of-the-art descriptions of the fundamental physical phenomena along with new features, such as local mass transfer coefficients for the active species, precise sulfuric acid dissociation kinetics, and experimentally determined electrochemical parameters and electrolyte properties. The model is validated at different states of charge, flow rates, and operating temperatures using polarization, conductivity, and open circuit voltage measurements. Then, the contribution of operating conditions to battery performance is studied by analyzing its separate effect on the various phenomena that affect cell performance, such as local pore mass transfer limitations, parasitic hydrogen evolution reactions, crossover, and self-discharge fluxes. After model calibration, a parametric study is carried out to explore the role of the operating temperature, deconvoluting the different contributions to cell heating and providing practical guidance about the thermal effects induced by operating conditions. The results reveal that i) increasing the cell temperature enhances species mass transfer but negatively affects activation losses, ii) the cell suffers higher overheating during charge than during discharge, and iii) cell heating increases proportionally with cell length. Lastly, we propose using asymmetric electrolyte temperatures as a performance improvement strategy for electrochemical storage systems hybridized with thermal energy storage. The resulting model is a reliable tool that can be used to assess the relevance of the coupled phenomena that take place simultaneously within the reaction cell. This vital information is critical to optimize cell components, reactor design and selecting optimal operating conditions.

[03277] A Model Framework for Lithium Ion Intercalation Cells

Format : Talk at Waseda University

Author(s) : Manuel Landstorfer (Weierstrass Institute for Applied Analysis and Stochastics (WIAS))Alireza Selahi (Weierstrass Institute for Applied Analysis and Stochastics (WIAS))

Abstract : We present a model framework for Lithium-ion batteries based on non-equilibrium thermodynamics. It emphasizes thermodynamic consistency, especially for reaction rates and concentration-dependent diffusion coefficients. A coupled two-scale PDE system is derived using periodic homogenization. Numerical simulations are finally shown, predicting the cell voltage during cycling at different C-Rates. We compare single- and many-particle electrode models and discuss the impact of material functions, diffusion coefficients, and reaction rate models based on numerical simulations.

[02810] Asymptotic reduction of a model for mechanical stresses in cylindrical batteries

Format : Talk at Waseda University
Author(s) : Jon Chapman (University of Oxford)Robert Timms (University of Oxford)Steven Psaltis (Queensland University of Technology)Colin Please (University of Oxford)
Abstract : Macroscopic mechanical stresses in lithium-ion batteries are known to significantly affect the long-term degradation mechanisms. These stresses are created by expansion and contraction of the different parts of the structure, due both to thermal variations and lithiation state. Predicting the resulting stresses using numerical techniques is made difficult due to the small-scale geometry of current collectors, separator and regions of active material.
Here we use the methods of boundary layer analysis and homogenisation, exploiting the small-scale periodic structure of a spirally-wound cylindrical battery, to derive a reduced-order model to determine approximations to the resulting stresses.

[05025] Microstructural resolved simulations of NVP-C electrodes for Sodium-ion batteries

Format : Talk at Waseda University
Author(s) : Paul Maidl (German Aerospace Center)Simon Hein (German Aerospace Center)Timo Danner (German Aerospace Center)Matthias Neumann (University Ulm)Marcel Häringer (Karlsruher Institue of Technology)Luca Schneider (Karlsruher Institue of Technology)Werner Bauer (Karlsruher Institue of Technology)Ingo Manke (Helmholtz-Zentrum Berlin)Volker Schmidt (University Ulm)Joachim R. Binder (Karlsruher Institue of Technology)Arnulf Latz (German Aerospace Center)
Abstract : Sodium-ion batteries are a promising candidate for sustainable future energy storage technologies. Although they have some similarities with Lithium ion batteries, today's modelling and simulation techniques for Sodium-ion batteries is lacking behind their Lithium counterpart. One interesting material for both anode and cathode is NVP-C ($Na_3V_2(PO_4)_3$ with added carbon). In our contribution we show simulation approaches for virtual material characterization of its complex three-dimensional microstructure and its influence on cell performance.

[04382] Modeling Solid Oxide Fuel Cells based on Electrode Microstructure Information

Format : Talk at Waseda University
Author(s) : Masashi Kishimoto (Kyoto University)Hiroshi Iwai (Kyoto University)
Abstract : Understanding the effect of the porous microstructure of SOFC electrodes on the electrochemical performance is essential in predicting their macroscopic performance and thereby optimizing electrode microstructure. We present several numerical simulation models of SOFCs with quantitative information of the electrodes obtained by 3D imaging technique based on focused ion beam scanning electron microscope (FIB-SEM). Typical results of microscopic distribution within the electrodes and macroscopic performance, such as overpotential and impedance characteristics, are overviewed.

[05164] Improving Lithium-ion Battery Models for Porous Secondary Particles: A Comparison of Homogenized and Microscopic 3D Models

Format : Talk at Waseda University
Author(s) : Javid Piruzjam (Mercedes-Benz AG)Phillip Gräfensteiner (Ulm University)Matthias Neumann (Ulm University)Lukas Rubacek (Mercedes-Benz AG)Volker Schmidt (Ulm University)Thomas Carraro (Helmut Schmidt University / UniBw Hamburg)
Abstract : We present a study on a homogenized model for porous secondary particles of lithium-ion batteries in comparison with microscopic 3D models. The 3D microstructures are based on FIB-SEM tomography, which provides high-resolution images of the secondary particles. Homogenized electrode-level models are widely used in battery applications due to their computational efficiency, e.g., in the electric vehicle industry. However, the accuracy of these models can be improved if the transport processes within the porous particles are considered, especially when complex microstructures are involved. Our investigation aims to improve the quantitative prediction of multiscale models. To perform a comprehensive study, we use digital twins to obtain adequate stochastic representations of the microstructure.

[01145] High dimensional recent computational approaches in finance and control

Session Time & Room :

01145 (1/2) : 5B (Aug.25, 10:40-12:20) @D505

01145 (2/2) : 5C (Aug.25, 13:20-15:00) @D505

Type : Proposal of Minisymposium
Abstract : Most high-dimensional problem in quantitative finance face computational difficulties. However, recent advances in training of neural networks provide an excellent opportunity to reconsider these models. Indeed, the influential papers of E, Han and Jentzen combine these optimization techniques with Monte-Carlo type regression for the off-line construction of optimal feedback actions.This approach, has proven to be highly effective in numerous closely related studies, reporting impressive numerical results in problems with large number of states.

All proposed speakers have been contacted and agreed to participate in the session should it be approved. This list of speakers is diverse in many ways, including both senior and junior members of the community and also it represents several different scientific approaches.

[03950] Learning to Simulate Tail-Risk Scenarios

Format : Talk at Waseda University
Author(s) : Rama Cont (University of Oxford)Mihai Cucuringu (University of Oxford)Renyuan Xu (University of Southern California)Chao Zhang (University of Oxford)
Abstract : The estimation of loss distributions for dynamic portfolios requires the simulation of scenarios representing realistic joint dynamics of their components. Scalability to large or heterogeneous portfolios involving multiple asset classes is particularly challenging, as is the accurate representation of tail risk.

We propose a novel data-driven approach for the simulation of realistic multi-asset scenarios with a particular focus on the accurate characterization of tail risk for a given class of static and dynamic portfolios selected by the user. By exploiting the joint elicitability property of Value-at-Risk (VaR) and Expected Shortfall (ES), we design a Generative Adversarial Network (GAN) architecture capable of learning to simulate price scenarios that preserve tail risk features for these benchmark trading strategies, leading to consistent estimators for their VaR and ES.

From a theoretical perspective, we show that different choices of score functions lead to different optimization landscapes and different complexities in GAN training. In addition, we prove that the generator in our GAN architecture enjoys a universal approximation property under the criteria of tail risk measures. In addition, we prove the bi-level optimization formulation between the generator and the discriminator is equivalent to a max-min game, leading to a more effective and practical formulation for training. From an empirical perspective, we demonstrate the accuracy and scalability of our method via extensive simulation experiments using synthetic and market data. Our results show that, in contrast to other data-driven scenario generators, our proposed scenario simulation method correctly captures tail risk for both static and dynamic portfolios in the input datasets.

[04737] Learning mappings on Wasserstein space with mean-field neural networks

Format : Talk at Waseda University
Author(s) : HUYEN PHAM (Université Paris Cité)Xavier Warin (EDF)
Abstract : We study the machine learning task for models with operators mapping between the Wasserstein space of
probability measures and a space of functions. Two classes of neural networks based on bin density and on

cylindrical approximation, are proposed to learn these so-called mean-field functions, and are theoretically supported by universal approximation theorems. We perform numerical experiments for training these two mean-field neural
networks, and show their accuracy in the generalization error with various test distributions.

[04743] Neural Optimal Stopping Boundary

Format : Talk at Waseda University
Author(s) : Anders Max Reppen (Boston University Questrom School of Business)Halil Mete Soner (Princeton University)Valentin Tissot-Daguette (Princeton University)
Abstract : A method based on deep artificial neural networks and empirical risk minimization is developed to calculate the boundary separating the stopping and continuation regions in optimal stopping. The algorithm parameterizes the stopping boundary as the graph of a function and introduces relaxed stopping rules based on fuzzy boundaries to facilitate efficient optimization. Several financial instruments, some in high dimensions, are analyzed through this method, demonstrating its effectiveness. The existence of the stopping boundary is also proved under natural structural assumptions.

[05236] MFG-OMO: An optimization framework for mean field game

Format : Talk at Waseda University
Author(s) : Xin Guo (UC Berkeley)
Abstract : We propos a new mathematical paradigm to analyze discrete-time mean-field games. It removes the contractive and the monotone assumptions and the uniqueness of the Nash equilibrium imposed in existing approaches for mean-field games. We show that finding Nash equilibrium solutions for a general class of discrete-time mean-field games is equivalent to solving an optimization problem with bounded variables and simple convex constraints, called MF-OMO. This equivalence framework enables finding multiple (and possibly all) Nash equilibrium solutions of mean-field games by
standard algorithms. For instance, projected gradient descent is shown to be capable of retrieving all possible Nash equilibrium solutions when there are finitely many of them, with proper initializations.
Moreover, analyzing mean-field games with linear rewards and mean-field independent dynamics is reduced to solving a finite number of linear programs, hence solvable in finite time.

Based on joint work with Anran Hu (University of Oxford) and Junzi Zhang (Amazon).

01145 (2/2) : 5C @D505 [Chair: A. Max Reppen]

[03993] Statistical Learning with Sublinear Regret of Propagator Models

Format : Talk at Waseda University
Author(s) : Yufei Zhang (London School of Economics and Political Science)Eyal Neuman (Imperial College London)
Abstract : We consider a class of learning problems in which an agent liquidates a risky asset while creating both transient price impact driven by an unknown convolution propagator and linear temporary price impact with an unknown parameter. We characterize the trader's performance as maximization of a revenue-risk functional, where the trader also exploits available information on a price predicting signal. We present a trading algorithm that alternates between exploration and exploitation phases and achieves sublinear regrets with high probability. For the exploration phase we propose a novel approach for non-parametric estimation of the price impact kernel by observing only the visible price process and derive sharp bounds on the convergence rate, which are characterised by the singularity of the propagator. These kernel estimation methods extend existing methods from the area of Tikhonov regularisation for inverse problems and are of independent interest. The bound on the regret in the exploitation phase is obtained by deriving stability results for the optimizer and value function of the associated class of infinite-dimensional stochastic control problems.

[04781] ROBUST UTILITY OPTIMIZATION VIA A GAN APPROACH

Format : Talk at Waseda University
Author(s) : Hanna Wutte (ETH Zurich)Florian Krach (ETH Zurich)Josef Teichmann (ETH Zurich)
Abstract : We study the robust expected utility maximization problem. In this problem, an agent wants to maximize the expected utility of final wealth X_T^π under her trading strategy π in an uncertain market environment that chooses the worst case market measure P for the given trading strategy, i.e., $\sup_\pi \inf_P \mathbb{E}_P[U(X_T^\pi)]$. This problem can be understood as a two-player zero-sum game between the agent and the market. We restrict our attention to markets consisting of one risk-free and d risky assets S. Risky assets S are given by Itô processes,

where the drift μ and diffusion σ are chosen by the market player out of a set of admissible candidate functions. To make this tractable, we consider a penalized version of the robust utility optimization problem, where the market model can choose any such continuous functions, but is penalized for deviating from a reference market model via a penalty functional F . We suggest an algorithm to solve this problem using two recurrent neural networks (RNNs) with parameters θ and ω, one for the agent and one for the market, respectively. Those RNNs are trained iteratively by competing in the zero-sum game

\begin{equation}\sup*{\theta}\inf*{\omega}\mathbb{E}[U(X^{\pi*theta,\mu*\omega,\sigma*omega}*T) + F (\mu*omega,\sigma*\omega ,S)] .\end{equation}
On a high level, this can be interpreted as a generative adversarial network (GAN) approach, where the generator produces a trading strategy π_θ and the adversarial discriminator tries to find the worst case market model $(\mu_\omega, \sigma_\omega)$. Importantly, the use of RNNs allows both players to learn non-Markovian strategies. The utility function U as well as the penalty function F can be chosen freely. We examine several set-ups to empirically show the quality of our proposed algorithm. At first, we consider log-utility in a friction-less market and instantaneous penalization of the market parameters. In this case, an analytic solution is known to exist which is replicated by our trained model. When introducing friction to the market, or when using other utility functions or path-dependent penalties, analytic solutions no longer exist. Therefore, we construct new evaluation metrics and we observe that our trained model achieves convincing results.

This is joint work with Florian Krach and Josef Teichmann.

[05102] Deep Learning in Portfolio Selection under Market Frictions

Format : Talk at Waseda University
Author(s) : Chen Yang (The Chinese University of Hong Kong)
Abstract : Incorporating market frictions in portfolio selection problems often leads to high-dimensionality even when the number of stocks is low, which makes it challenging for traditional grid-based numerical method. In this talk, we explore the application of deep learning method in portfolio selection problems with market frictions such as price impact, transaction cost, and capital gain taxes, and discuss the potential challenges.

[05342] Machine Learning Surrogates for Parametric and Adaptive Optimal Execution

Format : Talk at Waseda University
Author(s) : Michael Ludkovski (U California at Santa Barbara)Tao Chen (U of Michigan)Moritz Voss (U California at Los Angeles)
Abstract : We investigate optimal order execution with dynamic parametric uncertainty. Our base model features discrete time, stochastic transient price impact generalizing Obizhaeva and Wang (2013). We first consider learning the optimal strategy across a multi-dimensional range of model configurations, including price impact and resilience parameters, as well as initial stochastic states. We develop a numerical algorithm based on dynamic programming and deep learning, utilizing an actor-critic framework to construct two neural-network (NN) surrogates for the value function and the feedback control. We then apply the lens of adaptive robust stochastic control to consider online statistical learning of model parameters along with a worst-case min-max optimization. Thus, the controller is dynamically learning model parameters based on her observations while explicitly accounting for Bayesian uncertainty of the learned parameter estimates. We propose a modeling framework which allows a time-consistent 3-way marriage between dynamic learning, dynamic robustness and dynamic control. We extend our NN approach to tackle the resulting 8-dimensional adaptive robust optimal order execution problem, and illustrate with comparisons to alternative frameworks, such as adaptive or static robust strategies.

[01149] Sparse optimization techniques and applications

Session Time & Room : 4E (Aug.24, 17:40-19:20) @D515

Type : Proposal of Minisymposium
Abstract : Natural data that arise in several applications (such as biomedical imaging) are inherently sparse in suitable transformation domains provided in general by the gradient, wavelets, and their other variants. Such data sets can be stored in terms of a few samples, which in turn can be used for retrieving the original data with minimal or no loss of information via sparsity-seeking optimization techniques. A wealth of recent developments -

going by the name of compressive sensing - aim at signal acquisition compressively and sparse (or economical) description of data of certain types. Of late, this area of research has seen some fascinating developments, which include adaptive solvers, sparsity-driven deep learning methods, hardware-friendly algorithms suitable for biomedical imaging and impedance tomography, etc. The symposium aims at discussing some recent developments in sparse representation/optimization theory that pertain to fundamental as well as application-centric topics.

[05057] Efficient Magnetic Resonance Imaging via Adaptive Sparse Optimization

Format : Online Talk on Zoom

Author(s) : NAJIYA K Z (Post Doctoral Fellow)

Abstract : Magnetic resonance imaging via compressed sensing techniques gives good-quality reconstructions due to the sparse nature of images in the gradient domain. In routine medical scanning scenarios, the consecutive MRI images need not differ much in general. In this talk, we explain an MR imaging technique via sparse minimization by incorporating additional information about the support estimate into the optimization process to recover images from a lesser number of measurements.

[05058] A new matrix factorization for sparse representation of over-determined systems

Format : Talk at Waseda University

Author(s) : NAJIYA K Z (PhD Scholar)C S Sastry (IIT Hyderabad)

Abstract : This presentation aims at discussing a novel method that finds a sparse approximation of a matrix system y- Ax (where A has a bigger row size compared to its column size). While highlighting the need for such an approximation through some applications, the presentation realizes its objective via a new matrix factorization. Besides, it compares and contrasts the proposed method with established ones that have similar objectives.

[05060] Sparse optimization-based ERT algorithms for multiphase flows

Format : Talk at Waseda University

Author(s) : NAJIYA K Z (PhD Scholar)Shantam Gulati (IIT Hyderabad)

Abstract : We discuss applications of the compressed sensing framework mainly in the field of Electrical Impedance tomography (EIT). EIT is a scanning technique that draws a relationship between the impedance inside the domain and the current to voltage map on the boundary at the electrodes. In particular, we wish to address the ill-posed inverse problem in the circular domain. The idea is to draw comparisons and improve upon the existing techniques with L 1 and the weighted-norm approaches.

[05061] Hardware-friendly binary frames for sparse optimization

Format : Talk at Waseda University

Author(s) : NAJIYA K Z (PhD Scholar)Prasad Theeda (Vellore Institute of Technology)

Abstract : Binary matrices are preferred as compressed sensing (CS) matrices because they are hardware-friendly and support low-complexity sparse recovery algorithms. In this talk, we discuss that the disjunctness property of a binary matrix, which has been used in non-adaptive group testing, can also be very useful for recovering sparse signals. Disjunct matrices are particularly well-suited as compressed sensing matrices because they can support a non-iterative, fast sparse recovery algorithm.

[01152] Recent trends in the mathematical theory for incompressible fluids

Session Time & Room :

01152 (1/3) : 4E (Aug.24, 17:40-19:20) @G703

01152 (2/3) : 5B (Aug.25, 10:40-12:20) @G703

01152 (3/3) : 5C (Aug.25, 13:20-15:00) @G703

Type : Proposal of Minisymposium
Abstract : Models for incompressible fluid flows are omnipresent in a.o. (geo-)physical, biological and engineering applications. Nonetheless, the intrinsic lack of regularity of solutions to systems such as the incompressible Euler and Navier-Stokes equations constitutes a central challenge in developing further their mathematical theory.
The mini-symposium approaches these regularity questions from both a deterministic and stochastic perspective with a focus on most recent results on singularity formation, regularization procedures, the emergence of quasi-periodic solutions and hydrodynamic stability.
We bring together speakers from diverse backgrounds in terms of region, gender, and specific research methods to foster and encourage scientific exchange between different communities.
Organizer(s) : Gennaro Ciampa, Lars Eric Hientzsch

Minisymposium Program :

01152 (1/3) : 4E @G703 [Chair: Lars Eric Hientzsch]

[03906] Geometric structures in incompressible fluids: vortex and magnetic reconnection

Format : Talk at Waseda University
Author(s) : Gennaro Ciampa (University of Milan)
Abstract : The goal of this talk is to provide examples of smooth solutions of the Navier-Stokes equations such that the topology of the vortex lines changes during the evolution without any loss of regularity. This phenomenon is known as vortex reconnection. We will also discuss the applications to Magnetohydrodynamics: we will construct smooth solutions of the MHD equations such that the topology of the magnetic field lines changes during evolution, providing analytical examples of magnetic reconnection.

[04219] On maximally mixed equilibria of two-dimensional perfect fluid

Format : Talk at Waseda University
Author(s) : Michele Dolce (EPFL)
Abstract : The motion of a 2D perfect fluid can be described as an area-preserving rearrangement of the initial vorticity that conserves the kinetic energy. In the infinite time limit, vorticity mixing can occur and is conjectured to be a generic phenomenon. We offer a new perspective on the ``maximally mixed states'' introduced by Shnirelman by proving that many of them can be obtained as minimizers of a variational problem and we discuss some of their properties.

[03417] Quasi-periodic invariant structures in incompressible fluids

Format : Talk at Waseda University
Author(s) : Luca Franzoi (New York University Abu Dhabi)Nader Masmoudi (New York University Abu Dhabi)RICCARDO MONTALTO (University of Milan)
Abstract : In this talk, I present a recent result about the existence of nontrivial steady flows near the Couette flow in the channel $\mathbb{R} \times [-1, 1]$ that are quasi-periodic in space and solve the incompressible Euler equations.
First, I recall the result of Lin & Zeng and their construction of periodic flows. Then, I state the main result for space quasi-periodic flows. Finally, I show what are the main issues in our construction and how to solve them.

[03123] Flows with lower dimensional dissipations

Format : Online Talk on Zoom
Author(s) : Luigi De Rosa (University of Basel)
Abstract : In my talk I will describe how to put in a rigorous framework the study of turbulent solutions, i.e. rough fluid flows, whose energy cascade accumulates on lower dimensional sets. This naturally connects to intermittency phenomena which have been playing a major role in the current mathematical research.

01152 (2/3) : 5B @G703 [Chair: Luca Franzoi]

[03363] Uniform in gravity estimates for 2D water waves

Format : Talk at Waseda University
Author(s) : Siddhant Agrawal (ICMAT)
Abstract : We consider the 2D gravity water waves equation on an infinite domain. We prove a local wellposedness result which allows interfaces with corners and cusps as initial data, such that the time of existence of solutions is uniform even as the gravity parameter $g \to 0$. As an application of the new energy estimate, we prove a blow up result for the water waves model where the fluid is homeomorphic to the disc.

[04740] Invariant KAM tori around annular vortex patches for 2D Euler equations

Format : Talk at Waseda University
Author(s) : Zineb Hassainia (NYUAD)Taoufik Hmidi (New York University Abu Dhabi)Emeric Roulley (SISSA International School for Advanced Studies)
Abstract : We shall discuss the emergence of quasi periodic vortex patch solutions with one hole for the 2D-Euler equations. We prove the existence of such structures close to any annular vortex patch provided that its modulus belongs to a Cantor set with almost full Lebesgue measure. The proof is based on Nash-Moser implicit function theorems and KAM theory.

[03663] Euler and Navier-Stokes equations. Quasi-periodic solutions and inviscid limit

Format : Talk at Waseda University
Author(s) : RICCARDO MONTALTO (University of Milan)
Abstract : In this talk I will discuss some recent results on Euler and Navier Stokes equations concerning the construction of quasi-periodic solutions. In particular, I will focus on the construction of vanishing viscosity quasi-periodic solutions for the Navier-Stokes equation in the inviscid limit. The key step of the analysis is to implement Normal Form techniques which allow to prove sharp estimates (uniform in time) w.r. to the viscosity.

[04625] Reducibility of a class of quasi-linear wave equation on the torus

Format : Talk at Waseda University
Author(s) : Shulamit Terracina (Università degli Studi di Milano)
Abstract : We discuss the reducibility of a linear wave equation on the torus perturbed by a pseudo-differential potential of order 2 depending quasi-periodically on time. Under suitable conditions on the frequency vector, we develop a general strategy, combining Egorov theory with straightening of vector fields, to reduce to constant coefficients a class of weakly dispersive operators. Finally, we discuss generalizations to operators arising from the linearization of fluid models such as pure gravity Water Waves.

01152 (3/3) : 5C @G703 [Chair: Gennaro Ciampa]

[02208] Nonuniqueness in Law for Stochastic Hypodissipative Navier--Stokes Equations

Format : Talk at Waseda University
Author(s) : Andre Schenke (Courant Institute of Mathematical Sciences at New York University)
Abstract : We study the incompressible hypodissipative Navier--Stokes equations with dissipation exponent $0 < \alpha < \frac{1}{2}$ on the three-dimensional torus perturbed by an additive Wiener noise term and prove the existence of an initial condition for which distinct probabilistic weak solutions exist. To this end, we employ convex integration

methods to construct a pathwise probabilistically strong solution, which violates a pathwise energy inequality up to a suitable stopping time. This paper seems to be the first in which such solutions are constructed via Beltrami waves instead of intermittent jets or flows in a stochastic setting.

[02509] Restoration of well-posedness of 2D fluid dynamics equations by transport noise

Format : Talk at Waseda University
Author(s) : Lucio Galeati (EPFL)Dejun Luo (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : A longstanding problem in fluid dynamics is whether solution to 2D Euler with L^p-valued vorticity are unique, for some $p < \infty$. A related question on the probabilistic side is whether one can find a physically meaningful noise that can restore such uniqueness. Here I will present some recent progress, concerning other closely related 2D equations, for which we can provide a positive answer. Based on a joint work with Dejun Luo.

[04785] Finite-time blowup for a 3D hypo-dissipative Navier-Stokes model equation

Format : Talk at Waseda University
Author(s) : Evan Miller (University of British Columbia)
Johannes Haubner (University of Graz)
Bastian Zapf (University of Oslo)
Abstract : In this talk, I will discuss a new blowup result for a model equation for the 3D hypo-dissipative Navier-Stokes equation based on considering a restricted constraint space. When imposing the right geometric conditions on initial data, involving planar stretching at the origin, this allows a forward energy cascade that generates finite-time blowup. This model equation respects both the energy equality and the identity for enstrophy growth.

[05631] Nonlinear Landau damping for the Vlasov-Poisson system in the whole space around Penrose-stable equilibria

Author(s) : Quoc Hung Nguyen (Academy of Mathematics and Systems Science,)Lingjia Huang (Fudan University, Shanghai)
Abstract : n this talk, will present recent results on the nonlinear asymptotic stability of the stable equilibria among solutions of the Vlasov Poisson system in $\mathbb{R}^2$ and $\mathbb{R}^3$.

[01158] Oblique derivative boundary volume problems - numerical methods and applications

Session Time & Room : 4C (Aug.24, 13:20-15:00) @E506

Type : Proposal of Minisymposium
Abstract : In this mini-symposium we will focus on recent efforts in developing various numerical approaches for solving the oblique derivative boundary volume problems. Namely, we will apply the finite element, finite volume and boundary element methods to solve different engineering problems which involve the oblique derivatives.
Organizer(s) : Marek Macák, Zuzana Minarechová

Minisymposium Program :

01158 (1/1) : 4C @E506

[02007] The finite element method for solving the oblique derivative boundary value problems in geodesy

Author(s) : Marek Macák (Slovak University of Technology)Zuzana Minarechová (Slovak University of Technology)Karol Mikula (Slovak University of Technology)Robert Cunderlik (Slovak University of Technology)

Abstract : We present approach to approximate the solution of the Laplace equation with an oblique derivative boundary condition by the finite element method. For this approach we perform testing experiments to study its behaviour and convergence. Finally, the usefulness of this approach is demonstrated by using it to gravity field modelling, namely, to approximate the solution of a geodetic boundary value problem in Himalayas.

[02121] Curvature and Torsion of Gravitational Plumb Lines

Author(s) : Zhi Yin (Jiangsu Ocean University)Nico Sneeuw (University of Stuttgart)Keifei Zhang (China University of Mining and Technology)

Abstract : In our previous research, we reformulate the gravitational field in terms of a potential flow; the gravitational vector field is mapped onto a potential-flow velocity field, in which the plumb line and the stream line are equivalent to each other. Here, we further investigate the curvature and the torsion of a gravitational plumb line by utilizing the fundamental equations of the potential flow. We expect them to have a good practical application in exploration geophysics.

[02131] The finite volume method for solving the oblique derivative BVP in geodesy

Author(s) : Zuzana Minarechová (Slovak University of Technology)Marek Macák (Slovak University of Technology)Karol Mikula (Slovak University of Technology)Róbert Čunderlík (Slovak University of Technology)

Abstract : We formulate the oblique derivative boundary value problem applied in gravity field and present two approaches to its solution by the finite volume method. In the first approach, the oblique derivative in the boundary condition is decomposed into normal and two tangential components and approximated by the central scheme. In the second approach, the oblique derivative in the boundary condition is treated by the first order upwind scheme. Both approaches are tested by various experiments.

[02887] Finite Volume Approximate Solutions of Some Oblique Derivative Boundary Value Problems and Applications

Author(s) : Abdallah BRADJI (University of Annaba-Algeria)

Abstract : In this work, we review previous works on FVMs (Finite Volume methods) for Elliptic and Parabolic equations with oblique derivatives boundary conditions. We start by the first two works with Gallouet (Aix-Marseille University, France) which dealt with FV on the so-called Admissible meshes for Elliptic equations.
We subsequently describe our work with Fuhrmann (WIAS, Berlin-Germany) which dealt with FV using the nonconforming meshes and the SUSHI for Elliptic and Parabolic equations with oblique derivatives boundary conditions.
Finally, we focus on FVMs for Elliptic equations with mixed oblique boundary equations and application to Inverse Problems. This work is done jointly with Lesnic (Leeds University, UK).
We sketch at the end some works, related to the subject, which are in progress.

[01161] Error-Controlled Adaptive Algorithms in Full-Order and Reduced-Order Model Simulations

Session Time & Room : 1C (Aug.21, 13:20-15:00) @E604

Type : Proposal of Minisymposium

Abstract : Controlling numerical errors is of high importance in simulation of various science and engineering problems, e.g., solids, fluids, and air. In full-order model simulations, the discretization error between the continuous solution and the discrete one plays a central role. In reduced-order model simulations, approximation errors during the reduction process is pivotal. Recent research advancements in both these domains have been on

development of error-controlled adaptive algorithms, which is the focus of this minisymposium.
Organizer(s) : Kapil Ahuja, Marc C. Steinbach, and Thomas Wick

[01786] Modeling and multigoal-oriented a posteriori error control for heated material processing using a generalized Boussinesq modell

Format : Talk at Waseda University
Author(s) : Sven Beuchler (IfAM, Leibniz University Hanover)Bernhard Endtmayer (IfAM, Leibniz University Hanover)Johannes Lankeit (IfAM, Leibniz University Hanover)Thomas Wick (IfAM, Leibniz University Hanover)
Abstract : In this presentation, we develop a posteriori error control for a generalized Boussinesq model. The stationary Navier-
Stokes equations with temperature dependent viscosity are coupled with a stationary heat equation. We use the dual-
weighted residual method in which an adjoint problem is utilized to obtain sensitivity measures with
respect to several goal functionals. The error localization is done with the help of a partition-
of-unity in a weak formulation. The resulting error estimators are used within an adaptive algorithm. Finally, numerical examples are presented.

[04451] Error-Controlled Local Interpolation of Moment Matching Reduced Order Models for Vibroacoustics

Format : Talk at Waseda University
Author(s) : Harikrishnan K. Sreekumar (Technische Universität Braunschweig, Institut für Akustik)Ulrich Römer (Technische Universität Braunschweig, Institut für Dynamik und Schwingungen)Matthias Bollhöfer (Technische Universität Braunschweig, Institut für Numerische Mathematik)Christopher Blech (Technische Universität Braunschweig, Institut für Akustik)Sabine C. Langer (Technische Universität Braunschweig, Institut für Akustik)
Abstract : Surrogate modeling for high-dimensional parametric problems is computationally challenging and therefore demands techniques to capture the essential features with the least effort. To this end, we present an adaptive error-controlled strategy to drive accurate modeling at two levels: moment matching reduced-order models approximating the frequency response and sparse grid interpolation for parametric approximation. We compare dimension-adaptive and spatially-adaptive refinement strategies with respect to convergence, demonstrated using problems from vibroacoustics.

[04671] Advances in A Posteriori Error Estimation and Adaptive Model Order Reduction

Format : Talk at Waseda University
Author(s) : Sridhar Chellappa (Max Planck Institute for Dynamics of Complex Technical Systems, Magdeburg)Lihong Feng (Max Planck Institute for Dynamics of Complex Technical Systems, Magdeburg)Peter Benner (MPI for Dynamics of Complex Technical Systems, Magdeburg)
Abstract : Reduced-order models (ROMs) play an important role in applications such as engineering design, control, optimization, etc. which require reliable simulations of large-scale systems in real-time. We discuss our recent work on a posteriori error estimation and adaptivity. The objective of this work is to reduce the training cost for ROM. We discuss several new error estimators and illustrate their use in adaptive basis enrichment and adaptive parameter sampling. The benefits of the adaptive methods are demonstrated on several numerical examples.

[05257] Stable Linear Solves in Parametric Model Order Reduction

Format : Online Talk on Zoom
Author(s) : Kapil Ahuja (Indian Institute of Technology Indore (IIT Indore))Navneet Pratap Singh (Bennett University)
Abstract : We study stability of class of algorithms for model order reduction (MOR) of parametric linear dynamical systems, with respect to inexact linear solves. Our most novel contribution is achieving backward stable MOR algorithms. To achieve this, we first adapt the underlying linear solver such that it satisfies orthogonalities

required for stability. Next, we demonstrate that by suitably using a recycling variant of the solver, these orthogonalities can be satisfied without any code changes and cheaply.

[01165] Adapted Wasserstein distance for robust finance

Session Time & Room : 5D (Aug.25, 15:30-17:10) @D505

Type : Proposal of Minisymposium
Abstract : The minisymposium brings together scientists working on the developments of new transport distances suited for the analysis of financial markets in case of model uncertainty. The four talks illustrate the powerful use of newly
developed tools in optimal transport, and in particular of the Adapted Wasserstein distance, to tackle crucial problems in finance, such as robustness of optimal decision making to model misspecification.
Organizer(s) : Beatrice AcciaioSponsor : This session is sponsored by the SIAM Activity Group on Financial Mathematics and Engineering.
Classification : 91G80, 49Q22
Minisymposium Program :

01165 (1/1) : 5D @D505 [Chair: Beatrice Acciaio]

[05605] Adapted Wasserstein distance for model-uncertainty in finance

Format : Talk at Waseda University
Author(s) : Beatrice Acciaio (ETH ZurichH Zurich)
Abstract : I will illustrate the suitability of adapted transport distances in the context of model-uncertainty in finance. I will then
present two consistent estimators for the Adapted Wasserstein distance, showing that we can recover the optimal rates of the classical empirical measure with respect to Wasserstein distance.

[05606] Adapted Wasserstein distance between the laws of SDEs

Format : Talk at Waseda University
Author(s) : Beatrice Acciaio (ETH Zurich)Sigrid Kallblad (KTH Royal Institute of Technology in Stockholm)
Abstract : We consider here an adapted optimal transport problem between the laws of Markovian stochastic differential equations (SDEs) and establish optimality of the so-called synchronous coupling between the given laws. The proof of this result is based on time-discretisation methods and reveals an interesting connection between the synchronous coupling and the celebrated discrete-time Knothe–Rosenblatt rearrangement. We also provide a result on equality of various topologies when restricting to certain types of laws of continuous-time processes. The talk is based on joint work with Julio Backhoff and Ben Robinson.

[05607] Adapted Wasserstein distance on the space of continuous time stochastic processes.

Format : Talk at Waseda University
Author(s) : Beatrice Acciaio (ETH Zurich)Xin Zhang (University of Vienna)
Abstract : Stochastic processes are often used as models for stock prices, and people were interested in the stability of optimal stopping problem in Finance with respect to the underlying model. We define the adapted Wasserstein distance on the space of stochastic processes, which is an extension of the usual Wasserstein distance between laws of stochastic processes. We prove that the optimal stopping problem is continuous with respect to the resulting topology, Martingales form a closed subset and approximation results like Donsker's theorem extend to the adapted Wasserstein distance.

[05608] On concentration of the empirical measure for general transport costs

Format : Talk at Waseda University
Author(s) : Beatrice Acciaio (ETH Zurich)Johannes Wiesel (CMU)
Abstract : Let μ be a probability measure on $\mathbb{R}^d$ and μ_N its empirical measure with sample size N. We prove a concentration inequality for the optimal transport cost between μ and μ_N for cost functions with polynomial local growth, that can have superpolynomial global growth. This result generalizes and improves upon estimates of Fournier and Guillin. By partitioning $\mathbb{R}^d$ into annuli, we infer a global estimate from local estimates on the annuli and conclude that the global estimate can be expressed as a sum of the local estimate and a mean-deviation probability for which efficient bounds are known. This talk is based on joint work with Martin Larsson and Jonghwa Park.

[01167] Recent development in mean field control and learning

Session Time & Room :

01167 (1/2) : 1E (Aug.21, 17:40-19:20) @F403

01167 (2/2) : 2C (Aug.22, 13:20-15:00) @F403

Type : Proposal of Minisymposium
Abstract : Mean field control problems have attracted massive interest and provide a promising approach dealing with multi-agent systems. The aim of this mini-symposium is to share the new trends of both theory and applications of this area. We would like to invite the frontier scholars to talk about recent developments in various learning methods for the mean field control problems under different application aspects, as well as analyzing HJB equation in the infinite dimensional spaces for the theory prospective.

[04658] Actor-critic learning for mean-field control in continuous time

Format : Talk at Waseda University
Author(s) : HUYEN PHAM (Université Paris Cité)Noufel Frikha (Université Paris 1)Maximilien Germain (Morgan Stanley)Mathieu Laurière (NYU Shanghai)Xuanye Song (Université Paris Cité)
Abstract : We study policy gradient for mean-field control in continuous time in a reinforcement learning setting. By considering
randomised policies with entropy regularisation, we derive a gradient expectation representation of the value function, which is amenable to actor-critic type algorithms, where the value functions and the policies are learnt alternately
based on observation samples of the state and model-free estimation of the population state distribution, either by offline or online learning.

[04674] Mean-field singular control problem: regularitiy and related mean-field reflected diffusion

Format : Talk at Waseda University
Author(s) : Jodi Dianetti (Bielefeld University)Xin Guo (UC Berkeley)Jiacheng Zhang (UC Berkeley)Huyên Pham (Université Paris Cité)
Abstract : We study a class of mean-field control problems with singular controls. Such a model represents the limit of the control problems in which a controller can adjust, through a bounded variation process, an underlying diffusion, which in turn affects an n-particle system. Adopting appropriate notions of convexities, we are able to establish the regularity of the value function of the problem and to show the existence of the optimal control. The

regularity of the value function allows to characterize the solution of the problem in terms of a related mean-field Skorokhod problem. This consists in keeping the optimally controlled state process in a region prescribed by the derivative of the value function, by using the optimal control in order to reflect the state at its boundary.

[04752] A non-asymptotic perspective on mean field control

Format : Talk at Waseda University
Author(s) : Lane Chun Yeung (Columbia University)Daniel Lacker (Columbia University)Sumit Mukherjee (Columbia University)
Abstract : We study a class of stochastic control problems in which a large number of players cooperatively choose their drifts to maximize an expected reward minus a quadratic running cost. For a broad class of potentially asymmetric rewards, we show that there exist approximately optimal controls which are decentralized, in the sense that each player's control depends only on its own state and not the states of the other players.

[05079] Signature SDEs with jumps and their tractability properties

Format : Talk at Waseda University
Author(s) : Christa Cuchiero (University of Vienna)Francesca Primavera (University of Vienna)Sara Svaluto Ferro (University of Verona)
Abstract : Signature-based models have recently entered the field of Mathematical Finance. Relying on recent advances on the signature of càdlàg paths, we introduce here a generic class of jump-diffusion models via so-called signature SDEs with jumps. We elaborate on their tractability properties and show that the signature-based models for asset prices proposed so far can be embedded in this framework. As a special case, we focus on jump-diffusions with entire characteristics, leading to a far-reaching extension of the class of polynomial processes.

01167 (2/2) : 2C @F403 [Chair: Jiacheng Zhang]

[05419] Markov $alpha$-Potential Game

Format : Online Talk on Zoom
Author(s) : Xinyu Li (UC Berkeley)Xin Guo (UC Berkeley)Chinmay Maheshwari (UC Berkeley)Manxi Wu (Cornell University)Shankar Sastry (UC Berkeley)
Abstract : We propose a new framework to study multi-agent interaction in Markov games: Markov α-potential games. Markov potential games are special cases of Markov α-potential games, so are two important and practically significant classes of games: Markov congestion games and perturbed Markov team games. In this paper, α-potential functions for both games are provided and the gap α is characterized with respect to game parameters. Two algorithms – the projected gradient-ascent algorithm and the sequential maximum improvement smoothed best response dynamics – are introduced for approximating the stationary Nash equilibrium in Markov α-potential games. The Nash-regret for each algorithm is shown to scale sub-linearly in time horizon. Our analysis and numerical experiments demonstrates that simple algorithms are capable of finding approximate equilibrium in Markov α-potential games.

[05421] MF-OMO: An Optimization Formulation of Mean-Field Games

Format : Online Talk on Zoom
Author(s) : Xin Guo (UC Berkeley)Anran Hu (University of Oxford)Junzi Zhang (Citadel Securities)
Abstract : The literature on theory and computation of mean-field games (MFGs) has grown exponentially recently, but current approaches are limited to contractive or monotone settings, or with an a priori assumption of the uniqueness of the Nash equilibrium (NE). In this talk, we present MF-OMO (Mean-Field Occupation Measure Optimization), a mathematical framework that analyzes MFGs without these restrictions. MF-OMO reformulates the problem of finding NE solutions in MFGs as a single optimization problem. This formulation thus allows for directly utilizing various optimization tools, algorithms and solvers to find NE solutions of MFGs in practice. We also provide convergence guarantees for finding (multiple) NE solutions using popular algorithms like projected gradient descent. For MFGs with linear rewards and mean-field independent dynamics, solving MF-OMO can be reduced to solving a finite number of linear programs, hence solved in finite time.

[05439] The convergence problem in mean field control

Format : Online Talk on Zoom
Author(s) : Joe Jackson (The University of Texas at Austin)Samuel Daudin (Université Côte d'Azur) François Delarue (Université Côte d'Azur)
Abstract : This talk will be about a recent joint work with Samuel Daudin and François Delarue concerning the convergence problem in mean field control. When the data is convex and sufficiently smooth, the (optimal) rate of convergence (of the N-player value function towards the limiting value function) is known to be $1/N$. The goal of our work is to identify the optimal rate of convergence in the more subtle non-convex setting.

[01168] Network based reduced-order models for forward and inverse PDE problems

Session Time & Room :

01168 (1/2) : 5B (Aug.25, 10:40-12:20) @E711

01168 (2/2) : 5C (Aug.25, 13:20-15:00) @E711

Type : Proposal of Minisymposium
Abstract : Reduced order models (ROMs) have been proven to be a powerful and versatile tool for a fast and robust large-scale simulations as well as imaging and inversion. In this minisymposium we will focus on a special class of ROMs, network-based ROMs, that originate from network synthesis. It allows to represent ROM in terms of sparsely-connected networks and enables a direct physical interpretation. We shall discuss various techniques to construct such ROMs as well as their applications.
Organizer(s) : Vladimir Druskin, Alexander Mamonov, Mikhail Zaslavskiy
Classification : 65R32, 65N21, 65M99, reduced-order models, inverse scattering problems, large-scale forward problems
Minisymposium Program :

[02869] Regularized Lippmann-Schwinger-Lanczos Algorithm for Inverse Scattering Problems in the Frequency Domain

Format : Talk at Waseda University
Author(s) : Justin Baker (University of Utah)Elena Cherkaev (University of Utah)Vladimir Druskin (Worcester Polytechnic Institute)Shari Moskow (Drexel University)Mikhail Zaslavsky (Schlumberger-Doll Research Center)
Abstract : Inverse scattering techniques have broad applicability in medical imaging, geophysics, and remote sensing. This talk presents a robust direct reduced order model (ROM) method for solving inverse scattering problems. The approach is based on a Lippmann-Schwinger-Lanczos (LSL)
algorithm in the frequency domain with two levels of regularization. Results of numerical experiments for Schrodinger and Helmholtz problems show that the proposed regularization scheme significantly improves the performance of the LSL algorithm, allowing for good reconstructions with noisy data.

[04821] Can one identify damped Stieltjes string from its spectral function?

Format : Talk at Waseda University
Author(s) : Vladimir Druskin (WPI)Jörn Zimmerling (Uppsala University)Rob Remis (Delft University University)
Abstract : The Stieltjes strings were introduced by Gantmakher and Krein as isomorphic mechanical representations of the Stieltjes spectral functions. However, dissipative strings cannot be uniquely identified for the continuous spectral functions, corresponding to the unbounded domains. Generally, any passive transfer function can be represented as a Stieltjes function, that yields a wide class of equivalent solutions. We analyze constraints

leading to the uniqueness for damped problems and numerical implementation in the data-driven ROM framework.

[04751] Inverse scattering in attenuating media -- a ROM approach

Format : Talk at Waseda University
Author(s) : Jörn Zimmerling (Uppsala University)Vladimir Druskin (WPI)Rob Remis (TU Delft)
Abstract : Inverse scattering problems in attenuating media arise in important applications in biomedical imaging or radar imaging. In inverse scattering the goal is to reconstruct the coefficients of a PDE based on remote measurements of scattered waves. Based on these measurements a reduced-order model can be constructed that goes beyond the typical data fitting. It has a special algebraic structure that allows analogies to finite-difference discretization of PDEs and facilitates efficient solution of the inverse problem.

01168 (2/2) : 5C @E711 [Chair: Vladimir Druskin]

[05171] REDUCED ORDER MODELING INVERSION OF MONOSTATIC DATA IN A MULTI-SCATTERING ENVIRONMENT

Format : Talk at Waseda University
Author(s) : Mikhail Zaslavskiy (Southern Methodist University)
Abstract : We consider the reduced order model approach for inversion in the monostatic formulation targeting the synthetic aperture radar (SAR) data in the time domain. The monostatic data is given as a series of single input/single output (SISO) responses due to moving collocated sources and receivers, that is, the diagonal of the matrix-valued MIMO transfer matrix. The ROMs are constructed to match the data for each source-receiver pair separately, and these are used to construct internal solutions for the corresponding source using only data-driven Gramian. The data from different locations is then coupled via the approximate Lippman-Schwinger integral equation. Numerical experiments illustrating the performance of our approach will be provided.

[05531] Waveform Inversion via Reduced Order Modeling

Format : Talk at Waseda University
Author(s) : Alexander Mamonov (University of Houston)Liliana Borcea (University of Michigan)Josselin Garnier (Ecole Polytechnique)Jorn Zimmerling (Uppsala University)
Abstract : We propose a novel approach to full waveform inversion (FWI), based on a data driven reduced order model (ROM) of the wave equation operator. The unknown medium is probed with pulses and the time domain pressure waveform data is recorded on an active array of sensors. The ROM is a projection of the wave equation operator on a subspace of wave equation solution snapshots. It can be constructed from the measured data via a nonlinear process and subsequently used for efficient velocity estimation. While the conventional FWI via nonlinear least-squares data fitting is challenging without low frequency information, and prone to getting stuck in local minima (cycle skipping effect), minimization of ROM misfit is behaved much better, even for a poor initial guess. For low-dimensional parametrizations of the unknown velocity the ROM misfit function is demonstrably close to convex. The proposed approach consistently outperforms conventional FWI in standard synthetic tests, as shown in the numerical experiments.

[05544] Correlation-informed dictionary learning for imaging in complex media

Format : Talk at Waseda University
Author(s) : Alexei Novikov (Penn State University)
Abstract : We propose an approach for imaging in strongly scattering media that uses dictionary learning and connectivity information to estimate the sensing matrices in these media. It has two steps. The first step estimates, with high accuracy, the true Green's function vectors using array data from multiple sparse sets of sources, whose locations and amplitudes are not known to us. This step yields a dictionary for wave propagation whose columns are those of the sensing matrix up to permutations. The second step orders these columns using Multi-Dimensional Scaling (MDS) with connectivity information derived from cross-correlations of the estimated Green's function vectors. For these two steps to work together, we must combine data from large and small arrays. Through simulation experiments, we show that the proposed approach is robust and is able to provide high-resolution images.

[01170] High Performance Multigrid Methods for Large-Scale Applications

Session Time & Room :

01170 (1/3) : 5B (Aug.25, 10:40-12:20) @E708

01170 (2/3) : 5C (Aug.25, 13:20-15:00) @E708

01170 (3/3) : 5D (Aug.25, 15:30-17:10) @E708

Type : Proposal of Minisymposium
Abstract : Multigrid methods are an optimal computational complexity linear solver and preconditioner that is often utilized to solve large-scale problems. The purpose of this minisymposium is to bring together researchers working on high-performance multigrid solvers. The presentations include topics on both performance aspects, advanced architectures, and applications.
Organizer(s) : Graham Harper, Peter Ohm
Classification : 65Mxx, 65Nxx, 65Fxx, 65Yxx, 65Zxx
Minisymposium Program :

01170 (1/3) : 5B @E708 [Chair: Graham Harper]

01170 (2/3) : 5C @E708 [Chair: Peter Ohm]

[03275] Block-structured and hierarchical hybrid grid matrix-free multigrid solvers for CFD applications at scale

Format : Talk at Waseda University
Author(s) : Harald Koestler (Friedrich-Alexander Universität Erlangen-Nürnberg)
Abstract : In this talk an overview of applications and performance for matrix-free multigrid solvers implemented in the HPC software frameworks HyTeG and ExaStencils is provided. This includes scaling and efficiency results on CPU and GPU clusters and sample applications from geophysics, charged particle and ocean simulations.

[03867] Performance improvements of algebraic multigrid algorithms on modern system architectures

Format : Talk at Waseda University
Author(s) : Luc Berger-Vergiat (Sandia National Laboratories)Jonathan Hu (Sandia National Laboratories)Christian Glusa (Sandia National Laboratories)Chris Siefert (Sandia National Laboratories)
Abstract : Multigrid methods are an important class of linear solvers and preconditioners for their high scalability on large computing systems. Implementing these algorithms on GPU based platforms remains a challenging task. In this talk we will discuss the current state of the MueLu package of Trilinos which provides algebraic multigrid methods on CPUs and GPUs and present results gathered on recent architectures.

[03020] Improving AMG Strength of Connection

Format : Talk at Waseda University
Author(s) : Wayne Mitchell (Lawrence Livermore National Laboratory)
Abstract : A crucial concept for algbraic multigrid (AMG) coarsening and interpolation is that of strength of connection (SoC) between degrees of freedom. The classical SoC measure is based on the relative sizes of entries in each row of the matrix and relies on heuristics that assume an M-matrix structure. This simple measure is cheap to evaluate and successful for many problems, but also relies on a user-defined strength threshold, which may need to be tuned for specific problems. In addition, the classical SoC measure can have difficulty identifying the proper strong connections for operators that are not M-matrices, particularly when there are both positive and negative off-diagonal entries in the same row. In this work, we examine low-cost techniques for building an auxiliary strength matrix that shares important properties with the original matrix operator while also being more amenable to the classical SoC measure. Applying classical SoC to this auxiliary strength matrix improves robustness of the SoC measure for a wider class of problems and across a wider range of strength thresholds.

[05263] Monolithic Multigrid and Block Preconditioning for Magnetic Confinement Fusion Relevant Resistive MHD Simulations

Format : Talk at Waseda University
Author(s) : Peter Ohm (RIKEN Center for Computational Science)John Shadid (Sandia National Laboratories)Jesus Bonilla (Los Alamos National Lab)Edward Phillips (Sandia National Laboratories)Raymond Tuminaro (Sandia National Laboratories)Jonathan Hu (Sandia National Laboratories)Xian-Zhu Tang (Los Alamos National Lab)Michael Crockatt (Sandia National Laboratories)
Abstract : A base-level mathematical basis for the continuum fluid modeling of dissipative plasma system is the resistive magnetohydrodynamic model. This model requires the solution of the governing partial differential equations (PDEs) describing conservation of mass, momentum, and thermal energy, along with various reduced forms of Maxwell's equations for the electromagnetic fields. The resulting systems are characterized by strong nonlinear and nonsymmetric coupling of fluid and electromagnetic phenomena, as well as the significant range of time- and length-scales that these interactions produce. These characteristics make scalable and efficient iterative solution, of the resulting poorly-conditioned discrete systems, extremely difficult.

In this talk we utilize Drekar, a multi-physics simulation code built on top of the Trilinos framework, for the simulation of various resistive MHD problems. We consider the use of block preconditioners as well as monolithic multigrid for solving coupled physics block systems.

01170 (3/3) : 5D @E708 [Chair: Graham Harper]

[03865] Combined On/Off Node Performance Model for SPMV in Multigrid

Format : Talk at Waseda University
Author(s) : Chris Siefert (Sandia National Laboratories)
Abstract : We propose combining traditional on-node memory-bandwidth based performance models (i.e., roofline) with inter-node performance models (i.e., ping-pong) to build a combined performance model to predict the performance of sparse matrix-vector products in the context of the Trilinos/MueLu algebraic multigrid software. We demonstrate the combined model on both CPU and GPU platforms and compare against actual Trilinos sparse matrix-vector product (SPMV) performance using Trilinos/MueLu.

[05232] Recent Advances in Linear Solvers for Ice Sheet Modeling

Format : Talk at Waseda University
Author(s) : Jonathan Hu (Sandia National Laboratories)Jerry Watkins (Sandia National Laboratories)Max Carlson (Sandia National Laboratories)Mauro Perego (Sandia National Laboratories)Kim Liegeois (Sandia National Laboratories)Oscar Antepara (Lawrence Berkeley National Laboratory)Samuel Williams (Lawrence Berkeley National Laboratories)
Abstract : We present recent ongoing work performed under the SciDAC FAnSSIE project to improve linear solver performance within land-ice simulations on GPU-based architectures. We'll review the current algorithmic approach that relies on specialized semicoarsening algebraic multigrid, challenges in adapting this approach to GPU architectures, and progress in improving performance and scaling. Finally, we'll present numerical results from the Albany simulation code on the HPE Cray Ex supercomputer Perlmutter.

[05118] A Matrix-Free Approach for Algebraic Multigrid for High-Order Systems

Format : Talk at Waseda University
Author(s) : Graham Harper (Sandia National Laboratories)
Abstract : We present a matrix-free approach for algebraic multigrid (AMG) for high-order systems. In particular, we focus on the case where an application may have a mix of domains with geometric structure and regions without geometric structure. We mix geometric multigrid (GMG) and AMG, but we approach the overall problem from a matrix-free AMG perspective on the finer levels. We present numerical results using Trilinos and MueLu to verify our methods.

[03319] Mixed formulations and monolithic multigrid methods for smectic-A liquid crystals

Format : Online Talk on Zoom
Author(s) : Abdalaziz Hamdan (Imperial College London)Patrick Farrell (University of Oxford)Scott MacLachlan (Memorial University of Newfoundland)
Abstract : Xia et al. recently proposed a new continuum model for smectic A liquid crystals. Here, we present a mixed finite-element formulation of that model and discuss the construction of solvers for the resulting nonlinear systems. We consider Newton-Krylov-Multigrid approaches, using Newton's method to linearize and develop monolithic geometric multigrid preconditioners for the resulting saddle-point systems. We demonstrate this is an effective solver strategy when using a coupled "star" relaxation scheme and nested iteration.

[01174] Hypernetworks and their dynamics in theory and applications

Session Time & Room : 5D (Aug.25, 15:30-17:10) @G704

Type : Proposal of Minisymposium
Abstract : Collective dynamics of interacting units are prevalent in nature and engineering, whether it is neurons in the brain or opinion building in social networks. Recently, there has been tremendous interest in simultaneous interactions between three or more units, so-called higher-order interactions. The drive comes from various disciplines, for example ecology, where simultaneous competition for resources of multiple species causes nonstationary fluctuations of species abundancies. Such advances suggest to model the underlying structures by hypernetworks represented by hypergraphs.

This minisymposium displays recent models in real-world applications and theoretical studies on hypernetwork dynamics to highlight development and connect experts from both communities.

[04246] Bridging between higher-order mechanisms and phenomena

Format : Talk at Waseda University
Author(s) : Giovanni Petri (CENTAI)
Abstract : Complex networks have become the main paradigm for modelling the dynamics of complex interacting systems.
However, networks are intrinsically limited to describing pairwise interactions, whereas real-world systems are often characterized by higher-order interactions involving groups of three or more units.
Higher-order structures, such as hypergraphs and simplicial complexes, are therefore a better tool to map the multilayered real organization of many social, biological and man-made systems. At the same time, higher-order observables, typically topological or information-theoretic in nature and often sharing the same simplicial language, have been gathering attention for their capacity to capture properties of complex systems that are invisible to standard statistical descriptions. This had led to a certain confusion between these two facets, mechanisms on one side, phenomena on the other.
Here, using recent examples from both dynamical models and neuroimaging analysis, I highlight collective behaviours induced by higher-order interactions, the difficulty in linking data and models through recent advances in topological data analysis and higher-order information theory, and finally outline key open questions for the physics of higher-order complex systems.

[03667] Emergent hypernetworks in weakly coupled oscillators

Format : Talk at Waseda University
Author(s) : Eddie Nijholt (Imperial College London)Jorge Luis Ocampo-Espindola (Saint Louis University)Deniz Eroglu (Kadir Has University)István Kiss (Saint Louis University)Tiago Pereira (Universidade de São Paulo)
Abstract : Networks of weakly coupled oscillators play a profound role in our understanding of complex systems.

Studies on model reconstruction from data show the emergence of hyper-connections corresponding to triplet and higher-order interactions among oscillators, even though such models were originally defined as networks with only pairwise interactions. We show that hypernetworks can spontaneously appear in the presence of pairwise, albeit nonlinear, coupling given certain frequency resonance conditions. The conceptual explanation is that model reconstruction finds the so-called normal form of the system instead, which allows us to predict the emergent hypernetwork in terms of appearing and forbidden motifs. These results are moreover demonstrated in experiments with electrochemical oscillators. This is joint work with Jorge Luis Ocampo-Espindola, Deniz Eroglu, István Z. Kiss and Tiago Pereira.

[04161] Do higher-order interactions promote coexistence in diverse ecological communities?

Format : Talk at Waseda University
Author(s) : Theo L Gibbs (Princeton University)Gabriel Gellner (University of Guelph)Simon Levin (Princeton University)Kevin McCann (University of Guelph)Alan Hastings (UC Davis)Jonathan Levine (Princeton University)
Abstract : Most ecological models assume that species interactions operate only between pairs of species. In a diverse community, however, higher-order interactions can emerge, in which two or more species jointly impact the growth of a focal species. In this talk, I will discuss two ways that higher-order interactions affect species coexistence. Randomly-sampled higher-order interactions do not promote coexistence, but additional constraints on the higher-order interactions can reverse exclusions caused by pairwise interactions.

[04389] Hypernetworks: cluster synchronization is a higher order effect

Format : Talk at Waseda University
Author(s) : Bob Rink (Vrije Universiteit Amsterdam)Eddie Nijholt (Imperial College London)Sören von der Gracht (Paderborn University)
Abstract : Many networked systems are governed by non-pairwise interactions that can be encoded by means of a hypernetwork. Here, we define dynamical systems on hypernetworks, and we explain how to classify robust cluster synchronization patterns by finding balanced partitions. We show that synchronization is determined by polynomial systems of high order. Hence, unlike in dyadic networks, cluster synchronization on hypernetworks is a higher-order, nonlinear effect. We show how this generates remarkable synchrony breaking bifurcations.

[01178] On the Interplay between Kinetic Theory and Quantum Dynamics

Session Time & Room :

01178 (1/2) : 2C (Aug.22, 13:20-15:00) @G802

01178 (2/2) : 2D (Aug.22, 15:30-17:10) @G802

Type : Proposal of Minisymposium
Abstract : The kinetic theory describes the non-equilibrium dynamics of a many-body system from the statistical viewpoint, which is acknowledged to be a significant model to bridge the microscopic and macroscopic regimes in classical mechanics. On the other hand, many novel quantum phenomena emerge in the physics and material fields, where the microscopic description is the quantum many-body system.

Hence, applying the kinetic philosophy to study the many-body systems in the quantum field becomes pretty natural, and this Minisymposium aims at fostering the development of multiscale modeling, mathematical analysis, and numerical simulation about the interplay between kinetic theory and quantum dynamics.

[04305] Emergent phenomena in an interacting Bose gas

Format : Online Talk on Zoom
Author(s) : Michael Hott (University of Minnesota)Thomas Chen (The University of Texas at Austin)
Abstract : The study of kinetic equations describing collisions between a BEC and the surrounding normal fluid go back to Kirkpatrick and Dorfmann '83, '85 and Eckern '84. Ever since, this subject has attracted a lot of attention as it relates to condensation. In this context, mathematicians have studied the quartic quantum Boltzmann equation in the presence of a BEC. In this talk, we will discuss some of the progress made on the PDE level of the quantum Boltzmann equation. Then, we will focus on the validity of the kinetic equations. We will describe the crucial scale separations needed to extract a Boltzmann equation from the quantum dynamics. Moreover, we will see how the interference of sound waves can produce some surprising effects if a Bose gas is trapped in a volume of unit size. This is based on joint work with Thomas Chen.

[05382] Fluid limits from Quantum Boltzmann equation

Format : Talk at Waseda University
Author(s) : Ning Jiang (Wuhan University)
Abstract : In his 2015 Ecole Polytechnique thesis, T.Zakrevskiy formally derived some fluid dynamics from quantum Boltzmann equation (Fermi-Dirac statistics). We rigorously justify two types of limits: incompressible Navier-Stokes-Fourier and compressible Euler (then acoustic) systems, by establishing some new nonlinear estimates on triple terms, and uniform estimates with respect to Kundsen number. A particular novelty is that the compressible Euler system derived from the quantum Boltzmann equation has a pressure law which is different and more general with that from the classical Boltzmann equation.

[04436] An explicit coercivity estimate of the linearized quantum Boltzmann operator

Format : Talk at Waseda University
Author(s) : YULONG ZHOU (Sun Yat-Sen University)
Abstract : The Boltzmann-Bose-Einstein equation describes a large system of Bose-Einstein particles in the weak-coupling regime. If the particle interaction is governed by the inverse power law, the corresponding collision kernel has angular singularity. We present a coercivity estimate of the linearized Boltzmann-Bose-Einstein operator for such kernel. The estimate may not be sharp but explicitly reveals the dependence on the fugacity parameter. Joint work with Prof. Tong Yang.

[04331] Frozen Gaussian Approximation for open quantum system

Format : Talk at Waseda University
Author(s) : Geshuo Wang (National University of Singapore)Zhenning Cai (National University of Singapore)Siyao Yang (National University of Singapore)
Abstract : We study the system-bath dynamics for open quantum systems applying frozen Gaussian approximation, which proposes an approximated ansatz for the wave function, converting the direct calculation of the Schrödinger equation into some ODEs of the parameters in the ansatz. We then derive the Dyson series under such approximation. To further improve the computational efficiency, we develop a fast algorithm known as the inchworm algorithm for the current framework.

01178 (2/2) : 2D @G802 [Chair: Ning Jiang]

[04798] Quantum Dynamics of Incommensurate System

Format : Talk at Waseda University
Author(s) : Diyi Liu (University of Minnesota, Twin Cities)
Abstract : Motivated by the need to develop accurate numerical methods for computing the electronic properties of twisted bilayer graphene, we consider the problem of numerically computing the dynamics of a general aperiodic discrete (tight-binding) Schrödinger equation in an infinite domain. We prove that, under appropriate conditions, these dynamics can be rigorously approximated by those of a finite-dimensional truncated model. The key role in the proof is played by speed of propagation estimates derived from Combes-Thomas estimates. Besides the general aperiodic medium, we further improve our truncation analysis and Combes-Thomas Estimate for aperiodic medium with low dimensional structure, general van der Waal heterostructures. We then present a range of numerical experiments showing the effectiveness of our analysis.

[04339] On the kinetic description of the objective molecular dynamics

Format : Talk at Waseda University
Author(s) : Kunlun Qi (University of Minnesota)Li Wang (University of Minnesota)
Abstract : In this talk, we will introduce a multiscale hierarchy framework for objective molecular dynamics (OMD), a reduced molecular dynamics with certain symmetry, that connects it to the statistical kinetic equation, and the macroscopic hydrodynamic model. In the mesoscopic regime, we exploit two interaction scalings that lead to either a mean-field type or a Boltzmann-type equation. At the macroscopic level, we also derive the corresponding reduced Euler and Navier-Stokes systems by conducting a detailed asymptotic analysis.

[01181] Variational methods for multi-scale dynamics

Session Time & Room :

01181 (1/2) : 4C (Aug.24, 13:20-15:00) @F401

01181 (2/2) : 4D (Aug.24, 15:30-17:10) @F401

Type : Proposal of Minisymposium
Abstract : Many interesting evolutionary problems in nature can be described by variational principles like gradient flows or Hamiltonian dynamics. Recent results have shown that exploiting the variational structure of the evolution equation provides a fruitful research area combining applied analysis and stochastic modeling. For real-world multi-scale problems, focusing on the variational structure is particularly vital as it forms a physically motivated basis.

The aim of this two-part minisymposium is inspiring and bringing together researchers interested in calculus of variations, PDEs and stochastic analysis for starting collaborations. Focus is placed on interacting particle systems and discrete-to-continuous limit passages, e.g. by evolutionary Gamma-convergence.

[04903] Controlling conservation laws: Entropy-Entropy flux pairs

Format : Talk at Waseda University
Author(s) : Wuchen Li (University of South Carolina)
Abstract : In this talk, we study a class of variational problems for regularized conservation laws with Lax's entropy-entropy flux pairs. We first introduce a modified optimal transport space based on conservation laws with diffusion. Using this space, we demonstrate that conservation laws with diffusion are "flux--gradient flows." We next construct variational problems for these flows, for which we derive dual PDE systems for regularized conservation laws. Several examples, including traffic flow and Burgers' equation, are presented. We successfully compute the control of conservation laws by incorporating both primal-dual algorithms and monotone schemes. This is based on joint work with Siting Liu and Stanley Osher.

[03821] Transport problems with non linear mobilities: a particle approximation result.

Format : Talk at Waseda University
Author(s) : Lorenzo Portinale (Hausdorff Center for Mathematics, Bonn)Simone Di Marino (Università di Genova)Emanuela Radici (Università degli Studi dell'Aquila)
Abstract : We study discretisation of generalised Wasserstein distances with non linear mobilities on the real line via a Riemannian metrics on the space of N ordered particles. In particular, we provide a Γ-convergence result for the associated discrete metrics as $N \to \infty$ to the continuous one and discuss applications to the approximation of one-dimensional conservation laws (of gradient flow type) via the so-called generalised minimising movements (or JKO scheme).

[04444] Variational convergence for irreversible population dynamics

Format : Talk at Waseda University
Author(s) : Jasper Hoeksema (Eindhoven University of Technology)
Abstract : We consider the forward Kolmogorov equations corresponding to measure-valued processes stemming from a class of interacting particle systems in population dynamics. In contrast to previous work, where we assumed detailed balance, we will now treat the irreversible case. We exchange gradient structures for more general dissipation structures, and show convergence of these structures in the large population limit. In particular we obtain convergence to the mean-field limit and establish entropic propagation of chaos.

[03883] Mathematical modeling of structured magnesium alloys

Format : Talk at Waseda University
Author(s) : Karel Svadlenka (Kyoto University)
Abstract : Structured materials, such as metallic alloys with atomic-scale layers, show peculiar deformation patterns, which may have significant implications on material properties. In this talk, I will discuss one possible approach to modeling of this kind of pattern formation through the so-called rate-independent evolution in the variational setting of finite-strain elasto-plasticity. Besides mentioning connections to homogenization via Gamma-convergence, I will present the underlying mathematical theory and show numerical simulations in comparison to experimental measurements.

01181 (2/2) : 4D @F401 [Chair: Jasper Hoeksema]

[04828] Variational numerical schemes for gradient flows

Format : Online Talk on Zoom
Author(s) : Yiwei Wang (University of California, Riverside)Chun Liu (Illinois Institute of Technology)
Abstract : We'll present a numerical framework for developing structure-preserving variational schemes for various types of gradient flows. The numerical approach starts with the energy-dissipation law of the underlying system and can combine different spatial discretizations, including Eulerian, Lagrangian, particle, and neural-network-based approaches. The numerical procedure guarantees the developed schemes are energy stable and can preserve the intrinsic physical constraints. Several applications and theoretical justifications will be discussed.

[04971] Quantitative coarse-graining of Markov chains

Format : Online Talk on Zoom
Author(s) : Upanshu Sharma (UNSW Sydney)Bastian Hilder (Lund University)
Abstract : Coarse-graining is the procedure of approximating large and complex systems by simpler and lower-dimensional ones. It is typically characterised by a mapping which projects the full state of the system onto a smaller set; this mapping captures the relevant (often slow) features of the system. Starting from a (non-reversible) continuous-time Markov chain and such a mapping, I will discuss an effective dynamics which approximates the true projected Markov chain and present error estimates on the approximation error.

[04391] Variational convergence from mean-field stochastic particle systems to the exchange-driven growth model

Format : Online Talk on Zoom
Author(s) : Chun Yin Lam (Universität Münster)André Schlichting (Universität Münster)
Abstract : We consider the hydrodynamic limit of mean-field stochastic particle systems on a complete graph using variational methods.
The evolution is driven by particle exchanges with its rate depending on the population of the initial and final vertices. This model is a generalisation of the zero-range process and has applications in cloud formation, polymerization, and wealth exchange.
Under detailed balance conditions, the evolution equation has a gradient structure motivated by the Large Deviations Principle. The variational formulation is based on the LDP rate function.

[05130] On time-splitting methods for gradient flows with two dissipation mechanisms

Format : Talk at Waseda University
Author(s) : Artur Stephan (Weierstrass Institute for Applied Analysis and Stochastics, Berlin, Germany)
Abstract : A gradient system consists of a state space X, an energy functional $E:X\to\mathbb{R}\cup\{\infty\}$ and a dissipation potential $R:X\to

[0,\infty[$ and defines a gradient-flow equation.

Considering the case where the dual dissipation potential R^* is given by the sum $R^*=R_1^*+R_2^*$, we show how convergence of a time-splitting method where the solution of the combined gradient system is approximated by concatenating the separate gradient-flows.
This is joint work with Alexander Mielke (Berlin) and Riccarda Rossi (Brescia).

[01188] Recent Developments in Fluid Dynamics

Session Time & Room :

01188 (1/3) : 2C (Aug.22, 13:20-15:00) @G405

01188 (2/3) : 2D (Aug.22, 15:30-17:10) @G405

01188 (3/3) : 2E (Aug.22, 17:40-19:20) @G405

Type : Proposal of Minisymposium
Abstract : Over the last years, substantial breakthroughs have arisen in mathematical fluid mechanics. For example, the smooth blowup of the incompressible, axisymmetric Euler equations via computer assisted proofs, or the smooth self-similar blowup solutions to compressible Euler and Navier-Stokes. The aim of this session is to bring together well-known experts and young researchers to present new developments in partial differential equations describing the dynamics of fluids. Particular emphasis has been put into explaining the aforementioned breakthroughs and exploring new directions from them. Other key topics include corners and cusps solutions in fluids models, and stability results for kinetic equations.
Organizer(s) : Bruno Vergara, Javier Gómez Serrano
Classification : 35-XX
Minisymposium Program :

[04609] Recent progress on singularity formation in incompressible fluids

Format : Online Talk on Zoom
Author(s) : Jiajie Chen (New York University)Thomas Y Hou (California Institute of Technology)
Abstract : I will talk about recent progress on singularity formation in incompressible fluids with smooth data.

[04708] Gravity Unstable Muskat Bubbles

Format : Online Talk on Zoom
Author(s) : Neel Patel (University of Maine)Siddhant Agrawal (ICMAT)Sijue Wu (University of Michigan)
Abstract : The Muskat problem describes the evolution of the interface between two fluids in porous media. Neglecting surface tension, the well-posedness of this problem depends on the Rayleigh-Taylor condition. For fluids of differing densities, it is required that the denser fluid is below. Otherwise, the system is gravity unstable. We will discuss the stability of a closed curve interface, or a bubble, in which the Rayleigh-Taylor condition cannot hold.

[04950] Whitham's highest cusped wave

Format : Talk at Waseda University
Author(s) : Bruno Vergara (Brown University)
Abstract : Whitham's equation is a nonlinear, nonlocal, very weakly dispersive shallow water wave model in one space dimension. As in the case of the Stokes wave for the Euler equation, non-smooth traveling waves with greatest height between crest and trough have been shown to exist for this model. In this talk I will discuss the existence of a unique cusped, convex and monotone traveling wave solution to the Whitham equation. Our results follow a strategy that combines different ideas from classical analysis and rigorous computer verification methods. Joint work with Alberto Enciso and Javier Gómez Serrano.

[03258] On the (in)stability of smooth self-similar solutions to the compressible Euler equations

Format : Talk at Waseda University
Author(s) : Anxo Farina Biasi (Ecole Normale Superieure-Paris)
Abstract : In this talk, I am going to describe recent progress in smooth self-similar solutions to the compressible Euler equations. I will explain how these solutions, initially found by Merle-Raphael-Rodnianski-Szeftel (2019), arise in the family of Guderley self-similar solutions (1942), how their (in)stability is studied under smooth perturbations, and which are some endpoints of unstable directions. The topic will be introduced making a contrast between its states during the 20th and 21st centuries.

01188 (2/3) : 2D @G405 [Chair: Bruno Vergara]

[04242] Small scale creation for the 2D Boussinesq Equation

Format : Talk at Waseda University
Author(s) : Alexander Kiselev (Duke university)Yao Yao (National University of Singapore)Jaemin Park (University of Basel)
Abstract : In this talk, we study long-time behaviors of the two- dimensional incompressible Boussinesq equations without thermal diffusion. While the 2D Boussinesq equations is known to possess global solutions with the presence of viscos- ity, it remains a outstanding open problem whether the inviscid case can exhibit a finite-time blow up. In the viscous case, we established algebraic growth of the Sobolev norms of the solu- tions for all time. For the inviscid case, we obtained the growth of the gradient of the temperature, assuming that the global so- lution exists for all time. The initial data under consideration in this work is not too restrictive. More precisely, we only require certain symmetry and sign conditions. The key ingredient of the proof is to derive a norm-inflation from the decay of an anisotropic Sobolev norm of the temperature, which can be ob- served in the conservation of energy. This work is a joint work with A. Kiselev and Y. Yao.

[05046] On the motion of an internal wave in two-dimensional viscous flow

Format : Talk at Waseda University
Author(s) : Rafael Granero-Belinchon (Universidad de Cantabria)
Abstract : In this talk we will review some recent results concerning the motion of an internal wave in two-phase viscous flow. In particular we will establish the local and global well-posedness of the free boundary problem associated to this physical situation. Finally, we will also prove an exponential instability result.

These results were obtained in a joint work with Francisco Gancedo and Elena Salguero.

[03025] Smooth imploding solutions for 3D compressible fluids

Format : Online Talk on Zoom
Author(s) : Gonzalo Cao Labora (Massachusetts Institute of Technology (MIT))
Abstract : We will talk about singularity formation for the 3D isentropic compressible Euler and Navier-Stokes equations for ideal gases. We will construct a new family of self-similar profiles corresponding to larger self-similar exponents than what was previously known. In particular, this will show singularity formation for all adiabatic

constants, giving the first known singularity formation result for monoatomic gases. These results are joint work with Tristan Buckmaster and Javier Gomez-Serrano.

01188 (3/3) : 2E @G405 [Chair: Bruno Vergara]

[04870] Stability of a point charge for the Vlasov-Poisson system

Format : Online Talk on Zoom
Author(s) : Benoit Pausader (Brown University)
Abstract : We consider solutions of the Vlasov-Poisson system starting from initial data (i) a dirac mass (the point charge) and (ii) some small density with respect to Liouville measure (the cloud). We show global existence of the solution and describe the asymptotic behavior in terms of modified scattering. This is joint work with K. Widmayer and J. Jiang.

[05033] Global axisymmetric Euler flows with rotation

Format : Online Talk on Zoom
Author(s) : Klaus Widmayer (University of Vienna & University of Zurich)Benoit Pausader (Brown University)Yan Guo (Brown University)
Abstract : We discuss the construction of a class of global, dynamical solutions to the 3d Euler equations near the stationary state given by uniform "rigid body" rotation. These solutions are axisymmetric, of Sobolev regularity and have non-vanishing swirl.

[02875] On the analyticity of the Muskat equation

Format : Online Talk on Zoom
Author(s) : Jia Shi (MIT)
Abstract : The Muskat equation describes the interface of two liquids in a porous medium. We will show that if a solution to the Muskat problem in the case of same viscosity and different densities is sufficiently smooth, then it must be analytic except at the points where a turnover of the fluids happens. We will also show analyticity in a region that degenerates at the turnover points provided some additional conditions are satisfied.

[01190] Recent Advances in Modeling Complex Systems and Multiscale Problems in Mathematical Biology

Session Time & Room :

01190 (1/2) : 5C (Aug.25, 13:20-15:00) @E802

01190 (2/2) : 5D (Aug.25, 15:30-17:10) @E802

Type : Proposal of Minisymposium
Abstract : Advances in our understanding of complex problems in biology are aided by mathematical modeling. A common challenge in this effort is incorporating a wide range of temporal and spatial scales into a single model. This symposium will explore a variety of biological systems, such as microtubule polymerization and blood coagulation, and the diversity of methods used to examine them, such as dynamical systems theory and numerical methods. Our proposed speakers from the US and Canada represent various stages in academia and highlight the versatility of modeling as a tool to answer active biological questions.

[04951] A Spatially Averaged Model for Platelet Cohesion by vWF

Format : Talk at Waseda University
Author(s) : Keshav Bhavesh Patel (University of Utah)Aaron Fogelson (University of Utah)
Abstract : Platelet aggregation in high shear rate environments, in both healthy and stenotic arterioles, is mediated by Von Willebrand Factor (vWF). Computational fluid dynamics (CFD) models can study this process but are time-intensive and unable to explore sets of physiologically relevant parameters. In this talk, we will discuss a spatially averaged dynamical systems model of platelet aggregation. We quantify how vWF reduces aggregation time at high shear rates and determine essential parameters involved in aggregate formation.

[04400] Investigating traveling waves in biophysical models of cardiac dynamics

Format : Talk at Waseda University
Author(s) : Stephanie Dodson (Colby College)Timothy Lewis (University of California Davis)
Abstract : Regular cardiac function is characterized by coherent traveling waves of electrical activity that drive heart beats. When this process goes awry, the ensuing irregular rhythms are known as arrhythmias, which can be life-threatening. Hence, it is crucial to understand conditions that influence arrhythmia onset. In previous work, these traveling waves have been mathematically investigated in qualitative models of excitable media. We investigate traveling wave properties and arrhythmia onset using biophysically realistic models of cardiac dynamics.

[05165] Modeling and Simulation of Mucin-like Polyelectrolyte Gels

Format : Talk at Waseda University
Author(s) : Owen Lewis (University of New Mexico)Jian Du (Florida Institute of Technology)Aaron L Fogelson (University of Utah)James P Keener (University of Utah)
Abstract : Volume phase transitions in polyeletrolyte gels play important roles in many biophysical processes such as mucus secretion, DNA packaging, nerve excitation, and cellular secretion. The swelling and deswelling of these charged polymer gels depend strongly on their ionic environment. In this paper, we present an extension to our previous two-fluid model for ion-binding-mediated gel swelling. The model treats the polyeletrolyte gel as a mixture of two continuum materials, the network and the solvent. We use mean-field arguments to derive the force densities that nano-scale species (ions and individual solvent particles) exert on these two species. The resulting model is suitable for the investigation of a large family of biologically relevant problems.

[04304] Adaptive IMEX method for fractional PDE in viscoelastic fluids

Format : Talk at Waseda University
Author(s) : Dipa Ghosh (IIIT DELHI)
Abstract : Fractional PDEs have emerged as a powerful tool for modelling multiphysics and multiscale processes in numerical simulations ranging from physics and biology to quantitative finance. We propose a novel family of time-asymptotically stable, implicit-explicit, adaptive time integration methods for the solution of the fractional advection-diffusion-reaction equations. The fractional diffusion equation (2D) and the incompressible, subdiffusive dynamics of the Rouse chain melts ($\alpha = 1/2$) and the Zimm chain solution ($\alpha = 2/3$) are used to assess the method.

01190 (2/2) : 5D @E802 [Chair: Anna Nelson]

[04322] A mathematical model of microtubule assembly and polarity in dendrites

Format : Talk at Waseda University
Author(s) : Anna Nelson (Duke University)Veronica Ciocanel (Duke University)Scott McKinley (Tulane University)
Abstract : The microtubule cytoskeleton is responsible for sustained transport of cellular cargo inside neurons. However, microtubules must also be dynamic and rearrange their orientation in response to injuries. We introduce a spatially-explicit mathematical model of dendritic microtubule growth dynamics using parameters informed by experimental data. We explore several hypotheses of microtubule growth using both a stochastic model and a continuum model, and use fluorescence microscopy experiments to validate mechanisms such as limited tubulin and length-dependent catastrophe.

[04441] Parameter Estimation for Mechanistic Models of Tear Film Breakup

Format : Talk at Waseda University
Author(s) : Rayanne A Luke (George Mason University)Richard J Braun (University of Delaware)Tobin A Driscoll (University of Delaware)Deborah Awisi-Gyau (Alcon Research LLC)Carolyn G Begley (Indiana University)
Abstract : Tear film breakup is related to dry eye disease. Breakup causes include evaporation and divergent flow; related quantities cannot be directly measured during breakup. We determine such variables by fitting thin film fluid dynamics models for breakup to experimental data. Our results suggest that evaporation and divergent flow cooperate to drive faster breakup; purely evaporative cases exhibit slower thinning. These results are the first to make a tight comparison between such models and experimental data.

[05183] Modelling Glucose Regulation: Lipotoxicity and the Progression to Type 2 Diabetes

Format : Talk at Waseda University
Author(s) : Katharine R Faulkner (University of British Columbia)
Abstract : As an individual moves from healthy to pre-diabetic to diabetic, there are many physiological changes that occur, but it is not known which of these changes are the main drivers of the progression to type II diabetes. In this talk, I will describe a simple model for glucose regulation and how modeling can help determine which of these physiological changes are capable of pushing an individual from healthy to diseased. By framing this problem in terms of bifurcations, we can find models that create qualitative changes to the system that allow for movement between healthy and diseased states. We will examine a model that includes the toxicity of lipids in the pancreas, and find a bifurcation that describes the progression to type II diabetes.

[04351] PIEZO1 regulates cellular coordination during collective cell migration

Format : Talk at Waseda University
Author(s) : Jinghao Chen (University of California, Irvine)Jesse Holt (University of California, Irvine)Beth Evans (University of California, Irvine)John Lowengrub (University of California, Irvine)Medha Pathak (University of California, Irvine)
Abstract : The mechanically-activated ion channel PIEZO1 was recently identified to play an inhibitory role during wound healing. Through an integrative experimental and mathematical modeling approach, we elucidate PIEZO1’s contributions to keratinocyte collective migration, an essential component of the healing process. Here, through a 2D-multiscale model of wound closure which links observations at both the single and multicell scales, and subsequent experimental validation, we identify cell directionality as being impacted by PIEZO1 activity during wound closure.

[01191] Recent advances on regularity and irregularity of fluids flows

Session Time & Room :

01191 (1/3) : 1C (Aug.21, 13:20-15:00) @G703

01191 (2/3) : 1D (Aug.21, 15:30-17:10) @G703

01191 (3/3) : 1E (Aug.21, 17:40-19:20) @G703

Type : Proposal of Minisymposium
Abstract : Building a satisfactory mathematical theory of turbulence remains one of the most significant challenges in the physical sciences, with several fundamental problems still open. Deeply tied to these problems are issues associated with the regularity and well-posedness of fluid flows. Recent developments have shed light on the chaotic behavior of turbulent flows, the role of criticality in ill-posedness, singularity formation in classical solutions, and the relation between irregularity, instability, and non-uniqueness of solutions. The goal of this session is to gather those who have contributed to these developments, promote the exchange of ideas, and inspire new ones.

[03313] Singularity formation for models of fluids

Format : Talk at Waseda University
Author(s) : Mimi Dai (University of Illinois at Chicago)
Abstract : Finite time singularity formation for fluid equations will be discussed. Built on extensive study of approximating models, breakthroughs on this topic have emerged recently for Euler equation. Inspired by the progress for pure fluids, we attempt to understand this challenging issue for magnetohydrodynamics (MHD). Finite time singularity scenarios are discovered for some reduced models of MHD. The investigation also reveals connections of MHD with Euler equation and surface quasi-geostrophic equation.

[03731] Vorticity estimates for the 3D incompressible Navier-Stokes equation

Format : Online Talk on Zoom
Author(s) : Jincheng Yang (University of Chicago)
Abstract : We show some a priori regularity estimates for the vorticity and its trace in the three-dimensional incompressible Navier-Stokes equation. These a priori estimates are obtained via the blow-up method and a novel averaging operator. The averaging operator can be used to provide regularity and trace estimates for PDEs with ε-regularity.

[04943] On criticality of the Navier-Stokes diffusion

Format : Online Talk on Zoom
Author(s) : zoran grujic (university of virginia)
Abstract : The main purpose of this talk is to present a mathematical evidence of criticality of the Navier-Stokes diffusion. In particular, considering a plausible candidate for a finite time blow-up, a two-parameter family of the dynamically rescaled profiles, we show that as soon as the hyper-diffusion exponent is greater than one, a new region in the parameter space (completely in the super-critical regime) is ruled out. As a matter of fact, the region is a neighborhood (in the parameter space) of the self-similar profile, i.e., the `approximately self-similar' blow-up is ruled out for all hyper-diffusive models.

[05062] Well-posedness of mildly regularized active scalars in Sobolev spaces

Format : Online Talk on Zoom
Author(s) : Anuj Kumar (Florida State University)Vincent Ryan Martinez (CUNY Hunter College)
Abstract : In this work, we consider the initial value problem for a family of active scalar equations when perturbed by a logarithmic order regularization in dissipation. These equations, commonly known as generalized surface quasi-geostrophic equations (gSQG) interpolate between the 2D incompressible Euler equation and the 2D SQG equation, and extrapolate beyond SQG to a family with more singular velocities. Ill-posedness at the threshold regularity for the
unperturbed models has been established in the celebrated works of Bourgain and Li, and Elgindi and Masmoudi for the 2D Euler equation, and recently by Cordoba and Zoroa-Martinez, and Jeong and Kim for the 2D SQG equation. In this work, we treat the positive side of well-posedness and consider a minimally dissipative regularization to recover local well-posedness (in the Hadamard sense) in the threshold Sobolev regularity. The proof is based on developing estimates for a suitably identified linear system that preserves the underlying commutator structure of the nonlinearity.

01191 (2/3) : 1D @G703 [Chair: Vincent Martinez]

[04347] Bounded weak solutions to the 2D quasi-geostrophic equation

Format : Online Talk on Zoom
Author(s) : Elaine Cozzi (Oregon State University)
Abstract : We outline a proof of global existence of bounded weak solutions to the 2D quasi-geostrophic equation (SQG), building on a result of Marchand. Our proof utilizes a Littlewood-Paley version of a Serfati type of identity for SQG. This is joint work with David Ambrose and Jim Kelliher.

[02935] On the support of anomalous dissipation measures

Format : Online Talk on Zoom
Author(s) : Theodore D. Drivas (Stony Brook University)
Abstract : By means of a unifying measure-theoretic approach, we establish lower bounds on the Hausdorff dimension of the space-time set which can support anomalous dissipation for weak solutions of fluid equations, both in the presence or absence of a physical boundary. Boundary dissipation, which can occur at both the time and the spatial boundary, is analyzed by suitably modifying the Duchon & Robert interior distributional approach. One implication of our results is that any bounded Euler solution (compressible or incompressible) arising as a zero-viscosity limit of Navier--Stokes solutions cannot have anomalous dissipation supported on a set of dimension smaller than that of the space. This is joint work with L. De Rosa and M. Inversi.

[03059] Kinetic shock profiles for the Landau equation

Format : Talk at Waseda University
Author(s) : Dallas Albritton (UW-Madison)
Abstract : Compressible Euler solutions develop jump discontinuities known as shocks. However, physical shocks are not, strictly speaking, discontinuous. Rather, they exhibit an internal structure which, in certain regimes, can be represented by a smooth function, the shock profile. We demonstrate the existence of weak shock profiles to the kinetic Landau equation. Joint work with Matthew Novack (Purdue University) and Jacob Bedrossian (UCLA).

[04056] On sharp-crested water waves and finite-time singularity formation

Format : Online Talk on Zoom
Author(s) : Nastasia Grubic (ICMAT, CSIC)
Abstract : We show that the 2d gravity water waves system is locally wellposed in weighted Sobolev spaces which allow for interfaces with corners. These singular points are not rigid; if the initial interface exhibits a corner, it remains a corner but generically its angle changes. Using a characterization of the asymptotic behavior of the fluid near a corner that follows from our a-priori energy estimates, we show the existence of initial data in these spaces for which the fluid becomes singular in finite time.

01191 (3/3) : 1E @G703 [Chair: Aseel Farhat]

[04796] Turbulent solutions of fluid equations

Format : Talk at Waseda University
Author(s) : Alexey Cheskidov (University of Illinois at Chicago)
Abstract : In the past couple of decades, mathematical fluid dynamics has been highlighted by numerous constructions of solutions to fluid equations that exhibit pathological or wild behavior. These include the loss of the energy balance, non-uniqueness, singularity formation, and dissipation anomaly. Interesting from the mathematical point of view, providing counterexamples to various well-posedness results in supercritical spaces, such constructions are becoming more and more relevant from the physical point of view as well. Indeed, a fundamental physical property of turbulent flows is the existence of the energy cascade. Conjectured by Kolmogorov, it has been observed both experimentally and numerically, but had been difficult to produce analytically. In this talk I will overview new developments in discovering not only pathological mathematically, but also physically realistic solutions of fluid equations.

[03868] A localized maximum principle and its application to the critical SQG on bounded domain

Format : Talk at Waseda University
Author(s) : Tsukasa Iwabuchi (Tohoku University)
Abstract : We discuss a spectral localization technique for the Dirichlet Laplacian on smooth bounded domain to deal with the fractional Laplacian of the derivative order one and commutator estimates in the framework of Besov spaces. It corresponds to a generalization of the analysis by the dyadic decomposition of the frequency through the Fourier transform in the Euclidean space. As an application, we show the existence of global solutions of the surface quasi-geostrophic equation with the critical dissipation for small initial data.

[03232] Speeding up Langevin Dynamics by Mixing

Format : Talk at Waseda University
Author(s) : Yuanyuan Feng (East China Normal University)Gautam Iyer (Carnegie Mellon University)Alexei Novikov (Penn State University)Alexander Christie (Penn State University)
Abstract : We add a drift to the Langevin dynamics (without changing the stationary distribution) and obtain quantitative estimates on the mixing time. We show that an exponentially mixing drift can be rescaled to make the mixing time of the Langevin system arbitrarily small.

[04760] On intermittent strong Onsager conjecture

Format : Online Talk on Zoom
Author(s) : Hyunju Kwon (ETH Zurich)
Abstract : Smooth solutions to the incompressible 3D Euler equations, which are spatially periodic, are known to conserve kinetic energy in every local region. Turbulent flows, however, exhibit anomalous dissipation of kinetic energy, indicating the existence of a weak solution to the Euler equations with dissipation of kinetic energy in some region, but no creation of energy everywhere in the domain. This motivates the strong Onsager conjecture, which combines the original Onsager conjecture with the local energy inequality. In this talk, I will discuss the flexibility side of the L^3-based strong Onsager conjecture, adapting to the intermittent nature of turbulence, and introduce a wavelet-based convex integration scheme. The talk is based on a joint work with Matt Novack and Vikram Giri.

[01195] Hyperbolic one-dimensional systems in networks: mathematical modeling and numerical approximations

Session Time & Room :

01195 (1/2) : 2D (Aug.22, 15:30-17:10) @G601

01195 (2/2) : 2E (Aug.22, 17:40-19:20) @G601

Type : Proposal of Minisymposium
Abstract : Gas flow in pipes, open channel flows, water distribution, traffic flow and blood flow are some modelling applications very often represented as hyperbolic one-dimensional systems in networks. Key modelling ingredients for these systems are the correct definition of boundary conditions at terminal network points, proper coupling conditions among one-dimensional domains and the coupling of one-dimensional domains to zero-dimensional models. Further complexity may be added: parameters varying in space and time, flow regimes varying from sub- to supercritical, diffusive and dispersive terms, etc. All these aspects result in challenging situations for numerical methods designed to discretise this type of models.

[02382] Control of advection-diffusion equations on networks and singular limits

Format : Talk at Waseda University
Author(s) : Nicola De Nitti (FAU Erlangen-Nürnberg)
Abstract : We consider advection-diffusion equations posed on a tree-shaped network with suitable transmission conditions at the junctions. We study the asymptotic behavior of the cost of the null-controllability as the diffusivity parameter vanishes: we show that it decays for a sufficiently large time and explodes for short times with an exponential rate.

[02297] A second order model of traffic with organization marker

Format : Talk at Waseda University
Author(s) : Abraham Sylla (University of Milano-Bicocca)
Abstract : We present a toy model for self-organized road traffic taking into account the state of orderliness in drivers' behavior. The model is reminiscent of the wide family of
generalized second-order models of road traffic. The orderliness marker is evolved along vehicles' trajectories and it influuences the fundamental diagram of the traffic flow. The coupling we have in mind is nonlocal, leading to a kind of "weak decoupling" of the resulting 2×2 system.

[02293] Limiting flow in atrial-ventricular function

Format : Talk at Waseda University
Author(s) : Javier Murillo (I3A, University of Zaragoza,)Juan Mairal (I3A, University of Zaragoza,)Pilar García-Navarro (I3A, University of Zaragoza,)
Abstract : To date, no methodology is available for coupling 1D blood flow to models of the peripheral vasculature, valves, or heart when the flow regime is other than subsonic. When modeling complex fluid networks using 1D approaches, boundary conditions can be imposed using 0D models. An application case is the modeling of the human circulation using closed-loop models. These can be considered a tool to investigate short-term transient hemodynamic responses to postural changes in atrial-ventricular function.

01195 (2/2) : 2E @G601 [Chair: Ernesto Pimentel-García]

[02299] The Junction Riemann Problems under transonic scenarios: application to veins.

Format : Talk at Waseda University
Author(s) : Juan Mairal (I3A - Universidad de Zaragoza)Javier Murillo (I3A, University of Zaragoza,)Pilar García-Navarro (I3A - Universidad de Zaragoza)
Abstract : Current 1D numerical methods for flow in junctions provide good results in most cases. In the 1D framework, the junction is a singular point. One of the shortcomings of existing methods is their inability to deal with transonic and supersonic flow at junctions in physiological flows. Existing methods that rely on coupling approaches for conservation of mass, energy or momentum and the characteristic equations for subsonic flow conditions are revisited here.

[02244] Numerical and physical impact of coupling conditions for one dimensional blood flow models

Format : Talk at Waseda University
Author(s) : Lucas Omar Müller (University of Trento)
Abstract : One dimensional blood flow models consist of hyperbolic or hyperbolic-dominant systems of balance laws. This specific mathematical property plays a key role in the derivation of coupling and boundary conditions necessary to model blood flow in networks of vessels. In this talk we will derive coupling and boundary conditions for a general velocity profile and study their physical and numerical impact in simulations of the arterial and venous system across several spatial scales.

[02355] High-order fully well-balanced numerical methods for one-dimensional blood flow in networks

Format : Talk at Waseda University
Author(s) : Ernesto Pimentel-García (University of Málaga)
Abstract : We are interested in the numerical study of one-dimensional blood flow model in networks with discontinuous mechanical and geometrical properties. We do an exhaustive investigation of all its stationary solutions and we propose high-order fully well-balanced numerical methods that are able to preserve all of them. These methods are able to deal with more than one discontinuous parameter and friction. Some numerical tests are shown to prove its well-balanced and high-order properties.

[01197] Numerical linear algebra in convex and nonconvex optimization

Session Time & Room : 3D (Aug.23, 15:30-17:10) @F311

Type : Proposal of Minisymposium
Abstract : Convex optimization has been instrumental in significant progress across science and technology. Nonconvex optimization methods are an exciting area of active research driven by modern applications. The efficiency and effectiveness of most optimization algorithms hinge on the numerical linear algebra algorithms that they utilize. Furthermore, optimization applications have motivated fundamental advances in numerical linear algebra. This minisymposium aims to bring together experts in both optimization and numerical linear algebra to discuss new developments and leading challenges in both areas.

[01875] Nonconvex accelerated gradient descent without parameter tuning

Format : Talk at Waseda University
Author(s) : Naoki Marumo (University of Tokyo)Akiko Takeda (University of Tokyo)
Abstract : We propose a new first-order method for minimizing nonconvex functions with a Lipschitz continuous gradient and Hessian. The proposed algorithm is an accelerated gradient descent method with two restart mechanisms. It finds a solution where the gradient norm is less than ε in $O(\varepsilon^{-7/4})$ function and gradient evaluations. Unlike existing algorithms with similar complexity bounds, our method requires no prior knowledge of problem-dependent parameters. Several numerical results illustrate that the proposed method is promising.

[02180] Low Rank Tensor Decompositions and Approximations

Format : Online Talk on Zoom
Author(s) : Jiawang Nie (University of California, San Diego)Li Wang (University of Texas, Arlington)Zequn Zheng (University of California, San Diego)
Abstract : There exist linear relations among tensor entries of low rank tensors. These linear relations can be expressed by multi-linear polynomials, which are called generating polynomials. We use generating polynomials to compute tensor rank decompositions and low rank tensor approximations. We prove that this gives a quasi-optimal low rank tensor approximation if the given tensor is sufficiently close to a low rank one.

[05344] Efficient and numerically stable interior-point algorithms for convex optimization

Format : Online Talk on Zoom
Author(s) : Ming Gu (UC Berkeley)
Abstract : We present efficient and numerically stable interior-point algorithms for linear programs, quadratic programs, as well as second order cone programs (socp), with supporting numerical results. In particular, our

stable algorithms for socp
achieves full machine precision accuracy, whereas existing interior-point methods for socp are known to be highly unstable.

[01199] Recent advances of scientific computing and applications

Session Time & Room : 2E (Aug.22, 17:40-19:20) @E508

Type : Proposal of Minisymposium
Abstract : There has been tremendous growth in various areas of scientific computing in the recent years. This mini-symposium intends to introduce the recent advances of scientific computing and the related interesting applications. The goal is to attract attention to scientific computing and build potential future collaborations.

Organizer(s) : Ying Wang

Minisymposium Program :

01199 (1/1) : 2E @E508

[04888] Plant virus propagation models with delay and stochasticity

Author(s) : Benito Chen-Charpentier (University of Texas at ArlingtonUniversity of Texas at Arlington)
Abstract : Plant diseases caused by a virus are mostly transmitted by a vector that bites an infected plant and bites a susceptible one. There is a delay between the time a plant gets bitten by an infected vector and the time it is infected. In this paper we consider two simple models of plant virus propagation and study different ways in which delays can be incorporated including the addition of an exposed class for the plants. Simulations are done and comparisons with the results for the models without delays are presented.

[05157] Numerical studies to the Chaplygin gas equation

Author(s) : Ying Wang (University of Oklahoma)
Abstract : In this talk, we will discuss the numerical solutions to the Riemann problem for Chaplygin gas equation, which is the Euler equations equipped with the state equation $p = -1/\rho$. The spatial discretization is performed using WENO reconstruction and time integration is achieved using TVD RK4. The numerical results confirm high order of accuracy. This is a joint work with Ling Jin.

[05160] Fully coupled averaging with singularities.

Author(s) : Alexander Grigo (University of Oklahoma)
Abstract : In this talk I will present an averaging theorem for a fully coupled system with singularities. Specifically, I will discuss a particular fast-slow system that arises in modeling energy transport in an open system of interacting hard-spheres. The technical part of this work addresses how to deal with singularities of the dynamics and the fact that the dynamics is fully coupled.

[01200] New Trends in Optimal Control and Their Applications

Session Time & Room :

01200 (1/2) : 1C (Aug.21, 13:20-15:00) @F312

01200 (2/2) : 1D (Aug.21, 15:30-17:10) @F312

Type : Proposal of Minisymposium

Abstract : This proposal belongs to the area of optimal control for sweeping processes and their applications to optimization-related and control problems, as well as some practical models. By now, the sweeping process has been recognized as a class of nonsmooth dynamical systems involving normal cones to moving sets. The controlled sweeping processes have been studied with applications relating to the theory of plasticity, ferromagnetism, ferroelectricity, and elastoplasticity. Further developments also apply to various problems of hysteresis, phase transitions, modelling systems with contact, friction, and impacts. These systems frequently arise in applications such as mechanical systems, switched electrical circuits, and biological systems.

[01202] Analysis and modelling of human flows

Session Time & Room : 4E (Aug.24, 17:40-19:20) @G302

Type : Proposal of Minisymposium

Abstract : People are moving from one location to another in their daily lives, for commuting, shopping, entertainment, schools, etc. This human flow provides vital information for location decision-making for commercial or public buildings, optimization of transportation systems, urban planning by policymakers, and measures for movement restrictions under a pandemic like COVID-19. This mini-symposium will discuss recent developments in the modeling and analysis of human mobility from an interdisciplinary perspective, including urban studies, spatial economics, network science, and applied mathematics.

Organizer(s) : Takaaki Aoki and Naoya Fujiwara

Classification : 05C21

Minisymposium Program :

[03707] Recent Public Data Related with Urban Vehicle Traffic Simulation

Format : Talk at Waseda University

Author(s) : Takeshi Uchitane (Aichi Institute of Technology)

Abstract : Various kinds of social data are available in Japan in order to realize and evaluate vehicle simulations within an urban-scale digital map. In such the social data, open data is becoming more and more common. In our discussion, two case studies of vehicle simulations and related open data are explained. Because the target locations are different between Kobe city and Aichi prefecture, different kinds of open data are required to make appropriate origin-destination pairs.

[04718] Urban scale pedestrian simulation and analysis around Kobe City center

Format : Talk at Waseda University

Author(s) : Daigo Umemoto (RIKEN R-CCS)Maiko Kikuchi (NTT DOCOMO, INC)Ayako Terui (NTT DOCOMO, INC)Koutarou Abe (NTT DOCOMO, INC)Ryuushi Shimizu (NTT DOCOMO, INC)Katsuki Hirashige (NTT DOCOMO, INC)Nobuyasu Ito (RIKEN R-CCS)Itsuki Noda (Hokudai)

Abstract : We constructed a pedestrian evacuation simulator for Kobe City center, using population based on cell phone demographics provided by NTT DoCoMo, Inc., pedestrian simulator CrowdWalk, and Open Street Map with manually added signals. The evacuation time was initially simulated as 25,685 seconds. Decentralizing evacuation routes reduced it to 17,780 seconds. The signal removal further reduced it to 9,550 seconds. The signal removal alone gave 12,475 seconds: interestingly, overall reduction was about 50% in both cases.

[02895] Potential field of human flow extracted by Hodge-Kodaira decomposition

Format : Talk at Waseda University
Author(s) : Takaaki Aoki (kagawa university, japan)Shota Fujishima (Hitotsubashi University)Naoya Fujiwara (Tohoku University)
Abstract : People are moving daily from one location to another for commuting, shopping, entertainment, schools, etc. Human movements provide vital information for unfolding the actual shapes of cities. Here, we show the potential of human flows using the orthogonal decomposition of the combinatorial Hodge theory for the origin-destination matrix. The potential landscape visualizes an intuitive perspective of the urban structure behind the massive movements and helps us examine the complex spatial structures in contemporary metropolitan areas.

[03549] Towards science of multi-scale human flow

Format : Talk at Waseda University
Author(s) : Naoya Fujiwara (Tohoku University)
Abstract : In this talk, we present our recent findings in data analysis and mathematical models of human mobility, with an emphasis on characteristics of different temporal and spatial scales. The examples include data analysis of evacuation behaviors for severe disasters, change in the mobility patterns after COVID-19 pandemic, and mathematical models for long-term migration patterns. These results would provide hints to obtain a general framework for studying and understanding human mobility.

[01211] Generalized and non-Gaussian Tensor Decompositions

Session Time & Room :

01211 (1/2) : 1C (Aug.21, 13:20-15:00) @G306

01211 (2/2) : 1D (Aug.21, 15:30-17:10) @G306

Type : Proposal of Minisymposium
Abstract : Tensor decompositions are a foundational unsupervised machine learning method for data science, with applications across all of science and engineering. Traditionally, tensor decompositions seek low-rank tensors that best fit the data with respect to the least squares loss. However, other choices of loss function can be more appropriate for non-Gaussian data such as count data, binary data, and data with outliers. This minisymposium presents state-of-the-art advances in developing efficient algorithms and rigorous theory for tensor decompositions with respect to general losses.
Organizer(s) : David Hong

[05616] Generalized Canonical Polyadic Tensor Decomposition: Algorithms and Applications

Format : Talk at Waseda University
Author(s) : David Hong (University of Delaware)
Abstract : Canonical polyadic (CP) tensor decomposition is a fundamental method for finding underlying patterns in data tensors by fitting a low-rank tensor to the data with respect to the least-squares loss. This talk gives an introduction to the generalized CP (GCP) tensor decomposition, which allows general user-selected losses (i.e., non-Gaussian/non-Euclidean/non-least-squares losses). We will describe first-order algorithms for computing GCP and show various demonstrations of GCP on data from science and engineering.

[05224] Recent Improvements in CP Poisson Tensor Algorithms

Format : Online Talk on Zoom
Author(s) : Jeremy Myers (Sandia National Laboratories)Daniel Dunlavy (Sandia National Laboratories)
Abstract : The challenge of fitting a low-rank, non-negative canonical polyadic tensor model to Poisson-distributed multi-way data is often formulated as a nonconvex optimization problem. A common approach is to use local methods initialized from many random starting points to improve the probability of convergence to the global minimum, which is costly. Our mitigation is a heuristic that identifies and teleports away from suboptimal solutions to improve the probability of convergence and reduce computational cost.

[04808] Second-order algorithms for canonical polyadic decomposition with non-least-squares cost functions

Format : Talk at Waseda University
Author(s) : Michiel Vandecappelle (Televic Rail NV)Nico Vervliet (KU Leuven)Lieven De Lathauwer (KU Leuven)
Abstract : Signal processing and data analysis applications often rely on rank-1 terms to extract meaningful information from tensor data. By using the least-squares loss when computing this canonical polyadic decomposition, one implicitly assumes normally distributed errors, which might not be suitable for, e.g., count data. Therefore, we derive a generalized Gauss-Newton-type algorithm for non-least-squares loss functions and discuss how exploiting tensor structure and randomization lead to an efficient algorithm.

[05553] Efficient Algorithms and Software for Generalized Tensor Completion

Format : Online Talk on Zoom
Author(s) : Navjot Singh (University of Illinois Urbana-Champaign)Edgar Solomonik (University of Illinois at Urbana-Champaign)
Abstract : We present novel algorithms and systems infrastructure which enable efficient parallel implementation of algorithms for CP tensor completion with generalized loss functions.
Specifically, we consider alternating minimization, coordinate minimization, and a quasi-Newton (generalized Gauss-Newton) method.
By extending the Cyclops library, we implement all these methods in high-level Python syntax using new sparse tensor kernels. We demonstrate the generalizability of our framework with the first large-scale implementation for Poisson loss completion.

01211 (2/2) : 1D @G306 [Chair: David Hong]

[03326] Stochastic Mirror Descent for Low-Rank Tensor Decomposition Under Non-Euclidean Losses

Format : Talk at Waseda University
Author(s) : Wenqiang PU (Shenzhen Research Institute of Big Data)Xiao FU (Oregon State University)
Abstract : This talk considers low-rank canonical polyadic decomposition (CPD) under a class of non-Euclidean loss functions that frequently arise in statistical machine learning and signal processing. These loss functions are often used for certain types of tensor data, e.g., count and binary tensors, where the least squares loss is considered unnatural. Compared to the least squares loss, the non-Euclidean losses are generally more challenging to handle. Non-Euclidean CPD has attracted considerable interests and a number of prior works exist. However, pressing computational and theoretical challenges, such as scalability and convergence issues, still remain. This talk offers a unified stochastic algorithmic framework for large-scale CPD decomposition under a variety of non-Euclidean loss functions. Our key contribution lies in a tensor fiber sampling strategy-based flexible stochastic mirror descent framework. Leveraging the sampling scheme and the multilinear algebraic structure of low-rank tensors, the proposed lightweight algorithm ensures global convergence to a stationary point under reasonable conditions. Numerical results show that our framework attains promising non-Euclidean CPD performance. The proposed framework also exhibits substantial computational savings compared to state-of-the-art methods.

[03666] Generalized Tucker tensor estimation: An optimal statistical and computational framework

Format : Online Talk on Zoom
Author(s) : Anru Zhang (Duke University)Rungang Han (Duke University)Rebecca Willett (University of Chicago)
Abstract : We describe a flexible framework for generalized low-rank tensor estimation problems. The proposed estimator consists of finding a low Tucker rank tensor fit to the data under generalized parametric models. To overcome the difficulty of nonconvexity, we introduce a unified approach of projected gradient descent. We establish both an upper bound on the statistical error and the linear rate of computational convergence. We demonstrate the superiority of the proposed framework on real data.

[01218] Challenges in single-cell data science: theory and application

Session Time & Room :

01218 (1/3) : 4E (Aug.24, 17:40-19:20) @E804

01218 (2/3) : 5B (Aug.25, 10:40-12:20) @E804

01218 (3/3) : 5C (Aug.25, 13:20-15:00) @E804

Type : Proposal of Minisymposium
Abstract : Single-cell data science aims to understand cells and their functions at individual cells and accelerate progress in the biomedical sciences via the analysis of single-cell omics data. The largest hurdle to this is the difficulty of extracting complex biological structures from millions of pieces of information across varied cell data. This mini-symposium focuses on theoretical studies of single-cell data analysis and its applications, in which biologists, applied mathematicians, and bioinformaticians working in single-cell data science worldwide will come together to discuss their research and the future development.
Organizer(s) : Yusuke Imoto, Keita Iida, Kazumitsu Maehara

[03514] Resolution of the curse of dimensionality in single-cell RNA sequencing data analysis

Format : Talk at Waseda University
Author(s) : Yusuke Imoto (Kyoto University)
Abstract : We have developed a novel noise reduction method for single-cell RNA sequencing (scRNA-seq) data, RECODE, to resolve the curse of dimensionality (COD) in high-dimensional data analysis. RECODE can reduce technical noises in scRNA-seq data based on high-dimensional statistics theory. In this talk, we will explain biological verification, applicability, and recent progress of RECODE. Moreover, we will overview mathematical/informatical grand challenges in single-cell data science, which is the theme of this minisymposium, at the beginning.

[05223] Trajectory inference framework by entropic Gaussian mixture optimal transport

Format : Talk at Waseda University
Author(s) : Toshiaki Yachimura (Tohoku University)
Abstract : In 1957, C.H. Waddington introduced the epigenetic landscape for cell differentiation. Recently, many attempts have been made to reconstruct this conceptual model from gene expression data. In this talk, I will introduce scEGOT, a novel trajectory inference framework of cell differentiation for time series scRNA-seq data based on Entropic Gaussian mixture optimal transport. scEGOT allows us to infer the dynamics of gene expression associated with cell differentiation. This talk is based on the WPI-ASHBi project.

[03619] Dissecting cell identity via network inference and in-silico gene perturbation

Author(s) : Kenji Kamimoto (Washington University in St.Louis)
Abstract : Single-cell omics technology enables the acquisition of multi-dimensional data in a high-throughput manner, revealing diverse and heterogeneous cellular identities. However, understanding biological events from a gene regulatory networks (GRNs) perspective remains difficult. Here, we have developed a new method, CellOracle, for the inference and analysis of GRNs. The method can perform in silico transcription factor perturbations, simulating the consequent changes in cell identity and promoting new mechanistic insights into the regulation of cell identity.

[03878] Experimental guidance for discovering genetic networks from time series

Format : Talk at Waseda University
Author(s) : Tomas Gedeon (Montana State University)Breschine Cummins (Montana State University)Steve Haase (Duke University)Konstantin Mischaikow (Rutgers University)
Abstract : We describe an iterative network hypothesis reduction from time-series data in which dynamic expression of individual, pairs, and entire collections of genes are used to infer core network models. The result of our work is a computational pipeline that prioritizes targets for genetic perturbation to experimentally infer network structure. We apply this computational pipeline to synthetic and yeast cell-cycle data.

01218 (2/3) : 5B @E804 [Chair: Kazumitsu Maehara]

[03512] Geometry-aware high-dimensional vector field reconstruction using Hodge decomposition

Format : Talk at Waseda University
Author(s) : Kazumitsu Maehara (Kyushu University)
Abstract : We propose a method based on Hodge decomposition for analyzing high-dimensional and complex molecular dynamics using single-cell omics data. Drawing inspiration from topology and differential geometry, we developed a data-driven vector field reconstruction method that smoothly captures key features of dynamics (e.g., potential, divergence, curl, and Jacobian) with reduced computational costs through appropriate connections and regularization. Our approach has the potential to contribute to biological discoveries and understanding.

[03922] Reconstructing single cell dynamics on graphs

Format : Talk at Waseda University
Author(s) : Jianhua Xing (University of Pittsburgh)
Abstract : Single-cell (sc)RNA-seq, together with RNA velocity and metabolic labeling, reveals cellular states and transitions at unprecedented resolution. A frontier of research is how to extract dynamical information from the snapshot data. I will first discuss our recently developed dynamo framework (Qiu et al. Cell, 2022), focusing on the underlying mathematical framework. Then I will discuss our recent efforts of reconstructing full dynamical equations using discrete calculus on graphs (Zhang et al. to be submitted).

[04897] Deep generative models to reveal cellular level dynamics and communication

Format : Talk at Waseda University
Author(s) : Teppei Shimamura (Tokyo Medical and Dental University)
Abstract : In this talk, we present a deep generative model for investigating the dynamic changes and interactions between cells that alter various states during the onset and progression of diseases from single-cell and spatial omics data.

01218 (3/3) : 5C @E804 [Chair: Keita Iida]

[03515] Functional annotation-driven unsupervised clustering for single-cell data

Format : Talk at Waseda University
Author(s) : Keita Iida (Osaka University)
Abstract : Single-cell and spatial transcriptomics have enhanced our knowledge of molecular complexity in terms of gene expression heterogeneity in cell populations. However, conventional gene-based approaches may be insufficient in capturing such complexity as genes can interact with each other to regulate a number of biological functions. Here, we introduce ASURAT, a computational tool for simultaneous clustering and functional annotation of single-cell and spatial transcriptomes in terms of cell type, disease, biological process, and signaling pathway activity.

[03908] Modelling cell differentiation: from psuedo-time to energy landscape

Format : Online Talk on Zoom
Author(s) : Jifan Shi (Fudan University)
Abstract : Interactions between genes determine cell development and differentiation. We first introduce pseudo-time of cells, which is also known as pluripotency. Next, we will focus on models from the perspective of energy landscape. We propose an energy landscape decomposition theory for cell differentiation with proliferation effect. Two energy landscapes collectively contribute to the establishment of non-equilibrium steady differentiation. We will also demonstrate feasible numerical methods and several interesting applications.

[03682] Integrating data and dynamics in scRNA-seq data analysis

Format : Talk at Waseda University
Author(s) : Tiejun Li (Peking University)
Abstract : In this talk, I will review some research progress of my group on the scRNA-seq data analysis in recent years. I will mainly focus on the integration of data and dynamics approach in this area, which includes the theory and algorithms for the RNA velocity, dynamical approach for the scRNA-seq data with temporal information, and deep learning type methods. This is a series of joint works with Prof. Luonan Chen, Qing Nie, and Dr. Peijie Zhou, Jifan Shi, Yichong Wu, Qiangwei Peng, et al.

[01221] FreeFEM software package for finite element modeling of PDEs

Session Time & Room : 2E (Aug.22, 17:40-19:20) @E504

Type : Proposal of Minisymposium
Abstract : FreeFEM is a software package for finite element computation and has been developing at the Laboratory of Jacques-Louis Lions, Sorbonne University for 25 years. The main feature of FreeFEM is having a domain specific language based on C++ grammar, which is designed to describe variational formulation of the partial differential equations and discretized matrices by using numerical quadrature on triangle and tetrahedral elements. Now it is drastically enhanced to perform large scale three dimensional computation using domain decomposition methods by linking with tetrahedral mesh generators and parallel linear solvers. FreeFEM allows us to tackle a new mathematical modeling and solution by expressing nonlinear weak formulation with surface and domain integration and by direct manipulation of finite element matrices.This mini-symposium focuses on recent advancement of FreeFEM and application in mathematical modeling.

[02183] Phase field crack growth simulation using IPOPT package

Format : Talk at Waseda University
Author(s) : Takeshi Takaishi (Musashino University)
Abstract : As the energy gradient flow equation of the Bourdin model, we introduced the time evolution model of irreversible crack growth by the phase field method. Its weak solution can be written in terms of variational inequalities, since it includes the irreversible crack state. Simulation results for this model with the IPOPT package in FreeFEM shows the energy dissipation process of crack growth precisely.

[02252] Direct factorization of indefinite matrix for constrained problem in finite element modeling

Format : Talk at Waseda University
Author(s) : Atsushi Suzuki (RIKEN Center for Computational Science)
Abstract : Finite element computation of some physical problem with constraint uses a variational problem with Lagrange multipliers as dual variables. Physical constraints are supposed as incompressibility of the fluid, boundary conditions on internal interfaces, and so on. A linear system obtained by a discretization becomes indefinite and then the multifrontal method for parallelization of direct methods may suffer pseudo singularity of subproblems. Careful pivoting with keeping pair of primal and dual unknowns makes the factorization stable.

[02281] An easy-to-use framework for the density-based topology optimization of multiphysics systems written in FreeFEM-PETSc-ParMmg

Format : Talk at Waseda University
Author(s) : Hao Li (Kyoto University)Minghao Yu (China Academy of Engineering Physics)Pierre Jolivet (LIP6, Sorbonne Universite)Joe Alexandersen (University of Southern Denmark)Atsushi Suzuki (Osaka University)Shinji Nishiwaki (Kyoto University)
Abstract : Large-scale 3D topology optimization has been a big trend in the previous decade. However, it features a high computational cost, which may not always be available to general users. We constructed an easy-to-use and fully distributed framework written in FreeFEM-PETSc-ParMmg. We present various 2D and 3D benchmarks including a structural problem, a transient thermal cloaking design, and a thermal-fluidic problem.

[02204] Recent advances with FreeFEM in parallel and its interface to PETSc

Format : Talk at Waseda University
Author(s) : Pierre Jolivet (CNRS)
Abstract : In this talk, I will present some new features of FreeFEM and its interface to PETSc and SLEPc. Coupled together, these libraries offer a flexible infrastructure to deal with coupled and/or high-dimensional systems, using MPI for distributed-memory parallelism. I will showcase some examples from fluid dynamics, radiative transfer, and boundary integral equations.

[01229] Cauchy problem for Deterministic and Stochastic nonlinear dispaersive equations

Session Time & Room : 5C (Aug.25, 13:20-15:00) @G709

Type : Proposal of Minisymposium
Abstract : We consider Cauchy problem for Deterministic and Stochastic nonlinear dispersive equations. For the Deterministic nonlinear Schrödinger equation (NLS), some global dynamics will be discussed, that is scattering, blowing up, growing up, or uniform bound for the solutions of NLS. For the Stochastic NLS, we will deal with nonlinear equation with a multiplicable noise. We also intoroduce and discuss paracontrolled calculus to prove local well-posedness of a renormalized version of the stochastic nonlinear wave equation.

[03890] The well-posedness of the stochastic nonlinear Schrödinger equations in H^2

Format : Talk at Waseda University
Author(s) : Shunya Hashimoto (Saitama university)
Abstract : We consider the well-posedness of H^2-solutions in initial value problems for the stochastic nonlinear Schrödinger equations with power-type nonlinear terms with multiplicative noise. For the proof, we use the rescaling approach, which transforms the stochastic equation into a random equation in which no white noise appears. Unlike L^2- and H^1-solution, there are two difficulties in the H^2-solution: first, the lack of the smoothness of nonlinear functions, and second, the treatment of white noise that reappears.

[04966] Time beharior of solutions to nonlinear Schr"odinger equation with a potential

Format : Talk at Waseda University
Author(s) : Masaru Hamano (Waseda University)
Abstract : In this talk, we deal with the Cauchy problem of a nonlinear Schr"odinger equation with a potential. In particular, we consider time behavior of solutions to the equation with initial data, whose energy is equal to that of the Talenti function.

[03584] Well-posedness for the fourth-order Schrödinger equation with third order derivative nonlinearities

Format : Talk at Waseda University
Author(s) : Noriyoshi Fukaya (Tokyo University of Science)
Abstract : We study the Cauchy problem to the semilinear fourth-order Schr"odinger equations with third order derivative nonlinearities.
The purpose of this presentation is to prove well-posedness of the problem in the lower order Sobolev space $H^s(\mathbb{R})$ or with more general nonlinearities than previous results. Our proof of the main results is based on the contraction mapping principle on a suitable function space employed by D. Pornnopparath (2018). To obtain the key linear and bilinear estimates,
we construct a suitable decomposition of the Duhamel term introduced by I. Bejenaru, A. D. Ionescu, C. E. Kenig, and D. Tataru (2011). Moreover we discuss scattering of global solutions and the optimality for the regularity of our well-posedness results, namely we prove that the flow map is not smooth in several cases.

[05020] Convergence of the intermediate long wave equation from a statistical perspective

Format : Talk at Waseda University
Author(s) : Guopeng Li (The Maxwell Institute for Mathematical Sciences)
Abstract : The intermediate long wave equation (ILW) models water waves of finite depth, connecting the Benjamin-Ono equation (deep-water limit) and the KdV equation (shallow-water limit). Convergence problems of ILW (in both the deep-water and shallow-water limits) have attracted attention from both the applied and theoretical points of view. In this talk, I will discuss convergence problems from a statistical viewpoint. I first consider the convergence problem of the Gibbsian ensembles. In this case, I establish convergence of the Gibbs measures and then also show convergence of invariant Gibbs dynamics to that of the Benjamin-Ono and KdV equations (without
uniqueness).
ILW is known to be completely integrable and thus possesses infinitely many conservation laws. In the second part of the talk, I consider invariant dynamics for ILW associated with higher order conservation laws. Due to a complicated nature of the dispersion, even the construction of measures associated with higher order conservation laws turns out to be highly non-trivial. By considering a suitable combination of higher order conservation laws, I overcome this issue and construct invariant dynamics for ILW with a fixed depth parameter. In the final part, I will discuss convergence of the invariant dynamics associated with higher order conservation laws.

This talk is based on a joint work with Tadahiro Oh (Edinburgh), Guangqu Zheng (Liverpool), and Andreia Chapouto (UCLA).

[01272] Interface motion and related topics

Session Time & Room :

01272 (1/2) : 4D (Aug.24, 15:30-17:10) @G710

01272 (2/2) : 4E (Aug.24, 17:40-19:20) @G710

Type : Proposal of Minisymposium
Abstract : Understanding the interface dynamics, such as in crystal growth and moving boundaries between two phases, is a topic of great mathematical interest and is also important from engineering, materials science, and other perspectives.
This mini-symposium aims to bring together researchers working on interfacial motion and related topics to share recent advances and discuss this domain of interest.
Topics to be presented include mathematical analysis of interface behavior, numerical methods specific to interface motion, and applied research such as the shape optimization.
Organizer(s) : Michal Beneš, Tetsuya Ishiwata

[02736] Numerical computation of the Plateau problem by the method of fundamental solutions

Format : Talk at Waseda University
Author(s) : Koya Sakakibara (Okayama University of Science / RIKEN)Yuuki Shimizu (The University of Tokyo)
Abstract : We propose a numerical scheme for the Plateau problem based on the method of fundamental solutions. After giving the existence of approximate surfaces and convergence analysis, some numerical experiments show the usefulness of the proposed scheme.

[04050] Novel numerical methods for solving nonlinear evolutionary equations with application in mathematical finance optimization problems

Format : Talk at Waseda University
Author(s) : Cyril Izuchukwu Udeani (Comenius University in Bratislava)Daniel Sevcovic (Comenius University)
Abstract : This study employs physics-informed DeepONet (PI-DeepONet), which incorporates known physics into the neural network via two networks, to approximate the solution operator of a nonlinear Hamilton--Jacobi--Bellman (HJB) equation arising from the stochastic optimization problem, where an investor's goal is to maximize the conditional expected value of the terminal utility. We first transform the nonlinear HJB equation into a quasilinear parabolic equation using the Ricatti transform and then approximate the solution of the transformed equation using PI-DeepONet.

[02939] Mathematical modeling of flame/smoldering front-evolution and its application

Format : Talk at Waseda University
Author(s) : Shunsuke Kobayashi (University of Miyazaki)Shigetoshi Yazaki (Meiji University)Kazunori Kuwana (Tokyo University of Science)
Abstract : The Kuramoto--Sivashinsky equation is well-known as a mathematical model describing the interfacial dynamics of combustion phenomena. In this talk, we focus on flame spreading over thin solid fuels and report the results of applying the Kuramoto--Sivashinsky equation to the following two topics:

1. the behavior of flame/smoldering fronts expanding circle with time.
2. the spreading speed of flame front in a spatially non-uniform region with a bellows shape.

[04059] Multidimensional partial integro-differential equation in Bessel potential spaces with applications

Format : Talk at Waseda University
Author(s) : Daniel Sevcovic (Comenius University)Cyril Izuchukwu Udeani (Comenies University)
Abstract : In the talk we analyze solutions of a non-local nonlinear partial integro-differential equation (PIDE) in multidimensional spaces. We employ the theory of abstract semilinear parabolic equations in order to prove existence and uniqueness of solutions in the scale of Bessel potential spaces. We prove existence and uniqueness of a solution to the PIDE. As an application to option pricing in the one-dimensional space, we consider a general shift function arising from nonlinear option pricing models.

01272 (2/2) : 4E @G710 [Chair: Tetsuya Ishiwata]

[04426] Qualitative and numerical aspects of dynamics of diffusion and transport mechanisms on evolving curves

Format : Talk at Waseda University
Author(s) : Miroslav Kolar (Czech Technical University in Prague)
Abstract : In this talk we discuss the model of diffusion and transport acting on evolving curves. The model is coupled with the geometrical evolution equation for moving interfaces in form $\text{normal velocity} = \text{curvature} + \text{force}$. This model is being developed within the context of study of the vortex dynamics. The technique of incorporation an artificial tangential velocity for the stabilisation of numerical calculations is discussed and qualitative and quantitative computational results in 2D and 3D are shown.

[02845] Numerical solution to a free boundary problem for the Stokes equation using the coupled complex boundary method in shape optimization settings

Format : Talk at Waseda University
Author(s) : Julius Fergy Tiongson Rabago (Kanazawa University)Hirofumi Notsu (Kanazawa University)
Abstract : A new reformulation of a free boundary problem for the Stokes equations governing a viscous flow is proposed. Using the shape derivative of the cost associated with the new cost functional, a Sobolev-gradient based descent method is employed to solve the shape optimization problem. For validation and evaluation of the method, numerical experiments are carried out both in two and three dimensions which are compared with the ones obtained via the classical Dirichlet-data tracking approach.

[03222] Structure-preserving numerical methods for gradient flows of planar closed curves

Format : Talk at Waseda University
Author(s) : Tomoya Kemmochi (Nagoya University)Yuto Miyatake (Osaka University)Koya Sakakibara (Okayama University of Science)
Abstract : In this talk, we consider numerical approximation of constrained gradient flows of planar closed curves. We will develop structure-preserving methods for these equations that preserve both the dissipation and the constraints. To preserve the energy structures, we introduce the discrete version of gradients according to the discrete gradient method and determine the Lagrange multipliers appropriately. Some numerical examples are presented to verify the efficiency of the proposed schemes.

[02751] Motion of Space Curves by Binormal and Normal Curvature

Format : Talk at Waseda University
Author(s) : Michal BENEŠ (Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague)Miroslav KOLÁŘ (Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague)Daniel ŠEVČOVIČ (Faculty of Mathematics, Physics and Computer Science, Comenius University in Bratislava)
Abstract : We discuss the motion of closed non-intersecting space curves by curvature in binormal and normal directions with application in vortex dynamics. We formulate the general motion law in space by binormal and normal curvature and mention its analytical properties. The finite-volume scheme allows to solve the motion

numerically with stabilization by the tangential velocity redistributing discretization nodes. We demonstrate behavior of the solution on several computational studies combining normal and binormal velocity and mutual interactions.

[01383] Sustainable Logistics and Transportation under Uncertain Environments

Session Time & Room : 3D (Aug.23, 15:30-17:10) @D505

Type : Proposal of Industrial Minisymposium
Abstract : Sustainable logistics mention the processes and practices aimed at enriching sustainability of supply chain operations, starting from supply of raw materials to transferring process, storage, packaging, distributions, and customers at the end of life cycle of items. Logistics and transportation problems are examined within a sustainability perspective to offer a comprehensive assessment of economical, environmental, and social performance measures. Sustainable logistics and transportation under uncertain environments provide an appropriate idea for many authorities and decision-makers.

[01445] Deep Learning, Preconditioning, and Linear Solvers

Session Time & Room :

01445 (1/2) : 5C (Aug.25, 13:20-15:00) @E507

01445 (2/2) : 5D (Aug.25, 15:30-17:10) @E507

Type : Proposal of Minisymposium
Abstract : The numerical solution of linear systems of equations is the computational bottleneck in a whole spectrum of applied mathematics and computational science problems. Recently, a number of works have investigated how deep learning can accelerate this critical solution process. This minisymposium will showcase cutting-edge innovations in using deep learning techniques to design and accelerate preconditioners and solvers for linear systems. Researchers will share recent work on topics like combining neural networks with multigrid solvers or conjugate direction methods. An emphasized application will be large, sparse linear systems that arise from discretized partial differential equations in computational physics and simulation problems.

[03314] Deep Learning, Preconditioning, and Linear Solvers

Format : Talk at Waseda University
Author(s) : David Hyde (Vanderbilt University)
Abstract : We will survey techniques for using learning to accelerate linear solvers and preconditioners. Some methods use learning to determine high-quality initial guesses for iterative systems; other approaches learn parameters for classical preconditioners like algebraic multigrid; further techniques replace the entire role of a preconditioner with learning; and still other works replace entire linear solvers with neural network evaluations. After surveying these approaches, we will suggest some avenues of research, open questions, and opportunities for collaboration.

[04332] Fourier Neural Solver for Large Sparse Linear Algebraic Systems

Format : Talk at Waseda University

Author(s) : Kai Jiang (Xiangtan University)

Abstract : In this talk, we propose an interpretable neural solver, the Fourier neural solver (FNS), to solve sparse linear algebraic systems. Based on deep learning and fast Fourier transformation, FNS combines a stationary iterative method and frequency space correction approach to efficiently eliminate different frequency components of the error. The local Fourier analysis indicates that FNS can detect error components within the frequency domain that cannot be eliminated effectively using stationary methods, even though the error removed by the latter is problem-dependent. Numerical experiments on several classical equations show that the FNS is more efficient and more robust than the existing neural solvers. If time permits, we will update our latest progress in this area.

[03199] Accelerating multigrid solvers for the acoustic and elastic Helmholtz equation.

Format : Talk at Waseda University

Author(s) : Rachel Yovel (Ben-Gurion University of the Negev)Eran Treister (Ben-Gurion University of the Negev)Bar Lerer (Ben-Gurion University of the Negev)

Abstract : We develop multigrid solvers for the acoustic and elastic Helmholtz equations and accelerate them using deep learning methods. Based on the shifted Laplacian approach, which is typically used for the acoustic version, we build a GPU-friendly geometric multigrid preconditioner for the elastic Helmholtz equation. Moreover, we present a block-acoustic preconditioner for the elastic version and utilize a trained CNN acoustic solver to solve the elastic Helmholtz equation through this reduction.

[03141] On learning neural operators of PDEs with interfacial jump conditions for accelerating simulations of physical systems

Format : Talk at Waseda University

Author(s) : Pouria Akbari Mistani (NVIDIA Corp)Samira Pakravan (University of California Santa Barbara)Frederic Gibou (University of California Santa Barbara)

Abstract : Elliptic (free boundary) problems with jump conditions are commonly used to model multiscale physical systems. Despite the availability of optimal numerical solvers, obtaining solutions over large spatiotemporal scales remains challenging. Pre-trained compact neural operators offer fast inference oracles to accelerate simulations on modern hardware. In this talk we present our work on training accurate neural operators for this class of problems. We also introduce JAX-DIPS, a publicly available library, to promote research in this area.

01445 (2/2) : 5D @E507 [Chair: David Hyde]

[03614] A Deep Conjugate Direction Method for Iteratively Solving Linear Systems

Format : Talk at Waseda University

Author(s) : ayano kaneda (waseda university)David Hyde (Vanderbilt University)Osman Aker (University of California) Joseph Teran Michael (University of California, Davis)

Abstract : We present a novel deep learning approach to approximate the solution of large, sparse, symmetric, positive-definite linear systems of equations. Motivated by the conjugate gradients algorithm that iteratively selects search directions for minimizing the matrix norm of the approximation error, we design an approach that utilizes a deep neural network to accelerate convergence via data-driven improvement of the search direction at each iteration. Our method leverages a carefully chosen convolutional network to approximate the action of the inverse of the linear operator up to an arbitrary constant. We demonstrate the efficacy of our approach on spatially discretized Poisson equations, which arise in computational fluid dynamics applications, with millions of degrees of freedom. Unlike state-of-the-art learning approaches, our algorithm is capable of reducing the linear system residual to a given tolerance in a small number of iterations, independent of the problem size. Moreover, our method generalizes effectively to various systems beyond those encountered during training.

[03251] Wasserstein GAN and Transfer Learning in physics-informed neural networks

Format : Talk at Waseda University
Author(s) : Yihang Gao (The University of Hong Kong)Michael Kwok-Po Ng (The University of Hong Kong)
Abstract : We study a physics-informed algorithm for Wasserstein Generative Adversarial Networks (WGANs) for uncertainty quantification in solutions of PDEs. By using groupsort activation functions in adversarial network discriminators, network generators are utilized to learn the uncertainty in solutions of PDEs observed from initial/boundary data. Under mild assumptions, we show the convergence of the obtained model. Moreover, we also study a SVD-based transfer learning method which stabilize the training and reduce the storage for PINNs.

[01494] Queues and Related Stochastic Models

Session Time & Room :

01494 (1/2) : 2D (Aug.22, 15:30-17:10) @E501

01494 (2/2) : 2E (Aug.22, 17:40-19:20) @E501

Type : Proposal of Minisymposium
Abstract : In this mini-symposium, we invite high-quality contributions in queues and related stochastic models arising from operations research. Queues and related stochastic models have various applications in service systems, such as call centers, computer and communication networks, and transportation systems. This mini-symposium discusses recent advances in queues and stochastic models and their applications.

Keywords
- stochastic models
- matrix analytic methods
- asymptotic analysis of queueing models
- game theoretic analysis of queues
- fluid and diffusion limits, large deviation analysis of queues
- stochastic analysis of risk models
- matching queues
- multidimensional Markov chains
- novel queueing models in applications

[02929] Strategic revenue management for discriminatory processor sharing queues

Format : Talk at Waseda University
Author(s) : Dieter Fiems (Ghent University)
Abstract : We consider revenue management for discriminatory processor sharing (dps) queues. The server receives revenue per customer, as well as a fee if customers opt for premium service. We study the optimal parameter allocation of the dps discipline, assuming that customers rationally select between premium and non-premium service. It is shown that the optimal dps discipline is a strict priority discipline when customers cannot balk, while a non-degenerate dps discipline is optimal with balking.

[03027] Bounding performance of stochastic models for server virtualization in cloud computing

Format : Talk at Waseda University

Author(s) : Ken'ichi Kawanishi (Gunma University)

Abstract : In recent years, ICT systems are constructed with virtual servers on the cloud computing by virtualization technology. The cloud computing is based on a huge number of physical servers in data centers. One of the important issues is to reduce server power consumption while ensuring performance. In this talk, we consider stochastic models for server virtualization in cloud computing and propose a method to evaluate performance bounds while suppressing computational costs even in large-scale systems.

[03114] Strategic behaviour of reserved customers in a queueing model with multiple reservation zones

Format : Talk at Waseda University

Author(s) : Yutaka Sakuma (Department of Computer Science, National Defense Academy of Japan)Emiko Fukuda (Department of Industrial Engineering and Economics, Tokyo Institute of Technology)Hiroyuki Ichihara (Deptartment of Management Synthesis, Chubu University)Hiroyuki Masuyama (Graduate School of Management, Tokyo Metropolitan University)

Abstract : We consider the strategic behavior of customers in a queueing system with multiple reservation zones. In this system, customers are assigned to the reservation zones, and they face the problem of when to arrive within their reservation zone, where early arrival is allowed. The customers are assumed to be homogeneous and non-cooperative, and they try to find a mixed strategy that minimizes their expected waiting time. We propose a numerical algorithm to obtain the customers' mixed strategy in equilibrium for each reservation zone.

[02958] Analysis of time-dependent queues with generally distributed retrials

Format : Talk at Waseda University

Author(s) : Raik Stolletz (University of Mannheim)Ömer Özümerzifon (University of Mannheim)Benjamin Legros (EM Normandie)

Abstract : Time-dependent queueing systems are present in various service systems. Often customers leave the queue before being served due to a lack of patience. However, impatient users may join the system after the so-called retrial time. We analyze the time-dependent performance of multi-server queues with generally distributed retrial times and develop a stationary backlog-carryover (SBC) approach. The numerical study analyzes the reliability of the approach and demonstrates the impact of retrial time distributions on performance measures.

01494 (2/2) : 2E @E501 [Chair: Tuan Phung-Duc]

[03351] The rational outcome of queueing games: A fixed-point iteration based approach

Format : Talk at Waseda University

Author(s) : Hung Q Nguyen (Advanced Artificial Intelligence Innovation Center, Hitachi, Ltd. Research & Development Group)Tuan Phung-Duc (University of Tsukuba)

Abstract : In this study, we consider a class of queueing games characterized by the following feature: expected waiting times of enqueued agents are affected by joining strategies of later comers. We survey several queueing models and generalize an iterative algorithm that may universally apply in a class of queueing game problems to computationally solve for the rational outcome of the game.

[03189] Workload analysis of fluid polling models

Format : Online Talk on Zoom

Author(s) : Stella Kapodistria (Eindhoven University of Technology)

Abstract : In this presentation, we analyze a two-queue random time-limited Markov-modulated polling model. In the first part of the talk, we investigate the fluid version: fluid arrives at the two queues as two independent flows with deterministic rate. There is a single server that serves both queues at constant speeds. The server spends an exponentially distributed

amount of time in each queue. After the completion of such a visit time to one queue, the server instantly switches to the other queue, i.e., there is no switch-over time.

For this model, we derive a functional equation for the LST of the two-dimensional workload distribution that leads to a Riemann–Hilbert boundary value problem (BVP). After taking a heavy-traffic limit, and restricting ourselves to the symmetric case, the BVP simplifies and can be solved explicitly.
In the second part of the talk, allowing for more general (Lévy) input processes and server switching policies, we investigate the transient process limit of the joint workload in heavy traffic. Again solving a BVP, we determine the stationary distribution of the limiting process. We show that, in the symmetric case, this distribution coincides with our earlier solution of the BVP, implying that in this case the two limits (stationarity and heavy traffic) commute.
This is joint work with M. Saxena, O.J. Boxma and O. Kella.

[01532] Recent Trends in Fluid Mechanics and its Applications

Session Time & Room :

01532 (1/2) : 1C (Aug.21, 13:20-15:00) @G704

01532 (2/2) : 1D (Aug.21, 15:30-17:10) @G704

Type : Proposal of Minisymposium
Abstract : The aim of this minisymposium is to bring together mathematicians to share their recent progress and to inspire new ideas in applied mathematics.

This minisymposium may address modeling various phenomenum arising from gas dynamics, astrophysics, engineering, and material science, as well as theoretic analysis in problems of kinetic theory, planetary atmospheric science, traffic flow, and semiconductor etc.

[01972] Global BV solution and relaxation limit for Greenberg-Klar-Rascle model

Author(s) : Ying-Chieh Lin (National University of Kaohsiung)Shih-Wei Chou (Soochow University)John M. Hong (National Central University)Hsin-Yi Lee (National Cheng Kung University)
Abstract : In this talk, we consider the Greenberg-Klar-Rascle multi-lane traffic flow model. This model is a relaxation system with the equilibrium state that is a discontinuous function of the car density. We study the existence of global entropy solutions and the relaxation limit for the GKR model. To construct the approximate solutions, we find two sequences of invariant regions under some suitable condition of initial data. As the relaxation time approaches 0, we prove that the limit of the entropy solutions for the GKR model is a weak solution of its equilibrium equation. It is interesting that the equilibrium equation is a scalar conservation law with discontinuous flux.

[02450] Global Transonic Solutions of Compressible Euler-Poisson Equations in Semiconductors

Author(s) : Shih-Wei Chou (Soochow University)Chia-Chieh Jay Chu (National Tsing Hua University)John M Hong (National Central University)
Abstract : In this talk, we consider an initial-boundary value problem of compressible Euler-Poisson equations arising in semiconductors. The equations form a 3-by-3 hyperbolic system of balnace laws with the global source. We establish the global existence of the transonic entropy solution by framework of a generized Glimm scheme. This is a joint work with John Hong and Jay Chu.

[02456] Finite Speed of Propagation of the Relativistic Landau and Boltzmann Equations

Author(s) : Ming Jiea Lyu (Chung Yuan Christian University)Kung Chien Wu (National Cheng Kung University,)Baoyan Sun (Yantai University)
Abstract : In this talk, we will study the relativistic Boltzmann and Landau equations in the whole space $\mathbb{R}^3$ under the closed to equilibrium setting. We recognize the finite speed of propagation of the solution in $L^\infty_{v,p}L^\infty_x$ and $L^2_vL^\infty_x$.

[02865] Global Transonic Solutions of Hot-Jupiter Model for exoplanetary atmosphere

Author(s) : Po-Chih Huang (Natonal Chung Cheng University)
Abstract : The hydrodynamic escape problem (HEP) for Hot Jupiter model, which is characterized by a inital-boundary value problem of Euler equation with exoplanetary gravity, heat, and tidal force cuased by star, is crucial for investigating the evolution of planetary atmospheres. In this paper, the global existence of transonic solutions to the HEP is established using the generalized Glimm method. The new version of Riemann and boundary-Riemann solvers, are provided as building blocks of the generalized Glimm method by inventing the contraction matrices for the homogeneous Riemann or boundary-Riemann solutions. The extended Glimm-Goodman wave interaction estimates are investigated for obtaining a stable scheme and the lower bound of the gas velocity, which matches the physical observation. The limit of approximation solutions serves as an entropy solution of bounded variations. Moreover, the range of the feasible hydrodynamical region is also obtained.

[01545] Interplay between controllability and qualitative aspects of stochastic dynamical systems

Session Time & Room :

01545 (1/2) : 4D (Aug.24, 15:30-17:10) @A207

01545 (2/2) : 4E (Aug.24, 17:40-19:20) @A207

Type : Proposal of Minisymposium
Abstract : This minisymposium highlights recent applications of control-theoretic methods in the study of problems arising in mathematical physics and engineering. Special attention is paid to the interplay between deterministic controllability of dynamical systems and qualitative properties of their counterparts driven by stochastic noise. Both, the regulation of dynamical systems via control forces, and the qualitative investigation of randomness in mathematical models, are strongly motivated by real-world applications. The talks will reflect on current challenges concerning finite-dimensional and infinite-dimensional stochastic systems, deterministic control theory, and the synergetic effects that arise when bringing both topics closer together.

[05477] Mixing via controllability

Format : Talk at Waseda University
Author(s) : Vahagn Nersesyan (NYU Shanghai)
Abstract : In this talk, we will review some recent results where controllability is used to derive mixing for PDEs perturbed by bounded noise.

[05602] Multi-bubble blow-ups and multi-solitons to focusing (stochastic) nonlinear Schrödinger equations

Format : Talk at Waseda University

Author(s) : Deng Zhang (Shanghai Jiao Tong University)

Abstract : In this talk we mainly review the recent results on multi-bubble blow-ups and multi-solitons to the focusing (stochastic) nonlinear Schrödinger equations. In the mass-critical case, the construction and conditional uniqueness of multi-bubble Bourgain-Wang type blow-up solutions will be presented, which provide new examples for the mass quantization conjecture. In the deterministic case without noise, this also provides new examples of non-pure multi-solitons (including dispersive part) for the soliton resolution conjecture. Furthermore, the refined uniqueness of pure multi-bubble blow-ups and multi-solitons in the very low asymptotic regime is obtained. At last, in both the mass critical and subcritical cases, the direct construction of stochastic multi-solitons will also be presented, particularly, in the absence of the classical pseudo-conformal symmetry.

[04445] Controllability results for a class of bilinear degenerate wave equations

Format : Talk at Waseda University

Author(s) : Piermarco Cannarsa (University of Rome Tor Vergata)Patrick Martinez (Université de Toulouse)Cristina Urbani (University of Rome Tor Vergata & Accademia Nazionale dei Lincei)

Abstract : I will present a result of exact controllability along the ground state for a degenerate wave equation by means of a bilinear control. We prove that there exists a threshold time T_0 such that: for $T > T_0$ (and $T = T_0$ and strong degeneracy) a classical controllability result can be achieved; for $T

[02831] Small-time approximate controllability for nonlinear Schrödinger equations via bilinear controls

Format : Talk at Waseda University

Author(s) : Alessandro Duca (Centre Inria Nancy - Grand Est)

Abstract : Consider the nonlinear Schrödinger equation (NLS) on a torus of arbitrary dimension in presence of an external potential field whose time-dependent amplitude plays the role of control. We ensure the approximate controllability between eigenstates in arbitrarily small time with respect to the L^2-norm. We use specific saturation properties to develop a multiplicative version of the geometric approach introduced for additive controls by Agrachev and Sarychev.

01545 (2/2) : 4E @A207 [Chair: Manuel Rissel]

[03022] Small-time control of bilinear PDEs via infinite-dimensional Lie brackets

Format : Online Talk on Zoom

Author(s) : Eugenio Pozzoli (Università di Bari)

Abstract : We consider PDEs with multiplicative control terms, such as Schrödinger, heat and wave equations. Following a bilinear control strategy recently introduced by Duca and Nersesyan, that is a small-time asymptotic of conjugated dynamics, we investigate some approximate controllability properties of these systems, which hold in arbitrarily small times. We moreover comment on the relation between the controllability properties of the systems and the Lie brackets (a.k.a. commutators) of the operators that generate the dynamics.

[01547] Optimization in BV and Measure Spaces: Theory and Algorithms

Session Time & Room :

01547 (1/3) : 1C (Aug.21, 13:20-15:00) @F402

01547 (2/3) : 1D (Aug.21, 15:30-17:10) @F402

01547 (3/3) : 1E (Aug.21, 17:40-19:20) @F402

Type : Proposal of Minisymposium
Abstract : We consider optimization problems that are posed in the space of Radon measures as well as the space of functions of bounded variation. We present recent theoretical advances, in particular with respect to optimization problems that involve integrality conditions on the distributed optimization variables. These include approximation results in function space that are based on Gamma-convergence, optimality conditions, and consistent discretization schemes. Moreover, the presentations also include recent algorithmic convergence analysis and discrete and stochastic algorithms that allow for efficient solutions of the arising subproblems.

[02974] Proximal methods for point source localisation

Format : Talk at Waseda University
Author(s) : Tuomo Valkonen (Escuela Politécnica Nacional & University of Helsinki)
Abstract : Point source localisation is generally modelled as a Lasso-type problem on measures. However, optimisation methods in such non-Hilbert spaces are not yet very well understood. Most numerical algorithms are based on the Frank-Wolfe conditional gradient method. We develop extensions of proximal-type methods to spaces of measures. This includes forward-backward splitting, its inertial version, and primal-dual proximal splitting. Their convergence proofs follow standard patterns. We demonstrate their numerical efficacy.

[04816] Nonsmooth minimization in Banach spaces meets sparse dictionary learning

Format : Talk at Waseda University
Author(s) : Daniel Walter (Humboldt Universität zu Berlin)
Abstract : We propose a novel method for problems involving nonsmooth regularization terms over infinite dimensional function spaces . It resembles a dictionary learning algorithm which updates a dictionary $\mathcal{A}_k$ of extremal points of the unit ball of the regularizer and of a sparse represenation of the iterate u_k in its conic hull. Imposing additional assumptions on the dual variables, its asymptotic linear convergence is shown.

[04270] L^q-quasinorm sparse optimal control problems with controls in BV functions

Format : Talk at Waseda University
Author(s) : Pedro Martín Merino (Escuela Politécnica Nacional)
Abstract : We consider an elliptic optimal control of elliptic linear partial differential equations that involves a nonconvex regularization in terms of the L^q quasi–norm (with q in (0, 1)) together with a TV penalization in the cost function, given by:

$\mathcal{F}(y,u) = \frac{1}{2}\|y-y_d\|^2_{L^2(\Omega)} + \frac{\alpha}{2}\|u\|^2_{L^2(\Omega)} + \beta\int_\Omega |u|^q dx + \gamma\int_\Omega |Du|,$
where u is control and y are the control and state variables, respectively.

When $\gamma = 0$, the classical direct method fails to argue the existence of solutions due to the lack of lower semicontinuity of $\mathcal{F}$. However, given the topological properties of $BV(\Omega)$ and the continuity of the L^q-quasinorm in $L^1(\Omega)$, the existence of solutions can be obtained for controls in $BV(\Omega)$. In this talk, we address the optimality conditions for this problem and a numerical approach for its numerical solution based on primal-dual splitting methods.

[04282] Robust Optimal Experimental Design for Bayesian Inverse Problems

Format : Talk at Waseda University
Author(s) : Ahmed Attia (Argonne National Laboratory)Todd Munson (Argonne National Laboratory)Sven Leyffer (Argonne National Laboratory)
Abstract : An optimal design is defined as the one that maximizes a predefined utility function which is

formulated in terms of the elements of an inverse problem. An example being optimal sensor placement for parameter identification. This formulation generally overlooks misspecification of the elements of the inverse problem such as the prior or the measurement uncertainties. In this talk, we present efficient recipes for designing optimal experimental design schemes, for Bayesian inverse problems, such that the optimal design is robust with respect to misspecification of elements of the inverse problem.

01547 (2/3) : 1D @F402 [Chair: Paul Manns]

[03634] Opial property in Wasserstein spaces and applications

Format : Talk at Waseda University
Author(s) : Emanuele Naldi (TU Braunschweig)
Abstract : The Opial property is a metric characterization of weak convergence for a suitable class of Banach spaces. It plays an important role in the study of weak convergence of iterates of mappings and of the asymptotic behavior of nets satisfying some metric properties. Since it involves only metric quantities, it is possible to define this property also in metric spaces provided with a suitable notion of weak convergence. This is the case for spaces of probability measures endowed with the Kantorovich-Rubinstein-Wasserstein metric deriving by optimal transport. In particular, in this talk, we present an Opial property in the Wasserstein space of Borel probability measures with finite quadratic moment on a separable Hilbert space. We present applications of this property to convergence of Wasserstein gradient flows of lower semicontinuous and geodesically convex functionals defined on the space of probability measures. We show further application to convergence of sequences generated by the proximal point algorithm and a proximal gradient algorithm when the functional satisfy some additional hypothesis. We conclude with one last application of the property to convergence to a fixed point for iterations of a non-exapansive map defined on a weakly closed set.

[03671] An Optimal Transport-based approach to Total-Variation regularization for the Diffusion MRI problem

Format : Talk at Waseda University
Author(s) : Rodolfo Assereto (University of Graz)Kristian Bredies (University of Graz)Marion I. Menzel (GE Global Research, Munich)Emanuele Naldi (TU Braunschweig)Claudio Mayrink Verdun (TU München)
Abstract : Diffusion Magnetic Resonance Imaging (dMRI) is a non-invasive imaging technique that draws structural information from the interaction between water molecules and biological tissues. Common ways of tackling the derived inverse problem include, among others, Diffusion Tensor Imaging (DTI), High Angular Resolution Diffusion Imaging (HARDI) and Diffusion Spectrum Imaging (DSI). However, these methods are structurally unable to recover the full diffusion distribution, only providing partial information about particle displacement. In our work, we introduce a Total-Variation (TV) regularization defined from an optimal transport perspective using 1-Wasserstein distances. Such a formulation produces a variational problem that can be handled by well-known algorithms enjoying good convergence properties, such as the primal-dual proximal method by Chambolle and Pock. It allows for the reconstruction of the complete diffusion spectrum from measured undersampled k/q space data.

[04791] A minimization problem in the space of bounded deformations arising in visco-plastic fluid flows

Format : Talk at Waseda University
Author(s) : Lukas Holbach (Johannes Gutenberg University Mainz)Christian Meyer (TU Dortmund)Georg Stadler (New York University)
Abstract : Plasticity and material failure play an important role in Earth's plate motion. These phenomena are commonly modeled by incompressible Stokes flows with visco-plastic rheologies. Weak solutions of these nonlinear equations can be characterized as minimizers of a convex energy functional. While the solution is unique and lies in H^1 if a lower-bound regularization on the viscosity is employed, the problem becomes singular without regularization and the solution must be sought in the space of bounded deformations (BD).

We present an existence result in BD and show that the regularized solutions converge to a solution of the singular problem with respect to a suitable topology when the regularization parameter tends to zero.

01547 (3/3) : 1E @F402 [Chair: Paul Manns]

[03554] Solving Discrete Subproblems of a Trust-Region Algorithm for MIOCP

Format : Talk at Waseda University
Author(s) : Marvin Severitt (TU Dortmund University)Paul Manns (TU Dortmund University)
Abstract : We consider a trust-region algorithm for the solution of control problems, where the control input is an integer-valued function and is regularized with a total variation term in the objective. A class of integer linear programs arises as discretizations of the trust-region subproblems. We discuss how, in the one-dimensional case, the discretized subproblems can be solved with a graph-based approach and how the information obtained can be used for the two-dimensional case.

[03555] Regularization and outer approximation for optimal control problems in BV

Format : Talk at Waseda University
Author(s) : Annika Müller (TU Dortmund University)Christian Meyer (TU Dortmund University)
Abstract : We consider optimal control problems with a constraint on the TV-seminorm of the control. We replace the TV-seminorm by a regularized version and solve the resulting optimization problems with an outer approximation algorithm. We prove convergence of the algorithm to the globally optimal solutions, which in turn converge to the optimal solution to the original problem as the regularization parameter vanishes.

[03256] On integer optimal control problems with total variation regularization

Format : Talk at Waseda University
Author(s) : Jonas Marko (BTU Cottbus-Senftenberg)Gerd Wachsmuth (BTU Cottbus-Senftenberg)
Abstract : We investigate integer optimal control problems of the form

Minimize $\quad F(u) + \beta \mathrm{TV}(u) \quad \text{s.t.} \quad u(t) \in \{\nu_1, \ldots, \nu_d\} \subset \mathbb{Z}$ for a.a. $t \in (0, T)$
with $\beta > 0$. The contribution F is assumed to be differentiable and could e.g. realize the tracking of the state given by an ODE or PDE dependent on u.

We show local optimality conditions of first and second order as well as non-local optimality conditions. Also, we will calculate numerical solutions exemplary on two specific control problems.

[04006] Non-uniform Grid Refinement for the Combinatorial Integral Approximation

Format : Talk at Waseda University
Author(s) : Christoph Hansknecht (TU Clausthal)Paul Manns (TU Dortmund University)
Abstract : We examine mixed-integer optimal control problems (MIOCP) with a discrete-valued control variable distributed on a two-dimensional domain.

We compute integral controls by rounding fractional ones according to the combinatorial integral approximation (CIA) framework with switching costs modeling total variation. The rounding problem becomes computationally challenging in two dimensions, leading us to examine both heuristic and exact solution approaches, reducing the number of problem variables based on non-uniform grid refinements.

[01605] Recent advances in computational methods for kinetic and hyperbolic equations

Session Time & Room :

01605 (1/2) : 5B (Aug.25, 10:40-12:20) @E702

01605 (2/2) : 5C (Aug.25, 13:20-15:00) @E702

Type : Proposal of Minisymposium

Abstract : In recent years, there have been significant advances in computational algorithms for kinetic and hyperbolic equations. New methods have been designed that can achieve efficient simulations while preserving key structures of the underlying solutions. This minisymposium will bring experts in this area to present some key advances, including numerical methods and model reduction for wave equations and kinetic equations. Novel schemes and their properties will be discussed with applications in electromagnetic waves, plasma simulations and applications in gas dynamics and nuclear engineering.

[03143] A Natural Model Reduction Framework for Kinetic Equations

Format : Talk at Waseda University
Author(s) : Ruo Li (Peking University)
Abstract : To investigate a kinetic equation with prescribed low dimensional input data set, the solutions provided by the equation has to be confined in a low dimensional manifold. We propose in this article a natural framework for the model reduction of the kinetic equation with such the setup that an approximate solution manifold with finite dimension is available. The method results in a symmetric hyperbolic system automatically with natural assumptions. As the applications of the framework, we present some interesting cases, some of which gives brand-new models with elegant features. A few essential factors, including conservative quantities and entropy increasing, can be discussed in terms of the properties of the approximate the solution manifold.

01622 (1/3) : 3D (Aug.23, 15:30-17:10) @D408

01622 (2/3) : 3E (Aug.23, 17:40-19:20) @D408

01622 (3/3) : 4C (Aug.24, 13:20-15:00) @D408

Type : Proposal of Minisymposium
Abstract : Weather is a good example of large-scale chaotic complex systems, with a strong sensitivity to initial conditions tied to the intrinsic limit to predictability. The sensitivity suggests effective control in which small modifications to the atmospheric conditions grow rapidly and result in big changes. Weather predictability has been studied extensively in the past decades, and prediction skills have been improving. With accurate weather prediction, we are now ready to study weather controllability. This mini-symposium consists of solicited presentations about the mathematics behind the predictability and controllability of complex systems such as weather and other problems.

[02251] Sequential data assimilation and data driven control

Format : Online Talk on Zoom
Author(s) : Sebastian Reich (University of Potsdam)
Abstract : Sequential data assimilation can be considered a coupling of measure problem which can be tackled using optimal transport or Schroedinger bridges. In this talk, we will present an approximate bridging approach

which leads to a data-driven term being added to the underlying model dynamics. The added control term is of mean-field type and can be implemented easily within a Monte Carlo context. The control term is also closely related to continuous time ensemble Kalman-Bucy filter formulations. One can extend the proposed controlled DA approach to cost functions other than those derived from the data likelihood.

[02790] Data-driven Reconstruction of Partially Observed Dynamical Systems

Format : Talk at Waseda University
Author(s) : Pierre Tandeo (IMT Atlantique)Pierre Ailliot (Univ. Brest)Florian Sévellec (CNRS)
Abstract : The goal of this work is to obtain predictions of a partially observed dynamical system, without knowing the model equations. To account to those strong assumptions, a combination of machine learning and data assimilation techniques is proposed with the introduction of latent variables. We find that the latent variables inferred by the procedure are related to the successive derivatives of the observed components of the dynamical system.

[02800] Sensor selection by greedy method for linear dynamical systems

Format : Talk at Waseda University
Author(s) : Shun Takahashi (Tokai University)Kumi Nakai (National Institute of Advanced Industrial Science and Technology)Takayuki Nagata (Tohoku University)Keigo Yamada (Tohoku University)Yasuo Sasaki (Tohoku University)Yuji Saito (Tohoku University)Taku Nonomura (Tohoku University)
Abstract : Sensor optimization using a greedy method based on the snapshot-to-snapshot Fisher information matrix, observability Gramian, and Kalman filter indices in linear time-invariant systems is discussed. The objective functions and computational times are compared for the resulting sensor sets with a background of application to sensor selection in large systems.

[02804] Fast Linear-regression-based Sensor Selection and its Applications

Format : Talk at Waseda University
Author(s) : Yasuo Sasaki (Tohoku University)Yuji Saito (Tohoku University)Takayuki Nagata (Tohoku University)Keigo Yamada (Tohoku University)Taku Nonomura (Tohoku University)
Abstract : We consider a ridge-regression-based sensor selection problem in which sensors are selected so that dependent variables can be estimated as easily as possible. For this problem, a fast greedy algorithm is derived by means of one-rank update law of covariance matrices. To verify the effectiveness of this greedy algorithm, it is applied to sensor selection for estimation of the sea surface temperature and for optimal feedback control of flow around a circular cylinder.

01622 (2/3) : 3E @D408 [Chair: Sebastian Reich]

[02789] Identifying Coherent Structures within Turbulent Flows over Roughness Obstacles

Format : Talk at Waseda University
Author(s) : Tetsuya Takemi (Kyoto University)
Abstract : Large-eddy simulations for turbulent flows over roughness obstacles are conducted to investigate the characteristics of coherent structures within turbulent flows for a possible application for controlling flow structures in urban districts. Idealized and realistic urban districts are examined as rough surfaces. Turbulence and dispersion properties associated with coherent structures are demonstrated. Understanding such properties will lead to identify an approach to control flows within urban districts.

[02825] Quantifying Weather Controllability and Mitigatable Flood Damage Based on Ensemble Weather Forecast

Format : Talk at Waseda University
Author(s) : Shunji Kotsuki (Chiba University)
Abstract : For realizing a weather-controlled society, we need to discuss the way to maximize the effect of manipulations to the atmosphere. For that purpose, this project aims at developing methods that quantify weather controllability and mitigatable flood damage based on ensemble weather forecasts. To quantify weather controllability, this project investigates meteorological landscapes that separate disaster and non-disaster regimes

which may be controllable with small manipulations. We also estimate economic damages under non-controlled/controlled scenarios, in order to quantify avoidable damage by weather control.
We have started illustrating directed graphs as the first step in understanding the meteorological landscape. Typhoon Prapiroon in 2018 was used for the case study. Singular value decomposition (SVD) is employed for Japan Meteorological Agency's operational meso-scale ensemble prediction data to extract principle components of atmospheric states, followed by a clustering using density-based spatial clustering of applications with noise known as DBSCAN. The illustrated graph succeeded in detecting separated two clusters that correspond to faster and slower movements of predicted Parapiroon. The developed algorithm is currently applied to other disastrous events as well as further investigations on non-linear data compression methods beyond SVD. This presentation includes the most recent achievements up to the time of the conference.

[02885] Ensemble sensitivity and its potential applications in weather control

Author(s) : Le Duc (University of Tokyo)Yohei Sawada (University of Tokyo)
Abstract : Ensemble sensitivity has been proved to be a very useful sensitivity measure in practice. In this study, we show the relevance of ensemble sensitivity in another important problem. We have proved that changes of the forecast response are maximized along the direction of the vector consisting of ensemble sensitivities which forms the most sensitive perturbation. We will demonstrate how the new understanding on ensemble sensitivities can qualitatively give potential solutions for weather control.

[02518] Chaos implies effective controllability of extreme weather

Format : Talk at Waseda University
Author(s) : Takemasa Miyoshi (RIKEN)Qiwen Sun (RIKEN)Koji Terasaki (RIKEN)Yasumitsu Maejima (RIKEN)
Abstract : Since the weather system is chaotic, and even more so for storms, small differences generally lead to big differences, particularly for high-impact weather events. This presentation will summarize the concept and methodology of Control Simulation Experiment (CSE) with some proof-of-concept demonstrations with toy models and realistic Numerical Weather Prediction (NWP) models. This is an attempt to a potential paradigm change of NWP research from decades of predictability to the new era of controllability.

01622 (3/3) : 4C @D408 [Chair: Takashi Sakajo]

[02814] Noise Calibration for the Stochastic Rotating Shallow Water Equations

Format : Talk at Waseda University
Author(s) : Alexander Lobbe (Imperial College London)Oana Lang (Imperial College London)Dan Crisan (Imperial College London)Peter Jan van Leeuwen (Colorado State University)Roland Potthast (Deutscher Wetterdienst DWD)
Abstract : We introduce a new method of noise calibration of the Stochastic Rotating Shallow Water (SRSW) model which is rigorously derived from a model reduction technique. The method is generic and can be applied to arbitrary stochastic models. In the (SRSW) case, we calibrate the noise by using the pressure variable of the model, as this is an observable easily obtainable in practical application.

[03049] Machine learning-based estimation of state-dependent forecast uncertainty

Format : Talk at Waseda University
Author(s) : Juan Jose Ruiz (University of Buenos Aires)Maximiliano Sacco (National Meteorological Service of Argentina)Manuel Pulido (Universidad Nacional del Nordeste)Pierre Tandeo (IMT Atlantique)
Abstract : Quantifying forecast uncertainty is a key aspect of state-of-the-art numerical weather prediction and data assimilation systems. State dependent uncertainty quantification in numerical weather prediction is a computation intensive task which has been performed using different approaches such as monte carlo sampling (ej. ensemble Kalman filter) and variational approaches (ej. adjoint based model sensitivity). Machine learning techniques consist of trainable statistical models that can represent complex functional dependencies among different groups of variables given a large enough dataset. In this talk we will describe the use of a machine learning approach based on neural networks for the estimation of forecast uncertainty. In particular, we will discuss the estimation of the forecast error covariance matrix, which is at the center of probabilistic forecasting and data assimilation systems. In addition, we will present a hybrid data assimilation method that combines the

optimal interpolation technique and a convolutional neural network to estimate the state dependent forecast error covariance matrix.

[03126] Observability of continuous-time Markov model and filter stability

Format : Talk at Waseda University
Author(s) : JIN WON KIM (University of Potsdam)
Abstract : In control theory, estimation and control are considered as dual problems. A fundamental relationship is the duality between controllability and observability, and it extends to Kalman filter and a linear quadratic control problem. Our contribution is to extend the duality to nonlinear models. I will review the classical duality and present the dual optimal control problem. The dual formulation is used to analyze the stability of the nonlinear filter, similar to the linear Gaussian case.

[03024] On random feature maps in prediction

Format : Talk at Waseda University
Author(s) : Nicholas Cranch (University of Sydney)Georg A. Gottwald (University of Sydney)Sebastian Reich (University of Potsdam)
Abstract : Random feature maps (RFs) can be viewed as a single hidden layer network in which the weights of the hidden layer are fixed. We show how the choice of the internal weights effects performance and generalisation. We propose how to best choose the internal weights. We show that RFs allow for sequential learning when combined with data assimilation, and can be used to learn subgridscale parametrizations and to detect critical transitions.

[01661] Recent Development on the Methods and Applications of Complex PDE systems

Session Time & Room :

01661 (1/2) : 2D (Aug.22, 15:30-17:10) @E606

01661 (2/2) : 2E (Aug.22, 17:40-19:20) @E606

Type : Proposal of Minisymposium
Abstract : Complex partial differential equations have been widely applied to different areas to understand the spatiotemporal dynamics of multiple interactive components, such as reaction-diffusion equations for modeling diffusive molecules in biology, Navier-Stokes equations for modeling fluid dynamics. Traditional numerical approaches may fail when applied to PDE models in applications due to specific features of application problems. In this minisymposium, we will focus on the recent development of new numerical approaches and applications of different PDE systems. The goal of this session is to bring together researchers in numerical PDEs and mathematical models to exchange ideas and explore collaborations.

[04291] A learned conservative semi-Lagrangian finite volume scheme for transport simulations

Format : Talk at Waseda University
Author(s) : Wei Guo (Texas Tech University)Yongsheng Chen (Zhejiang University)Xinghui Zhong (Zhejiang University)
Abstract : Semi-Lagrangian (SL) schemes are known as a major numerical tool for solving transport equations with many. In this talk, we introduce a novel machine learning-assisted approach to accelerate the conventional SL finite volume schemes. The proposed scheme avoids the expensive tracking of upstream cells but attempts to learn

the SL discretization from the data by incorporating specific inductive biases in the neural network, significantly simplifying the algorithm implementation and leading to improved efficiency.

[03990] A new type of simplified inverse Lax-Wendroff boundary treatment for hyperbolic conservation laws

Format : Talk at Waseda University
Author(s) : Shihao Liu (University of Science and Technology of China)Tingting Li (Henan University)Ziqiang Cheng (Hefei University of Technology)Yan Jiang (University of Science and Technology of China)Chi-Wang Shu (Brown University)Mengping Zhang (University of Science and Technology of China)
Abstract : In this talk, we will introduce a new kind of high order inverse Lax-Wendroff (ILW) boundary treatment for solving hyperbolic conservation laws with finite difference method on a Cartesian mesh, in which both scalar equations and systems are considered. This new ILW method decomposes the construction of ghost points into two steps: interpolation and extrapolation. At first, we approximate some special points value through interpolation polynomial given the interior points near boundary. Then, we will construct a Hermite extrapolation polynomial based on those special point values and spatial derivatives at boundary obtained through ILW process. This extrapolation polynomial will give us the approximation of the the ghost points value. Eigenvalue analysis shows that the new method can improve the computational efficiency on the premise of maintaining accuracy and stability. Numerical tests for one- and two-dimensional problems indicate that our method has high order accuracy for smooth solutions and non-oscillatory property for shock solution near boundary.

[02713] Transmission Dynamics of Tuberculosis with Age-specific Disease Progression

Format : Talk at Waseda University
Author(s) : Wing-Cheong Lo (City University of Hong Kong)
Abstract : In this talk, we develop a system of delay partial differential equations to model tuberculosis transmission in a heterogeneous population. The system considers demographic structure coupling with the continuous development of the disease stage. We determine the basic reproduction number and several numerical simulations are used to investigate the influence of various progression rates on tuberculosis dynamics. This is joint work with Yu Mu, Tsz-Lik Chan, and Hsiang-Yu Yuan.

[02985] Extended-release Pre-Exposure Prophylaxis and Drug Resistant HIV

Format : Talk at Waseda University
Author(s) : Yanping Ma (Loyola Marymount University)Yeona Kang (Howard University)Angelica Davenport (Florida State University)Jennifer Aduamah (University of Delaware)Kathryn Link (Pfzier)Katharine Gurski (Howard University)
Abstract : We present a within-host, mechanistic Differential Equation model of the HIV latency and infection cycle in CD4+ T-cells to investigate drug-resistant mutations. We develop a pharmacokinetic/pharmacodynamic model for long-acting cabotegravir (CAB-LA, injectable PrEP) to relate the inhibitory drug response to the drug concentration in plasma and rectal, cervical, and vaginal fluids and tissue. And we will report some of our important findings in the talk.

01661 (2/2) : 2E @E606 [Chair: Weitao Chen]

[04493] A Level-Set Framework for Implicit Solvation

Format : Talk at Waseda University
Author(s) : Li-Tien Cheng (UC San Diego)
Abstract : Implicit solvation involves the study of the effects solute atoms have on a surrounding solvent, which can be particularly important in, for example, the process of protein docking. An implicit treatment of the solvent gives rise to an interface between solute and solvent. We introduce a level-set framework applied to a variational free-energy setup for constructing such an interface, and consider efficient and accurate solvers in the presence of curvature, electrostatic, and mechanical effects.

[04909] Adaptive ANOVA and reduced basis methods to anisotropic stochastic PDEs

Format : Talk at Waseda University
Author(s) : Heyrim Cho (University of California Riverside)Bedřich Sousedík (University of Maryland, Baltimore County)Howard Elman (University of Maryland, College Park)
Abstract : The combination of reduced basis and collocation methods enables efficient and accurate evaluation of the solutions to parameterized PDEs. We study the stochastic collocation methods that can be combined with reduced basis methods to solve high-dimensional parameterized stochastic PDEs. We also propose an adaptive algorithm using a probabilistic collocation method (PCM) and ANOVA decomposition. This procedure involves two stages. First, the method employs an ANOVA decomposition to identify the effective dimensions, i.e., subspaces of the parameter space in which the contributions to the solution are larger, and sort the reduced basis solution in a descending order of error. Then, the adaptive search refines the parametric space by increasing the order of polynomials until the algorithm is terminated by a saturation constraint. We demonstrate the effectiveness of the proposed algorithm for solving a stationary stochastic convection-diffusion equation, a benchmark problem chosen because solutions contain steep boundary layers and anisotropic features. We also solve the Stokes-Brinkman equations that model fluid flow in highly heterogeneous porous media.

[04915] Theoretical Principles of Enhancer-Promoter Communication in Gene Expression

Format : Talk at Waseda University
Author(s) : Jiajun Zhang (Sun Yat-sen University)
Abstract : Recent experimental evidence strongly supports that long-range enhancer-promoter interactions have important influences on gene-expression dynamics, but it is unclear how the interaction information is translated into gene expression over time. To address this challenge, we develop a general theoretical framework that integrates chromatin dynamics, enhancer-promoter communication, and gene-state switching to study gene expression. Our model and results provide quantitative insight into both spatiotemporal gene-expression determinants and cellular fates during development.

[01671] Financial Modeling

Session Time & Room :

01671 (1/2) : 2D (Aug.22, 15:30-17:10) @D502

01671 (2/2) : 2E (Aug.22, 17:40-19:20) @D502

Type : Proposal of Minisymposium
Abstract : Financial activities are principally based on a variety of models, which have been modified over times according to the change of financial situation as well as the change of financial regulation. The corresponding stochastic mathematical models are also adjusted. In recent years, disaster risk financing and insurance strategy are of importance. In this minisymposium, we present researches of various aspects of financial modeling, from basic theory to real world problems.

[05403] Insurance design for the loss of epidemic outbreaks involving the Cramer -Lundberg model

Format : Talk at Waseda University
Author(s) : Naoyuki Ishimura (Chuo University)Chenwei Sun (Chuo University)Koichiro Takaoka (Chuo University)
Abstract : We consider the insurance design for the loss of epidemic outbreaks such as COVID-19. The new point of our model is to involve the Cramer-Lundberg process in the risk theory. Utilizing the standard time-discrete SIR

model, we propose how to compute the insurance coverage due to the damage of epidemic bursts. The comparison between our theory and the empirical study employing the daily data of Tokyo area will be also discussed.

[02749] Micro-foundations of some financial models with bubbles

Format : Talk at Waseda University
Author(s) : Naohiro Yoshida (Keiai University)
Abstract : This presentation will discuss the micro-foundation of some financial models with bubbles.
The micro-foundation discussed is the excess demand model. In other words, the amount of demand for and supply of a security by each investor in the market are formulated, and the price of the security is determined so that they satisfy the market-clearing condition.
The main objective of this presentation is to propose some excess demand models of financial models with bubbles. We will discuss what characteristics of investor's demand and supply cause bubbles.

[02787] An Ito-Wentzell Formula for SDE Conditional Measure Flows

Format : Talk at Waseda University
Author(s) : Nizar Touzi (CMAP, Ecole Polytechnique)Assil Fadle (CMAP, Ecole Polytechnique)
Abstract : We provide general Ito and Ito-Wentzell formulas for functions of conditional measure flows of continuous semimartingales, using functional linear derivatives and standard stochastic analysis results. We provide applications for mean field optimal control and mean field optimal stopping with common noise.

[04500] A Generalized Cram{¥'e}r-Lundberg Model Driven by Mixed Poisson Processes

Format : Talk at Waseda University
Author(s) : Masashi Tomita (Meiji Yasuda Life Insurance Company)Koichiro Takaoka (Chuo University)Motokazu Ishizaka (Chuo University)
Abstract : We propose a generalized Cram{'e}r-Lundberg model of the risk theory of non-life insurance and discuss several mathematical properties including the ruin probability. Our model is an extension of that of Dubey (1977) to the case of multiple insureds, where the counting process is a mixed Poisson process and the continuously varying premium rate is determined by a Bayesian rule on the number of claims.

01671 (2/2) : 2E @D502

[01672] High accuracy compact methods for partial differential equations

Session Time & Room :

01672 (1/2) : 3C (Aug.23, 13:20-15:00) @E704

01672 (2/2) : 3D (Aug.23, 15:30-17:10) @E704

Type : Proposal of Minisymposium
Abstract : This minisymposium brings together researchers developing high accuracy compact finite difference schemes for the solution of a variety of partial differential equations. One of the aims of this minisymposium is to examine the progress made on the solution of a variety of fluid flow problems.

[05366] Spectral Element Method for Parabolic Problems with Corner Singularities

Format : Talk at Waseda University
Author(s) : Sanuwar Ahmed Choudhury (National Institute of Technology Silchar Assam India)Pankaj Biswas (National Institute of Technology Silchar Assam India)
Abstract : In many engineering applications, reconstruction of temperature generated from incomplete data causes corner singularities. In such cases, a solution of parabolic initial-boundary-value-problems(IBVP) on nonsmooth-domains is required. Spectral-element methods give exponential accuracy for smooth solutions. Generating geometric meshes at the neighborhood of the corners on the space-domain a parallel least-squares-spectral-element-method using MPI is presented here to resolve the singularities. Numerical scheme has been developed in the frame-work of Sobolev spaces and examples are presented to validate the estimates.

[01681] Recent advances in numerical methods for partial differential equations

Session Time & Room :

01681 (1/3) : 1C (Aug.21, 13:20-15:00) @E711

01681 (2/3) : 1D (Aug.21, 15:30-17:10) @E711

01681 (3/3) : 1E (Aug.21, 17:40-19:20) @E711

Type : Proposal of Minisymposium
Abstract : Partial differential equations are a family of powerful mathematical tools to model the physical world. In many practical situations, it is generally very difficult to obtain their analytical solutions, and thus numerical methods become critical for simulation. This mini-symposium aims to bring together scholars to discuss the recent advances and innovative techniques in this field including finite element exterior calculus, physics-preserving schemes, polytopal meshes and high-order methods. The mini-symposium will also deal with the applications onto electromagnetism, fluid dynamics and interface problems.

[03945] Geometrical degrees of freedom for high order Whitney forms

Format : Talk at Waseda University
Author(s) : Ana María Alonso Rodríguez (University of Trento)Francesca Rapetti (Université Côte d’Azur)Ludovico Bruni Bruno (Università dell'Insumbria)
Abstract : Finite element spaces extending Whitney forms to higher polynomial degrees are widely used for discretizing partial differential equations in electromagnetism, fluid dynamics or elasticity, and different degrees of freedom (dofs) can be considered for interpolation. In particular the so-called weights preserve the meaning of the natural degrees of freedom associated with Whitney forms as circulation, fluxes or densities since they are the integrals of a k-form on k-chains. Weights are a generalization of the evaluations of a scalar function at a set of nodes in view of its reconstruction on multivariate polynomial bases and allows to extend in a natural way well-known concepts as the Lebesgue constant. We rely on the flexibility of the weights with respect to their geometrical support to reduce the growth of the Lebesgue constant when increasing the degree of the polynomial interpolation of differential k-forms.

[02919] Energy-preserving Mixed finite element methods for a ferrofluid flow model

Format : Talk at Waseda University
Author(s) : Yongke Wu (University of Electronic Science and Technology of China)Xiaoping Xie (Sichuan University)
Abstract : In this talk, we introduce a class of mixed finite element methods for the ferrofluid flow model proposed by Shliomis [Soviet Physics JETP, 1972]. We show that the energy stability of the weak solutions to the model is preserved exactly for both the semi- and fully discrete finite element solutions. Furthermore, we prove the existence of the discrete solutions and derive optimal error estimates for both the the semi- and fully discrete schemes. Numerical experiments confirm the theoretical results.

[03132] Immersed CR element methods for the elliptic and Stokes interface problems

Format : Talk at Waseda University
Author(s) : Haifeng Ji (Nanjing University of Posts and Telecommunications)FENG WANG (NanJing Normal University)Jinru Chen (NanJing Normal University)Zhilin Li (North Carolina State University)
Abstract : In this talk, we shall discuss the immersed CR element method for solving the elliptic and Stokes interface problems with piecewise constant coefficients that have jumps across the interface. In the method, the triangulation does not need to fit the interface and the IFE spaces are constructed from the traditional CR element with modifications near the interface according to the interface jump conditions. The stability and the optimal error estimates of the proposed methods are also derived rigorously. The constants in the error estimates are shown to be independent of the interface location relative to the triangulation. Numerical examples are provided to verify the theoretical results.

[02917] A fast Cartesian grid method for unbounded interface problems with non-homogeneous source terms

Format : Talk at Waseda University
Author(s) : Jiahe Yang (Shanghai Jiao Tong University)Wenjun Ying (Shanghai Jiao Tong University)
Abstract : A Cartesian grid method is presented for interface problems of PDEs with non-homogeneous source terms on unbounded domains. The method adapts a compression-decompression technique and has algorithm complexity of only $O(n^2 \log n)$ as compared to $O(n^3)$ by traditional methods. This Cartesian grid method is an extension of the kernel-free boundary integral method, which avoids direct evaluation of singular or nearly singular integrals by reformulating them into solutions of equivalent but much simpler interface problems.

01681 (2/3) : 1D @E711 [Chair: Liuqiang Zhong]

[04905] Staggered DG methods for elliptic problems on general meshes

Format : Talk at Waseda University
Author(s) : Eun-Jae Park (Yonsei University)
Abstract : In this talk, we present our recent framework on staggered DG methods for elliptic equations on general meshes, which can be flexibly applied to rough grids such as highly distorted meshes. Adaptive mesh refinement is an attractive tool for general meshes due to their flexibility and simplicity in handling hanging nodes. We derive a simple residual-type error estimator. Numerical results indicate that optimal convergence can be achieved for both the potential and vector variables, and the singularity can be well-captured by the proposed error estimator. Then, some applications to Darcy-Forchheimer equations, Stokes equations, and linear elasticity equations are considered. This is joint work with Eric Chung, Dohyun Kim, Dong-wook Shin, and Lina Zhao.

[04160] Accelerated Gradient and Skew-Symmetric Splitting Methods for Monotone Operator Equations

Format : Online Talk on Zoom
Author(s) : Jingrong Wei (University of California, Irvine)Long Chen (University of California at Irvine)
Abstract : A class of monotone operator equations, which can be decomposed into sum of a gradient of a strongly convex function and a linear and skew-symmetric operator, is considered in this work. Based on discretization of the generalized accelerated gradient flow, accelerated gradient and skew-symmetric splitting (AGSS) methods are developed and shown to achieve linear rates with optimal lower iteration complexity when applied to smooth saddle point systems with bilinear coupling.

[03693] Solve electromagnetic interface problems on unfitted meshes

Format : Talk at Waseda University
Author(s) : Ruchi Guo (University of California Irvine)
Abstract : Electromagnetic interface problems widely appear in a lot of engineering applications, such as electric actuators, invasive detection techniques and integrated circuit， which are typically described by Maxwell equations with discontinuous coefficients. Conventional finite element methods require a body-fitted mesh to solve interface problems, but generating a high-quality mesh for complex interface geometry is usually very expensive. Instead using unfitted mesh finite element methods can circumvent mesh generation procedure, which greatly improve the computational efficiency. However, the low regularity of Maxwell equations makes its computation very senstive to the conformity of the approximation spaces. This very property poses challenges on unfitted mesh finite element methods, as most of them resort to non-conforming spaces. In this talk, we will present our recent progress including several methods for this topic.

[03714] Pressure-robust virtual element methods for the Stokes problem on polygonal meshes

Format : Talk at Waseda University
Author(s) : Gang Wang (Northwestern Polytechnical University)
Abstract : In this talk, we shall introduce two pressure-robust virtual element methods for the Stokes problem on polygonal meshes. The standard virtual element scheme involves a pressure contribution in the velocity error. To achieve the pressure-independent velocity approximation, we define an H(div)-conforming velocity reconstruction operator for the velocity test function and propose the modified scheme by employing it in the approximation of right-hand-side source term assembling. In the first method, we apply the H(div)-conforming elements on the polygons and construct a (theoretically) exactly pressure-robust virtual element scheme. Since basis functions of H(div)-conforming elements are not polynomials on general polygons, quadrature errors will affect the exact pressure-robustness in implementation. To solve it, we reconstruct a (theoretically and numerically) exactly pressure-robust virtual element scheme by designing H(div)-conforming element based on the sub-triangulation of polygon and the lowest-order Raviart-Thomas element. We give the error estimates of two methods and also show numerical examples to support our theories.

01681 (3/3) : 1E @E711 [Chair: Ruchi Guo]

[05142] Arbitrary order DG-DGLM method for hyperbolic systems of multi-dimensional conservation laws

Format : Talk at Waseda University
Author(s) : Mi-Young Kim (Inha University)
Abstract : An arbitrary order discontinuous Galerkin method with Lagrange multiplier in space and time is proposed to approximate the solution to hyperbolic systems of multi-dimensional conservation laws. Weak formulation is derived through the definition of weak divergence. Weak solution on the edge is characterized as the average of the solutions on the elements sharing the edge. Stability of the approximate solution is proved in a broken $L_2(L_2)$ norm. Error estimates of $O(h^r + k_n^q)$ with $P_r(E)$ and $P_q(J_n)$ elements $(r, q > 1 + d/2)$ are then derived in a broken $L_2(L_2)$ norm, where h and k_n are the maximum diameters of the elements and the time step of J_n, respectively, J_n is the time interval, and d is the dimension of the spatial domain. Some numerical examples are presented.

[04537] Implementation and Application of Virtual Element Method in FEALPy

Format : Talk at Waseda University
Author(s) : Huayi Wei HUAYI WEI (Xiangtan University)
Abstract : The virtual element method is a novel numerical solution technique for PDEs. It can be considered an extension of the finite element method to polygonal or polyhedral meshes. Due to its novelty, the program implementation of this method differs significantly from that of the traditional finite element method. Unfortunately, there are relatively few open-source program implementations available. FEALPy is an open-source numerical solution algorithm library for PDEs. It is built entirely on Python's basic scientific computing module and provides rich mesh data structures, meshes adaptive algorithms, and partial differential equation numerical discrete algorithms. This report primarily focuses on the design and implementation of the virtual element method in FEALPy, along with several typical application examples.

[05586] Convergence of an AWG method for indefinite time-harmonic Maxwell equations

Format : Talk at Waseda University
Author(s) : Yingying Xie (Guangzhou University)Liuqiang Zhong (South China Normal University)Ming Tang (South China Normal University)
Abstract : In this talk, an adaptive weak Galerkin (AWG) method for indefinite time-harmonic Maxwell equations is studied. Firstly, a residual type a posteriori error estimator is presented and analyzed. Then, a quasi-orthogonality is presented by introducing interpolator operators. And the convergence of AWG algorithm is also proved. Finally, some numerical experiments is provided to support the theoretical results.

[04955] High order stable generalized finite element method for interface problems

Format : Talk at Waseda University
Author(s) : Qinghui Zhang (Harbin Institute of Technology, Shenzhen)
Abstract : Generalized or Extended Finite Element Methods (GFEM/XFEM) of degree 1 (linear elements) for interface problems have been reported in the literature; they (i) yield optimal order of convergence in energy norm, i.e., O(h), (ii) are stable in a sense that conditioning is not worse than that of the standard FEM, and (iii) are robust in that the conditioning does not deteriorate as interface curves are close to boundaries of underlying elements. However, higher order GFEM/XFEM with the properties (i)-(iii) have not been successfully addressed yet. Various enrichment schemes for GFEM/XFEM based on D or DP_k (D is a distance function or the absolute value of level set function, and P_k is the polynomial basis of degree k) have been reported to obtain higher order convergence, but they are not stable or robust in general; in fact, they even may not yield the optimal orders of convergence. In this talk, we propose a stable GFEM/XFEM of degree 2 (SGFEM2) for the interface problems, where we use the enrichment scheme based on D{1, x, y}, instead of D or D{1,x, y, x^2, xy, y^2} in the literature. We prove that the SGFEM2 yields the optimal order of convergence, i.e., O(h^2), for the interface problems with curved (smooth) interfaces. A local principal component analysis technique is proposed, which ensures that the SGFEM2 is stable and robust. Numerical experiments for straight and curved interfaces have been presented to illuminate these properties.

[01718] On SDP relaxations of polynomial optimization

Session Time & Room :

01718 (1/2) : 3D (Aug.23, 15:30-17:10) @D501

[01976] Tightness conditions of SDP relaxation for QCQPs with bipartite graph structure

Format : Talk at Waseda University
Author(s) : Godai Azuma (Tokyo Institute of Technology)Mituhiro Fukuda (Federal University of ABC)Sunyoung Kim (Ewha Womans University)Makoto Yamashita (Tokyo Institute of Technology)
Abstract : We discuss a tightness condition of SDP, semidefinite programming, relaxation for QCQPs, quadratically-constrained quadratic programming problems, with bipartite graph structure, and this result generalizes that a condition that the SDP relaxation is tight for QCQPs with diagonal matrices due to Burer and Ye, and a condition based the signs of the elements in input data matrices analyzed by Sojoudi and Lavaei. Our condition to check the tightness of SDP relaxation demands to solve SDP systems, but it requires weaker assumptions than Sojoudi and Lavaei. Our approach also gives another proof for the tightness of SDP relaxations for QCQPs with off-diagonal nonpositive elements by converting such QCQPs into QCQPs with bipartite graph structure.

[02464] Equivalent Sufficient Conditions for Exact SDP Relaxation and the Saddle Point of Lagrangian Function of QCQP

Format : Talk at Waseda University
Author(s) : Sunyoung Kim (Ewha W. University)Masakazu Kojima (Chuo University)
Abstract : We study global optimality conditions for general quadratically constrained quadratic program (QCQP). For NP-hard nonconvex QCQP, there has been a great interest in the class of QCQPs whose global optimality can be obtained via convex relaxations. The exactness of optimal solutions of QCQP can determined by several methods: First, the optimal solution $X \in S^n_+$ of the semidefinite (SDP) relaxation of nonconvex QCQP is exact if its rank is 1 or the rank of dual optimal solution of the SDP relaxation is n-1 under strong duality. Second, the global optimality of solutions of QCQP can be also determined by the saddle point of the Lagrangian function of QCQP. Third, second-order sufficient condition for the global optimality can also be used. We examine the relationship among the three conditions and prove their equivalence. A QCQP instance is provided to illustrate the equivalent conditions.

[02214] Approximation Hierarchies for Copositive Cone over Symmetric Cone

Format : Talk at Waseda University
Author(s) : Mitsuhiro Nishijima (Tokyo Institute of Technology)Kazuhide Nakata (Tokyo Institute of Technology)
Abstract : We first provide an inner-approximation hierarchy described by a sum-of-squares constraint for the copositive cone over a general symmetric cone. We second provide inner- and outer-approximation hierarchies described by semidefinite but not by sum-of-squares constraints for the copositive cone over the direct product of a nonnegative orthant and a second-order cone. We also compare them with existing hierarchies. Numerical experiments show that, by combining them, we can solve copositive programming problems more accurately and efficiently.

[02008] An inexact projected gradient method with rounding and lifting for rank-one semidefinite relaxation of polynomial optimization

Format : Talk at Waseda University
Author(s) : Kim-Chuan Toh (National University of Singapore)Heng Yang (Harvard University)Ling Liang (National University of Singapore)Luca Carlone (MIT)
Abstract :
We consider solving high-order semidefinite programming (SDP) relaxations
of polynomial optimization problems (POPs) that often admit
degenerate rank-one optimal solutions. We propose
a new algorithmic framework that uses an inexact projected gradient method for solving the SDP, together with acceleration by
taking long, but safeguarded, rank-one steps generated by fast local solver for the underlying POP. Our framework

achieves state-of-the-art efficiency, scalability, and robustness in solving degenerate rank-one SDPs to high accuracy, even with millions of equality constraints.

01718 (2/2) : 3E @D501

[01768] Computer-assisted proofs in differential equations

Session Time & Room :

01768 (1/4) : 3C (Aug.23, 13:20-15:00) @G405

01768 (2/4) : 3D (Aug.23, 15:30-17:10) @G405

01768 (3/4) : 3E (Aug.23, 17:40-19:20) @G405

01768 (4/4) : 4C (Aug.24, 13:20-15:00) @G405

Type : Proposal of Minisymposium
Abstract : Several phenomena from biology, physics and chemistry are described by differential equations. While the presence of nonlinearities complicates the mathematical analysis, the challenges are greater for PDEs and delay equations, which are infinite dimensional. Numerics have therefore become the primary tool used by scientists, which leads to the question of validity of the outputs. To address this, the field of computer-assisted proofs (CAPs) in dynamics emerged at the intersection of scientific computing, nonlinear, numerical and functional analysis and approximation theory. This minisymposium will bring experts describing novel CAPs techniques to study cutting-edge problems in finite and infinite dimensional differential equations.

01768 (1/4) : 3C @G405 [Chair: Akitoshi Takayasu]

[04529] Numerical verification methods for ODEs with conservative quantity

Format : Talk at Waseda University
Author(s) : Nobito Yamamoto (The University of Electro-Communications)Koki Nitta (The University of Electro-Communications)
Abstract : We are treating ODEs with conservative quantity and interested in proving existence of time-global solutions remaining in a given sphere with common points on the surface. There is difficulty in computing the solution orbits for a long time due to drift between solutions of conservative systems.
Our method is based on verified computation of the conservative quantity and the flow on the surface of the sphere. Numerical examples derived from Schroedinger equation will be shown.

[04834] Computer-assisted Existence Proofs for Navier-Stokes Equations on an Unbounded Strip with Obstacle

Format : Talk at Waseda University
Author(s) : Michael Plum (Karlsruhe Institute of Technology)Jonathan Wunderlich (Karlsruhe Institute of Technology)
Abstract : The incompressible stationary 2D Navier-Stokes equations are considered
on an unbounded strip domain with a compact obstacle. A computer-
assisted existence and enclosure result for the velocity (in a suitable diver-
gence-free Sobolev space) is presented.
Starting from a numerical approximate solution (computed with divergence-free
finite elements), we determine a bound for its defect and a norm bound for the
inverse of the linearization at the approximate solution. For the latter, bounds
for the essential spectrum and for eigenvalues close to zero of an associated
self-adjoint operator play a crucial role.

To obtain the desired lower bounds for the eigenvalues below the essential spectrum we use a combination of the Rayleigh-Ritz method,
a corollary of the Temple-Lehmann-Goerisch theorem and a homotopy method.

[04194] Relative equilibria for the n-body problem

Format : Talk at Waseda University
Author(s) : Warwick Tucker (Monash University)Jordi-Lluis Figueras (Uppsala University)Piotr Zgliczynski (Jagiellonian University)
Abstract : We will discuss the classical problem from celestial mechanics of determining the number of relative equilibria a set of planets can display. Several already established results will be presented, as well as a new contribution (in terms of a new proof) for the restricted 4-body problem. We will discuss its possible extensions to harder instances of the general problem.

[05267] Chaos in Mackey-Glass: computation of transverse homoclinic orbits

Format : Talk at Waseda University
Author(s) : Olivier Hénot (McGill University University)
Abstract : The Mackey-Glass equation is a scalar delay differential equation, famous for its rich dynamics. Since 1977, the equation has become a primary example of chaos in infinite dimensions. Yet, a proof of existence of chaotic dynamics remains an open problem.
In this talk, we present a computational method for studying transverse homoclinic orbits for periodic solutions of delay differential equations. The connection is formulated as the zero of a nonlinear map representing a boundary value problem, with boundary conditions in the (finite dimensional) unstable and (infinite dimensional) stable manifolds of the periodic orbit; the transversality of the intersection is a by-product of the invertibility of the Fréchet derivative of the map. This technique is designed to be amenable for computer-assisted proofs through a Newton-Kantorovich type argument. As a notable illustration, we compute a transverse homoclinic orbit in the Mackey-Glass equation.

01768 (2/4) : 3D @G405 [Chair: Jean-Philippe Lessard]

[05182] Smooth imploding solutions for 3D compressible fluids

Format : Talk at Waseda University
Author(s) : Javier Gomez Serrano (Brown University)
Abstract : In this talk I will present results on singularity formation for the 3D isentropic compressible Euler and Navier-Stokes equations for ideal gases. These equations describe the motion of a compressible ideal gas, which is characterized by a parameter called the adiabatic constant. Finite time singularities for generic adiabatic constants were found in the recent breakthrough of Merle, Raphaël, Rodnianski and Szeftel. Our results allow us to drop the genericity assumption and construct smooth self-similar profiles for all values of the adiabatic constant. In particular, we will construct the first smooth self-similar profile for a monoatomic gas. Part of the proof is very delicate and requires a computer-assisted analysis. Joint work with Tristan Buckmaster and Gonzalo Cao-Labora.

[02910] Computer-assisted proofs of localized patterns in the planar Swift-Hohenberg equation

Format : Talk at Waseda University
Author(s) : Matthieu Cadiot (McGill University)Jean-Philippe Lessard (McGill University)Jean-Christophe Nave (McGill University)
Abstract : In this talk, I will present computer-assisted proofs of stationary localized patterns in the planar Swift-Hohenberg equation. Using a Newton-Kantorovich approach, we develop a numerical method to prove local existence and uniqueness of strong solutions in $\mathbb{R}^m$. In particular, I will explain how we manage to approximate the inverse of the linearization of the PDE around some approximated solution. Finally, I will expose the numerical details of some specific computer-assisted proofs.

[05035] Rigorous computation of Poincare maps

Format : Talk at Waseda University
Author(s) : Daniel Wilczak (Jagiellonian University)Tomasz Kapela (Jagiellonian University)Piotr Zgliczyński (Jagiellonian University)
Abstract : We present recent advances on interval methods for rigorous computation of Poincare maps. We also discuss the impact of choice of Poincare section and coordinate system on obtained bounds for computing Poincare map nearby fixed points.

[02908] Validation of Elliptic Invariant Tori in Hamiltonian Systems

Format : Talk at Waseda University
Author(s) : Chiara Caracciolo (Uppsala University)
Abstract : The applicability of KAM theorem to realistic physical problems can be significantly improved by CAPs. These proofs exploit the explicit computation of approximately invariant solutions by the mean of normal forms or parametrization methods. I will discuss the extension of these techniques to lower-dimensional elliptic tori and present an algorithm based on a parametrization method. I will discuss the main benefits of this technique and how it can be made completely rigorous.

Based on joint works with J-Ll. Figueras, A. Haro, U. Locatelli.

01768 (3/4) : 3E @G405 [Chair: Nobito Yamamoto]

[03720] Validated Numerics for divergent series via the Borel Transform

Format : Talk at Waseda University
Author(s) : Jason Desmond Mireles James (Florida Atlantic University)
Abstract : Parabolic invariant manifolds are associated with fixed points of diffeomorphisms which have one as an eigenvalue of the linearization, or equilibrium solutions of differential equations which have zero as an eigenvalue. Supposing that the map or vector field is real analytic, It is well known (for example Baldoma and Haro, 2008) that while the Taylor expansion of the manifold may diverge, it typically does so in a Gevery fashion. That is, the power series coefficients diverge like a factorial. In this case, some truncations of the divergent series may still provide useful approximation, and it is desirable to have quantitative bounds on the errors. This is in fact necessary if the expansion is going to be used as an ingredient of a subsequent computer assisted proof.

I will discuss a method for obtaining such bounds based on Borel resummation. The idea is that the Borel transform of the conjugacy equation describing the parabolic manifold has much nicer properties than the original equation. For example the transformed equation typically has analytic solutions. I will discuss methods for solving the transformed equation using validated numerics. If one can analytically continue this solution (in a process similar to numerical integration) to an open set covering the positive real axis in the complex Borel Plane, then it is possible to take a Laplace transform, recovering the solution to the original problem. This procedure also leads to validated computer assisted error bounds.

[04398] Characterising blenders via covering relations and cone conditions

Format : Talk at Waseda University
Author(s) : Hinke M Osinga (University of Auckland)Bernd Krauskopf (University of Auckland)Piotr Zgliczynski (Jagiellonian University)Maciej Capinski (AGH University of Science and Technology)
Abstract : A blender is an invariant hyperbolic set of a diffeomorphism with the property that its stable or unstable manifold has a dimension larger than expected from the underlying hyperbolic splitting. We present a characterisation of a blender based on the correct topological alignment of sets in combination with the propagation of cones. It is applicable to multidimensional blenders in ambient phase spaces of any dimension. The required conditions can be verified by checking properties of a single iterate of the diffeomorphism, which is achieved by positioning the required sets in such a way that they form a suitable sequence of coverings. This setup is flexible and allows for a rigorous, interval arithmetic based, computer assisted validation.

[03900] Validated integration of semilinear parabolic PDEs

Format : Talk at Waseda University
Author(s) : Maxime Breden (Ecole polytechnique)Jan Bouwe van den Berg (VU Amsterdam)Ray Sheombarsing (VU Amsterdam)
Abstract : Integrating evolutionary partial differential equations (PDEs) is an essential ingredient for studying the

dynamics of the solutions. Indeed, simulations are at the core of scientific computing, but their mathematical reliability is often difficult to quantify, especially when one is interested in the output of a given simulation, rather than in the asymptotic regime where the discretization parameter tends to zero. In this paper we present a computer-assisted proof methodology to perform rigorous time integration for scalar semilinear parabolic PDEs with periodic boundary conditions. We formulate an equivalent zero-finding problem based on a variations of constants formula in Fourier space. Using Chebyshev interpolation and domain decomposition, we then finish the proof with a Newton-Kantorovich type argument. The final output of this procedure is a proof of existence of an orbit, together with guaranteed error bounds between this orbit and a numerically computed approximation.
We illustrate the versatility of the approach with results for the Fisher equation, the Swift-Hohenberg equation, the Ohta-Kawasaki equation and the Kuramoto–Sivashinsky equation. We expect that this rigorous integrator can form the basis for studying boundary value problems for connecting orbits in partial differential equations.

[05270] Validated dynamics in neural networks: towards chaos

Format : Talk at Waseda University
Author(s) : Elena Queirolo (TUM)
Abstract : Neural networks, a class of machine learning algorithms, can be interpreted as dynamical systems an d can be studied by dynamical techniques. Here, we use validation techniques to understand how the reliability of the algorithm relates to dynamical behaviours. In particular, we want to investigate the co nnection between chaos and reliability. First, we prove or disprove the existence of chaos in a given neural net, then we draw behavioural conclusions based on its existence.

01768 (4/4) : 4C @G405 [Chair: Akitoshi Takayasu]

[05292] Global Dynamics and Blowup in Some Quadratic PDEs

Format : Talk at Waseda University
Author(s) : Jonathan Jaquette Jean-Philippe Lessard (McGill University)Akitoshi Takayasu (University of Tsukuba)
Abstract : Conservation laws and Lyapunov functions are powerful tools for proving the global existence of stability of solutions, but for many complex systems these tools are insufficient to completely understand non-perturbative dynamics. In this talk I will discuss a complex-scalar PDE which may be seen as a toy model for vortex stretching in fluid flow, and cannot be neatly categorized as conservative nor dissipative.

In a recent series of papers we have shown that this equation exhibits rich dynamical behavior that exist globally in time: non-trivial equilibria, homoclinic orbits, heteroclinic orbits, and integrable subsystems foliated by periodic orbits. On the other side of the coin, we show several mechanisms by which solutions can blowup. I will discuss these results, and current work toward understanding unstable blowup.

[05275] Worrisome Properties of Symbolic Representations of Deep Neural Network Controllers

Format : Talk at Waseda University
Author(s) : Jacek Cyranka (Warsaw University)Kevin Church (Université de Montréal)Jean-Philippe Lessard (McGill University)
Abstract : We studied dynamics of simple controlled problems like Pendulum and CartPole, where the controllers were trained using reinforcement learning algorithms. We raise concerns about symbolic controllers' robustness.
A typical symbolic controller reaching high mean return values still generates an abundance of unstabilized solutions, which is highly undesirable property, easily exploitable by an adversary. We provide an algorithm for a systematic robustness study and prove the unstabilized solutions and periodic orbits, using a computer-assisted proof methodology.

[05090] A rigorous integrator and global existence for higher-dimensional semilinear parabolic PDEs via semigroup theory

Format : Talk at Waseda University
Author(s) : Gabriel William Duchesne (McGill)
Abstract :
In this talk, we introduce a general constructive method to compute solutions of initial and boundary value problems of semilinear parabolic partial differential equations via semigroup theory and computer-assisted proofs.

We will present techniques to prove the global existence of solutions in the 2D/3D Swift-Hohenberg equation and to prove the existence of a solution of a projected boundary value problem in the 2D Ohta-Kawasaki equation.

[01800] Numerical methods for fluid-structure interaction and poroelasticity

Session Time & Room :

01800 (1/2) : 2D (Aug.22, 15:30-17:10) @E820

01800 (2/2) : 2E (Aug.22, 17:40-19:20) @E820

Type : Proposal of Minisymposium
Abstract : Fluid-structure interaction problems arise in many applications. In biomedicine, such models are used to describe the interaction between blood and arterial walls. Such models have also been used to describe the interaction between blood flow and biodegradable stents, blood flow in patient-specific models of abdominal aortas containing aneurysms, and blood flow and oxygen transport in a bioartifical pancreas. Other applications include geomechanics and aerodynamics. When a deformable structure is porous and allows flow through it, poroelastic models are commonly used to describe its behavior. The numerical simulation of fluid-elastic/poroelastic structure interaction problems has received considerable attention, but still remains a significant challenge in the mathematical and computational sciences. Main difficulties stem from the the intricate multiphysics nature of the problem, and strong nonlinearities. This minisymposium focuses on numerical methods for fluid-elastic or poroelastic structure interaction problems and applications. Possible topics include but are not limited to: 1) partitioned and monolithic numerical methods, 2) porous and poroelastic medium flow, 3) mathematical and numerical analysis, and 4) validation and verification of numerical solvers.

[03958] Space-time domain decomposition approach for Stoke flow coupled with poroelasticity

Format : Talk at Waseda University
Author(s) : Hyesuk Lee (Clemson University)Hemanta Kunwar (Clemson University)
Abstract : We consider decoupling iterative algorithms based on domain decomposition for the time-dependent Stokes-Biot model, in which different time steps can be used in the flow region and the poroelastic medium. The coupled system is formulated as a space-time interface problem based on interface conditions. The interface problem is then solved by an iterative method which involves the parallel solution of time-dependent homogeneous Stokes and Biot problems. Consequently, local discretization in both space and time can be used to handle multiphysics systems efficiently. Numerical results with nonconforming time grids are presented to illustrate the performance of the proposed methods.

[04129] Two-field any-order finite element solvers for poroelasticity problems

Format : Talk at Waseda University
Author(s) : Jiangguo James Liu (Colorado State University)
Abstract : In this talk, we present a family of 2-field finite element solvers for poroelasticity problems based on weak Galerkin (WG) spatial discretizations and the backward differentiation formulas (BDF) temporal discretization. In particular, both primal variables (fluid pressure and solid displacement) are approximated by WG degree k>=0 (scalar or vector) polynomial shape functions defined separately in element interiors and on edges of a quadrilateral mesh. The discrete weak gradients of WG basis functions are constructed in certain broken Arbogast-Correa spaces (of vectors or matrices). The discrete weak gradients, strains, and divergences will be utilized to approximate their continuous counterparts in the variational formulations. Degree-k WG polynomials

and BDF(k+1) are combined to develop time-marching schemes for linear poroelasticity. This combination results in a good balance of spatial and temporal discretizations. Numerical experiments on benchmarks will be presented to demonstrate the efficiency and flexibility of these new solvers. Extension to nonlinear poroelasticity problems will be discussed also. This is a joint work with Simon Tavener (Colorado State University, USA), Ruishu Wang (Jilin University, China), and Zhuoran Wang (Sun Yat-sen University, China).

[04672] A mathematical framework for poro-viso-elastic models

Format : Talk at Waseda University
Author(s) : Justin Thomas Webster (University of Maryland, Baltimore County)
Abstract : Recent works in poroelasticity have included viscous structural effects. Here, we clarify mathematical properties of linear, quasi-static Biot systems with the addition of Kelvin-Voigt viscoelasticity. We demonstrate time-regularization and dissipative effects of viscoelasticity through a priori estimates. We use the full system, as well as the framework of implicit, degenerate evolutions. Precise statements of admissible initial conditions in each scenario are given.

[04316] An energy stable second-order method for three-phase flows

Format : Talk at Waseda University
Author(s) : Catalin Trenchea (University of Pittsburgh)Giselle Sosa Jones (Oakland University)
Abstract : We present a time-stepping scheme for the numerical approximation of a thermodynamically consistent model of incompressible and immiscible three-phase flow in porous media, with an intrinsic free energy dissipation law.
The model consists of three nonlinear degenerate parabolic equations for the saturations of each phase.
We prove that the proposed scheme is second-order accurate, and preserves the discrete free energy dissipation.

01800 (2/2) : 2E @E820 [Chair: Martina Bukač]

[04829] Cell-Based Numerical Approach to Evaluate CTC Binding Behavior in Microfluidic Device

Format : Talk at Waseda University
Author(s) : YIFAN Wang (Texas Tech University)
Abstract : Circulating tumor cells (CTCs) are malignant cells that break free from the primary tumor and enter the bloodstream. Early detection of CTCs is crucial for diagnosis, but challenging because they are infrequent in blood samples. Microfluidic devices offer a promising detection technique, either actively enriching CTCs through external fields or passively separating them from other cells based on physical properties. A microfluidic device has been proposed by our collaborator at Texas Tech University to isolate CTCs from blood samples, with different micro-post sizes and layouts tested to optimize capture efficiency. However, the complex transport and adhesion behaviors of CTCs in blood cell suspensions remain incompletely understood. Here, we present a cell-based numerical approach based on the Lattice Boltzmann method to evaluate the binding behavior and trajectories of CTCs under different flow conditions, including cell size and coating density, microfluidic design, and cell collisions. Our validated results are used to improve the device design.

[02971] A Banach spaces-based fully-mixed formulation for the Navier–Stokes/Darcy coupled problem

Format : Talk at Waseda University
Author(s) : Segundo Villa Fuentes (Monash University)Ricardo Oyarzúa (Universidad del Bío-Bío)Sergio Caucao (Universidad Católica de la Santísima Concepción)
Abstract : In this work we present and analyze a fully-mixed formulation for the coupling Navier–Stokes/Darcy equations.

Our approach is based on the introduction of a modified pseudostress tensor in the Navier–Stokes equations for the fluid, whereas the standard dual-mixed formulation for the Darcy model is considered. With this, we obtain a Banach spaces-based mixed variational formulation and a twofold saddle point structure.

Fixed-point strategy, together with the Banach–Nečas–Babuška and Banach's fixed point theorems, are employed to prove the well-posedness of the continuous and discrete formulations.

[03829] Numerical simulation of the time-fractional Navier-Stokes-Fokker-Planck (tfNSFP) equation

Format : Talk at Waseda University
Author(s) : Jonas Beddrich (Technical University of Munich)Endre Süli (University of Oxford)Barbara Wohlmuth (Technical University of Munich)
Abstract : The tfNSFP system describes the flow of dilute polymeric fluids. It is attractive as it enhances standard models for the viscoelasticity of polymer molecules by accounting for memory effects. The problem is challenging since it is non-local in time and defined on the Cartesian product of two d-dimensional spaces. We present a numerical method that combines a rational approximation approach, a space-splitting approach, and the Hermite spectral method to solve the tfNSFP equation.

[01834] Structure analysis and dynamics modelling in graphs and networks

Session Time & Room :

01834 (1/2) : 3C (Aug.23, 13:20-15:00) @G304

01834 (2/2) : 3D (Aug.23, 15:30-17:10) @G304

Type : Proposal of Minisymposium
Abstract : In recent years, research on graphs and networks has received much attention, and it has emerged in the application of channel coding, biomedicine, social governance, and other fields. The mini-symposium will focus on structural analysis and dynamics modelling in complex networks, including influence maximization of high-order networks, evolutionary games, etc.
Organizer(s) : Cunquan Qu, Chenlu Ji, Fang Wang
Classification : 05Cxx, 91Dxx, 91Gxx, Network Science; Evolutionary Game Theory
Minisymposium Program :

01834 (1/2) : 3C @G304 [Chair: Cunquan QU]

[03989] Evolutionary Game Theory on Dynamic Networks

Format : Online Talk on Zoom
Author(s) : Qi Su (University of St Andrews)Alex McAvoy (University of Pennsylvania)Joshua B. Plotkin (University of Pennsylvania)
Abstract : The study of the evolution of cooperative behavior on static networks helps to understand how population structure can facilitate the spread of prosocial traits. However, real-world interactions are usually transient and subject to external restructuring, making the study of strategic behavior on dynamic networks difficult. This study provides an analytical treatment of cooperation on dynamic networks and demonstrates that transitions among network structures can promote the spread of cooperation, even if individual social networks inhibit it when static. The findings highlight the significant impact of dynamic social structures on the evolution of prosocial traits.

[02059] An efficient adaptive degree-based heuristic algorithm for influence maximization in hypergraphs

Format : Online Talk on Zoom
Author(s) : Xiu-Xiu Zhan (Hangzhou Normal University)
Abstract : Influence maximization (IM) has shown wide applicability in immense fields over the past decades. Previous researches on IM mainly focused on the dyadic relationship but lacked the consideration of higher-order relationship between entities, which has been constantly revealed in many real systems. An adaptive degree-based heuristic algorithm, i.e., Hyper Adaptive Degree Pruning (HADP) which aims to iteratively select nodes with low influence overlap as seeds, is proposed in this work to tackle the IM problem in hypergraphs. Furthermore, we extend algorithms from ordinary networks as baselines. Results on 8 empirical hypergraphs show that HADP surpasses the baselines in terms of both effectiveness and efficiency with a maximally 46.02% improvement. Moreover, we test the effectiveness of our algorithm on synthetic hypergraphs generated by different degree

heterogeneity. It shows that the improvement of our algorithm effectiveness increases from 2.66% to 14.67% with the increase of degree heterogeneity, which indicates that HADP shows high performance especially in hypergraphs with high heterogeneity, which is ubiquitous in real-world systems.

[04046] Identifying vital nodes through augmented random walks on higher-order networks

Format : Online Talk on Zoom

Author(s) : Xiao-Long Ren (Yangtze Delta Region Institute (Huzhou), University of Electronic Science and Technology of China)

Abstract : Identifying vital nodes is still unclear in the study of higher-order networks. We introduce a multi-order graph obtained by incorporating the higher-order bipartite graph and the classical pairwise and propose a Higher-order Augmented Random Walk model. Our model provides a new approach for ranking nodes at multiple scales. Our method outperforms other indicators in identifying vital nodes and can scale to various tasks in complex networks, including the information spread maximization and network dismantling problem.

[04449] Emergence of Cooperation Through Coevolving Time Scale in Spatial Prisoner's Dilemma

Format : Online Talk on Zoom

Author(s) : Zhihai Rong (Donghua University)

Abstract : Understanding the emergence of cooperation is a challenging problem and has drawn a wide attention from various fields including sociology, economics and biology. Evolutional game theory provides a powerful framework for investigating this problem. In the traditional networked evolutionary game theory, most researchers usually assume an individual will immediately update its strategy after one round of game with its neighbors. However, in the social and biological systems the strategy-selection time scale may be slower than the interaction time scale, i.e., an individual will hold its current strategy and play several rounds of game with its neighbors, and then update its behavior. In this talk, I will introduce some results about coevolving time scale in spatial Prisoner's dilemma. When the individuals can adjust their strategy-selection time scale according to some rules, optimal cooperation can be induced by proper adaptive rate in the strategy-selection time scale. The results are analyzed through the spatial pattern and feedback mechanism of individual behavior. This investigation may have potential implications in the design of consensus protocol in multi-agent systems.

01834 (2/2) : 3D @G304 [Chair: Chenlu JI]

[01988] information-opinion dynamics on social multilayer networks

Format : Online Talk on Zoom

Author(s) : Fei Jing (City University of Hong Kong)

Abstract : Here we model these two phenomena as a co-evolution dynamics of information and public opinion on heterogeneous multiplex networks, including a few extreme individuals with constant opinions and a vast majority of general individuals with vacillating views.

[04619] Characterizing Cycle Structure in Complex Networks

Format : Online Talk on Zoom

Author(s) : Tianlong Fan (University of Fribourg)

Abstract : A cycle is the simplest structure that brings redundant paths in network connectivity and feedback effects in network dynamics. In this work, we define the cycle number matrix, and the cycle ratio, an index that quantifies node importance. Numerical experiments on identifying vital nodes for network connectivity and synchronization and maximizing the early reach of spreading show that the cycle ratio performs overall better than other benchmarks.

[03130] Collaborative deep learning framework for network inference and dynamical prediction

Format : Online Talk on Zoom
Author(s) : Xiao Ding (Anhui University)
Abstract : How to use incomplete data to infer network structure as well as predict the dynamics simultaneously is a meaningful and challenging question. To this end, we develop a COllaborative deep learning framework for Network inference and Dynamical prediction (CoND). Extensive experiments demonstrate that COND outperforms the baseline methods regarding both tasks for different networks and dynamical models. To further validate the effectiveness of COND, we demonstrate the superior performance of CoND on two real datasets.

[05541] Multichannel game on structured populations

Format : Online Talk on Zoom
Author(s) : Fanpeng Song (Shandong University)
Abstract : In this talk, we introduce a framework of multichannel game on structured populations and explore the effect of topological properties to the evolutionary dynamics. Significantly, we find that the heterogeneity of populations is detrimental to the dynamics, especially in BA networks. In addition, modest population size and high interaction are in favor of the dynamics. These results are meaningful for the research on cooperation and human development.

[01858] Interplay among Manifold Learning, Stochastic Calculus, and Volatility Estimation

Session Time & Room :

01858 (1/3) : 2E (Aug.22, 17:40-19:20) @E503

01858 (2/3) : 3C (Aug.23, 13:20-15:00) @E503

01858 (3/3) : 3D (Aug.23, 15:30-17:10) @E503

Type : Proposal of Minisymposium
Abstract : We will review recent advances in Manifold Learning inviting top researchers in this field, and also invite some speakers who will deliver recent developments in Mallivin-Mancino's Fourier estimation method for estimating the "spot volatility process", and its application to the estimation of the diffusion matrix. The aim of the mini-symposium is to forecast how we can proceed to combine these two methods to refine the existing results and reach a new stage.
Organizer(s) : Jiro Akahori, Hau-Tieng Wu
Classification : 62G05, 60F99, 60H30, 53A99, 91G70
Minisymposium Program :

01858 (1/3) : 2E @E503 [Chair: Hau-Tieng Wu]

[02841] Convergence of Hessian estimator from random samples on a manifold

Format : Talk at Waseda University
Author(s) : Chih-Wei Chen (National Sun Yat-sen University)Hau-Tieng Wu (Duke University)
Abstract : We provide a systematic convergence analysis of the Hessian operator estimator from random samples supported on a low dimensional manifold. We show that the impact of the nonuniform sampling and the curvature on the widely applied Hessian operator estimator is asymptotically negligible.

[02848] Limit Theorems for the Positive Semidefinite Modification of Malliavin-Mancino Estimator for the Spot Volatility Process

Format : Talk at Waseda University
Author(s) : Reika Kambara (Nomura Asset Management Co., Ltd.)
Abstract : In this talk, the consistency, and the asymptotic normality of the class of Fourier-type estimators introduced by Akahori et al. will be discussed. The class, parameterized by a sequence of probability measures, is a modification of the Fourier series method introduced by Malliavin and Mancino, modified so that the estimator is positive semidefinite.

[04489] Convergence of Laplacian and its rate for submanifolds that are not necessarily smooth

Format : Talk at Waseda University
Author(s) : Masayuki Aino (Proxima Technology)
Abstract : The continuous limit of Laplacian Eigenmaps gives the eigenfunctions of the Laplacian on submanifolds in Euclidean space .
Such studies have been based on the assumption that a quantity called Reach is bounded from below.
Submanifolds with non-differentiable points cannnot be approximated under such an assumption.
In this talk, I discuss the convergence of Laplacian Eigenmaps and its rates when the Reach assumption is replaced by a weaker assumption such that non-differentiable points can appear.

01858 (2/3) : 3C @E503 [Chair: Hiroshi Kawabi]

[02761] On excursions inside an excursion

Format : Talk at Waseda University
Author(s) : Ju-Yi Yen (University of Cincinnati)
Abstract : The distribution of ranked heights of excursions of a Brownian bridge is given by Pitman and Yor in [1]. In this work, we consider excursions of a Brownian
excursion above a random level x, where x is the value of the excursion at an independent uniform time on $

[0,1]$. We analyze the maximum heights of these

excursions as Pitman and Yor did for excursions of a Brownian bridge.

[1] J. Pitman and M. Yor. On the distribution of ranked heights of excursions of a Brownian bridge. Ann. Probab., 29(1):361–384, 2001.

[02842] Diffusion Estimation with Fourier-Malliavin Method

Format : Talk at Waseda University
Author(s) : Takatoshi Hirano Jiro Akahori (Ritsumeikan university)Simona Sanfelici (Parma university)
Abstract : In this talk, the estimation of the diffusion coefficient of the solution to a stochastic differential equation using Fourier estimation method proposed by P. Malliavin and M.E. Mancino is discussed.

[02849] Statistical Analysis with Geodesics and Curvature in Data Space

Format : Talk at Waseda University
Author(s) : Kei Kobayashi (Keio University)Henry P. Wynn (London School of Economics)
Abstract : We proposed a method to perform data analysis after two types of metric transformation of the data space. The first transformation is based on the powered density integration and can be implemented approximately using an empirical graph. The second transformation corresponds to computing the extrinsic distance after embedding the data space into a metric cone. We proved both transformations monotonically change the curvature of the data space, but in different ways.

01858 (3/3) : 3D @E503 [Chair: Jiro Akahori]

[02840] A Quantitative Central Limit Theorem arising from Time-Frequency Analysis

Format : Talk at Waseda University
Author(s) : Gi-Ren Liu (National Cheng Kung University)
Abstract : In this talk, we will discuss the distribution distance
between the output F of the scattering transform (ST) of a Gaussian
process and its scaling limit G.
ST is a nonlinear transformation that involves a sequential
interlacing convolution and nonlinear operators, which is motivated to model the
convolutional neural network. We will show that the total variation distance
between the distributions of the output of
ST and a chi-square random variable with one degree of freedom
converges to zero at an exponential rate.
For achieving this goal, we derive a recursive
formula to represent the nonlinearity of ST by a linear combination of Wiener
chaos and then apply the Malliavin calculus and Stein's method to estimate the maximal difference
between the expectation values of $h(F)$ and $h(G)$ over a specific set of test functions h.
This talk is based on joint work with Yuan-Chung Sheu (National Yang Ming Chiao Tung University, Taiwan) and Hau-Tieng Wu (Duke University, USA).

[02846] Market Price-Volatility Simulator

Format : Talk at Waseda University
Author(s) : Riki Kitano (Ritsumeikan University)
Abstract : In this talk, a combination of the Fourier-Malliavin-Mancino method and the Lyons's signature method under a stochastic volatility diffusion setting will be discussed.

[02733] A graph discretized approximation of diffusions on Riemannian manifolds

Format : Talk at Waseda University
Author(s) : Hiroshi Kawabi (Keio University)Satoshi Ishiwata (Yamagata University)
Abstract : In this talk, we discuss a graph discretized approximation for diffusions on a complete Riemannian manifold M. More precisely, for a given drifted Schrödinger operator $\mathcal{A}=-\Delta-b+V$ on M, we introduce a family of random walks in the flow generated by the drift b with killing on a sequence of proximity graphs. The drifted Schrödinger semigroup $\{\mathrm{e}^{t\mathcal{A}}\}_{t\geq 0}$ is approximated by discrete semigroups generated by the family of random walks.

[01868] An introduction of "Journal of Machine Learning" for applied mathematicians

Session Time & Room :

01868 (1/2) : 4D (Aug.24, 15:30-17:10) @E818

01868 (2/2) : 4E (Aug.24, 17:40-19:20) @E818

Type : Proposal of Minisymposium
Abstract : Machine learning is an area characterized by rapid growth, broader impact and diverse audience. It is changing applied mathematics in a fundamentally way. At the same time, there is still a lack of proper venues for publishing research work in machine learning with an applied math orientation. Journal of Machine Learning (JML) is a newly launched journal to provide such a venue. It strives to accommodate both the special features of machine learning mentioned above, as well as the long-held tradition of applied mathematics. In this minisymposium, we invite authors who have published papers in JML to present their work.

[02598] Embedding Principle: A Hierarchical Structure of Loss Landscape of Deep Neural Networks

Format : Talk at Waseda University
Author(s) : Yaoyu Zhang (Shanghai Jiao Tong University)
Abstract : This talk is about the Embedding Principle of loss landscape of deep neural networks ((NNs)), i.e., loss landscape of an NN "contains" all critical points of all the narrower NNs. We will introduce a general class of embedding operators which map any critical point of a narrower NN to a critical point of the target NN preserving the output. Our results uncover a hierarchical structure of loss landscape special to the deep learning models.

[02247] Perturbational Complexity and Reinforcement Learning in Reproducing Kernel Hilbert Space

Format : Talk at Waseda University
Author(s) : Jihao Long (Princeton University)
Abstract : This talk will offer some fresh insight into the challenge for analyzing reinforcement learning (RL) in a general reproducing kernel Hilbert space (RKHS). We define a quantity called “perturbational complexity by distribution mismatch” and show that the perturbational complexity gives both the lower bound and upper bound of the error for the RL problem in RKHS. We will provide some concrete examples and discuss whether the complexity decays fast or not in these examples.

[02258] The Random Feature Method for Solving Partial Differential Equations

Format : Talk at Waseda University
Author(s) : Jingrun Chen (University of Science and Technology of China)
Abstract : In this presentation, we will give a description of the random feature method for solving partial differential equations, including its basic formulation for both static and time-dependent problems and the application for three dimensional problems with complex geometries.

[02957] DeePN^2: A deep learning-based non-Newtonian hydrodynamic model

Format : Talk at Waseda University
Author(s) : Huan Lei Lidong Fang (Michigan State University)Pei Ge (Michigan State University)Lei Zhang (Shanghai Jiao Tong University)Weinan E (Peking University)
Abstract : A long standing problem in the modeling of non-Newtonian hydrodynamics of polymeric flows is the availability of reliable and interpretable hydrodynamic models that faithfully encode the underlying micro-scale polymer dynamics. We developed a deep learning-based non-Newtonian hydrodynamic model, DeePN^2, that enables us to systematically pass the micro-scale structural mechanics information to the macro-scale hydrodynamics for polymer suspensions. The model retains a multi-scaled nature with clear physical interpretation, and strictly preserves the frame-indifference constraints.

01868 (2/2) : 4E @E818 [Chair: Yaoyu Zhang]

[02982] Generalization ability and memorization phenomenon of distribution learning models

Format : Talk at Waseda University
Author(s) : Hongkang Yang (Princeton University, Program in Applied and Computational Mathematics)
Abstract : Generative models and density estimators suffer from the memorization phenomenon (i.e. convergence to the finite training samples) as training time goes to infinity. This deterioration is in contradiction to the empirical success of models such as StableDiffusion and GPT-3. We resolve this paradox by proving that

distribution learning models enjoy implicit regularization during training. Specifically, prior to the onset of memorization, their generalization errors at early-stopping escape from the curse of dimensionality.

[04035] Approximation of Functionals by Neural Network without Curse of Dimensionality

Format : Talk at Waseda University
Author(s) : Yahong Yang (The Hong Kong University of Science and Technology)Tianyu Jin (The Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)
Abstract : In this paper, we establish a neural network to approximate functionals, which are maps from infinite dimensional spaces to finite dimensional spaces. The approximation error of the neural network is $O(1/\sqrt{m})$ where m is the size of networks, which overcomes the curse of dimensionality. Then, the proposed method is employed in several numerical experiments, such as evaluating the energy functionals and solving Poisson equations by the aforementioned network at one or a few given points.

[02256] Approximation of Functionals by Neural Network without Curse of Dimensionality

Format : Talk at Waseda University
Author(s) : Yahong Yang (Hong Kong University of Science and Technology)Yang Xiang (Hong Kong University of Science and Technology)
Abstract : In this paper, we establish a neural network to approximate functionals, which are maps from infinite dimensional spaces to finite dimensional spaces. The approximation error of the neural network is $O(1/\sqrt{m})$ where m is the size of networks. In other words, the error of the network is no dependence on the dimensionality respecting to the number of the nodes in neural networks. The key idea of the approximation is to define a Barron space of functionals.

[02998] Ab-Initio Study of Interacting Fermions at Finite Temperature with Neural Canonical Transformation

Format : Talk at Waseda University
Author(s) : Hao Xie (Institute of Physics, Chinese Academy of Sciences)Linfeng Zhang (DP Technology/AI for Science Institute)Lei Wang (Institute of Physics, Chinese Academy of Sciences)
Abstract : We present a variational density matrix approach to the thermal properties of interacting fermions in the continuum. The variational density matrix is parametrized by a permutation equivariant many-body unitary transformation together with a discrete probabilistic model. The unitary transformation is imple- mented as a quantum counterpart of neural canonical transformation, which incorporates correlation effects via a flow of fermion coordinates. As the first application, we study electrons in a two-dimensional quan- tum dot with an interaction-induced crossover from Fermi liquid to Wigner molecule. The present approach provides accurate results in the low-temperature regime, where conventional quantum Monte Carlo methods face severe difficulties due to the fermion sign problem. The approach is general and flexible for further ex- tensions, thus holds the promise to deliver new physical results on strongly correlated fermions in the context of ultracold quantum gases, condensed matter, and warm dense matter physics.

[01897] New Tools for Nonlinear Time Series Analysis

Session Time & Room :

01897 (1/2) : 3D (Aug.23, 15:30-17:10) @F309

01897 (2/2) : 3E (Aug.23, 17:40-19:20) @F309

Type : Proposal of Minisymposium
Abstract : Nonlinear time series analysis is the study of continuous-valued time series under the working hypothesis that they have been produced by a dynamical system of possibly higher dimensions. This assumption enables us to use methods, such as embedding theorems, and tools, such as Lyapunov exponents and attractor dimensions, that allow capturing data structure and information that traditional statistical approaches cannot.

Other recently developed tools include recurrence plots, complex networks, ordinal patterns, visibility graphs, homology groups, transcripts, and more. This Minisymposium is intended to showcase such tools and provide a discussion forum for researchers in the field.

[05007] Pattern-based approaches to identifying coupling structures among multivariate time series

Format : Talk at Waseda University
Author(s) : Reik V. Donner (Magdeburg-Stendal University of Applied Sciences)
Abstract : Nonlinear analysis methods based on the occurrences of patterns have recently proven valuable tools for time series analysis. In this talk, I will review some recently developed approaches based on co-occurrence statistics between ordinal patterns, graphlets, or extreme events in multivariate time series and their use for correctly distinguishing direct from indirect coupling in otherwise challenging situations, including examples of variables with poor observability characteristics.

[03507] Transition network approaches for nonlinear time series analysis

Format : Talk at Waseda University
Author(s) : Yong Zou (East China Normal University)
Abstract : Complex networks are powerful tools for nonlinear time series analysis, which are undergoing fast development in the recent decade. Here we propose a novel way to construct multi-scale transition networks from time series, which are based on coarse-graining partitions of phase space. Using time series from both discrete Henon map and continuous Rössler systems, we demonstrate that the multi-scale transition entropy values of the resulting networks show the same power as the Lyapunov exponents, identifying chaotic transitions successfully. The advantage is that our method works successfully when only a small number of 3–5bins is used for the partition generation, while the traditional static node entropy measures work poorly. Further experimental examples in fMRI and ECG analysis show that these entropy measures are able to characterizing different rhythmic states of subjects, showing high potential for time series analysis from complex systems.

[04058] Persistent homology induced by ordinal patterns for multivariate time series

Format : Talk at Waseda University
Author(s) : Taichi Haruna (Tokyo Woman's Christian University)
Abstract : We present a method to construct a filtered simplicial complex from a given multivariate time series using the intersections of ordinal patterns. The filtered complex reflects information about couplings among individual time series. A measure of the complexity of couplings can be defined from its persistent homology groups. The behavior of the complexity measure is investigated in terms of its mathematical properties and applications to examples.

[04580] Reconstruction of causal graphs with self loops

Format : Online Talk on Zoom
Author(s) : X. San Liang (Fudan University)
Abstract : Causality analysis is an important problem lying at the heart of science. An endeavor during the past years viewing causality as a real physical notion so as to formulate it from first principles, however, seems to have gone unnoticed. This study introduces to the community this line of work. The resulting formula is transparent, and can be implemented as a computationally very efficient algorithm for application. Different from the previous work along this line, here an algorithm is also implemented to quantify the influence of a unit to itself. While this forms a challenge in some causal inferences, here it comes naturally, and hence the identification of self-loops in a causal graph is fulfilled automatically as the causalities along edges are inferred. To demonstrate the power of the approach, presented here are two applications in extreme situations. The first is a network of multivariate processes buried in heavy noises (with the noise-to-signal ratio exceeding 100), and the second a network with nearly synchronized chaotic oscillators. In both graphs, confounding processes exist. While it seems to be a challenge to reconstruct from given series these causal graphs, an easy application of the algorithm immediately reveals the desideratum. Particularly, the confounding processes have been accurately differentiated.

01897 (2/2) : 3E @F309 [Chair: Reik V. Donner]

[03926] Power spectrum estimation for extreme events data

Format : Talk at Waseda University
Author(s) : Norbert Marwan (Potsdam Institute for Climate Impact Research (PIK))Tobias Braun (Potsdam Institute for Climate Impact Research (PIK))
Abstract : The estimation of power spectral density (PSD) of time series is an important task in many quantitative scientific disciplines. However, the estimation of PSD from discrete data, such as extreme event series is challenging. We present a novel approach for the estimation of a PSD of discrete data. Combining the edit distance metric with the Wiener-Khinchin theorem provides a simple yet powerful PSD analysis for discrete time series (e.g., extreme events). This method works directly with the event time series without interpolation or transformation to continuous data. We demonstrate the method's potential on some prototypical examples and on event sequences of atmospheric rivers (AR), narrow filaments of extensive water vapor transport in the lower troposphere. Considering the spatial-temporal event series of ARs over Europe, we investigate the presence of a seasonal cycle as well as periodicities in the multi-annual range for specific regions, likely related to the North-Atlantic Oscillation (NAO).

[04346] Constructing First Return Maps from Ordinal Partitioning of Time Series

Format : Talk at Waseda University
Author(s) : Zahra Shahriari (The University of Western Australia)
Abstract : We present a robust algorithm for constructing first return maps (FRM) of dynamical systems from time series that does not require embedding. Typically, an FRM is constructed utilizing the time series' maxima or zero-crossings. Our method is based on ordinal partitions, and we use consecutive ordinal symbols to construct the FRM. For each ordinal sequence, we generate a unique FRM and rank them using two entropy-based measures to select the "good" ones.

[04581] Optimization approaches in analyzing marked point process data

Format : Talk at Waseda University
Author(s) : Noriyoshi Sukegawa (Hosei University)Shohei Suzuki (Tokyo University of Science)Yoshiko Ikebe (Tokyo University of Science)Yoshito Hirata (University of Tsukuba)
Abstract : In this talk, we present an integer programming model for computing a median of a set of marked point processes under an edit distance. The marked point process is a time series of discrete events with marks observed in continuous time. The edit distance is a common metric originated by Victor and Purpura in 1997. We show numerical results on its application in earthquake prediction.

[02926] Generalized entropies in nonlinear time series analysis

Format : Talk at Waseda University
Author(s) : Jose M. Amigo (Universidad Miguel Hernandez)
Abstract : The concept of entropy plays an important role in both random and deterministic processes. In nonlinear time series analysis, entropy is mostly used to characterize the complexity of the data source. To this end, the concept of Shannon entropy is too rigid, so analysts prefer the more flexible concept of generalized entropy, which fulfills the first three Shannon-Khinchin axioms but not the fourth. These entropies include the Renyi and Tsallis entropies. In my talk I will show that generalized entropies are required to cope with the needs of time series analysis, in particular of symbolic representations with permutations.

[01933] Fluid-structure interactions in Stokes flows

Session Time & Room :

01933 (1/3) : 1C (Aug.21, 13:20-15:00) @D403

01933 (2/3) : 1D (Aug.21, 15:30-17:10) @D403

01933 (3/3) : 1E (Aug.21, 17:40-19:20) @D403

Type : Proposal of Minisymposium
Abstract : The minisymposium focuses on computational methods for low (zero) Reynolds number flows, where viscous effects dominate. Due to the linearity of the fluid governing equations at zero Reynolds number, considerable progress in numerical methods has been made to understand the fluid-structure interactions at this small scale. This minisymposium will cover recent developments in numerical methods for modeling and simulating systems involving small immersed structures and suspensions of rigid and deformable particles, such as cilia, capsules, microorganisms, actin filaments in the cell cytoskeleton, catalytic colloids, electrolyte solutions in microfluidics or batteries, and others.
Organizer(s) : Aleksandar Donev, Yuan-Nan Young
Classification : 76-10, 76-00, 74F10, fluid-structure interactions, boundary integral methods, immersed boundary methods
Minisymposium Program :

01933 (1/3) : 1C @D403 [Chair: Mike Miksis]

[04825] Cross-stream migration of vesicles in vortical flows

Format : Online Talk on Zoom
Author(s) : Gokberk Kabacaoglu (Bilkent University)
Abstract : We use numerical simulations to systematically investigate the vesicle dynamics in two-dimensional (2D) Taylor-Green vortex flow in the absence of inertial forces. We study the effects of two parameters on the vesicle dynamics: the ratio of the interior fluid viscosity to that of the exterior one and the ratio of the shear forces on the vesicle to the membrane stiffness (characterized by the capillary number).

[04962] Confinement effects on a suspension of squirmers

Format : Talk at Waseda University
Author(s) : Yuan Nan Young (New Jersey Institute of Technology)Bryan Quaife (Florida State University)Henry Shum (University of Waterloo)Sangwoo Shin (University at Buffalo)
Abstract : Using a model recently developed for the many-body hydrodynamics of amphiphilic JPs suspended in a viscous background flow (JFM, 941, 2022), we investigate how various swimming dynamics of squirmers that interact with the solvent through a hydrophobic potential (HP) may vary from tuning the hydrophobicity/hydrophilicity of the squirmers. In the absence of such HP, several configurations of squirmers are known to be stable for squirmers to swim together. We numerically investigate how HP may help stabilize/destabilize these configurations. These results are further compared with the Vicek model for schooling and flocking of swimmers. We further investigate the effects of confinement and how active control of HP may be used for a cluster of swimmers to swim in specific fashions, indicating that the squirmers may actively change their surface properties so the collective of squirmers may swim in certain ways.

[04477] Hydrodynamics and rheology of fluctuating, semiflexible, inextensible, and slender filaments in Stokes flow

Format : Talk at Waseda University
Author(s) : Aleksandar Donev (Courant Institute, New York University)
Abstract : Every animal cell is filled with a cytoskeleton, a dynamic gel made of inextensible filaments / bio-polymers, such as microtubules, actin filaments, and intermediate filaments, all suspended in a viscous fluid. Similar suspensions of elastic filaments or polymers are widely used in materials processing. Numerical simulation of such gels is challenging because the filament aspect ratios are very large.

We have recently developed new methods for rapidly computing the dynamics of non-Brownian and Brownian inextensible slender filaments in periodically-sheared Stokes flow. We apply our formulation to a permanently and dynamically cross-linked actin mesh in a background oscillatory shear flow. We find that nonlocal hydrodynamics can change the visco-elastic moduli by as much as 40% at certain frequencies, especially in partially bundled networks.

I will focus on accounting for bending thermal fluctuations of the filaments by first establishing a mathematical formulation and numerical methods for simulating the dynamics of stiff but not rigid Brownian fibers in Stokes flow. I will emphasize open questions for the community such as whether there is a continuum limit of the Brownian contribution to the stress tensor from the filaments.

[04813] Numerical simulations of swimming with multiple bacterial flagella

Format : Talk at Waseda University
Author(s) : Henry Shum (University of Waterloo)Vahid Nourian (University of Waterloo)
Abstract : To understand some of the consequences of different morphologies of flagellated bacteria, we numerically simulate their swimming motion using a boundary element-regularized Stokeslet method. The flagella are modelled as discretized Kirchhoff rods. We apply our model to: (i) bacteria with a pulling flagellum in front and a pushing flagellum at the rear, and (ii) bacteria with three pushing flagella. Bacterial hook flexibility and flagellar placement are important considerations, especially near a no-slip wall.

01933 (2/3) : 1D @D403 [Chair: Yuan-Nan Young]

[05143] A multiscale framework for rigid bodies in Stokes flow with applications to nanocellulose

Format : Talk at Waseda University
Author(s) : Anna Broms (KTH Royal Institute of Technology)Gusten Isfeldt (KTH Royal Institute of Technology)Mattias Sandberg (KTH Royal Institute of Technology)Jakob Wohlert (KTH Royal Institute of Technology)Fredrik Lundell (KTH Royal Institute of Technology)Anna-Karin Tornberg (KTH Royal Institute of Technology)
Abstract : The dynamics of rod-like nanocellulose crystals in an aqueous suspension is modelled with the rigid multiblob method for Stokes flow, with particle interactions from an accurate potential obtained from molecular dynamics data fed to a neural network. Tools to control the error from the hydrodynamic interactions and from discretising the overdamped Langevin equation, describing the Brownian motion of the particles, enable predictions of physical properties difficult to measure in the lab.

[04881] Bounds on particle configurations in an active suspension

Format : Talk at Waseda University
Author(s) : Scott Weady (Flatiron Institute)
Abstract : We present bounds on orientational order parameters in the Doi-Saintillan-Shelley kinetic theory of active suspensions. Using the energy method, we show isotropic suspensions are nonlinearly stable for sufficiently low activity. A similar approach admits nontrivial bounds on time averages of order parameters for all levels of activity that are consistent with nonlinear simulations. This work highlights the organizing role of activity in particle suspensions and places precise limits on how organized such systems can be.

[04858] Drag force on spherical particles trapped at a liquid interface

Format : Talk at Waseda University
Author(s) : Zhi Zhou (Northwestern University)Petia M Vlahovska (Northwestern University)Michael J Miksis (Northwestern University)
Abstract : Here we present a combined asymptotic and numerical investigation of the fluid motion past spherical particles attached
to a deformable interface undergoing uniform creeping flows in the limit of small Capillary number and small deviation of the contact angle from 90 degrees. The drag and torque coefficients are computed as
a function of the contact angle, the viscosity ratio, the Bond number, the slip coefficient along the particle surface, and the distance between two particles.

[05148] Bacterial collective motion and spread in porous media

Format : Talk at Waseda University
Author(s) : Yasser Almoteri (New Jersey Institute of Technology)Enkeleida Lushi (New Jersey Institute of Technology)
Abstract : We investigate through modeling, analysis and nonlinear simulations, the motion of micro-swimmers in fluids with resistance, which approximates porous wet media. We use a continuum model to describe the

dynamics of bacteria each performing run-and-tumble motions, coupled to the dynamics of the immersing fluid modeled by the Stokes-Brinkman equation with an added active stress. The linear stability of the uniform isotropic state reveals that the Brinkman resistance weakens or fully suppresses the chaotic motion of the bacterial suspension. Simulations of the full nonlinear PDE system confirm the analytical results. We discuss how the fluid resistance inhibits the spread of bacteria, and its interplay with auto-chemotactic interactions and food chasing give rise to non-trivial dynamics. Last, we discuss simulations of the coupled motion of many individually-traced micro-swimmers in Brinkman flows.

01933 (3/3) : 1E @D403 [Chair: Henry Shum]

[02866] Soft magnetic microrobots move more efficiently with a flat tire

Format : Talk at Waseda University
Author(s) : Brennan Sprinkle (Colorado School of Mines)Yan Gao (Colorado School of Mines)David Marr (Colorado School of Mines)Ning Wu (Colorado School of Mines)
Abstract : I'll discuss the rolling of active Pickering emulsions - small droplets (~10-100 um) covered in smaller (~1um) active particles that can be rolled along a surface by an external, AC magnetic field. Curiously, these droplets roll much faster and more efficiently when they have a larger area of contact with the confining surface. I'll describe experiments done by collaborators to validate this behavior and numerical simulations that I developed to quantify it.

[05297] Bacterial swarming above surfaces with friction

Format : Talk at Waseda University
Author(s) : Enkeleida Lushi (New Jersey Institute of Technology)
Abstract : We present a mathematical model and numerical simulations for the collective dynamics of swimming bacteria above surfaces with and without friction. The bacteria are modeled as self-propelling force-dipole ellipsoids that interact with each-other and the surface through hydrodynamics and direct collisions. The conditions for when the surface friction is sufficient to render an individual swimmer immobile are determined, as well as the swimmer density needed to collectively generate fluid flow disturbances that are strong enough to help regain mobility. Analysis of the characteristics of the emerging collective dynamics reveals a phase diagram of qualitatively distinct regimes for varying swimmer shape and population densities. Lastly, we compare our findings with recent experimental results of swarming Bacillus subtilis mutants.

[01935] Advances in Inverse Problems and Imaging

Session Time & Room :

01935 (1/3) : 1E (Aug.21, 17:40-19:20) @G809

01935 (2/3) : 2C (Aug.22, 13:20-15:00) @G809

01935 (3/3) : 2D (Aug.22, 15:30-17:10) @G809

Type : Proposal of Minisymposium
Abstract : With the promotion by both mathematics itself and the practical requirements from engineering, the interest of researches on inverse problems and imaging, has been growing vigorously recent decades. The characteristic of the ill-posedness for inverse problems and imaging makes it hard to construct solutions. To overcome difficulties, various regularization techniques must be introduced which are closely related to many mathematical branches such as partial differential equations, differential geometry, numerical analysis, machine learning, image processing, functional analysis, optimizations and computer science. This minisymposium will bring together experts to discuss recent progresses in this area and related topics.

[03733] Increasing stability in the linearized inverse Schrodinger potential problems

Format : Talk at Waseda University
Author(s) : Shuai Lu (Fudan University)
Abstract : Inverse Schrodinger potential problem concerns about the recovery of a potential function in the Schrodinger equation in a bounded domain throught the DtN map. In this talk, we introduce the linearized DtN map, and prove a stability estimate with explicit dependence on wavenumbers. This is an increasing stability result, in the sense that the logarithmic stable term decays when wavenumber increases. The talk is based on joint works with Victor Isakov (Wichita), Mikko Salo (Jyvaskyla), Boxi Xu (SUFE) and Sen Zou (Fudan).

[03422] High-order boundary integral equation solvers for layered-medium scattering problems

Format : Talk at Waseda University
Author(s) : Tao Yin (Chinese Academy of Sciences)
Abstract : This talk will present our recent works on the fast and highly accurate boundary integral equation (BIE) methods, including the windowed Green function (WGF) method and perfectly-matched-layer (PML) BIE method, for solving the acoustic and elastic wave scattering problems in both two- and three-dimensional layered-medium. 1) The WGF method utilize the free-space fundamental solution to derive the BIEs on the whole unbounded surface which requires to be truncated in practical computing. Based on the solutions due to the scattering by flat surface, a correction strategy is introduced to ensure uniform accuracy for all incident angles. 2) For the half-space and two layered-medium case, the original scattering problem can be truncated onto a bounded domain by the PML. Assuming the vanishing of the scattered field on the PML boundary, BIEs on local defects are derived only in terms of using the PML-transformed free-space Green's function. For the considered two methods, a high-order Chebyshev-based rectangular-polar singular-integration solver is used in numerical implementation. Numerical experiments for both two- and three-dimensional problems are carried out to demonstrate the accuracy and efficiency of the proposed solvers. Potential applications to the inverse problems of reconstructing unbounded surfaces will also be discussed.

[04333] An inverse boundary value problem for a nonlinear elastic wave equation

Format : Talk at Waseda University
Author(s) : Jian Zhai (Fudan University)
Abstract : We consider an inverse boundary value problem for a nonlinear model of elastic waves. We show that all the material parameters appearing in the equation can be uniquely determined from boundary measurements under certain geometric conditions. The proof is based on the construction of Gaussian beam solutions.

[03434] Inverse random scattering problems for stochastic wave equations

Format : Talk at Waseda University
Author(s) : Jianliang Li (Hunan Normal University)Peijun Li (Purdue University)Xu Wang (Chinese Academy of Sciences)
Abstract : Inverse random scattering problems with a random source or potential will be introduced for time-harmonic wave equations. The unknown random source or potential is assumed to be a generalized isotropic Gaussian random field. With information of the data observed in a bounded domain, the strength of the random source or potential is shown to be uniquely determined by a single realization of the magnitude of the wave field averaged over the frequency band almost surely.

01935 (2/3) : 2C @G809 [Chair: Bo Zhang]

[04564] An Inverse Problem for Nonlinear Time-dependent Schrodinger Equations with Partial Data

Format : Talk at Waseda University
Author(s) : Ting Zhou (Zhejiang University)Ru-Yu Lai (University of Minnesota)Xuezhu Lu (Northeastern University)
Abstract : In this talk, I will present some recent results on solving inverse boundary value problems for nonlinear PDEs, especially for a time-dependent Schrodinger equation with time-dependent potentials with partial boundary

Dirichlet-to-Neumann map. After a higher order linearization step, the problem will be reduced to implementing special geometrical optics (GO) solutions to prove the uniqueness and stability of the reconstruction. This is a joint work with my PhD student Xuezhu Lu and Prof. Ru-Yu Lai.

[04099] Inverse scattering problems with incomplete data

Format : Talk at Waseda University
Author(s) : Xiaodong Liu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : Inverse scattering problems aim to determine unknown scatterers with wave fields measured around the scatterers. However, from the practical point of views, we have only limited information, e.g., limited aperture data phaseless data and sparse data. In this talk, we introduce some data retrieval techniques and the applications in the inverse scattering problems. The theoretical and numerical methods for inverse scattering problems with multi-frequency spase measurements will also be mentioned.

[03745] Imaging of penetrable locally rough surfaces from phaseless total-field data

Format : Talk at Waseda University
Author(s) : Haiwen Zhang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Long Li (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Jiansheng Yang (Peking University)Bo Zhang (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : This talk is concerned with inverse scattering by a two-layered medium with a locally rough interface in 2D. We propose a direct imaging method to reconstruct the penetrable locally rough surface from phaseless total-field data. The theoretical analysis is mainly based on the results in our recent work (L. Li, J. Yang, B. Zhang and H. Zhang, arXiv:2208.00456) on the uniform far-field asymptotics of the scattered field for acoustic scattering in a two-layered medium.

[04075] A new approach to an inverse source problem for the wave equation

Format : Talk at Waseda University
Author(s) : Haibing Wang (Southeast University)
Abstract : Consider an inverse problem of reconstructing a source term from boundary measurements for the wave equation. We propose a novel approach to recover the unknown source through measuring the wave fields after injecting small particles, enjoying a high contrast, into the medium. For this purpose, we first derive the asymptotic expansion of the wave field, based on the time-domain Lippmann-Schwinger equation. The dominant term in the asymptotic expansion is expressed as an infinite series in terms of the eigenvalues of the Newtonian operator (for the pure Laplacian). Such expansions are useful under a certain scale between the size of the particles and their contrast. Second, we observe that the relevant eigenvalues appearing in the expansion have non-zero averaged eigenfunctions. By introducing a Riesz basis, we reconstruct the wave field, generated before injecting the particles, on the center of the particles. Finally, from these last fields, we reconstruct the source term. A significant advantage of our approach is that we only need the measurements for a single point away from the support of the source. This is a joint work with Prof. Mourad Sini from RICAM.

01935 (3/3) : 2D @G809 [Chair: Xiang Xu]

[04288] Recovering an infinite rough surface by acoustic measurements

Format : Talk at Waseda University
Author(s) : Jiaqing Yang (Xi'an Jiaotong University)
Abstract : In this talk, I will report some recent advances on inverse scattering by rough surfaces, where new uniqueness results and inversion algorithms will be presented to recover the shape and location of the rough surface from the near-field measurements associated with incident point sources. Moreover, several numerical examples will be provided to illustrate the effectiveness of the algorithms.

[03405] Uniqueness on recovering coefficients from localized Dirichlet-to-Neumann map for piecewise homogeneous piezoelectricity

Format : Talk at Waseda University
Author(s) : Xiang Xu (Zhejiang University)
Abstract : In this talk, we present an inverse problem on determining coefficients of piecewise homogeneous piezoelectric equations from a localized Dirichlet-to-Neumann map on partial boundaries. Assume the bounded domain can be divided into finite subdomains, in which the unknown coefficients including the anisotropic elastic tensor, the piezoelectric tensor, and the dielectric tensor are constants. Two different cases are considered: the subdomains are either known and Lipschitz or unknown and subanalytic. For both cases, the unknown coefficients can be uniquely determined from a given localized Dirichlet-to-Neumann map.

[01952] Mathematical models of morphogenesis and morphological deformation in living organisms

Session Time & Room : 4E (Aug.24, 17:40-19:20) @A512

Type : Proposal of Minisymposium
Abstract : The objective of our proposal is to present recent development of mathematical theory of morphogenesis and morphological deformation in living organisms. The topics are dynamics of endothelial cells is angiogenesis, i.e., the formation of networks of blood vessels, morphogenetic processes of organs, homeostasis of precursor cells in the brain and the genesis of a glioma and sol-gel transition of teleost muscular proteins. In each talk, both recent experimental results and the mathematical models, which can be used for the analysis of them, are presented.
Organizer(s) : Tetsuji Tokihiro
Classification : 92-10, 92C15, 92C37
Minisymposium Program :

01952 (1/1) : 4E @A512 [Chair: Tetsuji Tokihiro]

[02830] A kinetic model for sol-gel transition of teleost muscular proteins

Format : Talk at Waseda University
Author(s) : Yuri Kominami (The University of Tokyo)
Abstract : Various enzymatic reactions have a critical role in control of cellular function in living tissue. The enzymes can be activated in the tissue after organismal death and cause post-mortem changes. The enzymes delivered from animal tissue are also activated during food processing and affect product attributes. In this talk, the enzymatic reactions during sol-gel transition of teleost muscular proteins will be addressed and a kinetic model will be discussed.

[03680] Mathematical model for dynamics of endothelial cells in sprouting angiogenesis

Format : Talk at Waseda University
Author(s) : Tatsuya Hayashi (Yamato University)
Abstract : Angiogenesis is a morphogenic process that involves the emergence of new blood vessels from an existing vascular network. We propose a mathematical model based on the characteristic movements of endothelial cells in angiogenesis. In this presentation, we show that our model is able to reproduce the coordinated linear and rotational movements observed in a two-cell state, as well as angiogenic morphogenesis and the effects of cell adhesion molecules in a multicellular simulation.

[04407] Measurement and mathematical analysis of organ morphogenetic processes

Format : Talk at Waseda University
Author(s) : Yoshihiro Morishita (RIKEN Center for Biosystems Dynamics Research)
Abstract : The physical processes that govern the formation of almost all organs, namely, collective cell motion and tissue-level deformation, remain largely unknown. However, recent advances in microscopy have enabled the measurement and quantification of these dynamics. In this study, we investigate the early development of the forebrain and heart and present our findings on the morphogenetic rules that underlie their formation, based on our analysis of the measured morphogenetic dynamics.

[03395] A mathematical model for the evolution of low-grade gliomas before and after radiotherapy

Format : Talk at Waseda University
Author(s) : Mathilde Badoual (Paris Cité University)Leo Adenis (CNRS)Stephane Plaszczynski (CNRS)Jean-Eric Campagne (CNRS)Basile Grammaticos (CNRS)Johan Pallud (Sainte-Anne Hospital)
Abstract : Diffuse low-grade gliomas are slowly growing tumors that mainly affect adults around 40 years old and are incurable. After tens of years, they transform inexorably into more aggressive forms, jeopardizing the patient's life. Mathematical modeling could help clinicians to have a better understanding of the underlying biological process involved in the evolution of these tumors and their response to treatments. We present here a model of evolution of these tumors, based on a PDE that describes the evolution of the cell density and the effect of radiotherapy. This model is used to fit clinical data (MRI scans), and to predict the regrowth time after radiotherapy.

[01996] Control and inverse problems on waves, oscillations and flows

Session Time & Room :

01996 (1/3) : 2E (Aug.22, 17:40-19:20) @G809

01996 (2/3) : 3C (Aug.23, 13:20-15:00) @G809

01996 (3/3) : 3D (Aug.23, 15:30-17:10) @G809

Type : Proposal of Minisymposium
Abstract : The identification of unknown ingredients in wave, oscillation and flow phenomena governed by evolutionary PDEs from observational data is a central challenge in a variety of areas of science and engineering. This mini-symposium aims at gathering together international scientific researchers to share the latest progress on the related control and inverse problems. It provides a platform to discuss recent developments and emerging challenges, which include but are not limited to

1. Stability and controllability for inverse parabolic and hyperbolic problems;
2. Uniqueness of inverse problems for subdiffusion and viscoelasticity;
3. Data-driven inversion methods and optimal control;
4. Related numerical schemes for reconstruction.

[03795] Recovery in vivo viscoelasticity from elastography measured data

Format : Talk at Waseda University
Author(s) : Yu Jiang (Shanghai University of Finance and Economics)
Abstract : This talk will briefly describe how to solve the inverse problem of recovering in vivo viscoelasticity from elastography (magnetic resonance elastography, ultrasound elastography) measurements. To solve it robustly, one need to have a proper partial differential equation model to describe the wave motion inside living body. And based on this PDE model and given interior measurements, theoretical and numerical inverse analyzes need to be performed. As the PDE model, we start with a dynamic viscoelastic model and several simplified models are given. For inversion analysis, we give several practical numerical inversion methods to identify viscoelasticity, such as regularized numerical differentiation method etc.

[03880] Acousto-electric tomography imaging model and algorithm based on two-point gradient method

Format : Talk at Waseda University
Author(s) : Min Zhong (School of Mathematics, Southeast University)
Abstract : We study the numerical reconstruction problem in acousto-electric tomography of recovering the conductivity distribution in a bounded domain from interior power density data. We propose a numerical method for recovering discontinuous conductivity distributions, by utilizing the two point gradient method, the piecewise constant conductivity can be efficiently reconstructed. Extensive numerical experiments are presented to illustrate the feasibility of the proposed approach.

[04269] Numerical method for unique continuation of elliptic equations and applications

Format : Talk at Waseda University
Author(s) : Yu Chen (Shanghai University of Finance and Economics)Jin Cheng (Fudan University)
Abstract : Numerical method for unique continuation of elliptic equations is related to information reconstruction from interior local measurements. The conditional stability of unique continuation along analytic sub-manifolds in three dimensions will be provided. A stable numerical algorithm is constructed based on Tikhonov regularization according to the conditional stability, in order to deal with the ill-posedness. The evaluation of reliable region of a reconstruction and potential applications of the present method in atmospheric flows will be discussed.

[04089] Reconstruction of piecewise smooth diffusion coefficient and initial value with adaptive regularization

Format : Talk at Waseda University
Author(s) : Shuli CHEN (Hokkaido University)Haibing Wang (Southeast University)
Abstract : This talk will present an inverse problem of simultaneously reconstructing the piecewise smooth diffusion coefficient and initial value in a diffusion equation from extra measurements. The inverse problem is transformed into solving an optimization problem with a switchable regularization to simultaneously preserve multiple properties of unknown functions. The existence, stability and consistency result are rigorously analyzed by introducing a domain index. Then, we decompose the optimization problem into a SOLVE-MARK-REFINE-looping scheme and develop an adaptive iterative algorithm. Finally, we present several numerical examples to show the validity of the proposed algorithm.

[04229] Inverse problems for the Duffing equation in pediatrics

Format : Talk at Waseda University
Author(s) : Manabu Machida (Hamamatsu University School of Medicine)
Abstract : The prognostic prediction of the neonatal hypoxic-ischemic encephalopathy (HIE) has been tried with near-infrared spectroscopy. In this talk, the Duffing equation is proposed as a model which governs the time-evolution of the cerebral blood volume. We will consider an inverse problem of determining coefficients and initial values of the equation.

[04402] Unique determination of source and Robin coefficient in fractional diffusion equation

Format : Talk at Waseda University
Author(s) : Zhiyuan Li (Ningbo University)Daijun Jiang (Central Central China Normal UniversityChina Normal University)
Abstract : In this talk, we consider an inverse problem of simultaneously determining the spatially dependent source term and the Robin boundary coefficient in a time fractional diffusion equation, with the aid of extra measurement data at a subdomain near the accessible boundary. Firstly, the spatially varying source is uniquely determined in view of the unique continuation principle and Duhamel principle for the fractional diffusion equation. The Hopf lemma for a homogeneous time-fractional diffusion equation is proved and then used to prove the uniqueness of recovering the Robin boundary coefficient.

[05327] Fine-tuning neural-operator architectures for training and generalization

Format : Talk at Waseda University
Author(s) : Takashi Furuya (Shimane University)
Abstract : We investigate the generalization error of Neural Operators (NOs), which aim to approximate the forward operator in PDEs, and propose modifications of NOs, referred to as $s\mathrm{NO}+\varepsilon$. We establish generalization error bounds for both NOs and $s\mathrm{NO}+\varepsilon$, and we observe that our bound is sharper than that for NOs. Additionally, our experiments, particularly the wave equation experiment, demonstrate that our proposed network exhibits remarkable generalization capabilities, whereas NOs perform poorly in out-of-distribution scenarios.

[03684] Reconstruction of location for a single point target in time-domain fluorescence diffuse optical tomography

Format : Talk at Waseda University
Author(s) : Junyong Eom Gen Nakamura (Hokkaido University)Goro Nishimura (Hokkaido University)Chunlong Sun (Nanjing University of Aeronautics and Astronautics)
Abstract : The time-domain fluorescence diffuse optical tomography (FDOT) problem is to recover the distribution of fluorophores in biological tissue from the time-domain measurement on the boundary. The measurement is conducted by several pairs (S-D pairs) of a point source and a point detector. In this paper, we identify the location of the distribution of fluorophores over a point, refer as a point target. We first express a solution for the forward problem in a dimensionless form and consider its asymptotic expansion. Then, we theoretically investigate the minimal number of S-D pairs to determine the point target location, analyzing the sensitivity matrix. Finally, we numerically verify the invertibility of the matrix and demonstrate the local solvability for locating well-separated multiple point targets.

[05416] STABILITY ESTIMATES FOR AN INVERSE PROBLEM FOR SCHRODINGER OPERATORS AT HIGH FREQUENCIES FROM ARBITRARY PARTIAL BOUNDARY MEASUREMENTS

Format : Online Talk on Zoom
Author(s) : Ganghua Yuan Xiaomeng Zhao (Northeast Normal University)
Abstract : In this talk, we consider the partial data inverse boundary value problem for the Schrodinger operator at a high frequency in a bounded domain in $\mathbb{R}^n$, $n \geq 3$. Assuming that the potential is known in a neighborhood of the boundary, we obtain the logarithmic stability when both Dirichlet and Neumann data are taken on arbitrary open subsets of the boundary . We used a method combining the CGO solution, Runge approximation and Carleman estimate.

[04623] Carleman estimates and some inverse problems for the coupled quantitative thermoacoustic equations

Format : Online Talk on Zoom
Author(s) : Michel Cristofol (Aix-Marseille Université)Shumin Li (University of Science and Technology of China)Yunxia Shang (Shanghai Normal University)
Abstract : We consider the determination of a coefficient or the source term in a strong coupled quantitative thermoacoustic system of equations. For this purpose, we establish a Carleman estimate for the coupled quantitative thermoacoustic equations. Applying this Carleman estimate, we prove stability estimates of Hölder type for inverse problems involving the observation of only one component: the temperature or the pressure.

[02703] Numerical reconstruction of the spatially dependent source term in a time-fractional diffusion equation

Author(s) : Daijun Jiang (Central China Normal University)
Abstract : In this talk, we are concerned with the analysis on the numerical reconstruction of the spatial component in the source term of a time-fractional diffusion equation. This ill-posed problem is solved through a stabilized nonlinear minimization system by an appropriately selected Tikhonov regularization. The existence and the stability of the optimization system are demonstrated. The nonlinear optimization problem is approximated by a fully discrete scheme, whose convergence is established under a novel result verified in this study that the H1 -norm of the solution to the discrete forward system is uniformly bounded. The iterative thresholding algorithm is proposed to solve the discrete minimization, and several numerical experiments are presented to show the efficiency and the accuracy of the algorithm.

[04572] Unique continuation for wave equations in asymptotically anti-de Sitter spaces

Format : Talk at Waseda University
Author(s) : Hiroshi Takase (Kyushu University)
Abstract : An asymptotic anti-de Sitter space is a Lorentzian manifold with a Lorentz metric diverging at the boundary of the manifold. It is also used as a model of outer space, and in particular, the problem of determining the inner structure from the data at the boundary has attracted attention in theoretical physics as AdS/CFT correspondence. The wave equation in this space is a degenerate equation. In this talk, I will present results on the fundamental property of unique continuation for this wave equation.

[02012] Splitting Optimization: Theory, Methodology and Application

Session Time & Room :

02012 (1/4) : 2E (Aug.22, 17:40-19:20) @A207

02012 (2/4) : 3C (Aug.23, 13:20-15:00) @A207

02012 (3/4) : 3D (Aug.23, 15:30-17:10) @A207

02012 (4/4) : 3E (Aug.23, 17:40-19:20) @A207

Type : Proposal of Minisymposium
Abstract : With the development of artificial intelligence, big data and other applications, large-scale optimization problems have received more and more attention. The advantage of the splitting method is to make use of the problem structure to reasonably disassemble the large-scale optimization problem into a series of subproblems, and to solve the large-scale optimization problem efficiently through the "decomposition-integration" architecture. This minisymposium introduces splitting optimization through a series of reports, including theories, methods, and applications.

[02878] Decentralized Entropic Optimal Transport for Privacy-preserving Distributed Distribution Comparison

Format : Talk at Waseda University
Author(s) : Xiangfeng Wang (East China Normal University)
Abstract : Privacy-preserving distributed distribution comparison measures the distance between the distributions whose data are scattered across different agents in a distributed system and cannot be shared among the agents. In this study, we propose a novel decentralized entropic optimal transport (EOT) method, which provides a privacy-preserving and communication-efficient solution to this problem with theoretical guarantees. In particular, we design a mini-batch randomized block-coordinate descent (MRBCD) scheme to optimize the decentralized EOT distance in its dual form. The dual variables are scattered across different agents and updated locally and iteratively with limited communications among partial agents. The kernel matrix involved in the gradients of the dual variables is estimated by a distributed kernel approximation method, and each agent only needs to approximate and store a sub-kernel matrix by one-shot communication and without sharing raw data. We analyze our method's communication complexity and provide a theoretical bound for the approximation error caused by the convergence error, the approximated kernel, and the mismatch between the storage and communication protocols. Experiments on synthetic data and real-world distributed domain adaptation tasks demonstrate the effectiveness of our method.

[02881] An alternative extrapolation scheme of PDHGM for saddle point problem with nonlinear function

Format : Talk at Waseda University
Author(s) : Wenxing Zhang (University of Electronic Science and Technology of China)
Abstract : Primal-dual hybrid gradient method (PDHG) is a canonical and popular prototype for solving saddle point problem (SPP). However, the nonlinear coupling term in SPP excludes the application of PDHG on far-reaching real-world problems. In this talk, we devise a variant iterative scheme for solving SPP with nonlinear function by exerting an alternative extrapolation procedure. Under the metrically regular assumption on KKT mapping, we simplify the local convergence of the proposed method on contractive perspective. Numerical simulations on a PDE-constrained nonlinear inverse problem and parametric blind deconvolution demonstrate the compelling performance of the proposed method.

[02882] A balanced Douglas-Rachford splitting algorithm for convex minimization

Format : Talk at Waseda University
Author(s) : Xingju Cai (Nanjing Normal University)
Abstract : The Douglas-Rachford algorithm is a classical and effective splitting method to solve the inclusion problems. Recently, an adaptive Douglas-Rachford splitting algorithm is proposed for the monotone inclusion, which allow one operator be weakly monotone. We apply the idea of adaptive Douglas-Rachford splitting method (ADRSM) to differentiable convex optimization problems with abstract constraints, and more attractive results can be obtained for the convex optimization problem. We propose accurate and inaccurate versions of the algorithm respectively, and prove the global convergence of the algorithms. We extend these results to two separable convex optimization problems with linear constraints. In numerical experiments, we compare our algorithms with other commonly used algorithms and the results verify the effectiveness of our algorithms.

[02904] A projection-like method for quasimonotone variational inequalities without Lipschitz continuity

Format : Talk at Waseda University
Author(s) : Lingling Xu (Nanjing Normal University)Xiaoxi Jia (Institute of Mathematics, University of würzburg,)
Abstract : For most projection methods, the operator of a variational inequality problem is assumed to bemonotone (or pseudomonotone) and Lipschitz continuous. In this paper, we present a projection-like method to solve quasimonotone variational inequality problems without Lipschitz continuity. Under some mild assumptions, we prove that the sequence generated by the proposed algorithm converges to a solution. Numerical experiments are provided to show the effectiveness of the method.

02012 (2/4) : 3C @A207 [Chair: Deren Han]

[02918] A trust-region-based splitting method for linear constrained programs

Format : Talk at Waseda University
Author(s) : Deren Han (Beihang University)
Abstract : The augmented Lagrangian based splitting methods have found more and more applications in scientific and engineering computation, such as compressive sensing, covariance selection, image processing and transportation research. One of the basic difficulties in such algorithms is the selection of the parameter in the augmented Lagrangian function, a larger one may make the primal progress too small while a small one may slow down the dual progress. To overcome this difficulty, in this paper, we propose to solve the splitting subproblems in a trust-region manner, and the radius can be adjusted smartly. Under the same mild conditions as those for classical augmented Lagrangian based splitting methods, we prove the global convergence of the proposed algorithm. Moreover, the $\mathcal{O}(1/\epsilon)$ convergence rate is also analyzed in an ergodic sense. We present some preliminary numerical experiments on medical image recovery and traffic assignment, which show that the trust-region-based splitting method is efficient and promising.

[02995] A Decentralized Second-Order Multiplier Algorithm with Quasi-Newton Tracking

Format : Talk at Waseda University
Author(s) : Liping Wang (Nanjing University of Aeronautics and Astronautics)
Abstract : In this talk, we consider a decentralized optimization problem of minimizing a finite sum of strongly convex and twice continuously differentiable functions over a fixed connected undirected network. We propose a fully decentralized second-order multiplier algorithm (DSOM) where second-order information are approximated by simple algebraic calculations and at most matrix-vector products. It is the first work to study the second-order multiplier method in decentralized optimization which is equivalent to the primal-dual method with twice primal quasi-Newton steps and once dual BB step per iteration. Additionally, in DSOM the local direction on each node asymptotically approximates the global quasi-Newton direction. Under some mild assumptions, the proposed algorithm is illustrated to have global linear convergence rate. Numerical results are also reported for verifying its effectiveness.

[03066] Tight Convergence Rate in Subgradient Norm of the Proximal Point Algorithm

Format : Talk at Waseda University
Author(s) : Guoyong Gu (Nanjing University)Junfeng Yang (Nanjing University)
Abstract : Proximal point algorithm has found many applications, and it has been playing fundamental roles in the understanding, design, and analysis of many first-order methods. In this paper, we derive the tight convergence rate in subgradient norm of the proximal point algorithm, which was conjectured by Taylor, Hendrickx and Glineur [SIAM J. Optim., 27 (2017), pp. 1283--1313].

[03073] A fast PIRNN algorithm for nonconvex low-rank matrix minimization problems

Format : Talk at Waseda University
Author(s) : Zhili Ge (Nanjing Normal University of Special Education)
Abstract : In this paper, we propose a fast PIRNN algorithm with extrapolation for solving a class of nonconvex low-rank matrix minimization problems. The proposed method incorporates two different extrapolation steps with respect to the previous iterations into the backward proximal step and the forward gradient step of the classic proximal iteratively reweighted method. We prove that the proposed method generates a convergent subsequence under general parameter constraints, and that any limit point is a stationary point of the problem. Furthermore, we prove that if the objective function satisfies the KL property, the algorithm is globally convergent to a stationary point of the considered problem. Finally, we perform numerical experiments on a practical matrix completion problem with both synthetic and real data, the results of which demonstrate the efficiency and superior performance of the proposed algorithm.

02012 (3/4) : 3D @A207 [Chair: Xinxin Li]

[03085] Gradient methods using Householder transformation with application to hypergraph partitioning

Format : Talk at Waseda University

Author(s) : Xin Zhang (Suqian University)Jingya Chang (Guangdong University of Technology)Zhili Ge (, Nanjing Normal University of Special Education)Zhou Sheng (Anhui University of Technology)

Abstract : In this paper, we propose a constraint preserving algorithm for the smallest Z-eigenpair of the compact Laplacian tensor of an even-uniform hypergraph, where Householder transform is employed and a family of modified conjugate directions with sufficient descent is determined. Besides, we prove that there exists a positive step size in the new constraint preserving update scheme such that the Wolfe conditions hold. Based on these properties, we prove the convergence of the new algorithm. Furthermore, we apply our algorithm to the hypergraph partitioning and image segmentation, numerical results are reported to illustrate the efficiency of the proposed algorithm.

[03102] Solving saddle point problems: a landscape of primal-dual algorithm with larger stepsizes

Format : Talk at Waseda University

Author(s) : Fan Jiang (Nanjing University of Information Science and Technology)Hongjin He (Ningbo University)Zhiyuan Zhang (Xiamen University)

Abstract : We consider a class of saddle point problems frequently arising in the areas of image processing and machine learning. In this paper, we propose a simple primal-dual algorithm, which embeds a general proximal term induced with a positive definite matrix into one subproblem. It is remarkable that our algorithm enjoys larger stepsizes than many existing state-of-the-art primal-dual-like algorithms due to our relaxed convergence-guaranteeing condition. Moreover, our algorithm includes the well-known primal-dual hybrid gradient method as its special case, while it is also of possible benefit to deriving partially linearized primal-dual algorithms. Finally, we show that our algorithm is able to deal with multi-block separable saddle point problems. In particular, an application to a multi-block separable minimization problem with linear constraints yields a parallel algorithm. Some computational results sufficiently support the promising improvement brought by our relaxed requirement.

[03200] Inexact variable metric proximal incremental aggregated gradient algorithm for nonconvex nonsmooth optimization problem

Author(s) : zehui Jia (Nanjing University of Information Science and Technology)junru Hou (Nanjing University of Information Science and Technology)xingju Cai (Nanjing Normal University)

Abstract : This paper focuses on the problem that minimizing the sum of a nonconvex smooth function and a nonsmooth convex function, in which the smooth term is in the form of finite sum. In order to solve the problem efficiently, we introduce the idea of incremental aggregation and two different inexact criterions to the variable metric proximal gradient (VMPG) algorithms, and then propose the inexact variable metric proximal incremental aggregated gradient (iVMPIAG) algorithms, i.e., iVMPIAG-I, iVMPIAG-II. Under the Kurdyka-Łojasiewicz (KL) property, we show the global convergence of iVMPIAG-I and iVMPIAG -II. When the Łojasiewicz exponent is known, we can prove the convergence rate of iVMPIAG-I with respect to the objective function value and the convergence rate of iVMPIAG-II with respect to the iterative sequence. Note that, for the convergence analysis of iVMPIAG-I, a critical tool is introduced, i.e., the incremental aggregated forward-backward (FB) envelope, which is a continuously differential function and can cover the FB envelope as a special case. Based on this tool, we define a continuously differentiable surrogate function, which equals to the value of the objective function at the stationary point. Finally, we present the efficiency of the iVMPIAG method for large-scaled image restoration problem.

[03253] A Restricted Dual PRSM for a Strengthened DNN Relaxation for QAP

Format : Talk at Waseda University

Author(s) : Naomi Graham (University of British Columbia)Hao Hu (Clemson University)Jiyoung Im (University of Waterloo)Xinxin Li (Jilin University)Henry Wolkowicz (University of Waterloo)

Abstract : Splitting methods in optimization arise when one can divide an optimization problem into two or more simpler subproblems. They have proven particularly successful for relaxations of problems involving discrete variables. We revisit and strengthen splitting methods for solving doubly nonnegative, DNN, relaxations of the particularly difficult, NP-hard quadratic assignment problem, QAP. We use a modified restricted contractive splitting method, rPRSM, approach. In particular, we show how to exploit redundant constraints in the subproblems. Our strengthened bounds exploit these new subproblems, as well as new dual multiplier estimates, to improve on the bounds and convergence results in the literature.

[03002] High-order Structure-Preserving Schemes for Special Relativistic Hydrodynamics

Format : Talk at Waseda University
Author(s) : Huazhong Tang (Nanchang Hangkong University and Peking University)
Abstract : Abstract: This talk mainly reviews two high-order accurate structure-preserving finite difference schemes for the special relativistic hydrodynamics (RHD). The first is the physical-constraints-preserving (PCP) scheme, which preserves the positivity of the rest-mass density and the pressure and the bounds of the fluid velocity and is built on the local Lax-Friedrichs (LxF) splitting, the WENO reconstruction, the PCP flux limiter, and the high-order strong stability preserving time discretization. The key to developing such scheme is to prove the convexity and other properties of the admissible state set and to discover a concave function with respect to the conservative vector. The second is the entropy stable (ES) scheme, whose semi-discrete version satisfies the entropy inequality. The key is to technically construct the affordable entropy conservative (EC) flux of the semi-discrete second-order accurate EC schemes satisfying the semi-discrete entropy equality for the found convex entropy pair. As soon as the EC flux is derived, the dissipation term can be added to give the semi-discrete ES schemes satisfying the semi-discrete entropy inequality. The WENO reconstruction for the scaled entropy variables and the previous time discretization are implemented to obtain the fully-discrete high-order "ES" schemes. The performance of the proposed schemes has been demonstrated by numerical experiments. By the way, we also briefly review other relative works on the structure-preserving schemes for the special RHDs. Those works have been further to the general equation of state and the special relativistic magnetohydrodynamics etc., see our papers listed below for details.

[03400] High order entropy stable and positivity-preserving discontinuous Galerkin method for the nonlocal electron heat transport model

Format : Talk at Waseda University
Author(s) : Juan Cheng (Institute of Applied Physics and Computational Mathematics)
Abstract : The nonlocal electron heat transport model in laser heated plasmas plays a crucial role in inertial confinement fusion (ICF), and it is important to solve it numerically in an accurate and robust way. In this talk, we develop a class of high-order entropy stable discontinuous Galerkin methods for the nonlocal electron heat transport model. We further design our DG scheme to have the positivity-preserving property, which is shown, by a computer-aided proof, to have no extra time step constraint than that required by L2 stability. Numerical examples are given to verify the high-order accuracy and positivity-preserving properties of our scheme. By comparing the local and nonlocal electron heat transport models, we also observe more physical phenomena such as the flux reduction and the preheat effect from the nonlocal model.

[02764] A new cut-cell interface treating method for compressible multi-medium flow

Format : Talk at Waseda University
Author(s) : Chunwu Wang (Nanjing University of Aeronautics and Astronautics)
Abstract : In this work, a conservative sharp interface treating method is proposed for solving compressible multi-medium flow based on the cut-cell method. To overcome the small cell problem, which causes standard explicit scheme unstable, the most common approach is generating interface cells by merging small cut cells with their neighbors. We present a new and simple way to construct interface cells. Rather than considering various complex cell merging cases, we select some Cartesian cell nodes near the interface, and then connect these nodes to form the interface cells. Meanwhile, at the edges of the cell coinciding with the interface, the numerical fluxes are obtained by solving the local Riemann problem, thus the conservation of the flow variables is effectively maintained. Several numerical experiments indicate that our proposed method can capture the shock wave and material interface accurately and sharply, as well as being stable even for problems with significant density and pressure gradients.

[02690] A hybrid WENO scheme for steady Euler equations in curved geometries on Cartesian grids

Format : Talk at Waseda University
Author(s) : Yifei Wan (University of Science and Technology of China)Yinhua Xia (University of Science and Technology of China)
Abstract : For steady Euler equations in complex boundary domains, high-order shock-capturing schemes usually suffer not only from the difficulty of steady-state convergence but also from the problem of dealing with physical boundaries on Cartesian grids to achieve uniform high-order accuracy. In this work, we utilize a fifth-order finite difference hybrid WENO scheme to simulate steady Euler equations, and the same fifth-order WENO extrapolation methods are developed to handle the curved boundary. The values of the ghost points outside the physical boundary can be obtained by applying WENO extrapolation near the boundary, involving normal derivatives acquired by the simplified inverse Lax-Wendroff procedure. Both equivalent expressions involving curvature and numerical differentiation are utilized to transform the tangential derivatives along the curved solid wall boundary. This hybrid WENO scheme is robust for steady-state convergence and maintains high-order accuracy in the smooth region even with the solid wall boundary condition. Besides, the essentially non-oscillation property is achieved.

The numerical spectral analysis also shows that this hybrid WENO scheme possesses low dispersion and dissipation errors. Numerical examples are presented to validate the high-order accuracy and robust performance of the hybrid scheme for steady Euler equations in curved domains with Cartesian grids.

[03089] Error estimates to smooth solutions of high order Runge–Kutta discontinuous Galerkin method for scalar nonlinear conservation laws with and without sonic points

Format : Talk at Waseda University
Author(s) : Qiang Zhang (Nanjing University)
Abstract : In this talk we shall take the fourth order in time Runge--Kutta discontinuous Galerkin method, as an example of high order schemes, to establish a sharp a priori L^2-norm error estimates for sufficiently smooth solutions of one-dimensional scalar nonlinear conservation laws. The optimal order of accuracy in time is obtained under the standard Courant-Friedrichs-Lewy condition, and the quasi-optimal and/or optimal order of accuracy in space are achieved for many widely-used numerical fluxes, no matter whether the exact solution contains sonic points or not. Note that the convergence order in space strongly depends on the relative upwind effect of the used numerical flux, which is related to the local flowing speed and the strength of the numerical viscosity provided by the used numerical flux. Two main tools are used in this talk. One is the matrix transferring process, based on the temporal differences of stage errors. It gives a useful energy equation and help us to get the theoretical result under the acceptable temporal-spatial condition. The other is the generalized Gauss-Radau projection of the reference functions, which depends on the relative upwind effect and helps us to achieve the optimal order in space in many cases. Finally some numerical experiments are given to support the theoretical results.

[02994] Energy stable discontinuous Galerkin methods for compressible Navier–Stoles–Allen–Cahn System

Format : Talk at Waseda University
Author(s) : Qiaolin He (Sichuan University)Xiaoding Shi (Beijing University of Chemical Technology)
Abstract : In this work, we present a fully discrete local discontinuous Galerkin (LDG) finite element method combined with scalar auxiliary variable (SAV) approach for the compressible Navier--Stokes--Allen--Cahn (NSAC) system. We start with a linear and first order scheme for time discretization and the minimal dissipation LDG for spatial discretization, which is based on the SAV approach and is proved to be unconditionally energy stable for one dimensional case. The velocity, the density and the mass concentration of fluid mixture can be solved separately. In addition, a semi-implicit spectral deferred correction (SDC) method combined with the first order scheme is employed to improve the temporal accuracy. Due to the local properties of the LDG methods, the resulting algebraic equations at the implicit level are easy to implement. In particular, we use efficient and practical multigrid solvers to solve the resulting algebraic equations. Although there is no proof of stability for the semi-implicit SDC with LDG spatial discretization, numerical experiments of the accuracy and long time simulations are presented to illustrate the high order accuracy in both time and space, the discretized energy stability, the capability and efficiency of the proposed method. Numerical results show that the initial state determines the long time behavior of the diffusive interface for the two--phase flow, which are consistent with theoretical asymptotic stability results.

[02714] Superconvergence of LDG method for nonlinear convection-diffusion equations

Format : Talk at Waseda University
Author(s) : Xiong Meng (Harbin Institute of Technology)
Abstract : In this talk, we present superconvergence properties of the local discontinuous Galerkin (LDG) methods for solving nonlinear convection-diffusion equations in one space dimension. The main technicality is an elaborate estimate to terms involving projection errors. By introducing a new projection and constructing some correction functions, we prove the $(2k+1)$th order superconvergence for the cell averages and the numerical flux in the discrete L^2 norm with polynomials of degree $k \geq 1$, no matter whether the flow direction $f'(u)$ changes or not. Superconvergence of order $k+2$ $(k+1)$ is obtained for the LDG error (its derivative) at interior right (left) Radau points, and the convergence ord er for the error derivative at Radau points can be improved to $k+2$ when the direction of the flow doesn't change. Finally, a supercloseness result of order $k+2$ towards a special Gauss-Radau projection of the exact solution is shown. The superconvergence analysis can be extended to the generalized

numerical fluxes and the mixed boundary conditions. All theoretical findings are confirmed by numerical experiments.

[03001] An essentially oscillation-free discontinuous Galerkin method for hyperbolic conservation laws

Format : Talk at Waseda University
Author(s) : Yong Liu (ICMSEC, AMSS, CAS)Jianfang Lu (South China University of Technology)Chi-Wang Shu (Brown University)
Abstract : In this talk, we propose a novel discontinuous Galerkin (DG) method to control the spurious oscillations when solving the scalar hyperbolic conservation laws. The spurious oscillations may be harmful to the numerical simulation, as it not only generates some artificial structures not belonging to the problems but also causes many overshoots and undershoots that make the numerical scheme less robust. To overcome this difficulty, we introduce a numerical damping term to control spurious oscillations based on the classic DG formulation. Compared to the classic DG method, the proposed DG method still maintains many good properties, such as the extremely local data structure, conservation, L2-boundedness, optimal error estimates, and superconvergence. We also extend our methods to systems of hyperbolic conservation laws. Entropy inequalities are crucial to the well-posedness of hyperbolic conservation laws, which help to select the physically meaningful one among the infinite many weak solutions. By combining with quadrature-based entropy-stable DG methods, we also developed the entropy-stable OFDG method. For time discretizations, the modified exponential Runge--Kutta method can avoid additional restrictions of time step size due to the numerical damping. Extensive numerical experiments are shown to demonstrate our algorithm is robust and effective.

[03431] Structure-preserving methods for Boltzmann continuous slowing down equations

Format : Talk at Waseda University
Author(s) : Vincent Bosboom (University of Twente)Herbert Egger (Johannes Kepler Universität)Matthias Schlottbom (University of Twente)
Abstract : We discuss the linearized Boltzmann equation (LBE) describing the transport of particles under the influence of the Lorentz force and (inelastic) scattering. For this purpose, we consider the equation in the continuous slowing down approximation (CSDA).

We present a high-order discretization of the equation based on a mixed finite element P_N approximation that preserves the energy-conserving/dissipating nature of the different physical processes.

Additionally, we provide stability estimates of our discretization and present some numerical examples.

[03359] Positivity-preserving high-order DG method for weakly compressible two-phase flows

Format : Talk at Waseda University
Author(s) : Fan Zhang (University of Science and Technology Beijing)
Abstract : This work focuses on the development of a high-order DG method for solving a three-equation model of weakly compressible two-phase flows. A novel WENO limiter and a positivity-preserving limiter are designed and applied in the numerical simulations. Moreover, we prove that the proposed method satisfies the uniform-pressure-velocity criterion which is a necessary condition for maintaining an oscillation-free phase interface.

[03039] On Entropy Conservative and Stable Discontinuous Galerkin Spectral Element Methods

Author(s) : Gero Schnücke (Friedrich Schiller University Jena)
Abstract : The construction of high order numerical methods to solve conservation laws and related equations includes the
approximation of non-linear flux terms in the volume integrals. This terms can lead to aliasing and stability issues, e.g. due to under-resolution of vortical structures. The nodal discontinuous Galerkin spectral element method (DGSEM)

contains that discrete derivative approximations in space are summation-by-parts (SBP) operators. Furthermore, in order to avoid aliasing errors by the interpolation operator in the volume integrals, the split form DG framework from
Gassner et al. (1) is used in these methods. The SBP property and suitable two-point flux functions in the split form DG framework allow to mimic results from the continuous entropy analysis on the discrete level. In particular, semi-discrete DGSEMs can be constructed as provable entropy conservative or entropy dissipative schemes. Numerical experiments as well as results from the simulation of turbulent flows around airfoils will be presented to validate the capabilities of these methods.

[03065] Affine-Invariant WENO Weights and their applications for hyperbolic conservation laws

Author(s) : Wai Sun Don (Ocean University of China)
Abstract : Novel weights are devised for the Ai-WENO operator to reconstruct a function that undergoes an affine transformation. The WENO reconstruction and affine transformation become commutable for any given sensitivity parameter, as proven theoretically and validated numerically. The Ai-WENO scheme satisfies the ENO property and is intrinsically well-balanced. Examples in the shallow water wave equations and the Euler equations under gravitational fields are given. An Ai-WENO scheme enhances robustness and reliability for solving hyperbolic conservation laws.

[03094] Arbitrary high-order fully-decoupled numerical schemes for phase-field models of two-phase incompressible flows

Format : Talk at Waseda University
Author(s) : Ruihan Guo (Zhengzhou University)
Abstract : Due to the coupling between the hydrodynamic equation and the phase-field equation in two-phase incompressible flows, it is desirable to develop efficient and high-order accurate numerical schemes that can decouple these two equations. One popular and efficient strategy is adding an explicit stabilizing term to the convective velocity in the phase-field equation to decouple them. The resulting numerical methods are only first-order accurate in time, and it seems extremely difficult to generalize the idea of stabilization to the second-order version or higher. In this talk, we employ the spectral deferred correction method to improve the temporal accuracy, based on the first-order decoupled and energy stable scheme constructed by the stabilization idea. The novelty lies in how decoupling and linear implicit properties are maintained to improve efficiency. Within the framework of the spatially discretized local discontinuous Galerkin method, the resulting numerical schemes are fully decoupled, efficient, and high-order accurate in both time and space. Numerical experiments are performed to validate the high order accuracy and efficiency of the methods for solving phase-field models of two-phase incompressible flows.

[03096] Accuracy-enhancement of discontinuous Galerkin methods for PDEs containing high-order spatial derivatives

Format : Talk at Waseda University
Author(s) : Qi Tao (Beijing University of Technology)Liangyue Ji (Milton Keynes College)Jennifer K. Ryan (KTH Royal Institute of Technology in Stockholm)Yan Xu (University of Science and Technology of China)
Abstract : In this talk, we shall first introduce the accuracy-enhancement of discontinuous Galerkin (DG) methods for solving PDEs with high-order spatial derivatives. It is well known that there are highly oscillatory errors for finite element approximations to PDEs that contain hidden superconvergence points. To exploit this information, a Smoothness-Increasing Accuracy Conserving (SIAC) filter is used to create a superconvergence filtered solution. This is accomplished by convolving the DG approximation against a B-spline kernel. We then present theoretical error estimates in the negative-order norm for the local DG (LDG) and ultra-weak local DG (UWLDG) approximations to PDEs containing high order spatial derivatives. Numerical results will be shown to confirm the theoretical results.

[03105] A discontinuous Galerkin method for the Camassa-Holm-Kadomtsev-Petviashvili type equations

Format : Talk at Waseda University
Author(s) : Qian Zhang (Harbin Institute of Technology, Shenzhen)Yan Xu (University of Science and Technology of China)Yue Liu (The University of Texas at Arlington)
Abstract : This paper develops a high-order discontinuous Galerkin (DG) method for the Camassa-Holm-Kadomtsev-Petviashvili (CH-KP) type equations on Cartesian meshes. The significant part of the simulation for the CH-KP type equations lies in the treatment for the integration operator ∂^{-1}. Our proposed DG method deals with it element by element, which is efficient and applicable for most solutions. Using the instinctive energy of the original PDE as a guiding principle, the DG scheme can be proved as an energy stable numerical scheme. In addition, the semi-discrete error estimates results for the nonlinear case are derived without any priori assumption. Several numerical experiments demonstrate the capability of our schemes for various types of solutions.

[03349] High order finite difference WENO methods with unequal-sized sub-stencils for the DP type equations

Author(s) : Xinghui Zhong (Zhejiang University)
Abstract : In this talk, we present finite difference weighted essentially non-oscillatory (WENO) schemes with unequal-sized sub-stencils for solving the Degasperis-Procesi (DP) and μ- Degasperis-Procesi (μDP) equations, which contain nonlinear high order derivatives, and possibly peakon solutions or shock waves. By introducing auxiliary variable(s), we rewrite the DP equation as a hyperbolic-elliptic system, and the μDP equation as a first order system. Then we choose a linear finite difference scheme with suitable order of accuracy for the auxiliary variable(s), and finite difference WENO schemes with unequal-sized sub-stencils for the primal variable. Comparing with the classical WENO scheme which uses several small stencils of the same size to make up a big stencil, WENO schemes with unequal-sized sub-stencils are simple in the choice of the stencil and enjoy the freedom of arbitrary positive linear weights. Another advantage is that the final reconstructed polynomial on the target cell is a polynomial of the same degree as the polynomial over the big stencil, while the classical finite difference WENO reconstruction can only be obtained for specific points inside the target interval. Numerical tests are provided to demonstrate the high order accuracy and non-oscillatory properties of the proposed schemes.

[02015] Theory and applications of random/non-autonomous dynamical systems part II

Session Time & Room : 1D (Aug.21, 15:30-17:10) @F309

Type : Proposal of Minisymposium
Abstract : Dynamical systems evolving in the existence of noise, is called random dynamical systems. The basic properties, such as stability, bifurcation, and statistical properties, of such random or non-autonomous dynamical systems have not been well studied in mathematics and physics. Recently, cooperative research on random dynamical systems has been developed in the fields in statistical and nonlinear physics, dynamical system theory, ergodic theory, and stochastic process theory. In this mini-symposium, we consider theory and applications of random dynamical systems. In Part II, we discuss Newton methods and random dynamical systems.

[03870] Worked out examples of Random Relaxed Newton's Methods

Format : Talk at Waseda University
Author(s) : Takayuki Watanabe (Chubu University)
Abstract : We give some numerical results on Random Relaxed Newton's Methods which were proposed by Sumi to compute an approximate root of a given polynomial. He proved that this randomized algorithm almost surely

works well if large noise is inserted. In this talk, we demonstrate by numerical experiments that even small noise can make the randomized algorithm successful, and discuss a mathematical conjecture.

[02705] Complex two-dimensional random relaxed Newton's methods

Format : Talk at Waseda University
Author(s) : Hiroki Sumi (Kyoto University)
Abstract : We develop the theory of random dynamical systems of meromorphic maps on the complex two-dimensional projective space and we consider complex two-dimensional random relaxed Newton's methods to find backward images of the origin (0,0) in C^{2} under complex two dimensional regular polynomial maps on C^{2}. We will see the randomness or noise in the systems bring us very nice things, noise-induced order and collapsing of nasty attractors, which cannot hold in deterministic relaxed Newton's methods.

[02999] New Q-Newton's method and Backtracking line search

Format : Talk at Waseda University
Author(s) : Tuyen Trung Truong (University of Oslo)
Abstract : New Q-Newton's method is a variant of Newton's method which preserves the fast rate of convergence while having the additional good property of being able to avoid saddle points. It works by adding a term into the Hessian, and change the sign of negative eigenvalues. Backtracking line search boosts the convergence guarantee. This talk will describe the algorithm, good experimental performance (including finding roots of meromorphic functions), and good theoretical guarantees.

[05306] A Universal Fatou Component

Format : Talk at Waseda University
Author(s) : Mark David Comerford (University of Rhode Island)
Abstract : We show that, for the non-autonomous iteration of polynomials with suitably bounded degrees and coefficients, it is possible to obtain the whole of the classical schlicht family of normalized univalent functions on the unit disc as limit functions on a single Fatou component for a single bounded sequence of quadratic polynomials.

[02017] Recent progress in theory and applications of time-delay systems

Session Time & Room :

02017 (1/3) : 5B (Aug.25, 10:40-12:20) @G402

02017 (2/3) : 5C (Aug.25, 13:20-15:00) @G402

02017 (3/3) : 5D (Aug.25, 15:30-17:10) @G402

Type : Proposal of Minisymposium
Abstract : Time delays appear in several disciplines from engineering and natural sciences. Theory of delay differential equations and infinite dimensional dynamical systems has been extensively developed. Together with the development, applications of time-delay systems have been conducted in several fields including mechanistic engineering and biological sciences. In this mini-symposium, presenting recent progress in the research of time-delay systems from theoretical and application points of view, we aim to promote discussion and collaboration on theoretical and applied research and even deepen our understanding towards the time-delay systems and extend the spectrum of the applications.

[04818] Delay induced self-sustained oscillations in the Nonlinear Noisy Leaky Integrate and Fire model for networks of neurons.

Format : Talk at Waseda University
Author(s) : Pierre Roux (Mathematical Institute, University of Oxford)
Abstract : The emergence of patterned activity in a neural networks is a key process in human and animal brains. However, since they often arise from the interplay between a large number of cells, these mechanisms are very difficult to encompass whithout the use of simple, consistent and self-contained mathematical models. In this talk, I will present a time-delayed nonlinear partial differential equation, the so-called Nonlinear Noisy Leaky Integrate and Fire (NNLIF) model. In a recent work, my collaborators Kota Ikeda, Delphine Salort, Didier Smets and myself have obtained some new results and insights about the emergence and the shape of periodic self-sustained oscillations in this model. In particular, we have found and studied a simplified version of the problem in the form of a delayed differential equation.

[04601] Global stability of multi-cell reaction systems with arbitrary time delays

Format : Talk at Waseda University
Author(s) : Hirokazu Komatsu (National Institute of Technology Toyota College)
Abstract : In the present talk, we consider the stability of multi-cell chemical reaction systems with arbitrary time delays for each reaction, in which each intracellular chemical reaction network is weakly reversible and has zero deficiency. By constructing a Lyapunov functional and assuming additional conditions, we can show that any positive solution to the delay differential equation for the system with mass action kinetics globally converges to a positive equilibrium point in the functional state space.

[04324] Time lag monotonicity-breaking in time-delay systems with impulses

Format : Talk at Waseda University
Author(s) : Kevin Church (CIBC)
Abstract : In this talk, we prove that the solution manifold concept for differential equations with state-dependent delay (DE-SDD) has no "topologically generic" analogue for DE-SDD with impulses. Precisely, the existence of a semiflow is conditional on monotonicity of the time lag. We demonstrate pathologies that occur in the monotonicity-breaking case, which in some instances lead to dynamical behaviour completely different from what is possible in DE-SDD or impulsive differential equations with constant delays.

[03244] Mode Selection Rules for multi-Delay Systems

Format : Talk at Waseda University
Author(s) : Kin'ya Takahashi (Kyushu Institute of Technology)Taizo Kobayashi (Kyushu University)
Abstract : We investigate mode selection rules at the first bifurcation for a two-delay system. Selected modes are sensitively changed with the ratio of two delay times, but obey a definite selection rule if the strengths of two delays are fixed. When the strength of the short delay takes negative values, different types of mode selection rules are observed. We explore the underlying mechanism of the change of mode selection rules in the singular perturbation limit.

02017 (2/3) : 5C @G402 [Chair: Junya Nishiguchi]

[04187] Blow-up of solutions to some delay differential equations

Format : Talk at Waseda University
Author(s) : Tetsuya Ishiwata (Shibaura Institute of Technology)Yukihiko Nakata (Aoyama Gakuin University)
Abstract : Time lags sometimes play an essential role in the phenomena, and it is also well-known that the delay effects cause instability or oscillation.
In this talk, we consider the effects of time delay for such instabilities from the viewpoint of a finite time blow-up of the solutions and treat some delay differential equations.
We show mathematical results on the blow-up of solutions and give numerical observations.

[03602] Absolute stability and absolute hyperbolicity in systems with time-delays

Format : Online Talk on Zoom
Author(s) : Serhiy Yanchuk (Potsdam Institute for Climate Impact Research)
Abstract : We present criteria for the absolute stability of DDEs. For a single delay, the absolute stability is shown to be equivalent to asymptotic stability for sufficiently large delays. For multiple delays, the absolute stability is equivalent to asymptotic stability for hierarchically large delays. Additionally, we give necessary and sufficient conditions for a linear DDE to be hyperbolic for all delays. The latter conditions are crucial for determining whether a system can have bifurcations.

[03557] Delay-dependent stability switches in delay differential systems

Format : Talk at Waseda University
Author(s) : Hideaki Matsunaga (Osaka Metropolitan University)
Abstract : We will summarize some recent results on the stability properties of linear differential systems with delays. Some examples are provided to illustrate the delay-dependent stability switches for a system with delay in the diagonal terms. The proof technique is based on careful analysis of the existence and the transversality of characteristic roots on the imaginary axis. This is a joint work with Yuki Hata.

[05023] Stabilization of periodic orbits with complex characteristic multipliers via DFC

Format : Talk at Waseda University
Author(s) : Rinko Miyazaki (Shizuoka Univ.)Dohan Kim (Seoul National University)Jong Son Shin (Shizuoka University)
Abstract : The delayed feedback control (DFC) proposed by Pyragas (Pyhs. Lett. A, 1992) is a method to stabilize an unstable periodic orbit by using delayed terms. Recently we have succeeded in proving a stabilization regime under certain constraints. In this talk, we will focus on the case where the characteristic multiplier is complex.

02017 (3/3) : 5D @G402 [Chair: Yukihiko Nakata]

[03942] “Mild solutions” for hereditary linear differential systems

Format : Talk at Waseda University
Author(s) : Junya Nishiguchi (Tohoku University)
Abstract : In this talk, we discuss the variation of constants formula for delay differential equations by introducing the notion of a mild solution, which is a solution under an initial condition having a discontinuous history function. Then the principal fundamental matrix solution is defined as a matrix-valued mild solution, and we obtain the variation of constants formula with this function.

[04145] Linearized instability for neutral functional differential equations with state-dependent delays

Format : Talk at Waseda University
Author(s) : Jaqueline Godoy Mesquita (Universidade de Brasília)Bernhard Lani-Wayda (Justus-Liebig University)
Abstract : In this talk, I will present a linearized instability principle for neutral functional differential equations with state-dependent delays. Also, I will discuss open and developing problems in this field. This is a joint work with Professor Bernhard Lani-Wayda from Justus-Liebig University, in Giessen, Germany.

[03765] Morse decomposition of the global attractor for delay differential equations

Format : Talk at Waseda University
Author(s) : Abel Garab (University of Szeged)
Abstract : We consider unidirectional cyclic systems of delay differential equations of the form
\begin{equation}
\dot{x}^{i}(t)=g^i(x^i(t),x^{i+1}(t-\tau^{i})), \qquad 0\leq i\leq N,
\end{equation}
where the indices are understood modulo $N+1$. We show that if the global attractor exists, then it does not

contain any superexponential solution (i.e. that converges to 0 faster than any exponential function). This allows us to construct a Morse decomposition of the global attractor of such equations, which is based on an integer valued Lyapunov function.

[02023] Theory and applications of random/no-autonomous dynamical systems part IV

Session Time & Room : 2C (Aug.22, 13:20-15:00) @F309

Type : Proposal of Minisymposium
Abstract : Dynamical systems evolving in the existence of noise, is called random dynamical systems. The basic properties, such as stability, bifurcation, and statistical properties, of such random or non-autonomous dynamical systems have not been well studied in mathematics and physics. Recently, cooperative research on random dynamical systems has been developed in the fields in statistical and nonlinear physics, dynamical system theory, ergodic theory, and stochastic process theory. In this mini-symposium, we consider theory and applications of random dynamical systems. In Part IV, we discuss anomalous statistics and non-stationarity in random dynamical systems.

[05589] Physical applications of infinite ergodic theory

Format : Talk at Waseda University
Author(s) : Eli Barkai (Bar Ilan University)
Abstract : We show how non-normalised Boltzmann Gibbs measure can still yield statistical averages and thermodynamic properties of physical observables, exploiting a model of Langevin dynamics of a single Brownian particle in an asymptotically flat potential. Similar tools are applicable for a gas of sub-recoiled laser cooled atoms and weakly chaotic non-linear oscillators.

[03122] Transition to Anomalous Dynamics in A Simple Random Map

Format : Talk at Waseda University
Author(s) : Jin Yan (Max Planck Institute for the Physics of Complex Systems)Moitrish Majumdar (International Centre for Theoretical Sciences - TIFR)Stefano Ruffo (SISSA Trieste)Yuzuru Sato (Hokkaido University)Christian Beck (Queen Mary University of London)Rainer Klages (Queen Mary University of London)
Abstract : A random dynamical system consists of a setting where different types of dynamics are sampled randomly in time. Here we consider a simple yet universal example, where an expanding or a contracting map is randomly selected at each discrete-time with probability p or $1-p$, respectively. By continuously varying p between zero and one, we found anomalous behaviour characterised by an infinite non-normalisable invariant density, weak ergodicity breaking, and a power-law decay in correlations.

[05573] Arcsine law for random dynamics with a core

Format : Talk at Waseda University
Author(s) : Yushi Nakano (Tokai University)Fumihiko Nakamura (Kitami Institute of Technology)Hisayoshi Toyokawa (Kitami Institute of Technology)Kouji Yano (Osaka University)
Abstract : The arcsine law is a characterization of intermittent dynamics in infinite ergodic theory. A well-known model of intermittent dynamics is an interval with two increasing surjective branches being uniformly expanding except for indifferent fixed points at the boundary. We show that the arcsine law holds for random dynamics with a core, which is a class of random iterations of two interval maps without indifferent periodic points but "indifferent in average" at the boundary.

[05570] Infinite ergodic theory in physics

Format : Talk at Waseda University
Author(s) : Takuma Akimoto (Tokyo University of Science)
Abstract : Infinite ergodic theory provides a distributional behavior of time-averaged observables in dynamical systems. We show that the infinite ergodic theory plays an important role in physics. In particular, we show several distributional limit theorems for time-averaged observables in non-stationary stochastic processes that are models of anomalous diffusion and laser-cooled systems.

[02025] Recent Advances on the Analysis and Applications of Continuous and Discrete Integrable Systems

Session Time & Room :

02025 (1/3) : 3C (Aug.23, 13:20-15:00) @F310

02025 (2/3) : 3D (Aug.23, 15:30-17:10) @F310

02025 (3/3) : 3E (Aug.23, 17:40-19:20) @F310

Type : Proposal of Minisymposium
Abstract : Research in integrable systems has led to numerous important new concepts, ideas and techniques of mathematics and physics in the last few decades. The very concept of integrability has been found in deep connections with a large spectrum of mathematics such as algebraic geometry, differential geometry, representation theory, random matrix theory, nonlinear waves, etc. In this minisymposium, we will focus on the recent developments of both continuous and discrete integrable systems. Specially, it will cover discrete and ultradiscrete integrable systems, noncommutative integrable systems and rogue waves. This is a unique platform for the interaction of international researchers in relevant fields.

[03558] Integrable boundary conditions for quad-graph systems: classification and applications

Format : Talk at Waseda University
Author(s) : Cheng Zhang (Shanghai University)
Abstract : The notion of boundary conditions for quad-graph systems will first be introduced. The boundary conditions are naturally defined on triangles that arise as dualization of given quad-graphs with boundary. For three-dimensionally consistent quad-graph systems, the so-called integrable boundary conditions will be characterized as boundary conditions satisfying the boundary consistency condition that is a consistency condition defined on a half of a rhombic-dodecahedron. Based on these notions, three main results will then be presented: a classification of integrable boundary conditions for quad-equations of the ABS classification; Lax formulations of integrable boundary conditions; and the so-called open boundary reduction technique as systematic a means to construct integrable mappings from integrable initial-boundary value problems for quad-graph systems.

[03221] Geometric Aspects of Miura Transformations

Format : Talk at Waseda University
Author(s) : Changzheng Qu (Ningbo University)Zhiwei Wu (Sun Yat-sen University)
Abstract : The Miura transformation and its extensions play a crucial role in the study of integrable systems, which have been used to relate different kinds of integrable equations and to classify the bi-Hamiltonian structures. In this talk, we will discuss the geometric aspects of the Miura transformation. The generalized Miura transformations from the mKdV-type hierarchies to the KdV-type hierarchies are constructed under both algebraic and geometric settings. We show that the Miura transformations not only relate integrable curve flows in different

geometries but also induce the transition between different moving frames. Moreover, the Miura transformation gives the factorization of generating operators of constraint Gelfand-Dickey hierarchy. This talk is based on a recent joint work with Prof. Qu, Changzheng.

[04193] Curvature equation with conic singularities and integrable system

Format : Talk at Waseda University
Author(s) : Ting-Jung Kuo (National Taiwan Normal University)
Abstract : Let (E_τ, dz^2), $\tau \in \mathbb{H}$ be a flat torus. We consider the follwing PDE:
\begin{equation}
\Delta u+e^{u}=\sum{j=1}^{N}4\pi \alpha _{j}\delta _{p{j}}\text{ on }
E{\tau } --(1)
\end{equation}
where $\delta _{p{j}}isthediracmeasureand\alpha {j}>-1 . Intheliterature, equation(1)arisedfromconformalgeometry. Indeed, (1)isequivalenttosayingthattheconformalmetric ds^{2}=\frac{1}{2
}e^{u}\left\vert dz\right\vert ^{2}withconicsingulartiesatp{j}hastheGaussiancurvature1$. By classical Liouville theorem, the curvature equation is also an integrable system which yields a complex ODE (a generalization of the classical Lame equation) and the solvability of equation (1) is equivalent to saying that the corresponding complex ODE is always apparent and has unitary monodromy. The study of the monodromy of a general complex ODE is difficult in general. However, recently, we also discover its relation with KdV theory. In this talk, I will talk about this deep connection and focus on the study of the complex ODE from monodromy point of view.

[03194] A Generalization of an Integrability Theorem of Darboux and the Stable Configuration Condition.

Format : Talk at Waseda University
Author(s) : Irina A. Kogan (North Carolina State University)
Abstract : In his monograph "Systemes Orthogonaux" (1910), Darboux stated three theorems providing local existence and uniqueness of solutions to first order systems of PDEs, where for each unknown function a certain subset of partial derivatives is prescribed and the values of the unknown functions are prescribed along transversal coordinate affine subspaces. The more general of the theorems, Theorem III, was proved by Darboux only for the cases of 2 and 3 independent variables. We formulate and prove a generalization of Theorem III. Instead of partial derivatives, we prescribe derivatives of the unknown functions along vector fields. The values of the unknown functions are prescribed along arbitrary transversal submanifolds. We identify a certain Stable Configuration Condition (SCC). This is a geometric condition that depends on both the set of vector fields and on the initial manifolds. SCC is automatically met in the case considered by Darboux. Assuming the SCC and the relevant integrability conditions are satisfied, we establish local existence and uniqueness of a C^1-smooth solution via Picard iteration for any number of independent variables. If the SCC is not satisfied, we show on a concrete example that the uniqueness can fail the following strong sense: for the same initial data, there are two solutions that differ on any open subset of their domains. This talk is based on joint publications with Michael Benfield and Kris Jenssen.

02025 (2/3) : 3D @F310 [Chair: Cheng Zhang]

[03560] Rogue waves and their patterns in the vector nonlinear Schrödinger equation

Format : Talk at Waseda University
Author(s) : Baofeng Feng (University of Texas Rio Grande Valley)Peng Huang (Shenzhen University)Chengfa Wu (Shenzhen University)Guangxiong Zhang (Shenzhen University)
Abstract : This talk presents the general rogue wave solutions and their patterns in the vector (or M-component) nonlinear Schrödinger (NLS) equation. We derived the explicit solution for the rogue wave expressed by tau-functions that are determinants of K×K block matrices with an index jump of M+1. Patterns of the rogue waves for M=3,4 and K=1 are thoroughly investigated.

[03656] Whitham modulation theory of Riemann problem for nonlinear integrable equations

Format : Talk at Waseda University
Author(s) : Yaqing Liu (Beijing Information Science and Technology University)
Abstract : The Riemann problem of the nonlinear integrable equation with step-like initial value is explored by Whitham modulation theory, which is a modified version of the well-known finite-gap integration method. Based on the reparameterization of the solution with the use of algebraic resolvent of the polynomial defining the solution, the periodic wave solutions of the nonlinear integrable equation are described by the elliptic function along with the Whitham modulation equations. Complete classification of possible wave structures is given for all possible jump conditions at the discontinuity initial value. The proposed analytic results are confirmed through direct numerical simulations.

[03369] Quantum variational principle for Lagrangian 1-forms

Format : Talk at Waseda University
Author(s) : Sikarin Yoo-Kong (Naresuan University)
Abstract : In this talk, we will present a new type of the propagator associated with the Lagrangian 1-forms called the (continuous) multi-time propagator. With this new type of the propagator, a new paradigm on summing over possible paths arises since one needs to take into account not only summing over possible spatial paths but also summing over possible temporal paths. The quantum intragrability (a.k.a multi-dimensional consistency), which mainly relies on the classical Lagrangian 1-form closure relation, will be captured in the language of Feynman path integration.

[05098] Three-dimensional fundamental diagram of stochastic cellular automata

Format : Talk at Waseda University
Author(s) : Kazushige Endo (Kindai University)
Abstract : Cellular automata including Burgers cellular automaton are not only examples of ultradiscrete analogue of integrable systems, but also mathematical models which show fundamental mechanisms of traffic flow. For example, a phase transition from free flow to congested flow in a traffic system is well-known and has been studied using fundamental diagram. Fundamental diagram is an object showing relation between the density of traffic (particles) and their mean momentum. However, the density of particles is not a unique parameter to determine the mean momentum. Several systems whose mean momentum is uniquely determined by a pair of the density and another conserved quantity have been discovered. In this talk, we show a three-dimensional framework of the fundamental diagram of stochastic cellular automata and its theoretical derivation.

02025 (3/3) : 3E @F310 [Chair: Kenichi Maruno]

[05088] Beyond the Painlevé property

Format : Talk at Waseda University
Author(s) : Rod Halburd (University College London)
Abstract : The Painlevé property and associated tests have led to the identification of integrable cases of many families of equations. In this talk I will describe some generalisations of the Painlevé property that allow for the identification of a wider set of integrable equations. Various necessary conditions will be discussed and implemented. Examples from Newtonian and relativistic stellar models will be analysed

[05195] Constructing non-commutative systems with Pfaffian type solutions

Format : Talk at Waseda University
Author(s) : Claire Gilson (University of Glasgow)
Abstract : In this talk we look to construct non-commutative systems from quasi-determinants of Pfaffian type by considering quasi-determinant identities.

[03957] Addition formulae for ultradiscrete hafnians

Format : Talk at Waseda University
Author(s) : Hidetomo Nagai (Tokai University)
Abstract : Ultradiscrete hafnian is an ultradiscrete analogue of hafnian, which is signature free pfaffian. In this talk we propose some formulae for the ultradiscrete hafnians with some conditions, which are related to the ultradiscrete soliton solutions.

[05092] Recent Advances on the Analysis and Applications of Continuous and Discrete Integrable Systems

Format : Talk at Waseda University
Author(s) : Andrew Hone (University of Kent)
Abstract : "New discrete integrable systems from deformed cluster mutations"

We describe how to obtain integrable maps by deforming cluster algebra mutations that display Zamolodchikov periodicity. The simplest example is the general Lyness map in 2D, arising as a 2-parameter family of deformations of the cluster algebra of finite type A_2. Results will be presented on integrability of deformed mutations in type A_n, and other finite root systems. This is joint work with J.Grabowski, W.Kim, and T.Kouloukas.

[02056] Recent Advances in Partitioning Method for the Structures

Session Time & Room :

02056 (1/2) : 2D (Aug.22, 15:30-17:10) @E802

02056 (2/2) : 2E (Aug.22, 17:40-19:20) @E802

Type : Proposal of Minisymposium
Abstract : Despite numerous well-established algebraic techniques, infusion of the variational approach into computational mechanics is still under way. Among those, the partitioning method has played a pivotal role. It introduced a complicated matrix computation and additional unknowns which should be treated without degrading accuracy. Topics of this mini-symposium will include, but not limited to, the advances in partitioning method and their application; parallel computing, component mode synthesis, non-matching interface, inverse problems, and damage detection. The mini-symposium will bring researchers together working on both fundamental and applied aspects of computational mechanics to provide a forum for discussion, interaction, and assessment of techniques.
Organizer(s) : SangJoon Shin

Minisymposium Program :

02056 (1/2) : 2D @E802 [Chair: SangJoon Shin]

[03920] Displacement-only Partitioned Equations for Structures without Lagrange Multipliers

Format : Talk at Waseda University
Author(s) : K. C. Park (University of Colorado)
Abstract : A new formulation for the Displacement-only Partitioned (DP) equations of motion for linear structures is presented,
which employs: the partitioned displacement and applied force (u, f), the partitioned block diagonal mass and stiffness matrices (M, K); and, the coupling projector (P), yielding the partitioned coupled equations of motion:

```
M ü =P( f - K u)
```

The proposed DP formulation contains no Lagrange multipliers and offers wide practical applications as well as intellectual pleasure.

[04749] Displacement-based dynamic analysis of partitioned structural systems

Format : Online Talk on Zoom

Author(s) : José Ángel González Pérez (Universidad de Sevilla)K. C. Park (University of Colorado)

Abstract : An unconditionally stable implicit-explicit time integration algorithm is presented, which employs the displacement-only partitioned formulation for structures. The displacement-only partitioned equations of motion for linear and nonlinear structures are expressed in terms of the partitioned displacements, partitioned velocities, and partitioned accelerations, and are devoid of interface Lagrange multipliers and associated variables. Numerical examples illustrate both unconditional stability of the proposed algorithm, second-order accuracy, as well as computational simplicity and efficiency.

[04659] Partitioned Damage Identification of Structural Systems

Format : Talk at Waseda University

Author(s) : Hyeon-Jun Kim (KAIST)Yong-Hwa Park (KAIST)K. C. Park (University of Colorado)

Abstract : This study proposes a damage identification procedure by employing a recently developed displacement-only partitioned equations of motion for structures. Damage is identified by detecting changes in partitioned or elemental stiffness. Applications of the proposed damage identification procedure to sample problems show that the proposed procedure captures damage locations through numerical examples.

02056 (2/2) : 2E @E802 [Chair: K. C. Park]

[03098] Development of partitioning method for thermoelastic Interaction Problems with energy flux constraint

Format : Online Talk on Zoom

Author(s) : Chang-uk Ahn (Kyung Hee University)Alexandre Cortiella (University of Colorado)Jin-gyun Kim (Kyung Hee University)Kwang-chun park (Korea Advanced Institute of Science and Technology)

Abstract : This study presents a partitioned symmetric formulation for transient thermoelastic interaction problems. The thermoelastic interaction problem is a multiphysics problem in which the wave (i.e., hyperbolic type) equation and the diffusion (i.e., parabolic type) equation are coupled. The classical formulation of thermoelastic problems is non-symmetric, and its partitioned form has only been developed in ways that the domains are decoupled in the discrete domain. Based on this motivation, we propose a constraint of energy flux that allows partitioning the thermoelastic problem in a continuum domain. To do this, we construct two separate variational formulations of the uncoupled thermal conduction and uncoupled structural systems. In other words, two separate variational formulations of the uncoupled thermal conduction and uncoupled structural systems are augmented by the constraint of energy exchanges between the elastic body and the thermal conduction body via the method of Lagrange multipliers.

Finally, this study introduces a solution algorithm including implicit-implicit time integration strategies, and the present partitioned formula is verified by well-organized numerical examples.

[04222] A Componenet Mode Synthesis Method Using a Displacement-Based Partitioned Approach

Format : Online Talk on Zoom

Author(s) : Muhammad Faizan Baqir (Kyung Hee University)K. C. Park (University of Colorado)Jin Gyun Kim (Kyung Hee University)

Abstract : A new Partitioned component mode synthesis (P-CMS) is presented, which employs a recently developed Displacement-based Partitioned (DP) formalism. The reduced system matrices are generated via block-by-block substructural matrix computations, directly yielding reduced-order models. The proposed P-CMS method can provide a robust mode selection criterion that remains a challenge in most existing CMS methods. Details of the proposed P-CMS procedure along with numerical examples will be presented in this talk.

[03460] Iterative Algorithm for Quasistatic Structural Problems Employing Only Partitioned Displacements

Format : Talk at Waseda University
Author(s) : SANGJOON SHIN (Seoul National University)Seung-Hoon Kang (Seoul National University)Kwang-Chun Park (University of Colorado Boulder)
Abstract : We report some initial results from the ongoing research on partitioned parallel solution of quasistatic structural problems that employ only partitioned displacements. A notable feature of the present method is the absence of Lagrange multipliers that inevitably manifest in standard partitioned formalisms. Various preconditioning and regularizations that take advantages of the present Displacement-only Partitioned (DP) formulation will be presented and compared with FETI and its allied solution methods.

[02060] Topics in extremal graph theory

Session Time & Room : 4C (Aug.24, 13:20-15:00) @G302

Type : Proposal of Minisymposium
Abstract : Extremal graph theory is a fast emerging and growing area with many exciting developments in recent years. This mini-symposium will cover topics in Turan problem, sublinear expander and sparse pseudorandom graphs.
Organizer(s) : Jie Han, Donglei Yang
Classification : 05C05, 05C48, 05C35
Minisymposium Program :

02060 (1/1) : 4C @G302

[02678] Spanning trees in sparse pseudorandom graphs

Format : Online Talk on Zoom
Author(s) : Jie Han (Beijing Institute of Technology)Donglei Yang (Shandong University)
Abstract : Let $\mathcal{T}(n,\Delta)$ be the class of trees with n vertices and maximum degree at most Δ. Confirming a conjecture of Kahn, Montgomery established for every fixed tree $T\in\mathcal{T}(n,\Delta)$, the smallest value of p for which $G(n,p)$ a.a.s. contains a copy of T. There have been a wealth of results and open problems on embedding spanning trees in (pseudo)random graphs in the past few decades. In 2005, Alon, Krivelevich and Sudakov asked for determining the best possible spectral gap forcing an (n,d,λ)-graph to be $\mathcal{T}(n,\Delta)$-universal. In this talk, we introduce some recent works and open questions. Similar questions for expander graphs are also considered.

[03075] Extremal results on 4-cycles

Format : Talk at Waseda University
Author(s) : Tianchi Yang (National University of Singapore)
Abstract : The study of 4-cycles has important implications for the progression of Turan type problems, particularly in their degenerate forms. In this presentation, novel upper bounds are derived for the maximum number of edges in n-vertex graphs without cycles of length four. These findings not only augment our comprehension of combinatorial structures but also disprove certain conjectures of Erdos.

[03224] Many Hamiltonian subsets in large graphs with given density

Format : Talk at Waseda University
Author(s) : Stijn Cambie (Institute for Basic Science)Jun Gao (Institute for Basic Science)Hong Liu (Institute for Basic Science)
Abstract : A set of vertices in a graph is a Hamiltonian subset if it induces a subgraph containing a Hamiltonian cycle. Kim, Liu, Sharifzadeh and Staden proved that among all graphs with minimum degree d, K_{d+1} minimises the number of Hamiltonian subsets. We prove a near optimal lower bound that takes also the order and the structure of a graph into account. For many natural graph classes, it provides a much better bound than the extremal one ($\approx 2^{d+1}$). Among others, our bound implies that an n-vertex C_4-free graphs with minimum degree d contains at least $n2^{d^{2-o(1)}}$ Hamiltonian subsets.

This is a joint work with Stijn Cambie and Hong Liu.

[03146] Balanced Subdivisions in Graphs

Format : Talk at Waseda University
Author(s) : Donglei Yang (Shandong University)
Abstract : A balanced subdivision of a graph H is obtained from H by equally subdividing every edge. In 1984, Thomassen conjectured that for each integer $k \geq 1$, high average degree forces a balanced subdivision of K_k, and this was recently resolved by Liu and Montgomery. We give an optimal estimate on the average degree condition forcing every balanced H-subdivision, resolving a question of Fern'{a}ndez et al. Similar problems on clique immersions are also considered.

[02067] Recent topics on generalized orthogonal polynomials and their applications

Session Time & Room :

02067 (1/2) : 1C (Aug.21, 13:20-15:00) @G401

02067 (2/2) : 1D (Aug.21, 15:30-17:10) @G401

Type : Proposal of Minisymposium
Abstract : Orthogonal polynomials play crucial roles in a variety of fields including integrable systems, combinatorics, quantum information and so on. Generalization of orthogonal polynomials has thus been considered from many points of view and has led to successful application to such areas. This minisymposium aims to bring together latest research results on theory and applications of generalized orthogonal polynomials and aims to promote interdisciplinary discussions.
Organizer(s) : Satoshi Tsujimoto, Hiroshi Miki, Luc Vinet
Classification : 33Cxx, 05Exx, 81Rxx
Minisymposium Program :

02067 (1/2) : 1C @G401 [Chair: Satoshi Tsujimoto]

[04542] Meta algebras, biorthogonal rational functions and the Askey scheme

Format : Talk at Waseda University
Author(s) : Satoshi Tsujimoto (Kyoto University)Luc Vinet (IVADO & CRM, Université de Montréal)Alexei Zhedanov (School of Mathematics, Renmin University)
Abstract : Algebras that subsume those of the Askey-Wilson type and are designated by the suffix meta are introduced to explain in a unified way the bispectral properties of the orthogonal polynomials of the Askey scheme and of biorthogonal rational functions that can be associated to the entries of that scheme. The Hahn and Racah families will be used to illustrate the framework.

[04588] Introducing q→-1 limits of biorthogonal rational functions: two instructive examples

Format : Talk at Waseda University
Author(s) : Julien Gaboriaud (Kyoto University)Satoshi Tsujimoto (Kyoto University)
Abstract : We recall how $q \to -1$ limits of orthogonal polynomials have been introduced and we introduce analogous limits for biorthogonal rational functions (BRF). In order to illustrate the main properties of these $q \to -1$ BRF, we look at two "extremal" cases: the most general one (Wilson) and one of the simplest ones (Pastro).

[03379] CMV bispectrality of polynomials orthogonal on the unit circle

Format : Online Talk on Zoom
Author(s) : Alexei Zhedanov (School of Mathematics, Renmin University)
Abstract : We present new explicit results and examples concerning CMV bispectrality of the polynomials orthogonal on the unit circle.

[04976] The Element Distinctness Problem Revisited

Format : Online Talk on Zoom
Author(s) : Hajime Tanaka (Tohoku University)
Abstract : The element distinctness problem is the problem of deciding whether or not a list contains identical elements. In this talk, I will revisit Ambainis' famous quantum algorithm for the problem (2007) and its refinement by Portugal (2018) in terms of the Grover quantum walk on the Johnson graphs. I will explain how a result about orthogonal polynomials (i.e., Leonard pairs) plays a role here.

02067 (2/2) : 1D @G401 [Chair: Hiroshi Miki]

[02693] Christoffel Transformations for (Partial-)Skew-Orthogonal Polynomials and Applications

Format : Talk at Waseda University
Author(s) : Guofu Yu (Shanghai Jiao Tong University)
Abstract : In this talk, we consider the Christoffel transformations for skew-orthogonal polynomials and partial-skew-orthogonal polynomials. We demonstrate that the Christoffel transformations can act as spectral problems for discrete integrable hierarchies, and therefore we derive certain integrable hierarchies from these transformations. Some reductional cases are also considered. This is a joint work with Shi-Hao Li.

[02730] Multiple skew orthogonal polynomials and two-component Pfaff lattice

Format : Talk at Waseda University
Author(s) : Shi-Hao Li (Sichuan University)
Abstract : The relation between orthogonal polynomials and integrable system is a long-standing focus in mathematical physics, and sheds light in many related fields like random matrices, random walks, and so on. Skew orthogonal polynomials, which were proposed in the study of random matrices with orthogonal/symplectic symmetry, were found to be wave functions for integrable systems of DKP type. In this talk, we will generalize this frame by considering multiple skew orthogonal polynomials which involve several different weights. In particular, connections with integrable systems are also considered. Pfaffian expressions, recurrence relations and Cauchy transforms for multiple skew orthogonal polynomials will be performed to give rise to multiple-component Pfaff lattice hierarchy.

[04996] Another Type of Forward and Backward Shift Relations for Orthogonal Polynomials in the Askey Scheme

Format : Talk at Waseda University
Author(s) : Satoru Odake (Shinshu University)
Abstract : The forward and backward shift relations are basic properties of the (basic) hypergeometric orthogonal polynomials in the Askey scheme (Jacobi, Askey-Wilson, q-Racah, big q-Jacobi etc.) and they are related to the factorization of the differential or difference operators. Based on other factorizations, we obtain another type of forward and backward shift relations.

[02072] Theory and applications of random/non-autonomous dynamical systems: Part I

Session Time & Room : 1C (Aug.21, 13:20-15:00) @F309

Type : Proposal of Minisymposium

Abstract : Dynamical systems evolving in the existence of noise, is called random dynamical systems. The basic properties, such as stability, bifurcation, and statistical properties, of such random or non-autonomous dynamical systems have not been well studied in mathematics and physics. Recently, cooperative research on random dynamical systems has been developed in the fields in statistical and nonlinear physics, dynamical system theory, ergodic theory, and stochastic process theory. In this mini-symposium, we consider theory and applications of random dynamical systems. In Part I, we discuss computational ergodic theory and applications in random dynamical systems.

Organizer(s) : Hiroki Sumi, Yuzuru Sato, Kouji Yano, Takuma Akimoto

Minisymposium Program :

02072 (1/1) : 1C @F309 [Chair: Yuzuru Sato]

[03478] New characterizations of noise-induced order

Format : Talk at Waseda University

Author(s) : Yuzuru Sato (Hokkaido University)

Abstract : This talk includes a brief review of phenomenologies of non-autonomous / random dynamical systems, followed by a few examples of typical noise-induced phenomena in random dynamical systems.
In particular, we present recent results on new characterizations of noise-induced order.

[04094] Time-delayed feedback control for random dynamical systems

Format : Talk at Waseda University

Author(s) : Miki Kobayashi (Rissho University)Yuzuru Sato (Hokkaido University)

Abstract : We propose a framework of Pyragas control for random dynamical systems. The deterministic Pyragus control adopts delayed feedback controls to stabilize a UPO in the original deterministic strange attractor. We demonstrate a few examples including stochastic Rossler dynamics.

[03936] Rigorous enclosure of spectra and its applications

Format : Talk at Waseda University

Author(s) : Isaia Nisoli (Universidade Federal do Rio de Janeiro)Alex Blumenthal (Georgia Tech)Toby Taylor-Crush (Loughbourugh University)Yuzuru Sato (Hokkaido University)

Abstract : In this talk I will introduce a tool developed in collaboration with Dr. A. Blumenthal and Dr. T. Taylor-Crush to rigorously enclose the finite spectrum of a Markov operator. I will then introduce some applications to the study of the phenomenology of important examples of random dynamical systems developed by Prof. Y. Sato.

[03935] Recent developments on Lorenz-like attractors

Format : Talk at Waseda University

Author(s) : MARIA JOSE PACIFICO (Federal University of Rio de Janeiro)

Abstract : The Lorenz attractor has been playing a central role in the research of singular flows, i.e., flows generated by smooth vector fields with singularities. In this talk I shall survey about old and new results describing the dynamics of this kind of attractors from the topological as well as the ergodic point of view. I will end sketching the proof of my result establishing that in a C1-open and densely family of vector fields (including the classical Lorenz attractor), if the point masses at singularities are not equilibrium states, then there exists a unique equilibrium state supported on Λ. In particular, there exists a unique measure of maximal entropy for the ow X|Λ.

[02083] Integrable Aspects of Nonlinear Wave Equations, Solutions and Asymptotics

Session Time & Room :

02083 (1/3) : 4C (Aug.24, 13:20-15:00) @F309

02083 (2/3) : 4D (Aug.24, 15:30-17:10) @F309

02083 (3/3) : 4E (Aug.24, 17:40-19:20) @F309

Type : Proposal of Minisymposium
Abstract : The study of physical phenomena by means of mathematical models often leads to integrable systems, which admit rich solutions including the solitons. The study on interactions of solitary waves is an important part of the modern theory of nonlinear waves. Various methods have been developed to build their solutions. In addition, stability and long-time asymptotics of solutions to integrable systems are interesting topics and attracts much attentions in the past years.

The proposed minisymposium aims at bringing together the researchers in the fields and at offering an overview of some of the current research activities in this area.

[05581] Recent results on the Fractional Nonlinear Schroedinger Equation

Format : Talk at Waseda University
Author(s) : Alejandro Aceves (Southern Methodist University)
Abstract : The Fractional Nonlinear Schroedinger Equation (fNLSE) has been a topic of recent interest as it may have applications to nononlinear photonics. In this work we will present motivation for the models considered and recent results on discrete and continuous fNLSE.
In particular we will discuss the existence of discrete localized modes and their properties. Rigorous and numerical results on existence for the continuous fNLSE will also be presented.

[05588] Duality of positive and negative integrable hierarchiesvia relativistically invariant fields

Format : Online Talk on Zoom
Author(s) : Senyue Lou (Ningbo University)Xing-Biao Hu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Qingping Liu (China University of Mining and Tenchnology (Beijing))
Abstract : This talk concerns the relativistic invariance in integrable systems. Using the invariant sine-Gordon, Tzitzeica, Toda fields and second heavenly equations as dual relations, some well-known continuous and discrete integrable positive hierarchies are converted to the negative hierarchies. In (1+1)-dimensional cases the positive/negative hierarchy dualities are guaranteed by the mastersymmetry method and the relativistic invariance of the duality relations. Two elegant commuting recursion operators of the heavenly equation appear naturally from the formal series symmetry approach.

[04900] Integrable Deep Learning--PINN based on Miura transformations and discovery of new localized wave solutions

Format : Talk at Waseda University
Author(s) : Yong Chen (East China Normal University)
Abstract : We put forth two physics-informed neural network (PINN) schemes based on Miura transformations. The novelty of this research is the incorporation of Miura transformation constraints into neural networks to solve

nonlinear PDEs, which is an implementation method of unsupervised learning. The most noteworthy advantage of our method is that we can simply exploit the initial-boundary data of a solution of a certain nonlinear equation to obtain the data-driven solution of another evolution equation with the aid of Miura transformations and PINNs. In the process, the Miura transformation plays an indispensable role of a bridge between solutions of two separate equations. It is tailored to the inverse process of the Miura transformation and can overcome the difficulties in solving solutions based on the implicit expression. Moreover, two schemes are applied to perform abundant computational experiments to effectively reproduce dynamic behaviors of solutions for the well-known KdV equation and mKdV equation. Significantly, new data-driven solutions are successfully simulated and one of the most important results is the discovery of a new localized wave solution: kink-bell type solution of the defocusing mKdV equation and it has not been previously observed and reported to our knowledge. It provides a possibility for new types of numerical solutions by fully leveraging the many-to-one relationship between solutions before and after Miura transformations. Performance comparisons in different cases as well as advantages and disadvantages analysis of two schemes are also discussed. Based on the performance of two schemes and no free lunch theorem, they both have their own merits and thus more appropriate one should be chosen according to specific cases.

[04206] Drinfeld-Sokolov hierarchies and diagram automorphisms of affine Kac-Moody algebras

Format : Talk at Waseda University
Author(s) : Chaozhong Wu (Sun Yat-Sen University)
Abstract : For a diagram automorphism of an affine Kac-Moody algebra such that the folded diagram is still an affine Dynkin diagram, we show that the associated Drinfeld-Sokolov hierarchy also admits an induced automorphism. We also show how to obtain the Drinfeld-Sokolov hierarchy associated to the affine Kac-Moody algebra that corresponds to the folded Dynkin diagram from the invariant sub-hierarchy of the original Drinfeld-Sokolov hierarchy. This is based on a joint work with Si-Qi Liu, Youjin Zhang and Xu Zhou.

02083 (2/3) : 4D @F309

[04907] On the long-time asymptotics of the modified Camassa-Holm equation in space-time solitonic regions

Format : Online Talk on Zoom
Author(s) : Engui Fan (Fudan University)
Abstract : We study the long time asymptotic behavior for the Cauchy problem of the modified Camassa-Holm (mCH) equation in the solitonic regions. Our main technical tool is the representation of the Cauchy problem with an associated matrix Riemann-Hilbert (RH) problem and the consequent asymptotic analysis of this RH problem. Based on the spectral analysis of the Lax pair associated with the mCH equation and scattering matrix, the solution of the Cauchy problem is characterized via the solution of a RH problem in the new scale (y,t). Further using the ∂ generalization of the Deift-Zhou steepest descent method, we derive different long time asymptotic expansions of the solution u(y,t) in different space-time solitonic regions of $\xi = y/t$. We divide the half-plane $\{(y,t) : -\infty \;\; 0\}$ into four asymptotic regions: The phase function θ(z) has no stationary phase point on the jump contour in the space-time solitonic regions $\xi \in (-\infty, -1/4) \cup (2, +\infty)$, corresponding asymptotic approximations can be characterized with an N(Λ)-solitons with diverse residual error order O(t−1+2ρ); The phase function θ(z) has four phase points and eight phase points on the jump contour in the space-time solitonic regions $\xi \in (0, 2)$ and $\xi \in (-1/4, 0)$, respectively. The corresponding asymptotic approximations can be characterized with an N(Λ)-soliton as well as an interaction term between soliton solutions and the dispersion term with diverse residual error order O(t−3/4). Our results also confirm the soliton resolution conjecture and asymptotically stability of the N-soliton solutions for the mCH equation.

[05585] Local and global analyticity for a generalized Camassa-Holm system

Format : Talk at Waseda University
Author(s) : Hideshi Yamane (Kwansei Gakuin University)
Abstract : We solve the analytic Cauchy problem for the generalized two-component Camassa-Holm system introduced by R. M. Chen and Y. Liu.
We show the existence of a unique local/global-in-time analytic solution under certain conditions.
This is the first result about global analyticity for a Camassa-Holm-like system.
The proof is based the technique by Barostichi, Himonas and Petronilho.

[04390] Long-time asymptotics for the defocusing NLS equation with step-like boundary conditions

Format : Talk at Waseda University
Author(s) : Deng-Shan Wang (Beijing Normal University)
Abstract : The long-time asymptotics for the defocusing NLS equation with step-like boundary conditions is investigated by the Riemann-Hilbert formulation. Whitham modulation theory shows that there are six cases for this initial discontinuity problem according to the orders of the Riemann invariants. We formulate the leading-order terms and the corresponding error estimates for each region of the six cases by Deift-Zhou nonlinear steepest-descent method. It is demonstrated that the asymptotic solutions match very well with the results from Whitham modulation theory and the direct numerical simulations.

[05490] New revival phenomena for bidirectional dispersive hyperbolic equations

Format : Talk at Waseda University
Author(s) : Jing Kang (Northwest University)
Abstract : In this talk, the dispersive revival and fractalisation phenomena for bidirectional dispersive equations on a bounded interval subject to periodic boundary conditions and discontinuous initial profiles are investigated. Firstly, we study the periodic initial-boundary problem of the linear beam equation with step function initial data, and analyze the manifestation of the revival phenomenon for the corresponding solutions at rational times. Next, we extend the investigation to the periodic initial-boundary problems of more general bidirectional dispersive equations. We prove that, if the initial functions are of bounded variation, the dynamical evolution of such periodic initial-boundary problem depend essentially upon the large wave number asymptotics of the associated dispersion relations. Integral polynomial or asymptotically integral polynomial dispersion relations produce dispersive revival/fractalisation rational/irrational dichotomy effects, whereas those with non-polynomial growth results in fractal profiles at all times. Finally, numerical experiments are used to demonstrate how such effects persist into the nonlinear regime, in the concrete case of the nonlinear beam equation. This is a joint work with Peter J. Olver, Xiaochuan Liu and Changzheng Qu.

02083 (3/3) : 4E @F309

[05580] Darboux transformation and soliton solutions for a generalized Sasa-Satsuma equation

Format : Talk at Waseda University
Author(s) : Zuo-nong Zhu (Shanghai Jiao Tong University)Hongqian Sun (Shanghai Jiao Tong University)
Abstract : Sasa-Satsuma equation is an important integrable equation. In this talk, we will investigate a generalized Sasa-Satsuma equation introduced by Geng and Wu. Darboux transformation and soliton solutions including hump-type, breather-type solitons for the generalized Sasa-Satsuma equation are constructed.

[05584] Rogue waves and solitons of nonlinear integrable/nearly integrable systems

Format : Talk at Waseda University
Author(s) : Zhenya Yan (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk, we mainly discuss some properties of rogue waves and solitons of some nonlinear integrable/nearly integrable systems, which include stability, interactions and excitations of solitons, and rogue wave structures.

[05579] The modified KdV equation on the background of elliptic function solutions

Format : Talk at Waseda University
Author(s) : Liming Ling (South China University of Technology)
Abstract : In this talk, we first introduce the spectral stability and orbital stability of the elliptic function solutions for the focusing modified Korteweg-de Vries (mKdV) equation with respect to subharmonic perturbations and construct the corresponding breather solutions to exhibit the unstable or stable dynamic behavior. On the other

hand, by using the Darboux-Backlund transformation, we construct multi-elliptic-localized wave solutions. The asymptotic analysis of these multi-elliptic-localized wave solutions is also involved in this talk.

[04134] Pattern Transformation in Higher-Order Lumps of the Kadomtsev-Petviashvili I Equation

Format : Talk at Waseda University
Author(s) : Bo Yang (Ningbo University)
Abstract : Pattern formation in higher-order lumps of the Kadomtsev-Petviashvili I equation at large time is analytically studied. For a broad class of these higher-order lumps, we show that two types of solution patterns appear at large time. The first type of patterns comprises fundamental lumps arranged in triangular shapes, which are described analytically by root structures of the Yablonskii-Vorob'ev polynomials. As time evolves from large negative to large positive, this triangular pattern reverses itself along the x-direction. The second type of patterns comprise fundamental lumps arranged in non-triangular shapes in the outer region, which are described analytically by nonzero-root structures of the Wronskian-Hermit polynomials, together with possible fundamental lumps arranged in triangular shapes in the inner region, which are described analytically by root structures of the Yablonskii-Vorob'ev polynomials. When time evolves from large negative to large positive, the non-triangular pattern in the outer region switches its x and y directions, while the triangular pattern in the inner region, if it arises, reverses its direction along the x-axis. Our predicted patterns at large time are compared to true solutions, and excellent agreement is observed.

[02109] Recent Advances on Numerical Analysis of Integral and Integro-differential Equations

Session Time & Room :

02109 (1/3) : 4C (Aug.24, 13:20-15:00) @E802

02109 (2/3) : 4D (Aug.24, 15:30-17:10) @E802

02109 (3/3) : 4E (Aug.24, 17:40-19:20) @E802

Type : Proposal of Minisymposium
Abstract : Since integral equations, integro-differential and nonlocal equations play an important role as mathematical models in science, engineering and finance, recent years have seen major developments in the design and analysis of efficient numerical methods for such equations. It is the aim of this minisymposium to bring together leading experts in these fields, in order to describe recent achievements and further communication between numerical analysts and computational scientists working on these problems.

[02677] An hp-version of the discontinuous Galerkin method for fractional integro-differential equations with weakly singular kernels

Format : Talk at Waseda University
Author(s) : Yanping Chen (South China Normal University)
Abstract : In this talk, an hp-discontinuous Galerkin method is developed for the fractional integro-differential equations with weakly singular kernels. The key idea of our method is to first convert the fractional integro-differential equations into the Volterra integral equations, and then solve the equivalent integral equations using the hp-discontinuous Galerkin method. The prior error bounds for the proposed method are established in the L2-norm. Numerical results are presented to demonstrate the effectiveness of the proposed method.

[03691] Implicitly Linear Jacobi Spectral-Collocation Methods for Weakly Singular Volterra-Hammerstein Integral Equations

Format : Talk at Waseda University

Author(s) : Qiumei Huang (Beijing University of Technology)Huitinh Yang (Beijing University of Technology)

Abstract : Weakly singular Volterra integral equations of the second kind typically have nonsmooth solutions near the initial point of the interval of integration, which seriously affects the accuracy of spectral methods. We present Jacobi spectral-collocation method to solve two-dimensional weakly singular Volterra-Hammerstein integral equations based on smoothing transformation and implicit linear method. The solution of the smoothed equation is much smoother than the original one after smoothing transformation and the spectral method can be used. For the Hammerstein nonlinear term, the implicitly linear method is applied to simplify the calculation and improve the accuracy. Convergence analysis in the L∞−norm is carried out and the exponential convergence rate is obtained. Finally, we demonstrate the efficiency of the proposed method by numerical examples.

[03565] A collocation based approach for the numerical solution of singular fractional integro-differential equations

Format : Talk at Waseda University

Author(s) : Kaido Latt (University of Tartu)Arvet Pedas (University of Tartu)

Abstract : We consider a class of fractional integro-differential equations with certain type of singularities at the origin. We reformulate the original problem as a cordial Volterra integral equation and study the existence, uniqueness, and regularity of the exact solution. We also construct a collocation based numerical method for finding the approximate solution of the original problem and present some numerical examples.

[02147] Solutions of second kind Fredholm integral equations by discrete projection methods

Format : Talk at Waseda University

Author(s) : Gobinda Rakshit (Rajiv Gandhi Institute of Petroleum Technology, Jais Campus, Amethi, Uttar Pradesh 229304)

Abstract : We are interested in approximate solutions of the integral equation $x(s) - \int_0^1 \kappa(s,t,(x(t))dt = f(s)$, where f and the kernel κ are given. A class of projection methods are available for obtaining approximate solutions to the above integral equation. Modified projection method is recently proposed and it exhibits higher orders of convergence as compared to the Galerkin/collocation (projection) methods. Here, we define and analyze a discrete version of the above projection methods.

02109 (2/3) : 4D @E802

[03563] Numerical solution of fractional integro-differential equations

Format : Talk at Waseda University

Author(s) : Arvet Pedas (University of Tartu)Mikk Vikerpuur (University of Tartu)

Abstract : We consider a wide class of linear multi-term fractional integro-differential equations with Caputo derivatives and weakly singular kernels. First, we discuss the existence, uniqueness and smoothness of the exact solution. Then, using a suitable smoothing transformation and spline collocation techniques, we construct a high-order method for the numerical solution of the underlying problem. Finally, a numerical illustration of the proposed method is presented.

[04175] A new linearized maximum principle preserving and energy stability scheme for the space fractional Allen-Cahn equation

Format : Talk at Waseda University

Author(s) : Yin Yang (Xiangtan University)Biao Zhang (Xiangtan University)

Abstract : In this talk, we present a new linearized two-level second-order scheme for the space fractional Allen-Cahn equation, which is based on the Crank-Nicolson method in time, second-order weighted and shifted Gr" {u}nwald difference formula in space and Newton linearized technology to deal with nonlinear term. And we only need to solve a linear system at each time level. Then, the unique solvability of the scheme is given. Under the reasonable time step constraint, the discrete maximum principle, energy stability and error analysis are also studied. At last, some numerical experiments show that the proposed method is reasonable and effective.

[03914] High accuracy analysis of FEMs for several time-fractional PDEs

Format : Talk at Waseda University
Author(s) : Yanmin Zhao (Xuchang University)
Abstract : In this talk, convergence and superconvergence analysis for several kinds of time-fractional partial differential equations will be discussed by use of finite element methods and proper finite difference schemes. At the same time, unconditional stability properties of fully-discrete schemes are presented. Moreover, numerical experiments are provided to confirm the theoretical results. And, some relevant topics are included.

[02240] Discontinuous piecewise polynomial collocation methods for integral-algebraic equations of Hessenberg type

Format : Talk at Waseda University
Author(s) : Hui Liang (Harbin Institute of Technology, Shenzhen)Hecong Gao (Harbin Institute of Technology, Shenzhen)
Abstract : We mainly consider the integral-algebraic equations of Hessenberg type. The tractability index is investigated. The existence, uniqueness, and regularity are analyzed, and the resolvent representation is given. First, the convergence theory of perturbed collocation methods in discontinuous piecewise polynomial space is established for first-kind Volterra integral equations, then it is used to derive the optimal convergence properties of discontinuous piecewise polynomial collocation methods for Hessenberg-type integral-algebraic equations. Numerical examples illustrate the theoretical results.

02109 (3/3) : 4E @E802

[04726] Mean square exponential stability and practical mean square exponential stability of stochastic delay differential equations driven by G-Brownian motion and Euler-Maruyama approximations

Format : Online Talk on Zoom
Author(s) : Haiyan Yuan (Heilongjiang institute of technology)
Abstract : This paper investigates the mean-square (MS) exponential stability and the practical mean square (PMS) exponential stability of stochastic delay differential equations driven by G-Brownian motion (G-SDDEs) and the numerical solution generated by Euler-Maruyama (EM) method. We present a weaker condition to prove the MS exponential stability of G-SDDEs instead of choosing a Lyapunov function under the case that the origin is an equilibrium point. In order to study whether the performance of G-SDDEs near an unstable equilibrium point is acceptable, we introduce the practical stability and establish a new generalized Gronwall inequality based on which we prove the PMS exponential stability of G-SDDEs. We also study the numerical approximations for G-SDDEs. We first establish the stability equivalence between the discrete EM method and the continuous EM method, then we prove that the continuous EM method can reproduce the MS exponential stability and the PMS exponential stability of G-SDDEs under some restrictions on the step size. Furthermore, two numerical experiments are conducted to confirm our theoretical results.

[02676] Superconvergent postprocessing of the continuous and discontinuous Galerkin methods for nonlinear Volterra integro-differential equations

Format : Online Talk on Zoom
Author(s) : Lijun Yi (Shanghai Normal University)Mingzhu Zhang (Shanghai Normal University)
Abstract : In this talk, we introduce novel postprocessing techniques for improving the accuracy of the CG and DG methods for nonlinear Volterra integro-differential equations. We first show that the CG and DG method superconverge at the nodal points of the time partition. We further prove that the postprocessed CG and DG approximations converge one order faster than the unprocessed CG and DG approximations in the L^2-, H^1- and L^∞-norms. As a by-product of the postprocessed superconvergence results, we construct several a posteriori error estimators and prove that they are asymptotically exact. Numerical examples are presented to verify the theoretical results.

[02115] Theory and applications of random/non-autonomous dynamical systems Part III

Session Time & Room : 5B (Aug.25, 10:40-12:20) @F309

Type : Proposal of Minisymposium

Abstract : Dynamical systems evolving in the existence of noise, is called random dynamical systems. The basic properties, such as stability, bifurcation, and statistical properties, of such random or non-autonomous dynamical systems have not been well studied in mathematics and physics. Recently, cooperative research on random dynamical systems has been developed in the fields in statistical and nonlinear physics, dynamical system theory, ergodic theory, and stochastic process theory. In this mini-symposium, we consider theory and applications of random dynamical systems. In Part III, we discuss infinite ergodicity and random dynamical systems.

Organizer(s) : Hiroki Sumi, Yuzuru Sato, Kouji Yano, Takuma Akimoto

Classification : 37H05, 37A50, 37A05, 37H12

Minisymposium Program :

02115 (1/1) : 5B @F309 [Chair: Kouji Yano]

[04171] Arcsine and Darling--Kac laws for piecewise linear random interval maps

Format : Talk at Waseda University

Author(s) : Kouji Yano (Osaka University)

Abstract : We give examples of piecewise linear random interval maps satisfying arcsine and Darling--Kac laws, which are analogous to Thaler's arcsine and Aaronson's Darling--Kac laws for the Boole transformation. They are constructed by random switch of two piecewise linear maps with attracting or repelling fixed points, which behave as if they were indifferent fixed points of a deterministic map.

[04000] Generalized uniform laws for occupation times of intermittent maps

Format : Talk at Waseda University

Author(s) : Toru Sera (Osaka University)

Abstract : Interval maps with indifferent fixed points are called intermittent maps. In this talk, we impose the condition that the orbit stays away from indifferent fixed points at the final observation time. Under this condition, we study the scaling limit of occupation times. This talk is based on joint work with Jon. Aaronson (Tel Aviv).

[04085] Estimates of invariant measures for random maps

Format : Talk at Waseda University

Author(s) : Tomoki Inoue (Ehime University)

Abstract : We consider a random dynamical system such that one transformation is randomly selected from a family of transformations and then applied on each iteration. Especially, we consider random dynamical systems with indifferent fixed points and/or with unbounded derivatives. Under some conditions, such random dynamical systems have absolutely continuous invariant measures. We give some estimates of the absolutely continuous invariant measures.

[04503] probability and ergodic theory for inner functions

Format : Talk at Waseda University

Author(s) : jon aaronson (tel aviv university)Kouji Yano (Osaka University)

Abstract : An analytic endomorphism of the unit disk is called an inner function if it's boundary limit defines a transformation of
the circle - which is necessarily Lebesgue nonsingular. I'll review the ergodic theory of inner functions & present some
results recently obtained with Mahendra Nadkarni.

[02130] Fluid-structure interactions in geophysical flows

Session Time & Room :

02130 (1/2) : 4D (Aug.24, 15:30-17:10) @E820

02130 (2/2) : 4E (Aug.24, 17:40-19:20) @E820

Type : Proposal of Minisymposium
Abstract : Fluid-structure interactions appear on many different scales of our planet. For example, centimeter-scale pebble stones are shaped by flow erosion, while kilometer-scale karst terrains are a result of dissolution. Even the planetary-scale plate tectonics are believed to be driven by the convection in Earth's mantle. In this minisymposium, we focus on lab-scale experiments and math modeling of such geophysical fluid-structure interactions, exploring the connections between processes like convection, erosion, dissolution, and melting. With a diverse group of speakers, this minisymposium will initiate a new and combined effort to address these important geophysical phenomena.
Organizer(s) : Jinzi Mac Huang, Nick Moore

[04348] How Fluid-Mechanical Erosion Creates Anisotropic Porous Media

Format : Talk at Waseda University
Author(s) : Bryan Quaife (Florida State University)Nick Moore (Colgate University)Jake Cherry (Florida State University)Shang-Huan Chiu (Lehigh University)
Abstract : When a porous medium erodes, microscopic changes of the grain morphology give rise to larger-scale features such as channelization. Using a boundary integral formulation, we characterize these changes by simulating erosion of porous media. A Cauchy-integral formulation and associated quadrature formulas enable us to resolve dense configurations of nearly contacting bodies. We observe that substantial anisotropy develops over the course of erosion; that is, the configurations that result from erosion permit flow in the longitudinal direction more easily than in the transverse direction by up to a factor of six. These results suggest that the erosion of solid material from groundwater flows may contribute to previously observed anisotropy of natural porous media.

[04569] Moving boundaries in thermal convection

Format : Talk at Waseda University
Author(s) : Jun Zhang (New York University)
Abstract : With simple experiments, we study how mobile boundaries interact with thermally convective flows. When turbulence intensity in thermal convection is sufficiently large, flow patterns are random. However, if a mobile boundary is added to the system, and allowed to freely interact with the surrounding flows, the structure-fluid system may show orderly behaviors, and the flow patterns also become more regular. Geophysical motivations and potential applications will also be discussed in this talk.

[04835] Using asymptotic analysis to improve numerical methods for multiphase flows

Format : Talk at Waseda University
Author(s) : Eric William Hester (UCLA)Andrea Bertozzi (UCLA)
Abstract : Diffuse-interface methods approximate discontinuous boundary conditions with smooth source terms - avoiding the need to explicitly discretise multiphase interfaces. But this approximation only converges in the limit. Using the signed-distance function I will outline a general framework for the asymptotic analysis of diffuse-interface methods. I will thereby optimise diffuse-interface simulations of fluid-structure interaction, melting and dissolving ocean icebergs, and dynamic contact lines in three-phase fluids.

[04665] Laser shot on water and ice

Format : Online Talk on Zoom
Author(s) : Daosheng Deng (Fudan University)
Abstract : The strong interaction between laser and ice or water, arising from the strong photothermal effect, can lead the diverse intriguing phenomena. This talk will present the dancing bubble generated in water by laser, and report the melting of ice under the laser illumination.

02130 (2/2) : 4E @E820 [Chair: Jun Zhang]

[04383] A simple model on what drives continental drifts

Format : Talk at Waseda University
Author(s) : Jinzi Mac Huang (New York University Shanghai)
Abstract : It is well known that the continents of earth do not stay in place, and thermal convection in Earth's mantle is believed to be the driving force of these motions. How does mantle convection couple to the continental drift? Does the moving continent affect the mantle motion beneath it? We address these questions through a simple fluid-structure interaction model, exploring the fluid mechanical origin of continental drift and the possibility of modeling tectonic plate interactions.

[05512] Computing the diffusivity of a particle subject to dry friction with colored noise

Format : Talk at Waseda University
Author(s) : Laurent Mertz (City University of Hong Kong)Josselin Garnier (Polytechnique)
Abstract : Experimental studies and numerical simulations have been devoted to the motion of an object subjected to a dry friction and an external random force. The experimental and numerical observations suggest that the variance of the object displacement grows linearly with time. Here, the variance growth rate is called diffusivity. The goal of this paper is to propose efficient stochastic simulation methods for computing the diffusivity when the external random force is white or colored noise.

[04815] The Formation of Karst Pinnacles

Format : Online Talk on Zoom
Author(s) : Nick Moore (Colgate University)
Abstract : Recent experiments demonstrate how dissolution, in conjunction with gravitationally-induced convective flows, can create sharp geometric features. These laboratory-created structures give insight into geological features known as karst pinnacles. A new computational approach reveals convergence to a morphological attractor with high, yet finite, tip curvature. These results reverse previous hypotheses on shock formation (i.e. finite-time blowup of tip curvature), agree well with laboratory experiments, and enable simple estimates for the age of geological structures.

[02154] Hypergeometric functions in statistics and particle physics

Session Time & Room :

02154 (1/2) : 3C (Aug.23, 13:20-15:00) @G305

02154 (2/2) : 3D (Aug.23, 15:30-17:10) @G305

Type : Proposal of Minisymposium
Abstract : Recent years have shed new light on the theory of hypergeometric functions.
They appear as marginal likelihood integrals in statistics and as Feynman integrals in quantum field theory.
Evaluating these integrals is a central, but challenging problem in these areas.
Advances in algebraic methods provids new insights into this problem.
Such methods rest on graph theory, combinatorics of convex bodies, Gröbner bases, D-modules, and toric geometry, to name a few.

These new perspectives also raise fascinating new questions, both theoretical and computational.
We gather active researchers in this area to identify such questions, and to accelerate the progress.

[03807] Towards Algebraic Analysis of Hypergeometric Systems

Author(s) : Saiei-Jaeyeong Matsubara-Heo (Kumamoto University)
Abstract : A hypergeometric function is an analytic function defined in terms of an elementary integral. A hypergeometric system is a system of differential (or difference) equations that it satisfies, which ties analysis to various fields of algebra, such as ring/module theory (D-modules), homological algebra, or combinatorics of polytopes. This talk aims to provide the speaker's view on the current state of the art. A unifying thread is a study of algebraic equations.

[03843] D-Module Techniques for Solving Differential Equations in the Context of Feynman Integrals

Author(s) : Anna-Laura Sattelberger (Department of Mathematics, KTH Royal Institute of Technology)
Abstract : I explain how to compute series solutions of regular holonomic D-ideals with Gröbner basis methods via an algorithm due to Saito, Sturmfels, and Takayama. As a point in case, I consider a D-ideal originating from a triangle Feynman diagram. This talk is based on joint work (arXiv:2303.11105) with Johannes Henn, Elizabeth Pratt, and Simone Zoia. Therein, we compare D-module techniques to dedicated methods developed for solving differential equations in the context of Feynman integrals.

[04120] Distribution of eigenvalues of a singular elliptical Wishart matrix

Author(s) : Koki Shimizu (Tokyo University of Science)Hiroki Hashiguchi (Tokyo University of Science)
Abstract : We derive the exact distributions of eigenvalues of a singular Wishart matrix under the elliptical model. These distributions cover the results under the Gaussian model as a special case. The joint density of eigenvalues and distribution function of the largest eigenvalue for a singular elliptical Wishart matrix are represented in terms of generalized hypergeometric functions. Numerical computations for the distribution of the largest eigenvalue are conducted under Gaussian and Kotz-type models.

[04121] Restriction algorithms for holonomic systems and their applications

Author(s) : Nobuki Takayama (Kobe University)
Abstract : Definite integrals with parameters (in statistics and physics) satisfy holonomic systems (maximally overdetermined systems of linear PDEs). When parameters are restricted to an algebraic set, these integrals satisfy smaller or simpler holonomic systems. We will survey algorithms of finding these smaller or simpler systems with applications and numerical examples.

02154 (2/2) : 3D @G305

[04146] Twisted cohomology and likelihood ideals

Author(s) : Simon Telen (MPI MiS Leipzig)Saiei-Jaeyeong Matsubara-Heo (Kumamoto University)
Abstract : A likelihood function on a smooth very affine variety gives rise to a twisted de Rham complex. We show how its top cohomology vector space degenerates to the coordinate ring of the critical points defined by the likelihood equations. We obtain a basis for cohomology from a basis of this coordinate ring. We investigate the dual picture, where twisted cycles correspond to critical points. We show how to expand a twisted cocycle in terms of a basis, and apply our methods to Feynman integrals from physics.

[04152] Algebraic A-hypergeometric Laurent series and residues

Author(s) : Alicia Dickenstein (University of Buenos Aires)
Abstract : A-hypergeometric systems of partial differential equations (introduced by Gelfand, Kapranov and Zelevinsky) have natural geometric solutions, with singularities on the associated discriminant. We describe A-hypergeometric algebraic Laurent series associated with Cayley configurations of n lattice configurations in n space. These algebraic series are generated by certain combinatorially defined sums of point residues, whose computation can be interpreted in terms of a toric degeneration. Joint work with E. Cattani and F. Martinez.

[04334] Sampling from toric models and hypergeometric functions

Author(s) : Shuhei Mano (The Institute of Statistical Mathematics)
Abstract : The toric model is an important class of stochastic models, and sampling from toric models has various applications including statistics. The sampling problem is related with hypergeometric functions, because the normalizing constant of the probability function is a multi-variable polynomial and satisfies a GKZ-hypergeometric system. In this talk, I will review several problems in which the relationship works effectively.

[02163] Recent Developments in Stochastic Numerics and Computational Finance

Session Time & Room :

02163 (1/3) : 4C (Aug.24, 13:20-15:00) @E505

02163 (2/3) : 4D (Aug.24, 15:30-17:10) @E505

02163 (3/3) : 4E (Aug.24, 17:40-19:20) @E505

Type : Proposal of Minisymposium
Abstract : Stochastic numerical analysis becomes so important in probability theory, statistics and applied mathematics especially in machine learning and data science and achieves a great success in computational finance. The aim of the minisymposium is to highlight recent developments in stochastic numerical analysis and computational finance, and to interact with researchers working on the fields. Topics will include deep learning methods for stochastic differential equations and PDEs, new computational methods for pricing derivatives, portfolio optimization and risk management, and their theoretical analysis.

[03032] Policy improvement algorithm for an optimal consumption and investment problem under general stochastic factor models

Format : Talk at Waseda University
Author(s) : Kazuhiro Yasuda (Hosei university)Hiroaki Hata (Hitotsubashi university)
Abstract : In this talk, we propose a policy improvement algorithm for a consumption and investment problem on a finite time horizon to optimize a discounted expected power utility of consumption and terminal wealth. We employ a general stochastic factor model which means that the returns and volatilities of assets are random and affected by some economic factors, modeled as diffusion processes. We establish an iteration procedure converging to the value function and the optimal strategies obtained in Hata, Nagai and Sheu (2018). Some numerical results are shown to understand convergence behaviors of the algorithm.

[03381] Growth in Fund Models

Format : Talk at Waseda University
Author(s) : Hyeng Keun Koo (Ajou University)Constantinos Kardaras (London School of Economics)Johannes Ruf (London School of Economics)
Abstract : We study estimation of growth in fund models, i.e., statistical descriptions of markets where all asset returns are spanned by the returns of a lower-dimensional collection of funds, modulo orthogonal noise. The loss of growth due to estimation error in fund models under local frequentist estimation is determined entirely by the number of funds. A shrinkage method that targets maximal growth with the least amount of deviation is proposed.

[03015] Carbon Emissions Pricing by Forward and Double Barrier Backward SDE approach

Format : Talk at Waseda University
Author(s) : Tadashi Hayashi (Mitsubishi UFJ Trust and Banking Corporation)
Abstract : Under the circumstances of global warming caused by increasing in greenhouse gases, there are many theoretical and empirical studies in carbon emissions to control and reduce the gases. Our study is focused on the carbon emissions pricing via Forward and Double Barrier BSDE as another pricing approach. This modelling would be a new approach of carbon emissions pricing and therefore lead to a new chance of empirical simulation.

[03307] Irreversible consumption habit under ambiguity: singular control and optimal G-stopping time

Format : Talk at Waseda University
Author(s) : Kyunghyun Park (Nanyang Technological University)HOI YING WONG (The Chinese University of Hong Kong)Kexin Chen (The Hong Kong Polytechnic University)
Abstract : Consider robust utility maximization with an irreversible consumption habit, where an agent concerned about model ambiguity is unwilling to decrease consumption and must simultaneously contend with a disutility (i.e., an adjustment cost) due to a consumption increase. While the optimization is a robust analog of singular control problems over a class of consumption-investment strategies and a set of probability measures, it is a new formulation that involves non-dominated probability measures of the diffusion process for the underlying assets in addition to singular controls with an adjustment cost. This paper provides a novel connection between the singular controls in the optimization and the optimal G-stopping times in a G-expectation space, using a duality theory. This connection enables to derive the robust consumption strategy as a running maximum of the stochastic boundary, which is characterized by a free boundary arising from the optimal G-stopping times. The duality, which relies on arguments based on reflected G-BSDEs, is achieved by verifying the first-order optimality conditions for the singular control, the budget constraint equation for the robust strategies, and the worst-case realization under the non-dominated measures.

02163 (2/3) : 4D @E505 [Chair: Toshihiro Yamada]

[03674] New deep NN architecture using higher-order weak approximation

Format : Talk at Waseda University
Author(s) : Syoiti Ninomiya (Tokyo Institute of Technology)Yuming MA (Tokyo Institute of Technology)
Abstract : New deep learning neural networks based on high-order weak approximation algorithms for stochastic differential equations are proposed. The behavior of these new algorithms when applied to the problem of pricing financial derivatives is also reported. The architectural key to the deep learning neural network proposed here is a high-order discretization method of Runge-Kutta type, in which the weak approximation of stochastic differential equations is realized by iterative substitutions and their linear summation.

[03488] A higher order discretization scheme for backward stochastic differential equations combined with a non-linear discrete Clark-Ocone formula

Format : Talk at Waseda University

Author(s) : Kaori Okuma (Ritsumeikan University)

Abstract : In this talk, the author first introduces a discretization scheme of arbitrary order for backward stochastic differential equations. Then, by establishing a mathematical algorithm based on a non-linear discrete Clark-Ocone formula, which was previously established by the author and her collaborators, the author claims that the scheme is potentially implementable in a “deep solver” type numerical algorithm —- a scheme using approximation by deep neural networks and stochastic gradient descent — for a semi-linear partial differential equation.

[03622] New deep learning-based algorithms for high-dimensional Bermudan option pricing

Format : Talk at Waseda University

Author(s) : Riu Naito (Hitotsubashi University)Toshihiro Yamada (Hitotsubashi University)

Abstract : In this talk, we introduce efficient algorithms for pricing high-dimensional Bermudan options. The proposed methods provide an accurate approximation for Bermudan options by discretizing the interval of early-exercise dates with weak approximation schemes for stochastic differential equations. The deep learning-based approximation for conditional expectations at each exercise date works well for high-dimensional problems compared to the least squares Monte Carlo method. Numerical experiments confirm the validity of the methods.

[05412] On-Policy and Off-Policy q-Learning in Continuous Time

Format : Talk at Waseda University

Author(s) : Yanwei Jia (Chinese University of Hong Kong)Xunyu Zhou (Columbia University)

Abstract : We study the continuous-time counterpart of Q-learning for reinforcement learning (RL) under the entropy-regularized, exploratory formulation introduced by Wang et al (2020). As the conventional (big) Q-function collapses in continuous
time, we consider its first-order approximation and coin the term `(little) q-function". This function is related to the instantaneous advantage rate function as well as the Hamiltonian. We develop a`q-learning" theory around the
q-function that is independent of time discretization. Given a stochastic policy, we jointly characterize the associated q-function and value function by martingale conditions of certain stochastic processes, in both on-policy and off-policy
settings. We then apply the theory to devise different actor-critic algorithms for solving underlying RL problems, depending on whether or not the density function of the Gibbs measure generated from the q-function can be computed explicitly.

02163 (3/3) : 4E @E505 [Chair: Kazuhiro Yasuda]

[03150] An Approximation Scheme for Path-Dependent BSDEs

Format : Talk at Waseda University

Author(s) : Hyungbin Park (Seoul National University)Ji-Uk Jang (Seoul National University)

Abstract : In this work, we study an approximation scheme for solutions to forward-backward stochastic differential equations (FBSDEs) with non-anticipative coefficients. When the non-anticipative coefficients have Fréchet derivatives or can be approximated by non-anticipative functionals having Fréchet derivatives, we show the Picard-type iteration converges to the FBDSE solution and provide its convergence rate. Using this result, we establish a numerical method for solutions of second-order parabolic path-dependent partial differential equations. To achieve this, weak approximation of martingale representation theorem (Cont, Rama, and Yi Lu. “Weak approximation of martingale representations." Stochastic Processes and their Applications 2016) is employed. Our results generalize the scheme for Markovian cases in (Bender, Christian, and Robert Denk. “A forward scheme for backward SDEs." Stochastic processes and their applications, 2007)

[03659] Practical high-order recombination algorithms for weak approximation of stochastic differential equations : Recursive patch dividing and its effects to singularities of terminal conditions

Format : Talk at Waseda University
Author(s) : Syoiti Ninomiya (Tokyo Institute of Technology)Yuji Shinozaki (Bank of Japan)
Abstract : This study proposes practically feasible implementation algorithms of the high-order recombination to apply to the weak approximation problem of SDEs, by extending and refining the work of Lyons and Litterer(2012). Specifically, new recursive patch dividing algorithms, which are based on the refined patch radius criteria, are proposed. Our numerical experiments demonstrate that the new recursive patch dividing algorithms are still efficient even when the terminal condition f becomes more singular.

[03645] Extended Milstein scheme for hypoelliptic diffusions

Format : Talk at Waseda University
Author(s) : Yuga Iguchi (University College London)Toshihiro Yamada (Hitotsubashi University)
Abstract : For a wide class of diffusion processes, precisely hypoelliptic diffusions, we propose an effective and simple numerical scheme as an extension of Milstein scheme that outperforms Euler-Maruyama (EM) scheme (and standard Milstein scheme), though they share the same convergence rate in a weak sense. Analytic error term for the new scheme is derived and compared with that for EM scheme under non-smooth test functions. The effectiveness of the proposed scheme is also shown through numerical experiments for hypoelliptic diffusions appearing in finance.

[03489] Wong-Zakai approximation for stochastic PDEs and HJM model

Format : Talk at Waseda University
Author(s) : TOSHIYUKI NAKAYAMA (MUFG Bank, Ltd.)
Abstract : We talk about semi-linear stochastic differential equation (SPDE) driven by a finite dimensional Brownian motion.
$dX(t) = (AX(t) + b(X(t)))dt + \sum_{j=1}^{r} \sigma_j(X(t))dB^j(t), \quad X(0) = x_0.$
Our goal is to establish a convergence rate with the generator A which is allowed to be the infinitesimal generator of an arbitrary strongly continuous semigroup.
Finally, we will introduce an application example for SPDE called HJMM that appears in mathematical finance.
This talk is based on a co-authored paper with Stefan Tappe.

[02169] Recent advances on numerical methods for stochastic ordinary differential equations

Session Time & Room :

02169 (1/2) : 1E (Aug.21, 17:40-19:20) @E506

02169 (2/2) : 2C (Aug.22, 13:20-15:00) @E506

Type : Proposal of Minisymposium
Abstract : Stochastic differential equations appear nowadays as a modeling tool in many branches of science and industry as finance, biology, and mean field theory, etc. Numerical methods play a key role in understanding and exploring the dynamics of stochastic differential equations. Some new challenges arise from real-world applications, for example, a stochastic model with non-globally Lipschitz diffusion, singular initial value problems with white noises, mean-field interactions, or the positivity preserving property. The aim of this minisymposium is to bring the researchers in these fields together to discuss recent advances and influence more collaborations.

[03230] Deterministic implicit two-step Milstein methods for stochastic differential equations

Format : Talk at Waseda University
Author(s) : Hongjiong Tian (Shanghai Normal University)Quanwei Ren (Henan University of Technology)Tianhai Tian (Monash University)
Abstract : We propose a class of deterministic implicit two-step Milstein methods for solving Itô stochastic differential equations. Theoretical analysis is conducted for the convergence and stability properties of the proposed methods. We derive sufficient conditions such that these methods have the mean-square(M-S) convergence of order one, as well as sufficient and necessary conditions for linear M-S stability of the implicit two-step Milstein methods. Stability analysis shows that our proposed implicit two-step Milstein methods have much better stability property than those of the corresponding two-step explicit or semi-implicit Milstein methods. Numerical results are presented to confirm our theoretical analysis results.

[03158] Numerical methods for stochastic singular initial value problems

Format : Online Talk on Zoom
Author(s) : Nan Deng (Southeast University)Wanrong Cao (Southeast University)Guofei Pang (Southeast University)
Abstract : In this work, we investigate the strong convergence of the Euler-Maruyama method for second-order stochastic singular initial value problems with additive white noise. The singularity at the origin brings a big challenge that the classical framework for stochastic differential equations and numerical schemes cannot work. By converting the problem to a first-order stochastic singular differential system, the existence and uniqueness of the exact solution is studied. Moreover, under some suitable assumptions, it is proved that the Euler-Maruyama scheme is of $(1/2-\epsilon)$ order convergence in mean-square sense, where ϵ is an arbitrary small positive number, which is different from the consensus that the Euler-Maruyama method is convergent with first order in strong sense when solving stochastic differential equations with additive white noise. While, it is found that if the diffusion coefficient vanishes at the origin, the convergent order in mean-square sense will be raised to $1-\epsilon$. Our theoretical findings are well verified by numerical examples.

[03262] A Positivity Preserving Lamperti Transformed Euler-Maruyama Method for Solving the Stochastic Lotka-Volterra Competition Model

Format : Online Talk on Zoom
Author(s) : Yan Li (Southeast university)Wanrong Cao (Southeast University)
Abstract : A new positivity preserving numerical scheme is presented for a class of d-dimensional stochastic Lotka-Volterra competitive models, which are characterized by super-linear coefficients and positive solutions. The scheme, dubbed the Lamperti transformed Euler-Maruyama method, approximates the exact solution by integrating a Lamperti-type transformation with an explicit Euler-Maruyama method that has the benefit of being explicit and straightforward to implement. Even though the coefficients of the transformed models grow exponentially and do not satisfy the general monotonicity condition, based on the exponential integrability of the solution, it is proved that the proposed numerical method is of 1/2-order strong convergence. In particular, when matrix A of the model is a diagonal matrix, the first-order strong convergence is also obtained. Without any step size constraints, the method can preserve long-time dynamical properties such as extinction and pth moment exponential asymptotic stability. Numerical examples are given to support our theoretical conclusions.

[03037] Convergence rate in L^p sense of tamed EM scheme for highly nonlinear neutral multiple-delay stochastic McKean-Vlasov equations

Format : Online Talk on Zoom
Author(s) : Shuaibin Gao (Shanghai Normal University)Qian Guo (Shanghai Normal University)Junhao Hu (South-Central University For Nationalities)Chenggui Yuan (Swansea University)
Abstract : This paper focuses on the numerical scheme of highly nonlinear neutral multiple-delay stochastic McKean-Vlasov equation (NMSMVE) by virtue of the stochastic particle method. First, under general assumptions, the results about propagation of chaos in $\mathcal{L}^p$ sense are shown. Then the tamed Euler-Maruyama scheme to the corresponding particle system is established and the convergence rate in $\mathcal{L}^p$ sense is obtained. Furthermore, combining these two results gives the convergence error between the objective NMSMVE and numerical

approximation, which is related to the particle number and step size. Finally, two numerical examples are provided to support the finding.

[02178] Efficient computational methods for data matrices: exploiting sparsity and structure

Session Time & Room :

02178 (1/2) : 5B (Aug.25, 10:40-12:20) @E508

02178 (2/2) : 5C (Aug.25, 13:20-15:00) @E508

Type : Proposal of Minisymposium
Abstract : This mini-symposium focuses on new applications from data analysis where sparse and structured matrices arise, as opposed to well-studied applications in scientific and engineering simulation. In addition to these new applications, we shall highlight algorithmic advances for these objects with a focus on techniques like randomisation, parallelisation, and use of modern computer hardware. The overall goal of this gathering is to help researchers see connections among these newer data-driven application areas and identify new computational building blocks that might benefit multiple domains.
Organizer(s) : Richard Vuduc, Srinivas EswarSponsor : This session is sponsored by the SIAM Activity Group on Supercomputing.

[04733] Structured Matrices in Unsupervised Cross-Validation

Format : Talk at Waseda University
Author(s) : Srinivas Eswar (Argonne National Laboratory)
Abstract : We consider matrix low-rank approximation algorithms in the setting of unsupervised cross-validation. Unlike most structured matrix computations, a cross-validation user has more control of sparsity, with different choices implying different performance trade-offs. For example, controlling the rank of these matrices results in a trade-off between efficiency and cross-validation accuracy. This talk surveys these choices and trade-offs. Additionally, this presentation will also introduce the minisymposium.

[04283] Randomized Algorithms for Rank Structured Matrices

Format : Talk at Waseda University
Author(s) : Per-Gunnar Martinsson (University of Texas at Austin)
Abstract : The talk describes randomized algorithms for computing a data sparse representation of a rank structured matrix (HSS, HODLR, H-matrix, ...). The algorithms are black box in that they interact with the target matrix only through its action on vectors, making them ideal for tasks such as forming Schur complements or matrix matrix multiplication. When the target matrix can be applied in O(N) operations, the compression as a whole typically has linear complexity as well.

[03473] Scalable Data Analytics using Sparse Matrices

Format : Talk at Waseda University
Author(s) : Giulia Guidi (Cornell University)
Abstract : Massively parallel systems are vital for processing large data and play a critical role in data analysis. However, programming high-performance computing systems poses productivity and scalability challenges. Here, we focus here on advances in genome sequencing and the associated flood of genomic data, which present computational challenges and require new approaches.

This work demonstrates the feasibility of writing parallel code for irregular genomic computation through sparse matrix abstraction for de novo long-read genome assembly.

[04632] Structure of Fisher information matrices in deep learning

Format : Talk at Waseda University
Author(s) : Rio Yokota (Tokyo Institute of Technology)
Abstract : Fisher information matrices have many applications in deep learning such as continual learning, generalization metrics, hyperparameter prediction, model sparsification, and optimization. The Fisher information matrix has a Kronecker product structure, which can be exploited to accelerate its computation. This talk will cover the various applications of Fisher information matrices, and its relation to Hessian and Gauss-Newton matrices, along with the theory behind its approximation through Kronecker factorization.

02178 (2/2) : 5C @E508 [Chair: Srinivas Eswar]

[04795] Exploiting Supernodal Structures in Sparse All Pair Shortest Path Computation.

Format : Talk at Waseda University
Author(s) : Piyush K Sao (Oak Ridge National Laboratory)Prasun Gera (cerebras)Hao Lu (Oak Ridge National Laboratory)Ramki Kannan (Oak Ridge National Laboratory)Richard W Vuduc (Georgia Institute of Technology)Thomas Potok (Oak Ridge National Laboratory)
Abstract : We introduce a novel approach for efficiently solving all-pairs shortest path problems on sparse graphs. We leverage the techniques from sparse Cholesky factorization, including fill-in-reducing ordering, supernodal traversal, and elimination tree parallelism for APSP computation. Our method uses semi-ring notation to express graph algorithms in linear algebraic form and employs BLAS level-III semi-ring operations. Our parallel prototype implementation significantly outperforms a non-sparsity-exploiting Floyd-Warshall algorithm and competes with Dijkstra's algorithm for specific sparse graph classes.

[04585] Optimizations of H-matirx-vector Multiplication for Many-core Processors

Format : Talk at Waseda University
Author(s) : Tetsuya Hoshino (Nagoya University)Akihiro Ida (Japan Agency for Marine-Earth Science and Technology)Toshihiro Hanawa (The University of Tokyo)
Abstract : Hierarchical matrices (H-matrices) can robustly approximate the dense matrices that appear in the boundary element method (BEM). To accelerate the solving of linear systems in the BEM, we must speed up hierarchical matrix–vector multiplication (HiMV). This presentation discusses optimization methodologies of HiMV for modern multi/many-core CPUs: an H-matrix storage method for efficient memory access, a method that avoids write contentions, an inter-thread load-balancing method, and blocking and sub-matrix sorting methods for cache efficiency.

[04849] Distributed Graph Neural Network for Billion-Scale Graphs

Format : Online Talk on Zoom
Author(s) : Israt Nisa (AWS AI)
Abstract : GNN models are widely used in recommendation, fraud detection, and search. Real-world graphs from social media and co-purchase networks are large and heterogeneous, posing challenges for scaling training and inference. We demonstrate GraphStorm, a GNN framework that utilizes a distributed hybrid CPU/GPU architecture for efficient graph partitioning, asynchronous computation and data loading, data locality, and hardware utilization (CPU, GPU, network, PCIe).

[05081] A Framework to Exploit Data Sparsity in Tile Low-Rank Cholesky Factorization

Format : Online Talk on Zoom
Author(s) : Rabab Mohammad Alomairy (King Abdullah University of Science and Technology)Qinglei Cao (University of Tennessee)Yu Pei (University of Tennessee)george bosilca (University of Tennessee)Hatem Ltaief (King Abdullah University of Science and Technology)David Keyes (King Abdullah University of Science and Technology)Jack Dongarra (University of Tennessee)

Abstract : We accelerate the computations of 3D unstructured mesh deformation based on radial basis function interpolations by exploiting the rank structured property of the matrix. As we increase the accuracy threshold to satisfy the application requirements, the original dense operator gets further compressed and may become sparse enough to switch the dense solver to sparse direct solver. This talk highlights how PaRSEC redistributes the matrix, mitigates the data movement overheads, and copes with the load imbalance.

[02181] Numerical methods and analysis for linear systems and eigenvalue problems

Session Time & Room :

02181 (1/2) : 3C (Aug.23, 13:20-15:00) @E508

02181 (2/2) : 3D (Aug.23, 15:30-17:10) @E508

Type : Proposal of Minisymposium
Abstract : In this mini-symposium, speakers will present recent developments in the numerical methods for linear systems and eigenvalue problems. The topics of interest include, iterative methods such as IDR(s) and randomized block Kaczmarz methods for linear systems with single right-hand side, and block GMRES-type solvers for linear systems with multiple right-hand sides, acceleration and preconditioning techniques for both linear and nonlinear eigenvalue problems, and algorithms for computing eigenvalues of semi-infinite quasi-Toeplitz matrices.

[03254] Interpretation of partial convergence from space partition for linear systems

Format : Talk at Waseda University
Author(s) : Yanfei Jing (University of Electronic Science and Technology of China)Luc Giraud (Inria Bordeaux -- Sud-Ouest)Yanfei Xiang (Cerfacs, Inria Bordeaux -- Sud-Ouest)
Abstract : Efficient solution of large-scale systems of linear equations with multiple right-hand sides is important. Partial convergence and inexact breakdown detection mechanism in the block classical GMRES method characterized by Robbe and Sadkane is a significant progress.
We interpret such partial convergence from space partition, providing flexible choices for approximation search subspace at each iteration.
Beyond, we report our recent progress in block GMRES-type solvers, and show the efficiency of our solvers by some typical numerical experiments..

[04340] The FEAST algorithm accelerated by subspace expansion for eigenproblems

Format : Talk at Waseda University
Author(s) : Guojian Yin (Shenzhen University)
Abstract : The FEAST algorithm, a contour-integral based eigensolver, was developed for computing the eigenvalues inside a given region, along with their eigenvectors, of generalized eigenproblems. The FEAST algorithm is always fast, stable and easily parallelizable. It can be understood as an accelerated subspace iteration algorithm in conjunction with the Rayleigh–Ritz procedure. Unlike the classic subspace eigensolvers, the FEAST algorithm does not include a subspace expansion procedure when updating the search subspace but filters the search subspace iteratively using an approximate spectral projector. In this talk, I will introduce a subspace expansion scheme for the FEAST algorithm with the hope of producing a better search subspace and the improving convergence rate, especially when it comes to the ill-conditioned problems.

[03264] Computing eigenvalues of semi-infinite quasi-Toeplitz matrices

Format : Talk at Waseda University
Author(s) : Dario Bini (University of Pisa)Bruno Iannazzo (University of Perugia)Beatrice Meini (University of Pisa)Jie Meng (Ocean University of China)Leonardo Robol (University of Pisa)
Abstract : A quasi-Toeplitz (QT) matrix is a semi-infinite matrix of the form $A = T(a) + E$ where $T(a)$ is the Toeplitz matrix with
entries $(T(a))_{i,j} = a_{j-i}$, for $a_{j-i} \in \mathbb{C}$, $i, j \geq 1$, while E is a matrix representing a compact
operator in ℓ^2. The matrix A is finitely representable if $a_k = 0$ for $k < -m$ and for $k > n$, given $m, n > 0$, and
if E has a finite number of nonzero entries. The problem of numerically computing eigenpairs of a finitely
representable QT matrix is investigated, i.e., pairs (λ, v) such that $Av = \lambda v$, with $\lambda \in \mathbb{C}$, $v = (v_j)_{j \in \mathbb{Z}^+}$, $v \neq 0$, and $\sum_{j=1}^{\infty} |v_j|^2 < \infty$. It is shown that the problem is
reduced to a finite nonlinear eigenvalue problemof the kind $WU(\lambda)\beta = 0$, where W is a constant matrix and U depends on λ and can be given in terms of either a Vandermonde matrix or a companion matrix.
Algorithms relying on Newton's method applied to the equation $\det WU(\lambda) = 0$ are analyzed. Numerical experiments show the effectiveness of this approach.

[03454] Preconditioning techniques for nonlinear eigenvalue problem expressed in non-monomial basis

Format : Talk at Waseda University
Author(s) : Hongjia Chen (Nanchang University)
Abstract : One of the most successful methods for solving a polynomial (PEP) or rational eigenvalue
problem (REP) is to recast it, by linearization, as an equivalent but larger generalized eigenvalue problem which can be solved by standard eigensolvers. In this work, we investigate the
backward errors of the computed eigenpairs incurred by the application of the well-received
compact rational Krylov (CORK) linearization. Our treatment is unified for the PEPs or REPs
expressed in various commonly used bases, including Taylor, Newton, Lagrange, orthogonal,
and rational basis functions. We construct one-sided factorizations that relate the eigenpairs
of the CORK linearization and those of the PEPs or REPs. With these factorizations, we establish upper bounds for the backward error of an approximate eigenpair of the PEPs or REPs
relative to the backward error of the corresponding eigenpair of the CORK linearization.
These bounds suggest scaling techniques to improve the accuracy of the computed eigenpairs.
We show, by numerical experiments, that the actual backward errors can be successfully
reduced by scaling and the errors, before and after scaling, are both well predicted by the
bounds.

02181 (2/2) : 3D @E508

[04543] A variant algorithm of the IDR(s) method for solving linear systems

Format : Talk at Waseda University
Author(s) : Lei Du (Dalian University of Technology)
Abstract : The Induced Dimension Reduction method (IDR(s) proposed by Sonneveld and van Gijzen is an efficient method for solving large, sparse and nonsymmetric linear systems, after then many variants have been proposed. The method has also been generalized to solve matrix equations and eigenvalue problems. In this talk, we consider using the Anderson acceleration technique and propose a new variant to accelerate the IDR(s) method. Some numerical experiments are presented to show the efficiency of our proposed algorithm.

[03550] Randomized block Kaczmarz methods with k-means clustering for solving linear systems

Author(s) : Ke Zhang (Shanghai Maritime University)Xiang-Long Jiang (Shanghai Maritime University)Junfeng Yin (Tongji University)
Abstract : In this talk, by following the philosophy of the block Kaczmarz methods, we propose a randomized block Kaczmarz method with the blocks determined by the k-means clustering. It can be considered as an efficient variant of the relaxed greedy randomized Kaczmarz algorithm by using a practical probability criterion for selecting the working block submatrix per iteration. The new algorithm is proved to be convergent when the linear system is consistent. A practical variant of the new method is also given. Some numerical examples are given to verify the effectiveness of the proposed methods.

[02212] Modeling, Algorithms and Simulations for Flow and Transport in Porous Media

Session Time & Room :

02212 (1/3) : 2C (Aug.22, 13:20-15:00) @D403

02212 (2/3) : 2D (Aug.22, 15:30-17:10) @D403

02212 (3/3) : 2E (Aug.22, 17:40-19:20) @D403

Type : Proposal of Minisymposium
Abstract : Porous media flow and transport is important in wide applications, including carbon sequestration, subsurface hydrogen storage, and geothermal reservoirs. This mini-symposium seeks to highlight newest developments of porous media flow and transport both in physical models and numerical methods, to exchange ideas and to promote collaborations. Specific topics of interest include, but are not limited to: advanced physical models of porous media flow and transport; novel numerical methods for its simulation; its machine learning and deep learning algorithms; multiphase and multiphysics simulation; its error estimation, cross-scale analysis, and uncertainty quantification; applications especially in geological carbon sequestration and energy storage.

[03292] Stabilized enhancement for large time computation using exponential spectral process method

Author(s) : Xiang Wang (Jilin University)
Abstract : We propose an exponential spectral process (ESP) method for time discretization of spatial-temporal equations. The proposed ESP method uses explicit iterations at each time step, which allows us to use simple initializations at each iteration. This method has the capacity to obtain high accuracy (up to machine precision) with reasonably large time step sizes. Theoretically, the ESP method has been shown to be unconditionally energy stable for arbitrary number of iteration steps for the case where two spectral points are used. To demonstrate the advantages of the ESP approach, we consider two applications that have stability difficulties in large-time simulations. One of them is the Allen-Cahn equation with the symmetry breaking problem that most existing time discretizations face, and the second one is about the complex Ginzburg-Landau equation, which also suffers from large-time instabilities.

[03294] A pressure robust solver for Stokes flow based on a lifting operator

Author(s) : Ruishu Wang (Jilin University)
Abstract : We presents novel finite element solvers for Stokes flow that are pressure-robust due to the use of a lifting operator. Weak Galerkin (WG) finite element schemes are developed for the Stokes problem on quadrilateral and hexahedral meshes. Local Arbogast-Correa or Arbogast-Tao spaces are utilized for construction of discrete weak gradients. The lifting operator lifts WG test functions into H(div)-subspaces and removes pressure dependence of velocity errors.

[03331] Numerical Approaches and Analysis for The Generalized Maxwell-Stefan Equations

Author(s) : Xiuping Wang (King Abdullah University of Science and Technology)Shuyu Sun (King Abdullah University of Science and Technology)
Abstract : This talk presents an analysis of the thermodynamic properties of the generalized Maxwell-Stefan equations for the diffusion process in multi-component systems and proposes a corresponding numerical scheme. Detailed proofs show that the model satisfies Onsager's principle and the second law of thermodynamics. An energy-stable numerical scheme is established by a mixed finite element method and the backward Euler scheme.

[03419] The Undrained Split Phase Field Method for Modeling Hydraulic Fracture Propagation

Author(s) : Tameem Almani (Saudi Aramco)

Abstract : In this work, we present and analyze the undrained split iterative coupling scheme for coupling flow with geomechanics applied to the fracture propagation problem. In the undrained split scheme, the mechanics problem is solved first, followed by the flow problem, and the fluid content of the medium (i.e., porosity) is assumed to be constant during the mechanics solve. This sequential coupling approach was shown to be convergent in an earlier work, and has the advantage of being easier to integrate with legacy reservoir simulators compared to the standard fixed-stress split scheme. This is due to the fact that in the undrained split scheme, the regularization terms are added to the mechanics equation and not the flow equation. In this work, we will establish the convergence of this scheme when applied to the fracture prograpation problem using the phase field method. To the best of our knowledge, this is the first time in literature the undrained split scheme is applied to the fracture propagation problem using the phase field method, and the convergence of the combined scheme is established.

02212 (2/3) : 2D @D403

[03443] Accelerating Pressure-Temperature Flash Calculations with Physics-informed Neural Networks

Author(s) : Yuanqing Wu (Dongguan University of Technology)

Abstract : Pressure-Temperature (PT) flash calculations are a performance bottleneck of compositional-flow simulations. With physics-informed neural networks, the two heavy-burden routines of PT flash calculations: the successive substitution technique and stability analysis are be avoided in the offline stage, and therefore the computing burden in the offline stage is removed. After training, the phase condition and the compositions can be output by the neural network, which costs much less time than the PT flash calculations.

[03499] The numerical CFD-DEM model for polymer flooding in weakly consolidated porous media

Author(s) : Yerlan Amanbek (Nazarbayev Univesity)Daniyar Kazidenov (Nazarbayev Univesity)Sagyn Omirbekov (Nazarbayev Univesity)

Abstract : The study of sand production from the oil and gas reservoirs is an essential for ensuring the long-term viability and profitability of hydrocarbon production operations. In this talk, we present numerical model of polymer flooding using CFD coupled DEM for sand production in 3D. The Navier-Stokes equation is solved using CFD approach, and the DEM approach is based on the second Newton's law to simulate the behavior of individual particles in the porous medium. The modified JKR model is used to represent the weakly consolidated sandstone. The rheology of the injected polymer is described by the power law model. The laboratory experiment was conducted considering the polymer flooding. Numerical model was validated by the sand production rate of the laboratory experiment in the normalized setting.

[03503] Physics-Preserving Semi-Implicit Schemes for Porous Media Flow with Capillary Heterogeneity

Author(s) : Shuyu Sun (KAUST)

Abstract : Two-phase flow commonly occurs in environmental engineering and petroleum industry. We present our work on semi-implicit algorithms for two-phase flow in porous media with capillary heterogeneity; in particular, different capillary pressure functions are used for different rock types. Our proposed algorithms, derived from our novel splitting of variables, are locally conservative for both phases, handle capillary heterogeneity well, and are unbiased. The algorithms are also numerically more stable than classical approaches, demonstrated using numerical examples.

[04169] Efficient numerical methods for thermodynamically consistent model of two-phase flow in porous media

Author(s) : Huangxin Chen (Xiamen University)

Abstract : In this talk we will introduce a thermodynamically consistent mathematical model for incompressible and immiscible two-phase flow in porous media with rock compressibility. An energy stable numerical method will be introduced, which can preserve multiple physical properties, including the energy dissipation law, full

conservation law for both fluids and pore volumes, and bounds of porosity and saturations. Numerical results are given to verify the features of the proposed methods.

02212 (3/3) : 2E @D403

[05155] Geothermal management with an integrated optimization method accelerated by a general thermal decline model and deep learning

Author(s) : Bicheng Yan (King Abdullah University of Science and Technology)Manojkumar Gudala (King Abdullah University of Science and Technology)Shuyu Sun (KAUST)

Abstract : Geothermal modeling is complex due to the coupled thermo-hydro-mechanical physics, which brings computational challenges for geothermal management.

To tackle with this, we developed a parsimonious thermal decline model to capture the early thermal breakthrough and the later decline behavior. Further, a forward neural network maps the reservoir parameters to the decline model parameters, and it is integrated with a multi-objective optimizer, which considers reservoir uncertainties and subjects engineering constraints for robust reservoir optimization.

[05424] Gym-preCICE: Reinforcement Learning Environments for Active Flow Control

Author(s) : Ahmed H. Elsheikh (Heriot-Watt University)Mosayeb Shams (Heriot-Watt University)

Abstract : We introduce Gym-preCICE, a Python adapter to facilitate designing and developing Reinforcement Learning (RL) environments for single- and multi-physics Active flow control (AFC) applications. In an actor-environment setting, Gym-preCICE takes advantage of preCICE, an open-source coupling library for partitioned multi-physics simulations, to handle information exchange between a controller (actor) and an AFC simulation environment. The developed framework results in a seamless non-invasive integration of realistic physics-based simulation toolboxes with RL algorithms.

[05495] Ensemble schemes for the numerical solution of a random transient heat equation with uncertain inputs

Author(s) : Xianbing Luo (Guizhou University)Meng Li (Guizhou University)Tingfu Yao (Guizhou University)Changlun Ye (Guizhou University)

Abstract : Ensemble-based time stepping schemes are applied to solving a transient heat equation with random Robin boundary and diffusion coefficients. (1) By introducing ensemble mean, we use HDG method to obtain optimal convergence order for random diffusion coefficient problem. (2) By introducing two ensemble means of Robin boundary and diffusion coefficients, we propose a new ensemble Monte Carlo (EMC) scheme for the transient heat equation. (3) By introducing two Max ensemble for Robin boundary and diffusion coefficients problem, we propose a unconditional stability ensemble method. Stability analysis and error estimates are derived. Numerical examples verify the theoretical results and the validity of the ensemble method.

[02219] Pattern formation and propagation in reaction-diffusion systems on metric graphs

Session Time & Room :

02219 (1/2) : 3E (Aug.23, 17:40-19:20) @G602

02219 (2/2) : 4C (Aug.24, 13:20-15:00) @G602

Type : Proposal of Minisymposium

Abstract : This minisymposium concerns theoretical and numerical studies about partial differential equations on metric graphs. Partial differential equations on metric graphs have been applied to a variety of areas as mathematical models related to phenomena in network structures. In particular, this minisymposium focuses on pattern formation and wave propagation in many reaction-diffusion systems on metric graphs, such as Lotka-

Volterra systems, Gierer-Meinhardt systems, Allen-Cahn equations, and so on. This minisymposium will invite researchers to report their recent results on these subjects.
Organizer(s) : Satoru Iwasaki, Yuta Ishii, Shin-Ichiro Ei, Ken-Ichi Nakamura
Classification : 35K57, 35B35, 35B40, 35R02
Minisymposium Program :

02219 (1/2) : 3E @G602 [Chair: Yuta Ishii]

[05005] Invasion analysis for population dynamics models on simple metric graphs

Format : Talk at Waseda University
Author(s) : Satoru Iwasaki (Osaka University)Harunori Monobe (Osaka Metropolitan University)
Abstract : We are concerned with invasion processes of biological species in network shaped domains, that is metric graphs. In our model, invasions of biological species are restricted by some traps. In this presentation, we report the difference between results of one-dimensional domains case and those of metric graphs case. Particularly, in metric graphs case, we know that vanishing occurs with less traps than one-dimensional case due to an effect of junctions in metric graphs.

[02969] Propagation phenomena of Fisher-KPP equation in a shifting environment

Format : Talk at Waseda University
Author(s) : Jong-Shenq Guo (Tamkang University)
Abstract : In this talk, we shall discuss the propagation phenomena of the Fisher-KPP equation with a shifting intrinsic growth
rate. We divide the heterogeneous shifting term into two different classes, one is the devastating case and the other is the advantageous case. We shall present some results on the existence of forced waves and the spreading dynamics for solutions with compactly supported initial data.

[03115] Pulse dynamics for reaction-diffusion systems on various metric graphs

Format : Talk at Waseda University
Author(s) : Shin-Ichiro Ei (Hokkaido University)Haruki Shimatani (Hokkaido University)
Abstract : In this talk, we give pulse dynamics for reaction-diffusion systems on various metric graphs. In particular, we analyze the behavior of the pulse solutions by deriving an equation of the motion. Note an equation of the motion is an expression for the time evolution of the positions of pulse solutions. In the same way, we will also discuss front dynamics for reaction-diffusion systems on various metric graphs.

[03288] Reaction-advection-diffusion equations over simple graphs

Format : Talk at Waseda University
Author(s) : Bendong Lou (Shanghai Normal University)
Abstract : I will talk about the dynamical behavior of a species spreading in a river network, which is modeled by advective diffusion equations over simple graphs with Fisher-KPP or bistable reactions. Denote by c_* the (minimal) speed of the traveling waves of the corresponding equations without advections, I will present the long time behavior for the solutions in the special case where the water flow speed in upstream is larger than c_* and that in downstream is smaller than c_*, which includes washing out, persistence at carrying capacity or persistence below carrying capacity. (joint works with Y. Du, R. Peng, M. Zhou, Y. Morita).

02219 (2/2) : 4C @G602 [Chair: Satoru Iwasaki]

[04149] The effect of advection on spike solutions for the Schnakenberg model on Y-shaped metric graph

Format : Talk at Waseda University
Author(s) : Yuta Ishii (National Institute of Technology, Ibaraki College)
Abstract : In this talk, we consider one-peak solutions for the Schnakenberg model with advection term on Y-shaped metric graph. The location and amplitude of the spike are decided by the interaction of the advection with the geometry of Y-shaped graph. In particular, the effect of the advection on the location of the spike depends on the choice of boundary conditions strongly.

[03837] Turing instability and bifurcation in reaction-diffusion systems on metric graphs

Format : Talk at Waseda University
Author(s) : Junping Shi (College of William & Mary)
Abstract : We show that under a general framework, a constant equilibrium in a time-evolution system could lose its stability with
the addition of distinct dispersal rates for different species. Spontaneous symmetry breaking bifurcations occur so non-constant stationary patterns emerge. This is the classical Turing instability and bifurcations. We will show the application of this general scenario to the case of (i) an ODE system on a weighted directed graph, and (ii) a reaction-diffusion system on a metric graph.

[04417] Front propagation for Lotka-Volterra competition-diffusion system on unbounded star graphs

Format : Talk at Waseda University
Author(s) : Ken-Ichi Nakamura (Meiji University)
Abstract : We consider the 2-component Lotka-Volterra competition-diffusion system in an infinite star graph with a single junction. Under strong competition conditions, we give sufficient conditions for the success/failure of the invasion of superior species beyond the junction. The method is based on a standard argument by constructing super-subsolutions with the help of a new result on the speed of traveling waves for the Lotka-Volterra competition-diffusion system on the whole line.

[02221] Recent progress on mathematical theory of boundary layer

Session Time & Room :

02221 (1/2) : 2E (Aug.22, 17:40-19:20) @G802

02221 (2/2) : 3C (Aug.23, 13:20-15:00) @G802

Type : Proposal of Minisymposium
Abstract : Boundary effect and stability analysis in fluid mechanics involves many mathematical problems, including boundary layer, free boundary, stability and instability of the hydrodynamic equations under the high Reynolds number, etc. The research on these problems is not only mathematically important and challenging, but also provides specific views for explaining certain physical phenomena and mechanical laws. In order to enhance the exchange on the latest research results and facilitate the cooperations on hydrodynamic stability theory, we would like to organize a mini-symposium named “Recent progress on mathematical theory of boundary layer” .
Organizer(s) : Zhifei Zhang, Guilong Gui, Yong Lu, Chao Wang
Classification : 35QXX, 76FXX, 35FXX
Minisymposium Program :

02221 (1/2) : 2E @G802 [Chair: Zhifei Zhang]

[03046] Eckhaus instability of the compressible Taylor vortex

Format : Talk at Waseda University
Author(s) : Yoshiyuki Kagei (Tokyo Institute of Technology)
Abstract : This talk is concerned with the bifurcation and stability of the compressible Taylor vortex. It is shown that Taylor vortices bifurcate near the criticality for the incompressible problem when the Mach number is sufficiently small. The localized stability of the compressible Taylor vortices is considered and it is shown that the Eckhaus instability of compressible Taylor vortices occurs as in the case of the incompressible ones.

[03064] Stability of shear flows in inviscid and viscous fluids

Format : Talk at Waseda University
Author(s) : Weiren Zhao (New York University Abu Dhabi)
Abstract : In this talk, I will present some recent progress in the asymptotic stability of shear flows in both inviscid and viscous fluids. The inviscid damping and enhanced dissipation phenomenon will be discussed in both linear and nonlinear models.

[03247] Tollmien-Schlichting waves in the subsonic regime

Format : Talk at Waseda University
Author(s) : Di Wu (South China University of Technology)Nader Masmoudi (New York University Abu Dhabi)Yuxi Wang (Sichuan University)Zhifei Zhang (Peking University)
Abstract : The Tollmien-Schlichting (T-S) waves play a key role during the early stage of the boundary layer transition. In a breakthrough work, Grenier, Guo and Nguyen gave a first rigorous construction of the T-S waves of temporal mode for the incompressible fluid. In this paper, we construct the T-S waves of both temporal mode and spatial mode to the linearized compressible Navier-Stokes system around the boundary layer flow in the whole subsonic regime. The proof is based on a new iteration scheme via solving two quasi-compressible systems related to the incompressible part and compressible part respectively. For the incompressible part, the key ingredient is to solve an Orr-Sommerfeld type equation, which is based on a new Airy-Airy-Rayleigh iteration instead of Rayleigh-Airy iteration introduced by Grenier, Guo and Nguyen.

[04253] Global Existence of Weak Solutions for Compressible Navier--Stokes--Fourier Equations with the Truncated Virial Pressure Law

Format : Talk at Waseda University
Author(s) : Fei Wang (Shanghai Jiao Tong University)Didier Bresch (Univ. Savoie Mont Blanc)Pierre-Emmanuel Jabin (Pennsylvania State University)
Abstract : This paper concerns the existence of global weak solutions {\it `a la Leray} for compressible Navier--Stokes--Fourier system with periodic boundary conditions and the truncated virial pressure law which is assumed to be thermodynamically unstable. More precisely, the main novelty is that the pressure law is not assumed to be monotone with respect to the density. This provides the first global weak solutions result for the compressible Navier-Stokes-Fourier system with such kind of pressure law which is strongly used as a generalization of the perfect gas law. The paper is based on a new construction of approximate solutions through an iterative scheme and fixed point procedure which could be very helpful to design efficient numerical schemes. Note that our method involves the recent paper by the authors published in Nonlinearity (2021) for the compactness of the density when the temperature is given.

02221 (2/2) : 3C @G802 [Chair: Guiding Gui]

[03513] Nonlinear Stability of the Taylor-Couette flow

Format : Talk at Waseda University
Author(s) : Te Li (National University of Singapore)
Abstract : Hydrodynamic stability at high Reynolds number is a central topic in fluid mechanics. It is closely related to turbulence. Whereas the laminar velocity profile is linearly stable for all Reynolds number, Reynolds experiment reveals that laminar flows could be unstable and transit to turbulence at high Reynolds number. This phenomenon is described as subcritical transition. And the mechanism behind is not well understood yet. To investigate the dynamical nonlinear stability, we develop a systematic approach to establish sharp resolvent estimates for the linearized operator around the 2D Taylor-Couette flow. One of the main difficulties is that the linearized operator is non-self-adjoint. Based on the resolvent estimates, we first show the sharp enhanced-dissipation decay rate of the solution for the linearized system. We also derive the space-time estimates for the

nonlinear part using the resolvent estimates. Combining all above, we obtain the nonlinear transition threshold for the Taylor-Couette flow. This talk is based on a series of joint works by X. An-T. He-L.

[04401] On the solvability of the linearized Triple-Deck system

Format : Online Talk on Zoom
Author(s) : Yasunori Maekawa (Kyoto University)David Gerard-Varet (Universite Paris Cite et IMJ-PRG)Sameer Iyer (University of California)
Abstract : We establish the solvability of the linearized Triple-Deck system in Gevrey $3/2$ regularity in the tangential variable, under the concavity assumptions on the background flow. This talk is based on the joint work with David Gerard-Varet (Universite Paris Cite et IMJ-PRG) and Sameer Iyer (University of California).

[03016] On dynamic stability for steady Prandtl solutions

Format : Online Talk on Zoom
Author(s) : Yue Wang (Capital Normal University)
Abstract : In this talk, I will first review some properties of steady Prandtl solutions. Then I will introduce our recent work on dynamic stability of steady Prandtl solutions(a joint work with Yan Guo and Zhifei Zhang) and others' related results.

[02277] New regularizing algorithms for solving inverse and ill-posed problems

Session Time & Room :

02277 (1/6) : 3E (Aug.23, 17:40-19:20) @G809

02277 (2/6) : 4C (Aug.24, 13:20-15:00) @G809

02277 (3/6) : 4D (Aug.24, 15:30-17:10) @G809

02277 (4/6) : 4E (Aug.24, 17:40-19:20) @G809

02277 (5/6) : 5B (Aug.25, 10:40-12:20) @G809

02277 (6/6) : 5C (Aug.25, 13:20-15:00) @G809

Type : Proposal of Minisymposium
Abstract : Regularization methods are an important numerical technique in the robust solution of ill-posed inverse problems. In the recent years, many new regularization methods had been developed in various areas of applied mathematics and data science. This minisymposium focuses on the regularization theory of abstract (linear and nonlinear) operator equations and some efficient regularizing algorithms for solving parameter identification problems in (local and nonlocal) PDEs. Such regularizing algorithms includes stochastic asymptotic regularization for general operator equation, asymptotic expansion regularization for inverse problems in singularly perturbed PDEs, machine learning based approaches, etc. The speakers mainly from Russian and China.
Organizer(s) : Ye Zhang, Maxim Shishlenin, Anatoly Yagola and Sergey Kabanikhin
Classification : 35R30, 47A52, 65R30, 65N30, 35N25
Minisymposium Program :

02277 (1/6) : 3E @G809

[05628] Regularization of linear inverse problems and neural networks

Format : Online Talk on Zoom
Author(s) : Sergey Kabanikhin (Sobolev Institute of Mathematics)
Abstract : The report will consider methods of numerical regularization of linear inverse problems and neural networks in applications.

[05627] Applied inverse problems for parabolic equations

Format : Online Talk on Zoom
Author(s) : Maxim Shishlenin (Sobolev Institute of Mathematics)
Abstract : The report will consider inverse problems for parabolic equations in applications such as pharmacodynamics and financial mathematics.

[02806] Data-Driven Regularization in Variational Data Assimilation from An Ocean Perspective

Format : Talk at Waseda University
Author(s) : Long Li (Harbin Institute of Technology)Jianwei Ma (Peking University)
Abstract : Current machine learning-driven methods make a positive difference to outlook on data assimilation. However, its reliability remains to be studied since little deterministic information from physical laws is involved. In this talk, we will introduce our recent work about the efficient assimilation by the approximation of a deep neural network. The sparsity regularization is employed to improve the well-posedness. Results show the technique is robust for reconstructing the velocity of a fluid with vortex structures.

[02803] Uniqueness and numerical inversion in the time-domain fluorescence diffuse optical tomography

Format : Talk at Waseda University
Author(s) : Chunlong Sun (Nanjing University of Aeronautics and Astronautics)
Abstract : This work considers the time-domain fluorescence diffuse optical tomography. We recover the distribution of fluorophores in biological tissue by the boundary measurements. With the Laplace transform and the knowledge of complex analysis, we build the uniqueness theorem of this inverse problem. The numerical inversions are considered. We introduce an iterative inversion algorithm under the framework of regularizing scheme.

02277 (2/6) : 4C @G809

[02839] Stochastic asymptotical regularization for nonlinear ill-posed problems

Format : Talk at Waseda University
Author(s) : Haie Long (Shenzhen SMU-BIT University)
Abstract : In this paper, we establish an initial theory regarding the stochastic asymptotical regularization (SAR) for the uncertainty quantification of the stable approximate solution of ill-posed nonlinear-operator equations, which are deterministic models for numerous inverse problems in science and engineering. By combining techniques from classical regularization theory and stochastic analysis, we prove the regularizing properties of SAR with regard to mean-square convergence. The convergence rate results under the canonical sourcewise condition are also studied. Several numerical examples are used to show the accuracy and advantages of SAR: compared with the conventional deterministic regularization approaches for deterministic inverse problems, SAR can provide the uncertainty quantification of a solution and escape local minimums for nonlinear problems.

[03062] A new framework to quantify the uncertainty in inverse problems

Format : Talk at Waseda University
Author(s) : Wenlong Zhang (Southern University of Science and Technology)
Abstract : In this work, we investigate the regularized solutions and their finite element solutions to the inverse problems governed by partial differential equations, and establish the stochastic convergence and optimal finite element convergence rates of these solutions, under point wise measurement data with random noise. The regularization error estimates and the finite element error estimates are derived with explicit dependence on the noise level, regularization parameter, mesh size, and time step size, which can guide practical choices among these key parameters in real applications. The error estimates also suggest an iterative algorithm for determining an optimal regularization parameter.

[03104] Numerical algorithms for solving the nonlinear Schrödinger equation

Format : Talk at Waseda University

Author(s) : Shuang Liu (Novosibirsk State University)

Abstract : In this paper, the Physical Information Neural Networks algorithm is used to solve the nonlinear Schrödinger equation in a dispersed medium. Adaptive activation functions are used to accelerate PINN convergence, and this approach uses very little data to obtain an exact solution. Due to the approximation capability of the neural network, the results are used in semiconductor optical amplifier fiber lasers where nonlinear effects allow spectral tuning of the generated pulses.

[03354] Multidimensional Ill-Posed Problems in Applications

Format : Talk at Waseda University

Author(s) : Anatoly Yagola (Lomonosov Moscow State University)

Abstract : The report will consider applied multidimensional inverse problems of geophysics (magnetometry and gravimetry) and electron microscopy (electron backscattering), regularizing algorithms for their solution and the results of experimental data processing.

02277 (3/6) : 4D @G809

[04375] Solution of inverse problems in three-dimensional singularly perturbed PDEs

Format : Talk at Waseda University

Author(s) : Dmitrii Chaikovskii (Shenzhen MSU-BIT University)Ye Zhang (Beijing Institute of Technology)

Abstract : We present an efficient asymptotic expansion method for solving forward and inverse problems in a nonlinear, time-dependent, singularly perturbed reaction-diffusion-advection equation. We prove the existence and uniqueness of a smooth solution in 3D PDEs using asymptotic expansion. A simplified equation for the inverse source problem is derived, maintaining accuracy even with noisy data. We propose an asymptotic expansion regularization algorithm for the 3D inverse source problem and demonstrate its feasibility through a model problem.

[05101] The coupled complex boundary methods for inverse problems of partial differential equations

Format : Talk at Waseda University

Author(s) : Rongfang Gong (Nanjing University of Aeronautics and Astronautics)

Abstract : In this talk, a coupled complex boundary method (CCBM) is proposed for an inverse source problem. With the introduction of imaginary unit, the CCBM transfers the original real problem to a complex one. The CCBM has several merits and is further improved. Also, the applications of the CCBM to bioluminescence tomography, inverse Cauchy problem, chromatography etc. are delivered.

[05498] Physics-informed invertible neural network for the Koopman operator learning

Format : Talk at Waseda University

Author(s) : Yue Qiu (Chongqing University)

Abstract : The Koopman operator is used to embed a nonlinear system into an infinite, yet linear system with a set of observable functions. However, manually selecting observable functions that span the invariant subspace of the Koopman operator based on prior knowledge is inefficient and challenging, particularly when little or no information is available about the underlying systems. Furthermore, current methodologies tend to disregard the importance of the invertibility of observable functions, which leads to inaccurate results. To address these challenges, we propose the so-called FlowDMD, a Flow-based Dynamic Mode Decomposition that utilizes the Coupling Flow Invertible Neural Network (CF-INN) framework. FlowDMD leverages the intrinsically invertible characteristics of the CF-INN to learn the invariant subspaces of the Koopman operator and accurately reconstruct state variables. Numerical experiments demonstrate the superior performance of our algorithm compared to state-of-the-art methodologies.

02277 (4/6) : 4E @G809

02277 (5/6) : 5B @G809

02277 (6/6) : 5C @G809

[02285] New Trends in Tensor Networks and Tensor Optimization

Session Time & Room :

02285 (1/2) : 4D (Aug.24, 15:30-17:10) @A208

02285 (2/2) : 4E (Aug.24, 17:40-19:20) @A208

Type : Proposal of Minisymposium
Abstract : Tensors have been shown to be a powerful tool for capturing multiple interactions and inherent hierarchies in data sets from wide applications in scientific and engineering communities. This minisymposium aims to bring together recent advances in tensor network analysis and large-scale tensor optimization. The topics of interest include, but are not limited to
– new advances in tensor networks for machine learning,
– tensorial time series analysis and deep learning,
– tensor regularized generalization in reinforcement learning,
– structural tensor analysis and applications,
– multilinear PageRank and data clustering.

[03267] Efficient Machine Learning with Tensor Networks

Format : Online Talk on Zoom
Author(s) : Qibin Zhao (RIKEN AIP)
Abstract : Tensor Networks (TNs) are factorizations of high dimensional tensors into networks of many low-dimensional tensors, which have been studied in quantum physics, high-performance computing, and applied mathematics. In recent years, TNs have been increasingly investigated and applied to machine learning and signal processing, due to its significant advances in handling large-scale and high-dimensional problems, model compression in deep neural networks, and efficient computations for learning algorithms. This talk aims to present some recent progress of TNs technology applied to machine learning from perspectives of basic principle and algorithms, novel approaches in unsupervised learning, tensor completion, multi-model learning and various applications in DNN, CNN, RNN and etc.

[05506] Accelerated Doubly Stochastic Gradient Descent for Tensor CP Decomposition

Format : Talk at Waseda University
Author(s) : Chunfeng Cui (Beihang University)
Abstract : In this talk, we focus on the doubly stochastic gradient descent (SGD) method for computing the canonical polyadic decomposition (CPD) of tensors. This method not only exploits the block structure of CPD but also enables us to handle large-scale tensors. Based on the momentum acceleration and the variance reduction technique, we propose several acceleration methods, including the heavy-ball acceleration, inertial acceleration, and variance reduction. We also present the global convergence and convergence rates of the proposed methods.

[03184] Tensor network strcuture search

Format : Talk at Waseda University
Author(s) : Chao Li (RIKEN)
Abstract : In this talk, we present a novel problem related to model selection for tensor networks, which we call tensor network structure search (TN-SS). TN-SS aims to find the optimal tensor network structure for a given dataset and task by exploring a large space of possible network structures. We propose several promising solutions to the TN-SS problem, including evolutionary algorithms, stochastic search, and alternating enumeration. Our methods are designed to efficiently explore the space of tensor network structures and identify the most promising candidates based on their performance on the given task.

[04779] Towards Multi-modes Outlier Robust Tensor Ring Decomposition

Format : Talk at Waseda University
Author(s) : Yuning Qiu (Guangdong University of Technolog)
Abstract : The outliers assumption in conventional robust tensor decomposition is often not true in tensors since high-order tensors are prone to be corrupted by outliers in more than one direction. To mitigate this weakness, we propose a novel outlier robust tensor decomposition (ORTD) model by capturing low-rank tensors corrupted from multi-mode outliers. To theoretically guarantee statistical performance, we rigorously analyze a non-asymptotic upper bound of the estimation error for the proposed ORTD model.

02285 (2/2) : 4E @A208

[05508] Singular Value Decomposition of Dual Matrices and its Application to Traveling Wave Identification in the Brain

Format : Talk at Waseda University
Author(s) : Tong Wei (Fudan University)Weiyang Ding (Fudan University)Yimin Wei (Fudan University)
Abstract : atrix factorization in dual number algebra, a hypercomplex system, has been applied to kinematics, mechanisms, and other fields recently. We develop an approach to identify spatiotemporal patterns in the brain such as traveling waves using the singular value decomposition of dual matrices. Theoretically, we propose the compact dual singular value decomposition (CDSVD) of dual complex matrices with explicit expressions as well as a necessary and sufficient condition for its existence. Furthermore, based on the CDSVD, we report on the optimal solution to the best rank-k approximation under a newly defined quasi-metric in dual complex number system. The CDSVD is also related to the dual Moore-Penrose generalized inverse. Numerically, comparisons with other available algorithms are conducted, which indicate the less computational cost of our proposed CDSVD. Next, we employ experiments on simulated time-series data and a road monitoring video to demonstrate the beneficial effect of infinitesimal parts of dual matrices in spatiotemporal pattern identification. Finally, we apply this approach to the large-scale brain fMRI data and then identify three kinds of traveling waves, and further validate the consistency between our analytical results and the current knowledge of cerebral cortex function.

[03043] Multilinear Pseudo-PageRank for Hypergraph Partitioning

Format : Talk at Waseda University
Author(s) : Yannan Chen (South China Normal University)
Abstract : In this talk, we establish the higher-order pseudo-PageRank model, which is formulated as a multilinear system with nonnegative constraints. The coefficient tensor of the multilinear system is a kind of Laplacian tensor of the uniform hypergraph and no dangling corrections are involved. Then, a tensor splitting algorithm is utilized for solving the higher-order pseudo-PageRank problem, of which solutions exist but may not be unique. Numerical experiments illustrate that the proposed higher-order pseudo-PageRank method is powerful and effective for hypergraph partitioning problems.

[04276] Tensorial Time Series Prediction via Tensor Neural Differential Equations

Format : Talk at Waseda University
Author(s) : Mingyuan Bai (RIKEN AIP)
Abstract : The recent decade has witnessed the surge of models and applications in multi-dimensional, i.e., tensorial time series analysis, where their entanglement of different aspects of data, i.e., modes, appeals to both academia and industry, and raises a number of challenges for modeling and analysis. To address these challenges,

we aim to introduce tensor neural differential equations for tensorial time series analysis, including tensor neural ordinary differential equations and tensor neural controlled differential equations, etc.

[03838] A gradient projection method for semi-supervised hypergraph clustering problems

Format : Talk at Waseda University
Author(s) : Jingya Chang (Guangdong University of Technology)
Abstract : We use the hypergraph related tensor to construct an orthogonal constrained optimization model for the semi-supervised hypergraph problems, which is solved by a retraction method. A nonmonotone curvilinear search is implemented to guarantee reduction in the objective function value. Experiments on synthetic hypergraph and hypergraph given by real data demonstrate the effectivity of our method.

[02327] Stability of Numerical Linear Algebra Algorithms

Session Time & Room :

02327 (1/2) : 3E (Aug.23, 17:40-19:20) @E508

02327 (2/2) : 4C (Aug.24, 13:20-15:00) @E508

Type : Proposal of Minisymposium
Abstract : The stability of numerical linear algebra algorithms is a key component in large-scale and delicate computations such as solutions of linear systems of equations, eigenvalue problems, and matrix function computations. These computations in common require efficient but stable orthogonalization techniques. Understanding their numerical behaviors is thus equally important as their parallel efficiency. Recent low-synchronization and mixed-precision algorithms do improve parallel scaling while maintaining numerical stability when using next-generation high-performance computers. This minisymposium will foster interactions between new results of error analyses and new algorithmic innovations, and so will contribute to communication inside and beyond these two communities.
Organizer(s) : Keiichi Morikuni, Miroslav Rozložník

[02923] A projection method for singular eigenvalue problems of linear matrix pencils

Format : Talk at Waseda University
Author(s) : Keiichi Morikuni (University of Tsukuba)Akira Imakura (University of Tsukuba)
Abstract : Complex moments consisting of matrix resolvents filter out undesired eigencomponents and extract the desired ones from a pseudo-random matrix. This study extends a projection method using complex moments for regular eigenproblems to the singular nonsquare case. We establish conditions such that the method gives all finite eigenvalues in a prescribed region in the complex plane and the corresponding eigenvectors. Numerical experiments show that the new method is more robust and efficient than previous methods.

[03257] Backward stability in rational eigenvalue problems solved via linearization

Format : Talk at Waseda University
Author(s) : Froilán Martínez Dopico (Universidad Carlos III de Madrid)María del Carmen Quintana (Aalto University)Paul Van Dooren (Université catholique de Louvain)
Abstract : The numerical solution of nonlinear eigenvalue problems has attracted a lot of attention from the Numerical Linear Algebra community in the last twenty years. Among these problems, rational eigenvalue problems are particularly relevant because they appear directly in many applications and because they are often used to approximate other more general nonlinear eigenvalue problems. One of the most reliable methods for

solving numerically rational eigenvalue problems is via linearizations. In this talk we present recent results on the backward stability of this approach.

[03008] Computing the matrix sign function with the double exponential formula

Format : Talk at Waseda University
Author(s) : Tomoya Miyashita (The University of Electro-Communications)Shuhei Kudo (The University of Electro-Communications)Yusaku Yamamoto (The University of Electro-Communications)
Abstract : Matrix sign function plays an important role in many scientific computations. There are various methods for computing the matrix sign function, such as Newton's method, the Schur method, and methods based on integral representation. Among them, the integral-based methods are suitable for parallelization because the calculation at each sample point is independent. In this talk, we focus on the integral-based method using the double exponential (DE) formula recently proposed by Nakaya and Tanaka and evaluate its numerical accuracy and parallel performance on the Fugaku computer. We also show a new theoretical upper bound on its discretization and truncation errors.

[03899] Mixed Precision Strategies for Preconditioned Restarted GMRES

Format : Online Talk on Zoom
Author(s) : Theo Mary (Sorbonne Université, CNRS, LIP6)Alfredo Buttari (Université de Toulouse, CNRS, IRIT)Nicholas J Higham (The University of Manchester)Bastien Vieublé (The University of Manchester)
Abstract : The GMRES method, along with its flexible variants, is one of the most popular algorithms to solve large sparse linear systems. In its 40-year history, many different mixed precision strategies for GMRES have been proposed. Yet, there is no consensus on which of these strategies works best, nor even a good understanding of their numerical behavior.

The goal of this work is to develop a systematic error analysis of (preconditioned, restarted, possibly flexible) GMRES in a framework as generic as possible, that encompasses existing strategies and reveals new opportunities.

02327 (2/2) : 4C @E508 [Chair: Miroslav Rozložník]

[04236] Numerical stability of block classical Gram-Schmidt process

Format : Talk at Waseda University
Author(s) : Miroslav Rozloznik (Czech Academy of Sciences)Erin Claire Carson (Charles University)Kathryn Lund (Charles University)
Abstract : The block version of the classical Gram--Schmidt (BCGS) method is often employed to efficiently compute orthogonal bases for Krylov subspace methods and eigenvalue solvers, but a rigorous proof of its stability behavior has not yet been established. It is shown that the usual implementation of BCGS can lose orthogonality at a rate worse than $O(\varepsilon)\kappa^2(X)$, where X is the input matrix and ε is the unit roundoff. A useful intermediate quantity denoted as the Cholesky residual is given special attention and, along with a block generalization of the Pythagorean theorem, this quantity is used to develop more stable variants of BCGS. These variants are proven to have at most $O(\varepsilon)\kappa^2(X)$ loss of orthogonality with relatively relaxed conditions on the intrablock orthogonalization routine satisfied by the most commonly used algorithms. A variety of numerical examples illustrate the theoretical bounds.

[02742] Cross-interactive residual smoothing for block Lanczos-type methods for solving linear systems with multiple right-hand sides

Format : Talk at Waseda University
Author(s) : Kensuke Aihara (Tokyo City University)Akira Imakura (University of Tsukuba)Keiichi Morikuni (University of Tsukuba)
Abstract : Block Lanczos-type methods often exhibit large oscillations in the residual norms, leading to a large residual gap and a loss of attainable accuracy of the approximations. Cross-interactive residual smoothing (CIRS) was recently developed for the standard/global Lanczos-type methods to obtain smooth convergence behavior and reduce the residual gap. We therefore extend CIRS to the block version. Rounding error analysis and numerical experiments demonstrate the effectiveness of the presented approach.

[02706] Gauss-Seidel (MGS) - Jacobi (CGS) GMRES with Rank-1 Perturbation Smoothers

Format : Online Talk on Zoom
Author(s) : Stephen Thomas (Advanced Micro Devices)Miro Rozloznik (Czech Academy of Science)Erin Carson (Charles University)
Abstract : We introduce a low-synch GMRES algorithm based on Gauss-Seidel (MGS) and Jacobi (CGS) iterations. The correction matrix $T=(I+L)^{-1}$ for the projector $P=I-QTQ^T$ is a rank-1 perturbation, and results in low backward error. These ideas are applied to AMG. The smoother performs a triangular solve and subsequent iterations apply Jacobi or $(I-uv^T)r_k,\ u=L_{k,1:k-1}$ and $v=e_k$. GMRES convergence remains the same with this iterative refinement.

[05049] Improving convergence and stability of Krylov subspace methods for solving linear systems

Format : Talk at Waseda University
Author(s) : hassane sadok (université du Littoral Cote d OPale)
Abstract : Krylov subspace methods are widely used for the iterative solution of a large variety of linear systems of equations with one or several right hand sides or for solving nonsymmetric eigenvalue problems.
The purpose of this talk is to compare several variants of the implementation of Krylov subspace methods, including GMRES, QMR, and CMRH methods. These schemes are based on the two-sided Gram-Schmidt process methods and differ in their use of the inner product (=) where (P=I- C C^+) is a projector. We provide a unified description of the methods discussed and derive new expressions and bounds for the residual errors.

[02342] On dataset sparsification and data reconstruction in deep learning

Session Time & Room : 3D (Aug.23, 15:30-17:10) @E817

Type : Proposal of Minisymposium
Abstract : Recent successes in deep learning are partially driven by the ability to use ever larger datasets with overparametrized models. However, the ability to obtain similar performance over smaller datasets is clearly computationally advantageous. Furthermore, when learning with large models over large datasets, it has been shown that portions of the data can be reconstructed from the model parameters. This clearly poses a privacy risk. It turns out that dataset reconstruction and dataset distillation are closely related. This symposium will bring together researchers working on the latest advances in both dataset reconstruction and distillation.

[03191] Data sampling for surrogate modeling and optimization

Format : Talk at Waseda University
Author(s) : Tyler H Chang (Argonne National Laboratory)
Abstract : In surrogate modeling for nonconvex blackbox optimization, global convergence is driven by the global approximation error of an interpolatory model. For large complex problems, achieving global model accuracy can be prohibitively expensive, so model-based optimization techniques such as Bayesian optimization rely on adaptive sampling to tradeoff between exploration and exploitation. However, these techniques are known to scale poorly with dimension. Therefore, we analyze an alternative approach based on response surface methodology coupled with static design-of-experiments.

[03317] Bayesian inference via dataset sparsification

Format : Online Talk on Zoom
Author(s) : Trevor Campbell (UBC)
Abstract : A Bayesian coreset is a sparsified dataset that can be used to reduce the cost of inference. Constructing high-quality coresets remains a challenge. In this work we introduce a new method for coreset construction that involves subsampling the data, and then optimizing a variational flow parametrized by coreset weights. Theoretical results demonstrate that our method achieves exponential data compression in a representative model. Experiments demonstrate accurate inference with reduced runtime compared with standard inference methods.

[03934] Foundations of Information Leakage in Machine Learning

Format : Talk at Waseda University
Author(s) : Reza Shokri (National University of Singapore)
Abstract : This talk will explore the foundations of data privacy in machine learning, with a specific focus on membership inference attacks.

[04492] Understanding Reconstruction Attacks with Dataset Distillation

Format : Talk at Waseda University
Author(s) : Noel Loo (Massachusetts Institute of Technology)
Abstract : Dataset reconstruction attacks are attacks which aim to recover portions of training data from a trained neural network with access to only the model parameters. In this talk, we study the efficacy of these attacks in both infinite and finite-width regimes, and show that these reconstruction attacks are closely related to dataset distillation. In doing so, we study the properties of recovered images, namely what makes images easy to reconstruct, and how they affect training.

[02349] Deep Implicit and Explicit Models for Inverse Problems: Hybrid Data-Driven Models, Neural ODEs, PDEs and Beyond

Session Time & Room :

02349 (1/3) : 3E (Aug.23, 17:40-19:20) @E817

02349 (2/3) : 4C (Aug.24, 13:20-15:00) @E817

02349 (3/3) : 4D (Aug.24, 15:30-17:10) @E817

Type : Proposal of Minisymposium
Abstract : In this minisymposium, we will discuss the current developments of implicit and explicit deep learning models for inverse problems. Explicit deep learning models are based on stacking several discrete layers to solve a given downstream tasks. Another interesting perspective is implicit models, where one can specify the conditions to satisfy. Within this context our session will cover these two paradigms through new developments in Hybrid Models, Neural ODES – PDEs and Beyond. Moreover, discussing interesting real-world applications for a wide range of inverse problems.

[05633] Why Deep Surgical Models Fail?: Revisiting Surgical Action Triplet Recognition through the Lens of Robustness

Author(s) : Yanqi Cheng (University of Cambridge)
Abstract : Surgical action triplet recognition is of high relevance as it provides the surgeon with context-aware support and safety. The go-to strategy develops new network mechanisms. However, the performance of state-of-the-art techniques is substantially lower than other surgical tasks. Why is this happening? This is the question that we address in this work. We present the first study to understand the failure of existing deep learning models through the lens of robustness and explainability.

[05634] On Implicit Neural Representation

Author(s) : Zhenda Shen (City University of Hong Kong)
Abstract : In this talk, we explore a novel approach to implicit neural representations, introducing a novel function that capitalizes on the advantages of Strong Spatial and Frequency attributes. Unlike conventional methods, our proposed technique exhibits remarkable performance improvements across a diverse range of downstream tasks. Through rigorous experimentation and validation, we demonstrate the superior capabilities of our new function in critical applications such as denoising, CT reconstruction, and 3D reconstruction.

Implicit neural representations have garnered significant interest in recent years due to their ability to model complex and high-dimensional data without requiring explicit parameterization. Our novel function leverages both spatial and frequency domains, enhancing its ability to capture intricate patterns and relationships within the data.

During the presentation, we delve into the technical details of our approach, providing insights into how we use spatial and frequency information effectively. We highlight the advantages of our technique over existing methods, emphasizing the superior performance and efficiency it offers.

Through extensive experimental evaluations, we showcase how our new function excels in denoising tasks, enabling high-fidelity reconstructions even in noisy environments. Additionally, we demonstrate its exceptional capabilities in CT reconstruction, where our approach delivers accurate and robust results with reduced artifacts. Furthermore, in the realm of 3D reconstruction, our method outperforms existing techniques, offering more precise and detailed representations.

02349 (2/3) : 4C @E817 [Chair: Raymond H Chan & Angelica Aviles-Rivero]

[03463] Learning pair-wise homeomorphic image registration in a conformal-invariant hyperelastic setting

Format : Talk at Waseda University
Author(s) : Noémie DEBROUX (Université Clermont Auvergne)Jing Zou (The Hong Kong Polytechnic University)Lihao Liu (University of Cambridge)Angelica Aviles-Rivero (University of Cambridge)Jing Qin (The Hong Kong Polytechnic University)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : Deformable image registration is a fundamental task in medical image analysis and plays a crucial role in a wide range of clinical applications. Recently, deep learning-based approaches have been widely studied for deformable medical image registration and achieved promising results. However, existing deep learning image registration techniques
do not theoretically guarantee physically-meaningful transformations and usually require a lot of training data. In order to overcome these drawbacks, we propose a novel framework for pair-wise deformable image registration in a deep-learning framework. Firstly, we introduce a novel regulariser in the loss function based on conformal-invariant properties in a nonlinear elasticity setting. It theoretically guarantees that the obtained deformations are homeomorphisms and therefore preserve topology. Secondly, we boost the performance of our regulariser through coordinate MLPs, where one can view the to-be-registered images as continuously differentiable entities. We evaluate our model through extensive numerical experiments.

[03252] Spherical Image Inpainting with Frame Transformation and Data-driven Prior Deep Networks

Format : Talk at Waseda University
Author(s) : Tieyong Zeng (The Chinese University of Hong Kong)
Abstract : Spherical image processing has been widely applied in many important fields. In this talk, we focus on the challenging task of spherical image inpainting with deep learning-based regularizer. We employ a fast directional spherical Haar framelet transform and develop a novel optimization framework based on a sparsity

assumption. Furthermore, by employing progressive encoder-decoder architecture, a new and better-performed deep CNN denoiser is carefully designed and works as an implicit regularizer. Finally, we use a plug-and-play method to handle the proposed optimization model, which can be implemented efficiently by training the CNN denoiser prior. Numerical experiments are conducted and show that the proposed algorithms can greatly recover damaged spherical images and achieve the best performance over purely using deep learning denoiser and plug-and-play model. This is a joint work with Jianfei Li, Chaoyan Huang, Raymond Chan, Han Feng, and Michael Ng.

[05441] Learning to solve inverse problems with unsupervised nonlinear models

Format : Talk at Waseda University
Author(s) : Rihuan Ke (University of Bristol)Carola-Bibiane Schönlieb (University of Cambridge)
Abstract : Deep learning methods have recently demonstrated remarkable achievements in solving inverse problems. At the core of these methods lies the learning tasks of finding effective inverse problem solvers from a parameterised operator space, which is typically high dimensional. In the context of supervised learning, these learning tasks can be effectively tackled with sufficient supervised data, consisting of paired measurements and ground truth solutions. However, when the ground truth solutions are unknown, these learning tasks can be as challenging as solving the inverse problems themselves. In this talk, we present a hybrid method that addresses the learning tasks in an unsupervised learning setting for denoising and inverse problems more generally, where access to high-quality supervised data is restrictive or unavailable. We highlight a class of nonlinear operators that can be learned from noisy data and offer close approximations to the optimal solutions. Based on these nonlinear operators, we introduce a learning algorithm for solving inverse problems with limited knowledge of the underlying ground truth solutions and noise distributions.

[04181] A learning framework for mapping problems via Quasiconformal geometry

Author(s) : Ronald Lok Ming LUI (The Chinese University of Hong Kong)Qiguang Chen (The Chinese University of Hong Kong)
Abstract : Many imaging problems can be formulated as a mapping problem. A general mapping problem aims to obtain an optimal mapping that minimizes an energy functional subject to the given constraints. Existing methods to solve the mapping problems are often inefficient and can sometimes get trapped in local minima. An extra challenge arises when the optimal mapping is required to be diffeomorphic. In this talk, we address the problem by proposing a deep-learning based framework based on the Quasiconformal (QC) Teichmüller theories. The main strategy is to learn the Beltrami coefficient (BC) that represents a mapping as the latent feature vector in the deep neural network. The BC measures the geometric distortions under the mapping. As such, the proposed network based on QC theories is explainable. Another crucial advantage of the proposed framework is that once the network is successfully trained, the optimized mapping corresponding to each input data information can be obtained in real time. In this talk, we will illustrate our framework by applying it to solve the diffeomorphic image registration problem. The developed network, called the quasiconformal registration network (QCRegNet), outperforms other state-of-the-art image registration models. This work is supported by HKRGC GRF (Project IDs: 14305919, 14306721,14307622).

[05328] Physics Informed Graph Transformer for PDEs

Format : Online Talk on Zoom
Author(s) : Andrey Bryutkin (University of Cambridge)Angelica Aviles-Rivero (University of Cambridge)Jiahao Huang (Imperial College London)
Abstract : In recent years, robust PDE solvers have become increasingly important, necessitating more input variety. The physics-informed graph transformer (PhysGTN) uses graphs to solve underlying problems described on an irregular grid and combines multiple parameter inputs of the PDE. It applies a transformer network to learn specific resemblances of data and additional inputs, which the PDE provides. The architecture is designed to be discretization invariant and flexible enough to handle irregular meshes. The PhysGTN offers several advantages over traditional numerical methods, including increased computational efficiency, reduced time needed for obtaining solutions, and increased robustness to additional noise. This can lead to various challenges and applications for the setup.

[03627] Continuous U-Net: Faster, Greater and Noiseless

Format : Talk at Waseda University
Author(s) : Chun-Wun Cheng (City University of Hong Kong)Christina Runkel (University of Cambridge)Lihao Liu (University of Cambridge)Raymond Honfu Chan (City University of Hong Kong)Carola-Bibiane Schönlieb (University of Cambridge)Angelica Aviles-Rivero (University of Cambridge)
Abstract : Image segmentation is a fundamental task in image analysis and clinical practice. The current state-of-the-art techniques are based on U-shape type encoder-decoder networks with skip connections called U-Net. Despite the powerful performance reported by existing U-Net type networks, they suffer from several major limitations. These issues include the hard coding of the receptive field size, compromising the performance and computational cost, as well as the fact that they do not account for inherent noise in the data. They have problems associated with discrete layers, and do not offer any theoretical underpinning. In this work we introduce continuous U-Net, a novel family of networks for image segmentation. Firstly, continuous U-Net is a continuous deep neural network that introduces new dynamic blocks modelled by second order ordinary differential equations. Secondly, we provide theoretical guarantees for our network demonstrating faster convergence, higher robustness and less sensitivity to noise. Thirdly, we derive qualitative measures to tailor-made segmentation tasks. We demonstrate, through extensive numerical and visual results, that our model outperforms existing U-Net blocks for several medical image segmentation benchmarking datasets.

[02370] Recent advances in Ultrasound Biomedical Imaging

Session Time & Room : 5B (Aug.25, 10:40-12:20) @D515

Type : Proposal of Minisymposium
Abstract : Medical Ultrasound Imaging is the most widespread real-time non-invasive imaging system, and it is based on the ability of human tissue to reflect the ultrasound signals sent by a probe. The fundamental challenges shared by Ultrasound Imaging applications are arguably to achieve higher image resolution and to get fast real-time acquisitions, in both 2D and 3D settings. Such issues must be addressed from both a theoretical viewpoint, by optimizing the modelling of the signal acquisition and formation process, and from a computational perspective. In this respect, recent advances in computing power and data storage have allowed the development of new algorithms and array designs for cutting-edge ultrasound machines.
This minisymposium aims to gather leading experts in Ultrasound Imaging along with young researchers to present their contributions on theoretical, computational, and industrial topics, with the leading idea of ultimately improving ultrasound signal analysis and image reconstruction beyond the state-of-the-art. The presented research topics range from spatial coherence and PSF approximation, to optimal 2D and 3D array design, and are relevant to a wide variety of mathematical, medical, and industrial applications.

[05140] Applications of Spatial Coherence to Ultrasonic Imaging

Format : Talk at Waseda University
Author(s) : David Pierson Bradway (Duke University)Gregg Trahey (Duke University)Nick Bottenus (University of Colorado Boulder)Will Long (Duke University)James Long (Rice University)Katelyn Flint (Duke University)Matthew Huber (Duke University)
Abstract : Conventional pulse-echo ultrasound imaging relies primarily on signals' relative magnitudes and is limited in its ability to mitigate acoustic clutter and other types of image degradation. Advances in computing power have recently enabled an alternative data analysis method utilizing spatial coherence, a measure of the similarity of the signals received across an ultrasound array. The theory of spatial coherence and applications to diagnostic medical ultrasound imaging will be reviewed.

[04772] A local space-invariant approximation for DAS Point Spread Function computation

Format : Talk at Waseda University
Author(s) : Chiara Razzetta (DIMA - Università di Genova)Valentina Candiani (University of Genoa)Federico Benvenuto (DIMA - Università di Genova)Marco Crocco (Esaote S.p.A.)
Abstract : The Delay And Sum (DAS) algorithm is the standard technique for ultrasound image reconstruction, it is usually implemented on the hardware of the ultrasound device and it depends on several parameters set in the machine.
This makes it possible to produce real time images but at the same time it is a limitation in studying parameter optimization to obtain better reconstructions.
In this talk, we propose an approximation of the computation of the DAS algorithm by decomposing it into a sum of space-invariant operators by means of a partition of the unity.
This approximation allows parameter optimization algorithms to be applied to the DAS in order to increase the resolution of the reconstruction.

[03464] Design and 3-D medical applications of 2-D ultrasound sparse arrays

Format : Talk at Waseda University
Author(s) : Alessandro Ramalli (University of Florence)
Abstract : The talk will report on the design methods that are currently used for the development of 2-D sparse arrays. Sample implementations of 2-D sparse arrays based on piezoelectric and capacitive micromachined ultrasonic transducer technologies will be presented. Finally, images and videos of (real-time) 2-D sparse array applications to 3-D flow imaging, super-resolution imaging, and high frame rate imaging will be shown.

[04653] Recent advances in array and sequence design for 3D and high frame rate medical ultrasound imaging

Format : Online Talk on Zoom
Author(s) : Herve Liebgott (Université Lyon 1)
Abstract : Medical ultrasound imaging has been based for years on the transmission of short pulses inside a thin beam. While the beam sweeps over the whole medium, images are reconstructed by beamforming the raw radio-frequency signals. Following the emergence of compressed sensing, faster acquisition concepts based on coded excitations have been suggested. This talk will present some challenges raised by such approaches e.g. choice of the codes, the array, decoding, and image reconstruction algorithm, ...

[02376] Recent Advances in Dynamic Games and Control Theory and Their Connection to Data Science

Session Time & Room :

02376 (1/2) : 5B (Aug.25, 10:40-12:20) @D502

02376 (2/2) : 5C (Aug.25, 13:20-15:00) @D502

Type : Proposal of Minisymposium
Abstract : Dynamic games and control theory involve the study of how multiple agents make decisions and interact strategically over time. These problems have traditionally been challenging to solve. This mini-symposium focuses on the latest developments in dynamic games and control theory enabled by data science. We will discuss how learning-based control theory has advanced the field, as well as the connection between reinforcement learning and dynamic games. Additionally, we will explore how these advances are enabling new applications in autonomous systems, networked systems, cyber-physical systems, and mathematical finance. This symposium will foster innovative interdisciplinary research that potentially can break new ground.

[03672] The Role of Information Structure in Games and Learning

Format : Talk at Waseda University
Author(s) : Quanyan Zhu (New York University)
Abstract : The information structure of dynamic multi-agent systems plays a crucial role in determining the observation patterns of states, actions, and payoffs during interactions between agents. Differences in information structure can lead to surprising outcomes in a game. This talk aims to explore the role of information in dynamic games and learning. Specifically, we introduce the concept of the "price of information" and the "price of transparency" to quantify the gain or loss under different information patterns. We will discuss how information affects the strategic learning process, in which agents form beliefs based on their observations and generate policies based on those beliefs. Additionally, we will present how informational design can be used to incentivize agents and achieve the designer's goals at equilibrium in multi-agent systems.

[02854] Optimal transaction mechanism for dynamic storage management game in smart grid

Format : Talk at Waseda University
Author(s) : Yasuaki Wasa (Waseda University)
Abstract : In this talk, we discuss an optimal transaction mechanism for a dynamic storage management game in smart grids in order to minimize the imbalance penalty charge of the grid in the wholesale electricity market. Our proposed mechanism is inspired by the primal-dual decomposition technique and the contract theory in economics. First, we present that the optimal power charge control profiles of the storage devices constitute a dynamic market equilibrium with a real-time pricing mechanism in a distributed fashion. Under the linear-quadratic dynamic grid model, the optimal design of the reference adjustment to modify the real-time pricing mechanism is analytically derived. The effectiveness of our proposed mechanism is also illustrated and discussed through simulation.

[02858] Reinforcement Learning Algorithm for Mixed Mean Field Control Games

Format : Online Talk on Zoom
Author(s) : Jean-Pierre Fouque (University of California Santa Barbara)
Abstract : We present a new combined Mean Field Control Game (MFCG) problem which can be interpreted as a competitive game between collaborating groups and its solution as a Nash equilibrium between the groups. We propose a reinforcement learning algorithm to approximate the solution of such mixed Mean Field Control Game problems. We test the algorithm on benchmark linear-quadratic specifications for which we have analytic solutions.
Joint work with A. Angiuli, N. Detering, Mathieu Laurière, and J. Lin

[02930] Recent Advances on Fractional Optimal Control Problems

Format : Talk at Waseda University
Author(s) : Jun Moon (Hanyang University)
Abstract : In this talk, we study recent results on fractional control problems. We first consider the fractional optimal control problem with terminal and running state constraints in finite dimensions. Then we study the fractional optimal control problem (without state constraints) in infinite dimensions described by fractional evolution equations. For both problems, we obtain the Pontryagin maximum principle, which constitutes the necessary condition for optimality.

02376 (2/2) : 5C @D502 [Chair: Maggie Cheng]

[03245] Stabilizability of Nash equilibrium

Format : Talk at Waseda University
Author(s) : Renren Zhang (Shandong University)
Abstract : We investigate the stabilizability of Nash equilibrium of the game-based control system (GBCS), which was first introduced to model control systems whose structures involve rational agents. The stabilizability problem is whether the regulator can stabilize the system by regulating the Nash equilibrium formed by the agents. Some explicit conditions on the stabilizability of GBCS are given, by investigating the solvability relationship between the associated algebraic Riccati equations (AREs) and the algebraic Riccati inequalities (ARIs).

[04475] Cooperation and Cost Sharing Problems in Supply Networks

Format : Talk at Waseda University
Author(s) : Sanjith Gopalakrishnan (McGill University)Sriram Sankaranarayanan (Indian Institute of Management, Ahmedabad)
Abstract : Across several contexts such as supply chain security or traceability, costly actions by firms can yield payoffs to other firms in the network. Such positive externalities imply network-wide cooperative strategies can yield improvements over firms independently choosing individually-rational actions. However, cooperation can be hindered by disagreements over cost-sharing arrangements. In this talk, we review two recent applications and develop a general framework to identify implementable cost sharing mechanisms that can sustain network-wide cooperative actions.

[03268] Hodge allocation for cooperative rewards

Format : Online Talk on Zoom
Author(s) : Tongseok Lim (Purdue University)
Abstract : Lloyd Shapley's cooperative value allocation theory is a central concept in game theory that is widely used in various fields to allocate resources and assess individual contributions. The Shapley formula and axioms that characterize it form the foundation of the theory.

Shapley value can be assigned only when all players are assumed to eventually form the grand coalition. We discuss how to extend Shapley's theory to account for value allocation in every partial coalition state.

[02386] Recent advances on theory and algorithms in deep learning applications

Session Time & Room :

02386 (1/2) : 4E (Aug.24, 17:40-19:20) @E817

02386 (2/2) : 5B (Aug.25, 10:40-12:20) @E817

Type : Proposal of Minisymposium
Abstract : In recent years, supervised and unsupervised learning models based on deep neural networks play an increasingly important role in many directions, such as approximating continuous functions, constructing image models, and solving inverse problems. Meanwhile, many theoretical results are carried out to study the approximation and training properties of these approaches. This mini-symposium will bring together researchers in different areas to discuss recent advances in training algorithms and model applications, as well as relevant theoretical analysis. The aim is to assemble new understandings of the efficiency and limitation of deep learning models through the intersection discussion.

[03440] Vanilla Feedforward Neural Networks as a Discretization of Dynamical Systems

Format : Talk at Waseda University
Author(s) : Yongqiang Cai (Beijing Normal University)
Abstract : Deep learning has made significant progress in the fields of data science and natural science. Some studies have linked deep neural networks to dynamical systems, but the network structure is restricted to a residual network. It is known that residual networks can be regarded as a numerical discretization of dynamical systems. In this talk, we consider the traditional network structure and prove that vanilla feedforward networks can also be used for the numerical discretization of dynamical systems, where the width of the network is equal to the dimensions of the input and output. Our proof is based on the properties of the leaky-ReLU function and the numerical technique of the splitting method for solving differential equations. Our results could provide a new perspective for understanding the approximation properties of feedforward neural networks.

[03441] Phase Diagram of Initial Condensation for Two-layer Neural Networks

Format : Talk at Waseda University
Author(s) : Zhengan Chen (Shanghai Jiao Tong University)Yuqing Li (Shanghai Jiao Tong University)Tao Luo (Shanghai Jiao Tong University)Zhangchen Zhou (Shanghai Jiao Tong University)Zhiqin Xu (Shanghai Jiao Tong University)
Abstract : The phenomenon of distinct behaviors exhibited by neural networks under varying scales of initialization remains an enigma in deep learning research. In this paper, based on the earlier work by Luo et al.~\cite{luo2021phase}, we present a phase diagram of initial condensation for two-layer neural networks. Condensation is a phenomenon wherein the weight vectors of neural networks concentrate on isolated orientations during the training process, and it is a feature in non-linear learning process that enables neural networks to possess better generalization abilities. Our phase diagram serves to provide a comprehensive understanding of the dynamical regimes of neural networks and their dependence on the choice of hyperparameters related to initialization. Furthermore, we demonstrate in detail the underlying mechanisms by which small initialization leads to condensation at the initial training stage.

[03386] Robust Full Waveform Inversion: A Source Wavelet Manipulation Perspective

Format : Talk at Waseda University
Author(s) : Chenglong Bao (Tsinghua University)Lingyun Qiu (Tsinghua University)Rongqian Wang (Tsinghua University)
Abstract : Full-waveform inversion (FWI) is a powerful tool for high-resolution subsurface parameter reconstruction. Due to the existence of local minimum traps, the success of the inversion process usually requires a good initial model. Our study primarily focuses on understanding the impact of source wavelets on the landscape of the corresponding optimization problem. We thus introduce a decomposition scheme that divides the inverse problem into two parts. The first step transforms the measured data into data associated with the desired source wavelet. Here, we consider inversions with known and unknown sources to mimic real scenarios. The second sub-problem is the conventional full waveform inversion, which is much less dependent on an accurate initial model since the previous step improves the misfit landscape. A regularized deconvolution method and a convolutional neural network are employed to solve the source transformation problem. Numerical experiments on the benchmark models demonstrate that our approach improves the gradient's quality in the subsequent FWI and provides a better inversion performance.

[02945] Learning robust imaging model with unpaired data

Format : Talk at Waseda University
Author(s) : Chenglong Bao (Tsinghua University)
Abstract : In this talk, in the unpaired data regime, we discuss our recent progress in building AI-aided robust models and their applications in image processing. Leveraging the Bayesian inference framework, our model combines classical mathematical modeling and deep neural networks to improve interpretability. Experimental results on various real datasets validate the advantages of the proposed methods.

02386 (2/2) : 5B @E817 [Chair: Jiulong Liu]

[03329] Generative Models Based Statistical Priors for Compressive Sensing and Medical Imaging

Format : Talk at Waseda University

Author(s) : Jiulong Liu (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)

Abstract : Sparsity is a mathematically elegant tool for reducing the sampling rate for compressive sensing reconstruction and thereby its applications are also extended to many underdetermined imaging systems, such as MRI and CT. However, with the development of deep learning, there are many methods proposed to learn data representation and they are shown to be more efficient in signal and image processing. In order to efficiently and stably solve the under-determined and ill-conditioned inverse problems with fewer measurements, we established compressive sensing reconstruction methods using generative priors which are shown much more efficient than the traditional priors or some other data-driven priors. In this talk, I will introduce some of these methods and present our recent results for MRI reconstruction, phase retrieval, and some other nonlinear inverse problems.

[03483] Normalizing-flows based design of experiments for failure probability estimation

Format : Talk at Waseda University

Author(s) : Hongqiao Wang (Central South University)

Abstract : Failure probability estimation problem is an crucial task in engineering. In this work we consider this problem in the situation that the underlying computer models are extremely expensive, which often arises in the practice, and in this setting, reducing the calls of computer model is of essential importance. We formulate the problem of estimating the failure probability with expensive computer models as an sequential experimental design for the limit state (i.e., the failure boundary) and propose a series of efficient adaptive design criteria to solve the design of experiment (DOE). In particular, the proposed method employs the deep neural network (DNN) as the surrogate of limit state function for efficiently reducing the calls of expensive computer experiment. A map from the Gaussian distribution to the posterior approximation of the limit state is learned by the normalizing flows for the ease of experimental design. Three normalizing-flows-based design criteria are proposed in this work for deciding the design locations based on different assumption of generalization error. The accuracy and performance of the proposed method is demonstrated by both theory and practical examples.

[03477] Unsupervised learning driven by Langevin dynamics and its applications to inverse problems

Format : Talk at Waseda University

Author(s) : Ji Li (Capital Normal University)

Abstract : From the Bayesian view, the key component of image restoration is to estimate the posterior distribution. Generally, the sampling from posterior distribution is intractable. To this end, there have been some variational approaches to approximate the posterior distribution using a proxy distribution. In this talk, we first review the Langevin dynamics as an effective sampler for a given distribution. Then we apply it or embed it to the unsupervised learning solution to two image restoration problems with slight modifications.

[03450] Self-supervised Deep learning Methods in Imaging

Format : Online Talk on Zoom

Author(s) : Tongyao Pang (National University of Singapore)

Abstract : In this talk, I will share our recent research on using self-supervised deep learning techniques for image reconstruction. Deep learning has recently become a powerful tool in image restoration but it requires a large amount of paired training data. Our proposed self-supervised methods alleviate this requirement while still achieving comparable performance to supervised learning. Our methods are designed to find the minimum mean-squared error (MMSE) solution from a Bayesian inference perspective.

[02387] Recent Advances on Distributed Optimization

Session Time & Room : 2E (Aug.22, 17:40-19:20) @E804

Type : Proposal of Minisymposium
Abstract : Distributed algorithms have emerged as a key driving force in solving large-scale optimization and machine learning problems, with a wide range of applications spanning from training deep neural network models over GPU clusters to boosting edge intelligence over networks consisting of cellphones, tablets, and wearables. In this minisymposium, we will review recent advances in distributed optimization, with a focus on state-of-the-art sample and communication complexities, novel communication compression techniques, and new decentralized or federated algorithms. By bringing together leading researchers and practitioners in this field, we hope to identify key challenges and opportunities for advancing distributed optimization.

[03522] Optimal Gradient Tracking for Decentralized Optimization

Format : Talk at Waseda University
Author(s) : Ming Yan (The Chinese University of Hong Kong, Shenzhen)
Abstract : We focus on solving the decentralized problem over a network. Assuming smoothness and strong convexity, we propose Optimal Gradient Tracking (OGT), which simultaneously achieves the optimal gradient computation complexity and communication complexity. Its development involves two building blocks that are of independent interest. The first is the decentralized gradient tracking method, SSGT, which achieves optimal gradient computation. The second is a loopless method that achieves similar performance as Chebyshev acceleration.

[03541] Optimal Complexity in Distributed Learning with Communication Compression

Format : Talk at Waseda University
Author(s) : Yutong He (Peking University)Xinmeng Huang (University of Pennsylvania)Wotao Yin (Alibaba (US) Group)Kun Yuan (Peking University)
Abstract : Recent advances in distributed optimization and learning have shown that communication compression is one of the most effective means of reducing communication. While there have been many results on convergence rates under communication compression, a theoretical lower bound is still missing.

Analyses of algorithms with communication compression have attributed convergence to two abstract properties: the unbiased property or the contractive property. In this talk, we consider distributed stochastic algorithms for minimizing smooth convex and non-convex objective functions under communication compression. We establish convergence lower bounds for algorithms whether using unbiased or contractive compressors. To close the gap between the lower bound and the existing upper bounds, we further propose an algorithm, NEOLITHIC, which almost reaches our lower bound (up to logarithm factors) under mild conditions. The experimental results validate our findings.

[03556] Asymptotic Network Independence in Distributed Stochastic Gradient Methods

Format : Talk at Waseda University
Author(s) : Shi Pu (The Chinese University of Hong Kong, Shenzhen)
Abstract : We discuss the so-called asymptotic network independence property in distributed stochastic optimization, which is achieved whenever a distributed method executed over a network of n nodes asymptotically converges to the optimal solution at a comparable rate to a centralized method with the same computational power as the entire network; it is as if the network is not even there! We explain this property through examples involving the training of ML models and present a short mathematical analysis. We also discuss the transient times for

distributed stochastic gradient methods to achieve network independent convergence rates. Finally, we introduce some recent works on distributed random reshuffling (RR) methods.

[03570] Unified and Refined Analysis of Decentralized Optimization and Learning Algorithms

Format : Talk at Waseda University
Author(s) : Sulaiman A Alghunaim (Kuwait University)
Abstract : Decentralized multi-agent optimization is a powerful paradigm with numerous applications in learning and engineering design. In these setups, a network of agents is linked by a graph, and agents are only allowed to share information locally. Through localized interactions, they seek the minimizer of a global optimization problem. In decentralized consensus problems, the agents are linked by a common consensus variable on which they must agree.

This talk will present a unified and improved analysis for decentralized consensus optimization methods. We demonstrate how the analysis of several state-of-the-art bias-correction decentralized methods, such as EXTRA, Exact-Diffusion, NIDS, and Gradient-Tracking methods, can be unified by a decentralized algorithmic framework that encompasses these methods. We develop a novel analysis technique that establishes the framework's convergence under nonconvex, convex, and strongly convex objectives. We provide refined and improved convergence rate bounds. The analysis reveals important characteristics for these methods, such as how their performances are influenced by network graph.

[02392] Low-Rank Models in Data Science

Session Time & Room :

02392 (1/3) : 2C (Aug.22, 13:20-15:00) @G306

02392 (2/3) : 2D (Aug.22, 15:30-17:10) @G306

02392 (3/3) : 2E (Aug.22, 17:40-19:20) @G306

Type : Proposal of Minisymposium
Abstract : Due to their simplicity and versality that ranges from genomics data to computational physics, recommender systems and unsupervised learning, low-rank matrix models have emerged as a powerful tool in data science. However, only few related computational problems admit closed-form solutions. Convex or non-convex potentially non-smooth optimization problems with different statistical properties can be used to overcome involving computational challenges.
This minisymposium intends to shed light on recent advances in structured numerical optimization for low-rank models and their statistical and information theoretical properties by bringing together experts from applied mathematics and engineering working these topics, providing a forum for future collaborations.
Organizer(s) : Christian Kümmerle, Johannes Maly, Dominik Stöger
Classification : 15A83, 65F55, 65K10, 90C26

[02769] Low-rank models in data science: Applications and optimization challenges

Format : Online Talk on Zoom
Author(s) : Dominik Stöger (KU Eichstätt-Ingolstadt)
Abstract : Low-rank matrix models have emerged as a powerful tool in data science with applications ranging from recommender systems to computational physics. In this overview talk, we first highlight some applications where low-rank models arise. Next, we discuss which statistical and optimization challenges arise. Moreover, we highlight several advances which have been made in recent years to circumvent these issues.

[05455] Low Rank Matrix Recovery from Column-wise Projections: Fast and Communication-Efficient Solutions

Format : Online Talk on Zoom
Author(s) : Namrata Vaswani (Iowa State University)
Abstract : We study the following lesser-known low rank (LR) recovery problem: recover an n × q rank-r matrix, $X^* = [x_1^*, x_2^*, \ldots, x_q^*]$, with $r << min(n, q)$, from m independent linear projections of each of its q columns, i.e., from $y_k := A_k x_k^*, k \in [q]$, when y_k is an m-length vector with m < n . The matrices A_k are known and mutually independent for different k. We introduce a novel gradient descent (GD) based solution called AltGD-Min. We show that, if the A_k's are i.i.d. with i.i.d. Gaussian entries, and if the right singular vectors of X^* satisfy the incoherence assumption, then \epsilon-accurate recovery of X* is possible with order $(n+q)r^2 log(1/\epsilon)$ total samples and order $mqnrlog(1/\epsilon)$ time. Compared with existing work, this is the fastest solution, and in most practical settings, it also has the best sample complexity. For a federated implementation, it is also communication-efficient with a cost of only order nr per node per iteration.

A simple extension of AltGD-Min also provably solves the LR Phase Retrieval problem, which is a magnitude-only measurements' extension of the above problem.

[04491] Tensor-Norm Approaches to Low-Rank Matrix Recovery by Convex Program

Format : Online Talk on Zoom
Author(s) : Kiryung Lee (Ohio State University)
Abstract : Low-rank models have been shown effective for solving various inverse problems from classical system identification to modern matrix completion and sketching in signal processing and statistics. If each observation is a linear combination of a subset of matrix entries, the reconstruction is feasible only for a class of matrices incoherent to the measurement process. We propose an estimator that prefers a solution with low rankness and incoherence by a regularizer given by a pair of norms on the tensor product of two Banach spaces. The resulting optimization is cast as a convex semidefinite program and provides a near-optimal error matching the corresponding minimax bound in a low signal-to-noise ratio regime. We illustrate the efficacy of the estimator over selected applications in signal processing. We also present a scalable numerical optimization algorithm and study its empirical performance over large-scale synthesized data.

[04277] Algorithmic approaches to recovering sparse and low-rank matrices

Format : Talk at Waseda University
Author(s) : Johannes Maly (Ludwig-Maximilians-Universität München)
Abstract : In this talk, I consider the problem of recovering an unknown sparse and low-rank matrix X from measurements gathered in a linear measurement process. I discuss the challenges that come with leveraging several structures simultaneously and present two new algorithmic strategies to efficiently approach the problem. Both strategies come with local convergence guarantees.

02392 (2/3) : 2D @G306 [Chair: Johannes Maly]

[03939] Bures-Wasserstein Methods in Matrix Recovery

Format : Talk at Waseda University
Author(s) : Tyler Maunu (Brandeis University)
Abstract : We revisit the problem of recovering a positive semidefinite matrix from a linear map using tools from optimal transport. More specifically, we connect a variational formulation of this problem to the computation of Wasserstein barycenters. This new perspective enables the development of efficient first-order geometric methods. Experiments demonstrate the advantages of our new methodology over existing methods. We also discuss extensions to recovery in other settings of restricted positive semidefinite matrices.

[05442] Improved Global Guarantees for Low-Rank Models via Rank Overparameterization

Format : Talk at Waseda University
Author(s) : Richard Y Zhang (University of Illinois at Urbana-Champaign)
Abstract : We consider minimizing a twice-differentiable, L-smooth, and μ-strongly convex objective ϕ over an $n\times n$ positive semidefinite matrix $M\succeq 0$, under the assumption that the minimizer $M^{\star}$ has low rank $r^{\star}\ll n$. Following the Burer--Monteiro approach, we instead minimize the nonconvex objective $f(X)=\phi(XX^{T})$ over a factor matrix X of size $n\times r$. This substantially reduces the number of variables from $O(n^{2})$ to as few as $O(n)$ and also enforces positive semidefiniteness for free, but at the cost of giving up the convexity of the original problem. In this talk, we prove that if the search rank $r\geq r^{\star}$ is overparameterized by a \emph{constant factor} with respect to the true rank $r^{\star}$, namely as in $r>\frac{1}{4}(L/\mu-1)^{2}r^{\star}$, then despite nonconvexity, local optimization is guaranteed to globally converge from any initial point to the global optimum. This significantly improves upon a previous rank overparameterization threshold of $r\geq n$, which is known to be sharp if ϕ is allowed to be nonsmooth and/or non-strongly convex, but would increase the number of variables back up to $O(n^{2})$. Conversely, without rank overparameterization, we prove that such a global guarantee is possible if and only if ϕ is almost perfectly conditioned, with a condition number of $L/\mu<3$. Therefore, we conclude that a small amount of overparameterization can lead to large improvements in theoretical guarantees for the nonconvex Burer--Monteiro factorization.

[04377] Tensor Completion via Tensor Train Based Low-Rank Quotient Geometry under a Preconditioned Metric

Format : Talk at Waseda University
Author(s) : Ke Wei (Fudan University)
Abstract : Low-rank tensor completion problem is about recovering a tensor from partially observed entries. We consider this problem in the tensor train format and extend the preconditioned metric from the matrix case to the tensor case. The first-order and second-order quotient geometry of the manifold of fixed tensor train rank tensors under this metric is studied in detail. Algorithms, including Riemannian gradient descent, Riemannian conjugate gradient, and Riemannian Gauss-Newton, have been proposed for the tensor completion problem based on the quotient geometry. It has also been shown that the Riemannian Gauss-Newton method on the quotient geometry is equivalent to the Riemannian Gauss-Newton method on the embedded geometry with a specific retraction. Empirical evaluations on random instances as well as on function-related tensors show that the proposed algorithms are competitive with other existing algorithms in terms of completion ability, convergence performance, and completion quality.

[04975] Iteratively Reweighted Least Squares for Low-Rank Optimization: Optimality & Convergence Rates

Format : Talk at Waseda University
Author(s) : Christian Kümmerle (University of North Carolina at Charlotte)
Abstract : Convex or non-convex matrix functions such as Schatten-p (quasi-)norms have been successfully used as surrogates of the rank objective. Iteratively Reweighted Least Squares (IRLS) has emerged as a suitable algorithmic framework to scalably optimize such rank surrogates. We review the formulation, optimality and empirical data-efficiency of MatrixIRLS. We show that the algorithm, which optimizes Schatten-type objectives, exhibits a local superlinear convergence rate with a large basin of attraction, and linear convergence rates in the convex case.

02392 (3/3) : 2E @G306 [Chair: Dominik Stöger]

[04701] Multi-window Gabor phase retrieval

Format : Online Talk on Zoom
Author(s) : Palina Salanevich (Utrecht University)
Abstract : Phase retrieval is the non-convex inverse problem of signal reconstruction from its intensity measurements that is motivated by practical applications. In the talk, we are going to focus on phase retrieval with multi-window Gabor frames, where the measurement vectors follow time-frequency structure natural for imaging and acoustics. We will propose an explicit construction of such frames and show that for them phase retrievability can be achieved with a close to optimal number of phaseless measurements.

[02396] Recent Advances on Polynomial System Solving

Session Time & Room :

02396 (1/3) : 1C (Aug.21, 13:20-15:00) @G305

02396 (2/3) : 1D (Aug.21, 15:30-17:10) @G305

02396 (3/3) : 1E (Aug.21, 17:40-19:20) @G305

Type : Proposal of Minisymposium
Abstract : Polynomial systems are fundamental mathematical objects in algebraic geometry, automated geometric reasoning, cryptography, coding theory, biology, and many other areas of science and engineering, and thus finding the solutions of polynomial systems algorithmically is also of both theoretical and practical importance. This minisymposium aims at bringing together interested researchers to present and to discuss recent work and progress on the theories, algorithms, software, and applications of solving polynomial systems.
Organizer(s) : Deepak Kapur, Chenqi Mou
Classification : 13P15, 68W30, 13P10, 14Q30

02396 (1/3) : 1C @G305 [Chair: Changbo Chen]

[03796] Polynomial System Solving in a Nutshell

Format : Talk at Waseda University
Author(s) : Chenqi Mou (Beihang University)
Abstract : In this introductory talk of the minisympoisum “Recent Advances on Polynomial System Solving”, I will give a brief overview of the problem of solving polynomial systems, including its theories, methods, softwares, and applications. In particular, basic concepts of three typical methods of Gröbner bases, triangular decomposition, and homotopy continuation for solving polynomial systems will be presented, serving as an introduction of other talks in this minisympoisum to a wider audience of different backgrounds.

[04394] Signature-based algorithm and change of ordering for Groebner basis

Format : Talk at Waseda University
Author(s) : Masayuki Noro (Rikkyo University)
Abstract : Although the termination is not guaranteed, signature-based algorithm under non-compatible term orderings may give good performance for computing Groebner bases. In such cases, we can apply the notion of Hilbert function for guaranteeing the termination. The Hilbert function is given by a Groebner basis with respect to another term ordering and thus this algorithm is a kind of change of ordering. We compare its performance with the usual Hilbert driven algorithm.

[03913] Dimension results for polynomial systems over complete toric varieties

Format : Talk at Waseda University

Author(s) : Matías Bender (INRIA - CMAP, École polytechnique, IPP)Pierre-Jean Spaenlehauer (INRIA Nancy)

Abstract : A common computational approach to study affine varieties is to first homogenize the input defining equations. Among other reasons, we do so because the new equations have an associated grading that allows us to reduce our computations to a linear algebra problem. However, the homogenization process might introduce higher components at infinity, changing drastically the geometry of the affine object that we want to study. This is what happens when we homogenize, in the classical sense, sparse polynomials. To overcome this issue, a possible approach is to homogenize the input equations, using their Newton polytopes, over a Cox ring or a polytopal graded subring of it. However, other simpler homogenizations might be possible. In this work, we prove a combinatorial criterion to decide when a candidate homogenization is good, in the sense that it does not introduce higher components at infinity. Additionally, we use our criterion to decide which families of degrees on polytopal algebras lead to regular sequences.

[03633] On the computation of staggered linear bases

Format : Talk at Waseda University

Author(s) : Amir Hashemi (Isfahan University of Technology)Hans Michael Moller (Technical University Dortmund)

Abstract : Grobner bases are a powerful tool in polynomial ideal theory with many applications in various areas of science and engineering. Considering an ideal as a vector space, we investigate for such an ideal a particular linear basis, so-called staggered linear basis, which contains a Grobner basis as well. This notion was first introduced by Gebauer and Moller in 1988, however the algorithm that they described for computing these bases was not complete. In this talk, we present a simple and efficient algorithm to compute an staggered linear basis. The new framework is equipped with some novel criteria (including both Buchberger's criteria) to detect superfluous reductions. Finally, we discuss the efficiency of this algorithm compared to the existing methods using a set of benchmark polynomials.

02396 (2/3) : 1D @G305 [Chair: Chenqi Mou]

[03688] Square-Free Pure Triangular Decomposition of Zero-Dimensional Polynomial Systems

Format : Talk at Waseda University

Author(s) : Haokun Li (Peking University)Bican Xia (Peking University)Tianqi Zhao (Peking University)

Abstract : The concepts of pure chains and square-free pure triangular decomposition (SFPTD) of zero-dimensional polynomial systems are defined. We propose an algorithm for computing SFPTD and prove its arithmetic complexity can be single exponential in the square of the number of variables. We show experimentally that, on most examples in the literature, the algorithm is more efficient than a triangular-decomposition method in Maple, and the real solution isolation method based on SFPTD is very efficient.

[05286] On the bit complexity of roadmap algorithms

Format : Talk at Waseda University

Author(s) : Eric Schost (University of Waterloo)

Abstract : Roadmaps were introduced by Canny in order to reduce connectivity queries on semi-algebraic sets to similar questions on curves. In the last ten years, with Mohab Safey El Din, we proposed randomized algorithms with an improved complexity - in an algebraic cost model; the bit-complexity analysis remained to be done. I will report on recent work done in this direction with Jesse Elliott.

[03750] Solving semi-algebraic systems arising in applications

Format : Talk at Waseda University

Author(s) : Changbo Chen (Chongqing Institute of Green and Intelligent Technology, Chinese Academy of Sciences)

Abstract : Semi-algebraic systems, which are systems consisting of polynomial equations and inequalities, naturally appear in many applications. To solve them efficiently, it is important to exploit their particular structures. In this talk, I will present specialized algorithms designed for solving semi-algebraic systems arising in

several applications, namely computing the steady states of parametric biological systems, automatic parallelization of loops, and detecting quantum correlations.

[04993] Root Separation Bounds

Format : Talk at Waseda University
Author(s) : Vikram Sharma (The Institute of Mathematical Sciences Chennai)
Abstract : Root separation bounds are a classical topic in algebraic number theory. They also play an important role in the analysis of algorithms for finding the roots of polynomials. In this talk, we will start with some classical results of Mignotte and Davenport and trace the recent development that has occurred in this area.

02396 (3/3) : 1E @G305

[02402] Numerical methods for a class of time-dependent PDEs

Session Time & Room :

02402 (1/2) : 1C (Aug.21, 13:20-15:00) @E704

02402 (2/2) : 1D (Aug.21, 15:30-17:10) @E704

Type : Proposal of Minisymposium
Abstract : Many phenomena and problems in modern science, technology and engineering can be described by partial differential equations. For example, the Gross-Pitaevskii equation under a rotational frame, the nonlinear Klein-Gordon-Schr"{o}dinger equations in the nonrelativistic limit regime, Poisson-Nernst-Planck systems, etc. It is significant to design efficient numerical methods to solve the above PDEs with numerical analysis and provide an intuitive view for physical phenomena. The main purpose of this mini-symposium is to discuss recent developments of the numerical methods for solving time-dependent PDEs.

[02681] Unconditionally MBP-preserving linear schemes for conservative Allen-Cahn equations

Format : Talk at Waseda University
Author(s) : Jingwei Li (Lanzhou University)
Abstract : The maximum bound principle MBP, is an important property for semilinear parabolic equations, in the sense that the time-dependent solution of the equation with appropriate initial and boundary conditions and nonlinear operator preserves for all time a uniform pointwise bound in absolute value. It has been a challenging problem to design unconditionally MBP-preserving high-order accurate time-stepping schemes for these equations. Du Qiang et al have estiblished a unified analytical framework on the MBP preserving scheme for the semilinear parabolic equations which in this talk will be extended to conservative Allen-Cahn equation with the introduced Lagrange multiplier enforcing the mass conservation. Some sufficient conditions on the nonlinear potentials will be given under which the MBP holds and then the stabilized exponential time differencing scheme is proposed for time integration, which are linear schemes and unconditionally preserve the MBP in the time discrete level. Convergence of these schemes is analyzed as well as their energy stability. Various two and three dimensional numerical experiments are also carried out to validate the theoretical results and demonstrate the performance of the proposed schemes. These work are joint with Cai Yongyong, Feng Xinlong, Huang Qiumei, Jiang Kun, Ju Lili, Li Xiao, Lan Rihui et al.

[02717] Uniformly accurate nested Picard iterative integrators for the Klein-Gordon-Schr"{o}dinger equation in the nonrelativistic regime

Format : Online Talk on Zoom

Author(s) : xuanxuan zhou (beijing normal university)

Abstract : We establish a class of uniformly accurate nested Picard iterative integrator (NPI) Fourier pseudospectral methods for the nonlinear Klein-Gordon-Schr"{o}dinger equation (KGS) in the nonrelativistic regime, involving a dimensionless parameter $\varepsilon \ll 1$ inversely proportional to the speed of light. Actually, the solution propagates waves in time with $O(\varepsilon^2)$ wavelength when $0 < \varepsilon \ll 1$, which brings significant difficulty in designing accurate and efficient numerical schemes. The NPI method is designed by separating the oscillatory part from the non-oscillatory part, and integrating the former exactly. Based on the Picard iteration, the NPI method can be applied to derive arbitrary higher-order methods in time with optimal and uniform accuracy (w.r.t. $\varepsilon \in (0, 1]$), and the corresponding error estimates are rigorously established. In addition, the practical implementation of the second-order NPI method via Fourier pseupospectral discretization is clearly demonstrated, with extensions to the third order NPI. Some numerical examples are provided to support our theoretical results and show the accuracy and efficiency of the proposed schemes.

[02550] Structure-preserving scheme for the PNP equations

Format : Talk at Waseda University

Author(s) : Fenghua Tong (Beijing Normal University)

Abstract : Poisson-Nernst-Planck system is a macroscopic model to describe the ion transport process. We propose a novel method to construct the positivity preserving and mass conservation scheme for the Poisson-Nernst-Planck equations. The method is based on the discrete L_h^2 or H_h^1 projection strategy in which the solution projected from the intermediate solution computed by semi-implicit scheme inherits the positivity preservation and mass conservation with negligible additional computational cost resulting from the nonlinear algebraic equation.

[02553] Numerical simulation of rotational nonlinear Schrodinger equations with attractive interactions

Format : Talk at Waseda University

Author(s) : Yong Wu (Beijing Normal University)

Abstract : We consider the focusing Schr$\ddot{o}$dinger equation with rotation and numerically simulate the ground state and dynamic properties. We take the gradient flow with Lagrange multiplier (GFLM) method to compute the ground state and time splitting pseudospectral method to simulate dynamics. We numerically verify the nonexistence of vortices in harmonic symmetry potential and analytically derive that the symmetric state energy (m=0) is always lower than the central vortex state energy (m=1) when the attractive interaction is sufficiently small. For dynamics properties, we mainly simulated the condensate widths, a stationary state with a shifted center and stability of central vortex states and found that the conclusion is completely consistent with the repulsive interaction. Finally, we numerically simulate the global existence and finite time blow-up of solution in mass-supercritical case.

02402 (2/2) : 1D @E704

[02622] IMPROVED UNIFORM ERROR BOUNDS OF THE TIME-SPLITTING HERMITE SPECTRAL METHODS FOR THE LONG-TIME GROSS PITAEVSKII EQUATION WITH WEAK NONLINEARITY

Format : Online Talk on Zoom

Author(s) : Zhongyang Liu (Beijing Normal University)

Abstract : The aim of this research is to carry out a improved uniform error bounds for the Strang splitting Hermite pseudospectral methods for the long-time dynamics of the time-dependent Gross–Pitaevskii equation (GPE) with weak nonlinearity, while the nonlinearity strength is characterized by ϵ^2 with a dimensionless parameter $\epsilon \in (0, 1]$, for the long time dynamics up to the time at $O(\epsilon^{-2})$. We derive a improved uniform H_A^1 error bounds for full discretizations of the one-dimensional GPE by the Strang splitting Hermite pseudospectral method as $O(N^{\frac{2}{3}-\frac{m}{2}} + \epsilon^2\tau^2)$ up to the time at $O(1/\epsilon^2)$. The error bounds are uniformly accurate up to the time at $O(\epsilon^{-2})$ and uniformly valid for ϵ.

[02404] New Trends in Hierarchical Variational Inequalities and Optimization Problems

Session Time & Room :

02404 (1/4) : 1C (Aug.21, 13:20-15:00) @E606

02404 (2/4) : 1D (Aug.21, 15:30-17:10) @E606

02404 (3/4) : 1E (Aug.21, 17:40-19:20) @E606

02404 (4/4) : 2C (Aug.22, 13:20-15:00) @E606

Type : Proposal of Minisymposium
Abstract : It is well known that the bilevel programming problem has been widely investigated in the literature due to its applications in mechanics, network designs and so on. In particular, if the upper-level problem is a variational inequality problem and the lower-level is a fixed-point set of an operator, then such a bilevel problem is known as a hierarchical variational inequality problem. The signal recovery, beamforming and power control problems can be modelled as hierarchical variational inequality problems. This minisymposium will promote a few scholars to look into new trends in hierarchical variational inequalities and optimization problems together, and provide an opportunity to explore the latest developments.

[03031] Self-adaptive subgradient extragradient method with extrapolation procedure for MSVIs

Author(s) : Lu-Chuan Ceng (Shanghai Normal University)
Abstract : This article introduces a self-adaptive subgradient extragradient process with extrapolation to solve a bilevel split pseudomonotone variational inequality with common fixed points constraint of finite nonexpansive mappings. The proposed rule exploits the strong monotonicity of one operator at the upper level and the pseudomonotonicity of another mapping at the lower level. The strong convergence result for the proposed algorithm is established. A numerical example is used to demonstrate the viability of the proposed rule.

[03050] Subgradient-extragradient method for SEP, VIP and FPP of multi-valued mapping

Author(s) : Yun-shui Liang (Yichun Vocational Technique College)
Abstract : In this paper, via a subgradient extragradient implicit rule, we introduce a new iterative algroithm for solving split equilibrium problems, variational inequality problem and fixed point problem of nonspreading multi-valued mapping in Hilbert space. We show that the iteration converges strongly to a common solution of the considered problems. Our results extend and improve some well-known results in the literature. Finally, a numerical example is provided to verify the validity of the proposed algorithm.

[03061] Modified subgradient-extragradient method for monotone-bilevel-equilibria with VIP and CFPP constraints

Author(s) : Hui-ying Hu (shanghai normal university)
Abstract : In a real Hilbert space, let GSVI and CFPP represent a general system of variational inequalities and a common fixed point problem of a countable family of nonexpansive mappings and an asymptotically nonexpansive mapping, respectively. In this paper, we introduce and analyze two iterative algorithms for solving the monotone bilevel equilibrium problem (MBEP) with the GSVI and CFPP constraints. Some strong convergence results for the proposed algorithms are established under the mild assumptions.

[03072] New strong convergence theorems of generalized quasi-contractive mappings

Author(s) : Yangqing Qiu (Shanghai Polytechnic University)
Abstract : In this paper, the strong convergences and estimates of convergence rate for generalized quasi-contractive mappings and generalized set-valued quasi-contractive mappings are studied in a real Hilbert space. Firstly, the Picard iterative process is used to approximate the fixed point. Secondly, a characterization of strong convergence theorem of the Mann iterative sequence is proved. By virtue of the mean value theorem of integrals, the convergence rate and the error estimate of the iterative processes are given.

02404 (2/4) : 1D @E606

[03144] Mittag-leffler stability of Fractional-order Neural Networks with time-varying delays

Author(s) : wei ding xiang zhu (Shanghai Normal University)
Abstract : This paper mainly studies a kind of fractional-order neural networks with time-varying delays. By using the mean value theorem of integrals,
inequality technique and Banach fixed point theorem, the Mittag-leffler stability of the unique equilibrium point of the system can be proved when some satisfied conditions are built.

[03170] Singular Riemann problems and their applications

Author(s) : Aifang Qu (Shanghai Normal University)
Abstract : In this talk, we will focus on a class of singular Riemann problems which contain concentration supported at the initial discontinuity. It corresponds to the study of a class of measure partial differential equations. Further, we will briefly introduce some applications of these problems to the study of hypersonic limit flow passing a wedge, fluid-structure interaction problems and conservation laws with discontinuous flux.

[03270] Gas-liquid Phase Transition Problem for Non-isentropic Compressible Euler Equations

Author(s) : Pei-yu Zhang (Shanghai Normal University)
Abstract : We study gas-liquid phase transition problem described by one-dimensional non-isentropic Euler equations. For this purpose, we solve the Riemann problem for non-isentropic Euler equations in the class of Radon measure. The difficulty is to find a meaningful solution to Riemann problem that satisfies the occurrence of this gas-liquid phase transformation phenomenon. This provide a new way of thinking for the study of gas-liquid phase transition.

[03286] Accelerated subgradient-extragradient methods for VIPs and CFPPs implicating countable nonexpansive-operators

Author(s) : Yun-ling Cui (shanghai normal university)
Abstract : In a real Hilbert space, let the VIP and CFPP denote the variational inequality problem and common fixed-point problem of countable nonexpansive operators and asymptotically nonexpansive operator, respectively. In this paper, we construct two modified Mann-type subgradient extragradient rules with a linear-search process for finding a common solution of the VIP and CFPP. We demonstrate the strong convergence of the suggested rules to a common solution of the VIP and CFPP.

02404 (3/4) : 1E @E606

[03591] The Behaviors of Rupture Solutions for a Class of Elliptic MEMS Equations

Author(s) : Yanyan Zhang (East China Normal University)
Abstract : We will talk about the rupture solutions of a semilinear elliptic equation
$\Delta u = \frac{\lambda|x|^{\alpha}}{u^{p}}, \quad x \in \mathbb{R}^2\backslash\{0\}, u(0)=0, \lambda>0, p>0, \alpha>-2,$
which derived from fields such as Micro-Electro-Mechanical System(MEMS). The remarkable feature of MEMS equations is the singularity of nonlinear terms.

In this talk, we will firstly analysis the classification of all possible singularities at $x=0$ for rupture solutions $u(x)$. In particular, we show that for some (α, p), $u(x)$ admits only the isotropic singularity at $x=0$, and otherwise $u(x)$ may admit the anisotropic singularity at $x=0$. Secondly, global solutions in $\mathbb{R}^2\setminus\{0\}$(their existence and their behavior near $x=\infty$ as well as near $x=0$) are also studied.

These results contribute to providing theoretical basis for the design and application of MEMS devices.

This is a joint work with Y.J. Guo, F. Zhou and Qing Li.

[02406] European Research Council (ERC) information session

Session Time & Room : 3E (Aug.23, 17:40-19:20) @G301

Type : Proposal of Minisymposium
Abstract : The European Research Council is the premier European funding organisation for excellent frontier research. Its mission is to encourage highest quality research in Europe through competitive funding and to support investigator-driven frontier research across all fields, based on scientific excellence.
In this minisymposium, ERC laureates will present their work in various grant schemes. The ERC office in Brussels will present the main opportunities for researchers. The final talk will concentrate on how to build a specific grant office within a university mathematics department, to stimulate researchers to apply for many different types of grants, including those of the ERC.
Organizer(s) : Alfio Quarteroni, Wil Schilders
Classification : 00A05

02406 (1/1) : 3E @G301 [Chair: Wil Schilders and Alfio Quarteroni]

[03125] European Research Council (ERC): insight into funding opportunities

Format : Talk at Waseda University
Author(s) : Joan Vazquez Molina (European Research Council Executive Agency)
Abstract : The ERC's mission is to encourage the highest quality research in Europe through competitive funding and to support investigator-driven frontier research across all fields, based on scientific excellence. I will give an overview of our funding opportunities, which are open to researchers from any nationality and at any career stage. I will provide insight into our evaluation and selection process, focusing on details of particular interest for the industrial and applied mathematics community.

[05538] Building a new mathematical adventure with ERC support.

Author(s) : Alfio Quarteroni (Politecnico di Milano)
Abstract : The generous ERC support has enabled me to lay the scientific foundations for computational medicine, an immensely captivating field that presents extraordinary mathematical challenges while offering the opportunity to contribute to solving complex problems of clinical and societal significance. In this presentation, I will outline the key milestones of this journey, and briefly touch upon my decade-long experience as the chairman of the ERC Mathematical Panel for Consolidator Grants.

[05548] Extreme-scale Mathematically-based Computational Chemistry Synergy project

Author(s) : Laura Grigori (EPFL and PSI)
Abstract : In this talk we will describe the ERC Synergy project entitled Extreme-scale Mathematically-based Computational Chemistry. Molecular simulation is one of the most dynamic areas of scientific computing. Its field of application is very broad, ranging from theoretical chemistry and drug design to materials science and

nanotechnology. We will review in this talk some of the research topics, challenges and achievements of this multidisciplinary effort that was made possible by ERC-Synergy-type funding.

[05567] A dedicated Project Development Office for Mathematics

Author(s) : Wil Schilders (Eindhoven University of Technology)
Abstract : At Eindhoven University, end of 2013 we started a Project Development Office (PDO) within the Department of Mathematics and Computer Science. This office has all the knowledge and expertise to inform mathematicians about suitable project opportunities, disregarding less suitable options, and helps actively with the writing of proposals. Personal grants like ERC proposals are of prime importance, PDO has a database of successful proposals. It has turned out to be a very successful move, other university departments and universities are copying the concept.

[02408] Recent advances in two-phase flow influenced by thermal fluctuations

Session Time & Room :

02408 (1/3) : 5B (Aug.25, 10:40-12:20) @F412

02408 (2/3) : 5C (Aug.25, 13:20-15:00) @F412

02408 (3/3) : 5D (Aug.25, 15:30-17:10) @F412

Type : Proposal of Minisymposium
Abstract : Thermal fluctuations may influence the evolution of interfaces in multi-phase flow. For this reason, analysis and numerics of stochastic versions of Allen-Cahn or Cahn-Hilliard equations with multiplicative noise, sometimes coupled to momentum equations of fluid dynamics, gained the interest of researchers both in pde and in stochastics. Related to these questions is the investigation of stochastic thin-film equations with their fascinating interplay between degenerate parabolicity and multiplicative noise.
This mini-symposium is supposed to bring researchers together who recently made important contributions both to analysis and numerics of such problems and to foster new collaborations.
Organizer(s) : Günther Grün, Stefan Metzger
Classification : 60H15, 35Q35, 76A20, 76T10
Minisymposium Program :

02408 (1/3) : 5B @F412 [Chair: Stefan Metzger]

[03080] The stochastic Navier-Stokes-Allen-Cahn system with singular potential

Format : Talk at Waseda University
Author(s) : Andrea Di Primio (Politecnico di Milano)Maurizio Grasselli (Politecnico di Milano)Luca Scarpa (Politecnico di Milano)
Abstract : In this talk, I consider the stochastic Navier-Stokes-Allen-Cahn system in a bounded domain of $\mathbb{R}^d$, with $d \in \{2,3\}$, and give some insights on the existence of martingale (in two and three dimensions) and probabilistically-strong solutions (in two dimensions). With respect to its deterministic counterpart, two independent cylindrical stochastic perturbations, which account for thermodynamical effects (e.g., microscopic collisions), are introduced. Moreover, a singular potential is considered, as prescribed by the thermodynamical derivation of the model.

[03081] On some stochastic phase-field models of Cahn-Hilliard-Cook type with logarithmic potential

Format : Online Talk on Zoom
Author(s) : Luca Scarpa (Politecnico di Milano)
Abstract : We give an overview of some recent results on stochastic phase-field models with logarithmic potential, which cover the celebrated Cahn-Hilliard-Cook equation. Both the conservative and the non-conservative cases are considered, as well as degenerate and non-degenerate mobilities. Well-posedness, regularity, and long-time

behaviour of solutions are discussed, with a mention on uniqueness-by-noise. The works presented in the talk are based on joint collaborations with A. Di Primio, Prof. M. Grasselli, and Dr. M. Zanella.

02408 (2/3) : 5C @F412 [Chair: Max Sauerbrey]

[03044] Temperature Effects in Generalized Diffusions

Format : Talk at Waseda University
Author(s) : Chun Liu (Illinois Tech)
Abstract : Abstract: In this work, we will introduce a general framework to derive thermodynamics of a mechanical system, which guarantee the consistence between the energetic variational approaches with the laws of thermodynamics. In particular, we will focus on the coupling between the thermal and mechanical forces. We will also present some analysis results and difficulties to these systems.

[04783] Asymptotics of the stochastic Cahn-Hilliard equation with space-time white noise

Format : Online Talk on Zoom
Author(s) : Lubomir Banas (Bielefeld University)
Abstract : We study the sharp interface limit of the stochastic Cahn-Hilliard equation with space-time white noise. We show that for sufficiently strong scaling of the noise the solution of the equation converges to the solution of the deterministic Hele-Shaw problem. We also discuss corresponding results for the numerical approximation of the problem.

[03980] Weak error analysis for the stochastic Allen-Cahn equation

Format : Online Talk on Zoom
Author(s) : Dominic Breit (TU Clausthal)Andreas Prohl Tuebingen (University of Tuebingen)
Abstract : We prove strong rate {\em resp.}~weak rate $\mathcal{O}(\tau)$ for a structure preserving temporal discretization (with τ the step size) of the stochastic Allen-Cahn equation with additive {\em resp.}~multiplicative colored noise in $d = 1, 2, 3$ dimensions.
Direct variational arguments exploit the one-sided Lipschitz property of the cubic nonlinearity in the first setting to settle first order strong rate. It is the same property which allows for uniform bounds for the derivatives of the solution of the related Kolmogorov equation, and then leads to weak rate $\mathcal{O}(\tau)$ in the presence of multiplicative noise. Hence, we obtain twice the rate of convergence known for the strong error in the presence of multiplicative noise.

[03932] On a convergent SAV scheme for stochastic phase-field equations

Format : Talk at Waseda University
Author(s) : Stefan Metzger (FAU Erlangen-Nürnberg)
Abstract : In this talk, we discuss the numerical treatment of stochastic Cahn-Hilliard equations with stochastic dynamic boundary conditions. These equations can be used to describe contact line tension effects in two-phase flows. By applying a stochastic version of the SAV method, we derive a stable, fully discrete finite element scheme that is linear with respect to the unknown quantities. Furthermore, we establish convergence of the discrete solutions towards martingale solutions using Skorokhod-type arguments.

02408 (3/3) : 5D @F412 [Chair: Stefan Metzger]

[03355] Martingale solutions to the stochastic thin-film equation in two dimensions

Format : Talk at Waseda University
Author(s) : Max Sauerbrey (TU Delft)
Abstract : We construct solutions to the stochastic thin-film equation with quadratic mobility and Stratonovich gradient noise in the physically relevant dimension $d = 2$ and allow in particular for solutions with non-full support. The construction relies on a Trotter-Kato time-splitting scheme, which was recently employed in $d = 1$.

The additional analytical challenges due to the higher spatial dimension are overcome using α-entropy estimates and corresponding tightness arguments.

[04416] SOLUTIONS TO THE STOCHASTIC THIN-FILM EQUATION FOR INITIAL VALUES WITH NON-FULL SUPPORT

Format : Online Talk on Zoom
Author(s) : Manuel Victor Gnann (Delft University of Technology)Konstantinos Dareiotis (University of Leeds)Benjamin Gess (Bielefeld University and Max Planck Institute for Mathematics in the Sciences, Leipzig)Günther Grün (University of Erlangen-Nuremberg)Max Sauerbrey (TU Delft)
Abstract : We prove existence of non-negative martingale solutions to a class of stochastic degenerate-parabolic fourth-order PDEs arising in surface-tension driven thin-film flow influenced by thermal noise. The construction applies to a range of mobilities including the cubic one which occurs under the assumption of a no-slip condition at the liquid-solid interface. Since their introduction more than 15 years ago, by Davidovitch, Moro, and Stone, and by Gruen, Mecke, and Rauscher, the existence of solutions to stochastic thin-film equations for cubic mobilities has been an open problem, even in the case of sufficiently regular noise. Our proof of global-in-time solutions relies on a careful combination of entropy and energy estimates in conjunction with a tailor-made approximation procedure to control the formation of shocks caused by the nonlinear stochastic scalar conservation law structure of the noise. The construction of solutions with non-full support for the initial data using alpha-entropies shall be discussed.

[04240] Existence of positive solutions to stochastic thin-film equations in the case of weak slippage

Format : Talk at Waseda University
Author(s) : Lorenz Klein (FAU Erlangen-Nürnberg)Günther Grün (FAU Erlangen-Nürnberg)
Abstract : We study stochastic thin-film equations for flow governed by surface tension and conjoining/disjoining interface potentials. For mobility exponents $n \in (2,3)$, we construct martingale solutions via spatial discretization, energy-entropy estimates based on stopping time arguments, and stochastic compactness methods. A crucial ingredient to extend methods used in the case $n = 2$ are new discrete formulas for integration by parts which allow to treat nonlinearities related to Stratonovich correction terms.
This is joint work with G. Grün.

[04442] On finite speed of propagation for stochastic thin-film equations

Format : Online Talk on Zoom
Author(s) : Günther Grün (FAU Erlangen-Nürnberg)Lorenz Klein (FAU Erlangen-Nürnberg)
Abstract : In this talk, we present an energy method which allows to prove finite speed of propagation for sufficiently regular solutions to a class of stochastic thin-film equations with conservative multiplicative noise under periodic boundary conditions. Analytically, our approach is based on novel integral estimates combined with appropriate modifications of the technique previously used for stochastic porous-media and stochastic parabolic p-Laplace equations.

[02411] Recent Advances in Numerical Methods for Nonlinear Equations and Applications

Session Time & Room :

02411 (1/3) : 4C (Aug.24, 13:20-15:00) @E604

02411 (2/3) : 4D (Aug.24, 15:30-17:10) @E604

02411 (3/3) : 4E (Aug.24, 17:40-19:20) @E604

Type : Proposal of Minisymposium
Abstract : Nonlinear equations and systems of equations are commonly used to describe scientific and engineering challenges. There are more and more applications for these systems, and majority of the techniques, now in use, have limitations and drawbacks. Thus, it is crucial to create novel numerical techniques that are

exceptionally accurate, stable, and reliable. This symposium focuses on the contemporary design methodologies, including machine learning algorithms, conformable fractional equations, and others, to real-world problems such as metabolic pathways, drug delivery interaction problem, image segmentation etc. We bring researchers from a broad spectrum to discuss development and applications of these modern methods.

[03387] Efficient iterative scheme for system of nonlinear equations

Format : Online Talk on Zoom
Author(s) : Himani Arora (Guru Nanak Dev University, Amritsar)
Abstract : Solving systems of nonlinear equations is an important and interesting task in science and engineering. But finding a solution of these systems using analytical methods is almost impossible, so one has to rely on iterative techniques for solution of such problems. The main motive of this talk is to discuss an efficient iterative technique for solving systems of nonlinear equations. The most time consuming and hard task while designing an iterative scheme is the evaluation of the inverse of the derivative. The main feature of the scheme presented is that it only utilizes one inverse evaluation per iteration, which makes the scheme computationally efficient. The efficiency of the scheme is verified through a number of real-world problems like integral equations and boundary value problems etc.

[03084] Non-Linear GAC Model for GIS Image Segmentation of Deforestation in Nusajaya Malaysia

Format : Online Talk on Zoom
Author(s) : norma binti alias (universiti teknologi malaysia)fiza zafar (Bahauddin Zakariya University)
Abstract : Based on the statistical data from website Global Forest Watch, from year 2001 to 2021, Nusajaya , Johor Malaysia experience a loss of 745kha of tree cover which is equivalent to a 47% decrease and a 292Mt of increase in CO2 emissions . GIS images able to visualize the deforestation problem. Digital transformation of images can be analysed by non-linear GAC Model for image segmentation. Numerical performance evaluation obtained the validation and verification of the analysis.

[03352] Analysis of Love-type wave in a nonlocal piezoelectric composite

Format : Talk at Waseda University
Author(s) : Vanita Sharma (SVKM's NMIMS Chandigarh)
Abstract : The aim of this research article is to provide a more detailed investigation of the size influences in piezoelectric material subjected to Love-type wave propagation. With the goal to consider the size influences of the structure, the Eringen's nonlocal theory is utilized. The dispersion relations for piezoelectric composite are obtained. Thereafter, detailed investigations of various affecting parameters viz. nonlocal parameter, material parameters etc. on the wave dispersion characteristics of size-dependent nanoscaled structure are addressed.

[03396] Mathematical modelling of Wave Equation in Elastodynamics Problems

Format : Online Talk on Zoom
Author(s) : Maryam Abdullah Alharbi (UTM)Norma binti Alias (UTM)
Abstract : The study of the wave equation in elastodynamics is crucial for understanding various physical phenomena. We present a mathematical model that describes the behavior of waves in elastodynamics. The model is stable to solve using FDM, which means this model is convergent to the approximate solution. Additionally, we highlight the relationship between blood flow and elastodynamics. We discuss the behavior of blood vessels and their interaction with blood as a fluid.

02411 (2/3) : 4D @E604 [Chair: Alicia Cordero]

[03928] Iterative Newton type methods with fractional derivatives

Format : Online Talk on Zoom
Author(s) : Juan R. Torregrosa (Universitat Politècnica de València)Alicia Cordero (Universitat Politècnica de València)Paula Triguero Navarro (Universitat Politècnica de València)
Abstract : Recently, several iterative methods using fractional derivatives have been designed. In this work, we propose some iterative schemes with fractal and conformable derivatives for solving nonlinear equations $f(x) = 0$. We analyze the local convergence of these algorithms and study their stability and computational performance. This stability is compared with those of iterative procedures using standard derivatives.

[03702] A Hybrid Genetic Algorithm for Solving Nonlinear Systems and Applications

Format : Talk at Waseda University
Author(s) : Fiza Zafar (CASPAM, Bahauddin Zakariya University, Pakistan)Nabeera Ahmad Gillani (CASPAM, Bahauddin Zakariya University, Pakistan)
Abstract : In this talk, a hybrid genetic algorithm has been proposed to solve nonlinear systems of equations by combining genetic algorithm and a fourth order convergent Jarratt type method to guarantee convergence and to accelerate the process of obtaining the solution. The proposed method is then applied to optimize biochemical systems to maximize the production and minimize the reaction's concentration. The performance and computational time of genetic algorithm and hybrid genetic algorithm have also been analyzed.

[03357] Iterative Method for Efficiently Computing Generalized Inverses of Matrices

Format : Talk at Waseda University
Author(s) : MANPREET KAUR (Lovely Professional University)
Abstract : The study of generalized inverses of matrices has been extensively explored in recent years. An iterative approach for finding the Moore-Penrose inverse of a matrix is discussed. The method's convergence is analyzed, achieving fourth-order convergence under certain conditions, with a suggested parameter choice for improved convergence order. Testing on real-life matrices from the Matrix-Market Library shows the proposed scheme's superiority over existing methods. The study also investigates the most efficient parameter choice.

[03376] Globally convergent iterative method for evaluating matrix sign function

Format : Talk at Waseda University
Author(s) : Munish Kansal (Thapar Institute of Engineering and Technology, Patiala, Punjab 147004)
Abstract : The matrix sign function plays a vital role in the various fields of scientific computing. This work proposes an iterative method to compute the matrix sign function of a matrix having no eigenvalues on the imaginary axis and is analyzed for convergence and asymptotic stability. Global convergence behavior is provided by drawing basins of attraction. Numerical experiments of different dimensions support the theoretical results and illustrate the efficiency of the proposed method.

02411 (3/3) : 4E @E604 [Chair: Juan Ramon Torregrosa]

[03040] An Iterative scheme for finding simultaneous roots of nonlinear systems

Format : Talk at Waseda University
Author(s) : Neus Garrido (Universitat Politècnica de València)Paula Triguero Navarro (Universitat Politècnica de València)Alicia Cordero (Universitat Politècnica de València)Juan Ramón Torregrosa (Universitat Politècnica de València)
Abstract : Systems of nonlinear equations usually appear in many real-world applications. We give a general iterative algorithm to approximate simultaneous solutions of systems of nonlinear equations. We show that by adding a general sub-step to any iterative method, a new iterative scheme to approximate simultaneous roots of nonlinear systems with doubled convergence order can be obtained. We add this sub-step to some iterative methods of this domain and analyze the behavior of the new schemes.

[03925] High-order iterative methods for solving nonlinear systems

Format : Online Talk on Zoom
Author(s) : Alicia Cordero Renso V. Rojas-Hiciano (Pontificia Universidad Católica Madre y Maestra)Juan R. Torregrosa (Universitat Politècnica de València)
Abstract : In the last decades, many optimal iterative schemes have been developed for solving nonlinear equations, for simple or multiple roots. However, the amount of vectorial iterative procedures able to estimate the solutions of nonlinear systems could be higher. The computational cost of solving the linear systems involved in each iteration plays a key role in the design, seeking the efficiency of the method. We present a highly efficient scheme for solving nonlinear systems of equations.

[02423] Non-standard finite element methods

Session Time & Room :

02423 (1/2) : 2C (Aug.22, 13:20-15:00) @E711

02423 (2/2) : 2D (Aug.22, 15:30-17:10) @E711

Type : Proposal of Minisymposium
Abstract : This minisymposium is on the non-standard finite element methods, including mixed finite element methods, non-conforming finite elements methods, discontinuous Galerkin methods, virtual element methods, weak Galerkin methods, and so on. This minisymposium intended to focus on the latest research progress in the field of numerical methods of partial differential equations. It is expected that through the frontier progress report, scholars engaged in the research of numerical methods of partial differential equations can be exposed to the core problems in the field of mathematical theory, numerical methods, and practical applications.
Organizer(s) : Carsten Carstensen, Jun Hu, Ran Zhang
Classification : 65N30, 65M60, 65N25
Minisymposium Program :

02423 (1/2) : 2C @E711 [Chair: Jun Hu]

[04214] A posteriori error estimation for a C1-virtual element method of Kirchhoff plates

Author(s) : Jianguo Huang (Shanghai Jiao Tong University)
Abstract : A residual-type a posteriori error estimation is developed for a C^1-conforming virtual element method (VEM) to solve a Kirchhoff plate bending problem. As an outcome of the error estimator, an adaptive VEM is introduced using the mesh refinement strategy with the one-hanging-node rule. A series of numerical results are performed to verify the efficiency of the method. This is a joint work with Mingqing Chen and Sen Lin from Shanghai Jiao Tong University.

[03654] Stabilization-Free Virtual Element Methods

Author(s) : Xuehai Huang (Shanghai University of Finance and Economics)
Abstract : Stabilization-free virtual element methods (VEMs) in arbitrary degree of polynomial are developed for second order elliptic problems, including a nonconforming VEM in arbitrary dimension and a conforming VEM in two dimensions. The key is to construct local $H(\div)$-conforming macro finite element spaces such that the associated L^2 projection of the gradient of virtual element functions is computable, and the L^2 projector has a uniform lower bound on the gradient of virtual element function spaces in L^2 norm. Optimal error estimates are derived for these stabilization-free VEMs. Numerical experiments are provided to test the stabilization-free VEMs.

[03806] Discontinuous Galerkin methods for magnetic advection-diffusion problems

Author(s) : Jindong Wang (Peking University)Shuonan Wu (Peking University)

Abstract : We devise and analyze a class of the primal discontinuous Galerkin methods for magnetic advection-diffusion problems based on the weighted-residual approach. In addition to the upwind stabilization, we find a new mechanism under the vector case that provides more flexibility in constructing the schemes. For the more general Friedrichs system, we show the stability and optimal error estimate, which boil down to two core ingredients -- the weight function and the special projection -- that contain information of advection. Numerical experiments are provided to verify the theoretical results.

[03492] Some finite element divdiv complexes in three dimensions

Format : Talk at Waseda University
Author(s) : Rui Ma (Beijing Institute of Technology)

Abstract : This talk will present two families of finite element divdiv complexes on tetrahedral grids and one family on cuboid grids. They can be used to discretize the linearized Einstein-Bianchi system.

02423 (2/2) : 2D @E711 [Chair: Ran Zhang]

[04728] Adaptive FEM for Helmholtz equation with large wave number

Author(s) : Haijun Wu (Nanjing University)Songyao Duan (Nanjing University)

Abstract : A posteriori upper and lower bounds are derived for the finite element method (FEM) for the Helmholtz equation with large wavenumber. It is proved rigorously that the standard residual type error estimator seriously underestimates the true error of the FE solution for the mesh size h in the preasymptotic regime, which is first observed by [Babuska,~et~al., A posteriori error estimation for finite element solutions of Helmholtz equation. Part I, Int. J. Numer. Meth. Engrg. 40, 3443--3462 (1997)] for a one dimensional problem. By establishing an equivalence relationship between the error estimators for the FE solution and the corresponding elliptic projection of the exact solution, an adaptive algorithm is proposed and its convergence and quasi-optimality are proved under the condition that $k^{2p+1}h_0^{2p}$ is sufficiently small, where k is the wavenumber, h_0 is the initial mesh size.

[03581] Stable Finite Element Scheme for Dynamic Ginzburg-Landau Equations

Author(s) : Limin Ma (Wuhan University)

Abstract : We propose a decoupled numerical scheme of the time-dependent Ginzburg--Landau equations under the temporal gauge. The maximum bound principle of the order parameter and the energy dissipation law in the discrete sense are proved, which can guarantee the stability and validity of the numerical simulations, and further facilitate the adoption of adaptive time-stepping strategy. An optimal error estimate of the proposed scheme is also proved and verified by numerical examples.

[03508] Local bounded commuting projection operators for discrete finite element complexes

Author(s) : Ting Lin (Peking University)

Abstract : Local bounded commuting projection operators are an important tool in the analysis of finite element exterior and mixed finite element methods. However, so far only those of the standard finite element spaces have been discussed. In this talk, I will introduce the construction of local bounded commuting projection operators of the discrete finite element complexes, with some possible applications. The techniques developed here also give us a new perspective on the construction of finite element complexes.

[04168] The weak Galerkin method for elliptic eigenvalue problems

Author(s) : Qilong Zhai (Jilin University)

Abstract : In this report, we propose and analyze the elliptic eigenvalue problems by using the weak Galerkin method. In contrast to the conforming finite element method, the lower bounds of eigenvalues are considered. We prove that the weak Galerkin method produces asymptotic lower bounds by using the high order polynomials, and produces guaranteed lower bounds by using the lowest order polynomials. Some numerical acceleration

techniques are also applied to the weak Galerkin method, and the numerical experiments are presented to verify the theoretical analysis.

[02426] Mathematics of turbulent transport and coherent structures

Session Time & Room :

02426 (1/2) : 5B (Aug.25, 10:40-12:20) @D401

02426 (2/2) : 5C (Aug.25, 13:20-15:00) @D401

Type : Proposal of Minisymposium
Abstract : The transport of momentum and heat by coherent structures in turbulence has long been a central concern in fluid mechanics, especially because of its critical importance in industry, geophysics, and astrophysics. Significant progress has been made in recent years in Navier-Stokes-based variational principles, asymptotic analysis, and dynamical systems theory, finally producing meaningful results for practical applications. This mini-symposium aims to bring together experts with a wide range of related backgrounds, from applied to fundamental, to exchange the latest findings and to set new research directions.
Organizer(s) : Kengo Deguchi; Shingo Motoki
Classification : 76F25, 76F20, 35A15, 35C20
Minisymposium Program :

02426 (1/2) : 5B @D401 [Chair: Shingo Motoki]

[04104] Analysis of transport by coherent structures; overview

Format : Talk at Waseda University
Author(s) : Kengo Deguchi (Monash University)
Abstract : A primary ongoing problem in fluid mechanics is the need to comprehend the large-scale average transport features of turbulent flows. For example, the prediction or improvement of heat/momentum transport is critical in a wide range of applications, but currently it relies on trial and error with massive amounts of experiments/simulations. A natural question arises: can we explain the mechanism of the transport logically based on Navier-Stokes equations? The key to the answer seems to lie in the coherent structures in turbulence, and an overview of recent developments will be given in the talk.

[04490] Analysis, modeling, and simulation of slow-fast quasilinear dynamical systems

Format : Online Talk on Zoom
Author(s) : Greg Chini (University of New Hampshire)
Abstract : We describe a new formalism for quasilinear systems exhibiting slow mean and fast, possibly unstable, linearized fluctuation dynamics. Using ODE and PDE models, we show that a slaving relation for the fluctuation amplitude can be derived by exploiting the tendency for the dynamics to self-organize on a slow marginal-stability manifold. Transient, fully nonlinear bursting events also can be predicted and systematically incorporated into our formalism. We conclude with an application to strongly stratified Kolmogorov flow.

[04122] Steady coherent states in Rayleigh–Bénard convection

Format : Online Talk on Zoom
Author(s) : Baole Wen (New York Institute of Technology)David Goluskin (University of Victoria)Gregory Chini (University of New Hampshire)Charles Doering (University of Michigan)
Abstract : A central question in Rayleigh--B'enard convection is how the Nusselt number Nu depends on the Rayleigh number Ra as $Ra \to \infty$. Experiments/simulations have yet to rule out either `classical' 1/3 or`ultimate' 1/2 asymptotic scaling. Here we show that certain steady rolls have classical 1/3 scaling and they transport more heat than turbulent experiments/simulations at comparable parameters. If turbulent heat transport continues to be dominated by steady transport asymptotically, it cannot achieve ultimate scaling.

[04022] Optimal heat transport using branching flows

Format : Online Talk on Zoom

Author(s) : Anuj Kumar (University of California Santa Cruz)

Abstract : We are interested in the design of forcing in the Navier–Stokes equation such that the resultant flow maximizes the transport of a passive temperature between two differentially heated walls for a given power supply budget. Previous work established that the transport cannot scale faster than 1/3-power of the power supply. Recently, Doering & Tobasco (CPAM'19) constructed self-similar two-dimensional steady branching flows, saturating this upper bound up to a logarithmic correction to scaling. We present a construction of three-dimensional "branching pipe flows" that eliminates the possibility of this logarithmic correction and for which the corresponding passive scalar transport scales as a clean 1/3-power law in power supply. Our flows resemble previous numerical studies of the three-dimensional wall-to-wall problem by Motoki, Kawahara & Shimizu (J. Fluid Mech. vol.851, 2018, p.R4}). However, using an unsteady branching flow construction, it appears that the 1/3 scaling is also optimal in two dimensions. After carefully examining these designs, we extract the underlying physical mechanism that makes the branching flows "efficient."

02426 (2/2) : 5C @D401 [Chair: Kengo Deguchi]

[04552] Optimisation of horizontal periodicity in steady Rayleigh–Bénard convection

Format : Talk at Waseda University

Author(s) : Shingo Motoki (Osaka University)Genta Kawahara (Osaka University)Masaki Shimizu (Osaka University)

Abstract : Using a Newton–Krylov iteration, we have investigated steady solutions to the Boussinesq equations for Rayleigh–Bénard convection in a square periodic domain between horizontal walls with a constant temperature difference. We have found that a family of three-dimensional steady solutions with an optimal horizontal periodicity achieves higher wall-to-wall heat flux than those of two-dimensional solutions and turbulent states and exhibits the classical scaling commonly observed in convective turbulence.

[04406] Chaos and unstable periodic orbits in subcritical Taylor-Couette flow

Format : Talk at Waseda University

Author(s) : Baoying Wang (Universitat Politècnica de Catalunya)Roger Ayats (Institute of Science and Technology Austria (ISTA))Kengo Deguchi (Monash University)Alvaro Meseguer (Universitat Politècnica de Catalunya)Fernando Mellibovsky (Universitat Politècnica de Catalunya)

Abstract : Although spectral approximation of turbulence typically requires a large number of modes, for relatively low Reynolds numbers the turbulent attractor lies on a low-dimensional manifold in phase space. The most extreme case is when the main features of the chaotic attractor can be quantified by a one-dimensional map on Poincaré section. We find this can indeed happen in subcritical Taylor-Couette flow, which should offer an important test case for connecting turbulence and periodic orbit analysis.

[03988] The state-space structure of wall turbulence at high Reynolds numbers: a reduced-order model perspective

Format : Talk at Waseda University

Author(s) : Matthew McCormack (University of Edinburgh)André V. G. Cavalieri (Instituto Tecnológico de Aeronáutica)Yongyun Hwang (Imperial College London)

Abstract : Invariant solutions to the Navier-Stokes equations have been viewed to form the state-space skeleton of turbulence at low Reynolds numbers. However, as Reynolds number is increased, most of these invariant solutions currently computable were recently shown to be able to depict only partial processes of turbulence, and they neither resemble full-scale turbulence statistically nor dynamically. In this talk, I will present our recent efforts to understand the state-space structure of turbulence at moderately high Reynolds numbers in terms of invariant solutions utilising a reliable and robust reduced-order model.

[03140] Coherent structures and the direct cascade in two-dimensional turbulence

Format : Talk at Waseda University
Author(s) : Roman O Grigoriev (Georgia Institute of Technology)Mateo Reynoso (Georgia Institute of Technology)Dmitriy Zhigunov (Georgia Institute of Technology)
Abstract : We describe a mechanism of the direct cascade in 2D turbulence which explains when the predictions of the classical Kraichnan-Leith-Batchelor theory hold, when deviations are found, and what causes these deviations. Coherent structures of two types play a key role in our theory: the first type describes the dynamics of the largest scales accessible to the flow, while the second type describes the dynamics of small-scale filamentary vorticity stretched and folded by the large-scale flow.

[02435] Scaling Limits of Interacting Particle Systems

Session Time & Room :

02435 (1/3) : 4C (Aug.24, 13:20-15:00) @E501

02435 (2/3) : 4D (Aug.24, 15:30-17:10) @E501

02435 (3/3) : 4E (Aug.24, 17:40-19:20) @E501

Type : Proposal of Minisymposium
Abstract : This minisymposium aims to bring together young researchers in PDEs, probability and applied mathematics to share recent progress and complementary perspectives in the growing field of interacting particle systems. Such systems are not only important models in physics, biology, and many applied sciences, but also rich in mathematical structure.
Our topics include mean-field limits and propagation of chaos for large systems with singular interactions, limit theorems and large deviations for interacting particle systems on random graphs, particle and numerical methods of McKean-Vlasov PDEs, convergence theorems of SPDEs, and quasi-stationary behavior of SPDEs and their dual particle systems.

Organizer(s) : Wai-Tong (Louis) Fan, Zhenfu Wang, Ruoyu Wu
Classification : 60K35, 60F05, 35K55, 35Q49, 35Q70, interacting particle systems, mean-field limit, limit theorems of stochastic processes
Minisymposium Program :

02435 (1/3) : 4C @E501 [Chair: Zhenfu Wang]

[05450] Ergodic properties of rank-based diffusions

Format : Online Talk on Zoom
Author(s) : Sayan Banerjee (University of North Carolina, Chapel Hill)Amarjit Budhiraja (University of North Carolina, Chapel Hill)
Abstract : We investigate the long-time behavior of rank-based diffusions with infinitely many particles where the drift and diffusivity of each particle depends on its relative rank in the system. Unlike their finite dimensional analogues, such systems have infinitely many stationary measures and domains of attraction and extremality properties of such measures have been long-standing open questions. In this talk, we will explore some of these questions and provide answers to them in certain cases.

Based on joint works with Amarjit Budhiraja.

[04342] Systems with Riesz Interactions in the Mean-Field Regime

Format : Online Talk on Zoom
Author(s) : Matthew Rosenzweig (MIT)Sylvia Serfaty (Courant Institute, NYU)Antonin Chodron de Courcel (Ecole Polytechnique)
Abstract : We present recent results on the large particle number and large time effective behavior of conservative or gradient dynamics for particle systems with mean-field interactions governed by a Coulomb or more general

Riesz potential and subject to possible noise modeling thermal fluctuations. The talk will discuss modulated energy/free energy techniques for studying the rate of mean-field convergence, how the rate deteriorates with time, and how fluctuations around the mean-field limit behave.

[03026] Large Deviations for Multiscale Weakly Interacting Diffusions

Format : Online Talk on Zoom
Author(s) : Zachary Bezemek (Boston University)Konstantinos Spiliopoulos (Boston University)
Abstract : In this talk, we consider a collection of weakly interacting diffusion processes moving in a two-scale locally periodic environment. We study the large deviations principle of the empirical distribution of the particles' positions in the combined limit as the number of particles grow to infinity and the time-scale separation parameter goes to zero simultaneously. We derive several equivalent formulations of the rate function, making connections between a mean-field control formulation and the formulation of Dawson-Gärtner.

[05239] Hydrodynamic Limits of non-Markovian Interacting Particle Systems on Sparse Graphs

Format : Online Talk on Zoom
Author(s) : Ankan Ganguly (University of Pennsylvania)Kavita Ramanan (Brown University)
Abstract : We consider hydrodynamic limits of non-Markovian interacting particle systems on large sparse graphs. Under mild conditions on the jump intensities and underlying graphs, it is shown that if the sequence of interaction graphs G_n converges locally in probability to a limit graph G, then the corresponding sequence of empirical measures of the particle trajectories converges weakly to the law of the marginal dynamics at the root vertex of G.

02435 (2/3) : 4D @E501 [Chair: Zhenfu Wang]

[04551] Wave propagation for reaction-diffusion equations on infinite trees

Format : Online Talk on Zoom
Author(s) : Grigory Terlov (UNC Chapel Hill)Wai-Tong (Lous) Fan (Indiana University)Wenqing Hu (Missouri University of S&T)
Abstract : The asymptotic speed of the wavefront of the solution to FKPP equation on $\mathbb{R}$ is well understood. I will present a probabilistic approach to the same problem on infinite metric trees. When the reaction rate is large enough we show that a travelling wavefront emerges. Its speed is slower than that of the same equation on the real line, and we can estimate this slow-down in terms of the structure of the tree.

[03975] From the KPZ equation to the directed landscape

Format : Online Talk on Zoom
Author(s) : XUAN WU (University of Illinois Urbana-Champaign)
Abstract : This talk presents the convergence of the KPZ equation to the directed landscape, which is the central object in the KPZ universality class. This convergence result is the first to the directed landscape among the positive temperature models.

[05115] Longtime behaviour of the stochastic FKPP equation conditioned on non-fixation

Format : Online Talk on Zoom
Author(s) : Oliver Kelsey Tough (University of Bath)Wai-Tong (Louis) Fan (Indiana University)
Abstract : In population genetics, fixation is the phenomenon in which all members of a population have the same copy of a given gene. Whilst most genes are fixed (most genes are shared by all individuals), not all genes are fixed (individuals aren't identical). The prototypical continuum model for the spread of a genetic type in a spatially distributed population under the effects of genetic drift, selection and migration is the stochastic Fisher-Kolmogorov-Petrovsky-Piscunov (FKPP) equation. We consider the stochastic FKPP equation on the circle. We establish existence and uniqueness of the quasi-stationary distribution (QSD) for solutions of the stochastic FKPP, considered to be absorbed upon fixation. We show that the distribution of the solution conditioned on non-fixation converges to this unique QSD as time $t \to \infty$, for any initial distribution. Moreover we characterise the leading-order asymptotics for the tail distribution of the fixation time. This is based on joint work with Wai-Tong Fan.

[03336] The interacting multiplicative coalescent and Levy-like random fields

Format : Online Talk on Zoom
Author(s) : David J Clancy, Jr. (University of Wiscons)
Abstract : The multiplicative coalescent describes the evolution of blocks where blocks of masses x and y form a single block of mass $x + y$ at rate xy. This process naturally appears when studying many random graph models at criticality. Their marginal laws are described using (mixtures of) Levy-type processes. Using stochastic blockmodels, we show that one can describe the marginal law of two interacting multiplicative coalescences using a Levy-type random field. Based on work with V. Konarovskyi and V. Limic.

02435 (3/3) : 4E @E501 [Chair: Zhenfu Wang]

[03511] Graphon mean field systems

Format : Online Talk on Zoom
Author(s) : Ruoyu Wu (Iowa State University)Erhan Bayraktar (University of Michigan)Suman Chakraborty (Uppsala University)
Abstract : We consider heterogeneously interacting diffusive particle systems and their large population limit. The interaction is of mean field type with (random) weights characterized by an underlying graphon. The limit is given by a graphon particle system consisting of independent but heterogeneous nonlinear diffusions whose probability distributions are fully coupled. Well-posedness of the graphon particle system is established. A law of large numbers result is proved as the system size increases and the underlying graphons converge.

[03358] Strong convergence of propagation of chaos for McKean-Vlasov SDEs with singular interactions

Format : Online Talk on Zoom
Author(s) : Zimo Hao (Bielefeld University)
Abstract : In this work we show the strong convergence of propagation of chaos for the particle approximation of McKean-Vlasov SDEs with singular L^p-interactions as well as for the moderate interaction particle systems on the level of particle trajectories. One of the main obstacles is to establish the strong well-posedness of the SDEs for particle systems with singular interaction. To this end, we extend the results on strong well-posedness of Krylov and R"ockner to the case of mixed $L^{\boldsymbol{p}}$-drifts, where the heat kernel estimates play a crucial role. Moreover, when the interaction kernel is bounded measurable, we also obtain the optimal rate of strong convergence, which is partially based on Jabin and Wang's entropy method and Zvonkin's transformation.

[03721] Nonlocal approximation of nonlinear diffusion equations

Format : Talk at Waseda University
Author(s) : José Antonio Carrillo (University of Oxford)Antonio Esposito (University of Oxford)Jeremy S.-H. Wu (UCLA)
Abstract : Nonlinear diffusion equations are ubiquitous in several real world applications. They were introduced to analyse gas expansion in a porous medium, groundwater infiltration, and heat conduction in plasmas, to name a few applications in physics. In this talk, I will present recent joint work with José A. Carrillo and Antonio Esposito concerning a nonlocal approximation inspired by the theory of gradient flows for a general family of equations closely related to the porous medium equation with m>1. Our approximation is inspired by recent ideas to use (nonlocal) interaction equations to approximate (local) diffusion equations. We prove under very general assumptions that weak solutions to our nonlocal approximation converge to weak solutions of the original local equation. One byproduct of our analysis is the development of a deterministic particle method for numerically approximating solutions to nonlinear diffusion equations.

[04156] Entropy-dissipation Informed Neural Network for McKean-Vlasov Type PDEs

Format : Online Talk on Zoom
Author(s) : Zebang Shen (ETH Zürich)Zhenfu Wang (Peking University)
Abstract : We extend the concept of self-consistency for the Fokker-Planck equation (FPE)(Shen et al., 2022) to the more general McKean-Vlasov equation (MVE). While FPE describes the macroscopic behavior of particles under drift and diffusion, MVE accounts for the additional inter-particle interactions, which are often highly singular in

physical systems. Two important examples considered in this paper are the MVE with Coulomb interactions and the vorticity formulation of the 2D Navier-Stokes equation. We show that a generalized self-consistency potential controls the KL-divergence between a hypothesis solution to the ground truth, through entropy dissipation. Built on this result, we propose to solve the MVEs by minimizing this potential function, while utilizing the neural networks for function approximation. We validate the empirical performance of our approach by comparing with state-of-the-art NN-based PDE solvers on several example problems.

[02438] Recent advances in numerical multiscale methods

Session Time & Room :

02438 (1/2) : 4D (Aug.24, 15:30-17:10) @E703

02438 (2/2) : 4E (Aug.24, 17:40-19:20) @E703

Type : Proposal of Minisymposium
Abstract : Multiscale phenomena are ubiquitous in science and engineering, and many multiscale problems are modeled by partial differential equations with general rough coefficients. Direct numerical solution of such problems is often infeasible because a huge number of degrees of freedom are needed to resolve all details on all relevant scales. Numerical multiscale methods aim at reducing the computational cost by efficiently incorporating physically important fine-scale information into a coarse-grid representation. The scope of this minisymposium is to bring together experts in this field to present recent advances in the design and analysis of numerical multiscale methods.

Organizer(s) : Chupeng Ma, Robert Scheichl

02438 (1/2) : 4D @E703

[03763] Super-Localized Generalized Finite Element Method

Format : Talk at Waseda University
Author(s) : Moritz Hauck (University of Augsburg)Philip Freese (Technical University Hamburg)Tim Keil (University of Münster)Daniel Peterseim (University of Augsburg)
Abstract : We present a multi-scale method for elliptic PDEs with arbitrarily rough coefficients. The method constructs operator-adapted solution spaces with uniform algebraic approximation rates by combining techniques from numerical homogenization and partition of unity methods. Localized basis functions with the same super-exponential localization properties as the Super-Localized Orthogonal Decomposition (SLOD) allow for an efficient implementation of the method. We derive higher-order versions of the method and demonstrate its application to high-contrast channeled coefficients and Helmholtz problems.

[03861] An efficient multiscale approach for simulating Bose-Einstein condensates

Format : Talk at Waseda University
Author(s) : Christian Döding (Ruhr-University Bochum)Patrick Henning (Ruhr-University Bochum)Johan Wärnegård (Columbia University)
Abstract : In this talk we consider the numerical treatment of nonlinear Schrödinger equations as they appear in the modeling of Bose-Einstein condensates. We give numerical examples that demonstrate the influence of the discrete energy on the accuracy of numerical approximations and that a spurious energy can create artificial phenomena such as drifting particles. In order to conserve the exact energy of the equation as accurately as possible, we propose a combination of a class of conservative time integrators with a suitable multiscale finite element discretization in space. This space discretization is based on the technique of Localized Orthogonal Decompositions (LOD) and allows to capture general time invariants with a 6th order accuracy with respect to the chosen mesh size H. This accuracy is preserved due to the conservation properties of the time stepping method. The computational efficiency of the method is demonstrated for a numerical benchmark problem with known exact solution, which is however barely solvable with traditional methods on long time scales.

[04037] Multigrid/multiscale solver for the radiative transfer equation in heterogeneous media

Format : Talk at Waseda University

Author(s) : QINCHEN SONG (Shanghai Jiao Tong University)

Abstract : The radiative transfer equation describes the interaction between particles and media such as gases, semitransparent liquids , solids, and porous materials, which is widely used in nuclear engineering, thermal radiation transport, etc. In the first part of our work, we construct a multigrid scheme for 1D neutron transport equation based on a second-order discretization scheme that is uniform with respect to ϵ in the diffusion regime and valid up to the boundary layer and interface layer. We prove its multigrid convergence theoretically and justify it numerically. This multigrid scheme is special in a way that the smoothing procedure in the typical multigrid method can be skipped, which saves a large amount of computation. The 1D scheme can be adapted to the 2D case, and the resulting 2D scheme performs well in the diffusion regime. In the second part, we focus on the 2D radiative transport equation in the transport regime. After discretization of the equation, we get a sparse linear system of extremely high dimensions. Typically, we have 3 ways to solve the linear system: direct methods, iterative methods, and rank-structured methods, which requires computation cost of I^6, I^3 and I^3 respectively (provided that the physical domain is discretized as a $I \times I$ grid). In our work, we use a hybrid scheme of iterative methods and rank-structured methods and reduce the computation cost down to $I^{5/2}$. This is joint work with Min Tang (SJTU) and Lei Zhang (SJTU).

[03533] EXPONENTIALLY CONVERGENT MULTISCALE METHODS FOR HIGH FREQUENCY HETEROGENEOUS HELMHOLTZ EQUATIONS

Format : Talk at Waseda University

Author(s) : Thomas Y Hou (California Institute of Technology)Yifan Chen (California Institute of Technology)Yixuan Wang (California Institute of Technology)

Abstract : We present a multiscale framework for solving the high frequency Helmholtz equation in heterogeneous media without scale separation. Our methods achieve a nearly exponential rate of convergence without suffering from the well-known pollution effect. The key idea is a coarse-fine scale decomposition of the solution space that adapts to the media property and wavenumber. The coarse part is of low complexity while the fine part is local such that it can be computed efficiently.

02438 (2/2) : 4E @E703

[03853] A high-order method for elliptic multiscale problems

Format : Talk at Waseda University

Author(s) : Roland Maier (University of Jena)

Abstract : We present a multiscale approach for an elliptic multiscale setting with general unstructured diffusion coefficients that is able to achieve high-order convergence rates with respect to the mesh parameter and the polynomial degree. The method allows for suitable localization and does not rely on additional assumptions on the domain, the diffusion coefficient, or the exact (weak) solution as typically required for high-order approaches. Rigorous a priori error estimates with respect to the involved discretization parameters are presented and the interplay between these parameters as well as the performance of the method are studied numerically.

[04038] Hierarchical Attention Neural Operator for Multiscale PDEs

Format : Talk at Waseda University

Author(s) : Bo Xu (Shanghai Jiao Tong University)

Abstract : Complex nonlinear interplays of multiple scales give rise to many interesting physical phenomena and pose significant difficulties for the computer simulation of multiscale PDE models in areas such as reservoir simulation, high-frequency scattering, and turbulence modeling. In this talk, we apply hierarchical attention to a data-driven operator learning problem related to multiscale partial differential equations. An empirical H1 loss function is proposed to counteract the spectral bias of the neural operator approximation for the multiscale solution space. We perform experiments on the multiscale Darcy Flow, Helmholtz equation and Navier-Stokes equation. Our model exhibits noticeably higher accuracy compared to the current neural operator techniques, and it produces state-of-the-art results across a variety of datasets. This is joint work with Xinliang Liu (KAUST) and Lei Zhang (SJTU).

[04167] An abstract framework for multiscale spectral generalized FEMs

Format : Online Talk on Zoom
Author(s) : chupeng ma (Great Bay University)
Abstract : We present an abstract framework for multiscale spectral generalized FEMs based on locally optimal spectral approximations. A higher convergence rate for the local approximations than previously established is derived under certain conditions. The abstract theory is applied to various problems with strongly heterogeneous coefficients, including convection-diffusion problems, elasticity problems, high-frequency wave problems (Helmholtz, elastic wave, and Maxwell's equations), and fourth-order problems, both in the continuous and discrete settings.

[03857] Multiscale multicontinuum problems in fractured porous media: dimension reduction and decoupling

Format : Talk at Waseda University
Author(s) : Maria Vasilyeva (Texas A&M University-Corpus Christi)
Abstract : We consider the coupled system of equations that describe flow in fractured porous media. To describe such types of problems, multicontinuum and multiscale approaches are used. The presented decoupling technique separates equations for each continuum that can be solved separately, leading to a more efficient computational algorithm with smaller systems and faster solutions. This approach is based on the additive representation of the operator with semi-implicit approximation by time, where the continuum coupling part is taken from the previous time layer. We extend and investigate this approach for multiscale approximation on the coarse grid using the nonlocal multicontinuum method. We show that the decoupled schemes are stable, accurate, and computationally efficient.

[02440] Advances in Optimization I

Session Time & Room :

02440 (1/3) : 2D (Aug.22, 15:30-17:10) @A502

02440 (2/3) : 2E (Aug.22, 17:40-19:20) @A502

02440 (3/3) : 3C (Aug.23, 13:20-15:00) @A502

Type : Proposal of Minisymposium
Abstract : The two minisymposia on Advances in Optimization I and II will bring together a diverse group of leading researchers and practitioners from both continuous and combinatorial optimization, theoretical and applied. One of the goals of these two minisymposia is to raise awareness to the most recent advances in optimization theory, algorithms, and applications, and to develop connections and encourage collaboration.
Organizer(s) : Antoine Deza, Takashi Tsuchiya
Classification : 90Cxx, 49Mxx, 65Kxx, 52Bxx, 52Cxx
Minisymposium Program :

02440 (1/3) : 2D @A502 [Chair: Takashi Tsuchiya]

[04074] Some Recent Developments on Solving Variational Inequality Problems

Format : Talk at Waseda University
Author(s) : Shuzhong Zhang (University of Minnesota)
Abstract : In this talk, we will present several solution methods for solving non-monotone VI problems. As the VI formulation is generalized from the optimality condition for optimization, the results are immediately applicable to nonconvex and constrained continuous optimization. The focus is placed on the conditions of the non-monotone VI models, under which the newly designed solution algorithms would converge with guaranteed rates of convergence.

[05227] Monotone Variational Inequality (VI) for estimation and learning

Format : Talk at Waseda University
Author(s) : Yao Xie (Georgia Institute of Technology)
Abstract : We propose a new computational framework for estimating parameters in generalized generalized linear models (GGLMs), inspired by Juditsky and Nemirovsky's recent work. First, we extend GLMs to spatio-temporal data by accounting for dependencies among observations while using a monotone operator-based variational inequality method. We also present online instance-based bounds using martingale concentration inequalities and apply our algorithm to wildfire and police datasets. In addition, we demonstrate our approach to training neural networks.

[04577] Implementation of Interior Point Method for Nonlinear Programming for Real-life Applications.

Format : Talk at Waseda University
Author(s) : Takahito Tanabe (NTTDATA Mathematical Systems Inc.)
Abstract : In the modeling of real-life applications, we encounter some non-linearity.
In such a case, interior-point algorithm is one approach to choose because it is good at finding locally optimal solutions quickly for large-scale mildly nonlinear problems.
In this talk, we discuss some implementation issues related to interior-point method that originates from non-linearity, and review some applications.

[04650] Tropical convexity: application to linear programming and mean-payoff games

Format : Talk at Waseda University
Author(s) : Stephane Louis Gaubert (INRIA and Ecole polytechnique)
Abstract : Tropical geometry sets up a bridge between linear programming and mean-payoff games, exploiting a correspondence between generic convex semi-algebraic programs over nonarchimedean fields and different classes of zero-sum repeated games. We will discuss the application of this correspondence to the complexity analysis of interior point methods, showing in particular that no self-concordant barrier interior point method is strongly polynomial. This is based on a series of works with Allamigeon, Benchimol, Joswig and Vandame.

02440 (2/3) : 2E @A502 [Chair: Marcia Fampa]

[04479] Breaking the quadratic gap for strongly polynomial solvers to combinatorial linear programs

Format : Talk at Waseda University
Author(s) : Bento Natura (Georgia Tech)
Abstract : Recent years have seen tremendous progress in high-accuracy solvers for Maximum Flow, Minimum-Cost Flow and general Linear Programs (LP). Progress on strongly polynomial solvers for combinatorial LP on the other hand has stalled. For combinatorial LP beyond directed graphs this gap between exact and high-accuracy solvers is currently quadratic. We finally break the quadratic gap and design a strongly polynomial interior-point-method for combinatorial LP, which reduces the gap to only a linear factor.

[03172] Computational challenges in Flag Algebra proofs

Format : Talk at Waseda University
Author(s) : Aldo Kiem (Zuse Institute Berlin)Sebastian Pokutta (ZIB / TUB)Christoph Spiegel (Zuse Institute Berlin)
Abstract : Introduced by Razborov in 2007, flag algebras are a potent tool for computer-assisted proofs in extremal combinatorics. They combine first-order logic, model theory, and semidefinite programming to tackle classical Turán and Ramsey theory problems. This talk explores computational challenges, symmetry exploitation, and optimization ideas to broaden the method's scope. We'll demonstrate its practical application by determining the 4-color Ramsey multiplicity of triangles.

[03673] Improving Lower Bounds for Large Scale QAPs

Format : Talk at Waseda University
Author(s) : Koichi Fujii (tokyo institute of technology)
Abstract : We report our progress on the project for solving large scale quadratic assignment problems (QAPs).
Our main approach to solve QAPs is a parallel branch-and-bound method using the Ubiquity Generator framework (UG), utilizing Newton-bracketing method to solve doubly nonnegative cone (DNN) relaxations.
In this talk, we present some preliminary numerical results of DNN-based branch-and-bound method and report the result that we have succeeded to update the lower bounds of instances in QAPLIB.

[03941] Closing Nonzero Duality Gaps in SDPs through Perturbations

Format : Talk at Waseda University
Author(s) : Takashi Tsuchiya (National Graduate Institute for Policy Studies)Bruno Lourenço (Institute of Statistical Mathematics)Masakazu Muramatsu (The University of Electro-Communication)Takayuki Okuno (Seikei University)
Abstract : Consider a primal-dual pair of SDP with nonzero duality gap. There are arbitrary small perturbations to make the pair strongly feasible with a common primal-dual optimal value v, say, zeroing duality gap. v is not well-defined at zero (unperturbed problem) since the primal and dual have different optimal values, but it is continuous elsewhere. We analyze properties of v around zero to demonstrate a few surprising and beautiful properties and establish connections to interior-point methods.

02440 (3/3) : 3C @A502 [Chair: Hiroshi Hirai]

[04092] Maximum-Entropy Sampling: Algorithms and Application

Format : Talk at Waseda University
Author(s) : Jon Lee (University of Michigan)Marcia Fampa (Federal University of Rio de Janeiro)
Abstract : The maximum-entropy sampling problem (MESP) is to select a subset, of given size s, from a set of correlated Gaussian random variables, so as to maximize the differential entropy. MESP sits at the intersection of optimization, data science and information theory, and so it has attracted a lot of recent attention. We will give a broad overview of algorithmic work, concentrating on the many useful techniques related to various convex relaxations.

[03117] A role of semidefinite relaxation in mathematics of phase retrieval

Format : Talk at Waseda University
Author(s) : Ryoko Oishi-Tomiyasu (Kyushu University)
Abstract : In phase retrieval, a signal x is recovered from the amplitude |Ax| for a fixed linear operation A such as the Fourier transform. In crystallography, x is a sum of finitely many Gaussian-like functions that represents the periodic discrete structure of atoms. We introduce that semidefinite relaxation works to determine the uniqueness of solutions and gain all the global solutions in this type of problem, mentioning an application found in a joint work with scientists.

[03176] Exact Convergence Rate of Alternating Projections

Format : Talk at Waseda University
Author(s) : Yoshiyuki Sekiguchi (Tokyo University of Marine Science and Technology)Hiroyuki Ochiai (Kyushu University)Hayato Waki (Kyushu University)
Abstract : We investigate the exact convergence rate of alternating projections for the nontransversal intersection of S_+^n and an affine space. When the affine space is a line, we analyze the Newton polygon associated with the characteristic polynomial of the parametrizing matrix of the line and show that the convergence rate can be estimated by comparing ranks of submatrices of the basis matrix. We also investigate alternating projections for S_+^3 and a three dimensional affine space.

[05522] Bridging Distributional and Risk-sensitive Reinforcement Learning with Provable Regret Bounds

Format : Talk at Waseda University
Author(s) : Zhiquan Luo Zhi-Quan Luo (The Chinese University of Hong Kong, Shenzhen)
Abstract : Risk-sensitive decision-making is vital in high-stakes fields like finance and medicine. Risk-sensitive reinforcement learning maximizes a risk measure instead of expected return. The exponential risk measure is widely used but involves complex algorithms and regret analysis. We propose a novel distributional reinforcement learning (DRL) algorithm for RSRL with a regret guarantee. Our approach utilizes risk-sensitive distributional dynamic programming and provides a regret upper bound via distributional optimism, while fixing and tightening the minimax lower bound.

[02445] Advances in Optimization II

[05543] Optimal Diagonal Preconditioning: Theory and Practice

Format : Talk at Waseda University
Author(s) : Yinyu Ye (Stanford University)
Abstract : Preconditioning has long been a staple technique in optimization, often applied to reduce the condition number of a matrix and to speed up the convergence of algorithms. Although there are many popular preconditioning techniques in practice, most lack guarantees on reductions in condition number, and the degree to which we can improve over existing heuristic preconditioners remains an important question. In this paper, we study the problem of optimal diagonal preconditioning, that achieves maximal reduction in the condition number of any full-rank matrix by scaling its rows and/or columns with positive numbers. We first reformulate the problem as a quasi-convex optimization problem and provide a simple algorithm based on bisection. Then we develop an interior point algorithm with $O(\log(1/\epsilon))$ iteration complexity. Next, we specialize to one-sided optimal diagonal preconditioning problems, and demonstrate that they can be formulated as standard dual SDP problems. We then develop efficient customized solvers for the SDP approach and study the empirical performance of our optimal diagonal preconditioning procedures through extensive experiments. Our findings suggest that optimal diagonal preconditioners can significantly improve upon existing heuristics-based diagonal preconditioners at reducing condition numbers, and our SDP approach can find such optimal preconditioners efficiently for large matrices. We also extend our SDP approach to compute optimal mixtures of base preconditioners, which further improves its scalability and applicability.

[03259] Smart Initial Basis Selection for Linear Programs

Format : Talk at Waseda University
Author(s) : Yong Zhang (Huawei Technologies Canada Co., Ltd)
Abstract : The simplex method, introduced by Dantzig more than half a century ago, is still to date one of the most efficient methods for solving large-scale linear programming (LP) problems. While the simplex method is known to have the finite termination property under mild assumptions, the number of iterations until optimality largely

depends on the choice of initial basis. Existing strategies for selecting an advanced initial basis are mostly rule-based. These rules usually require extensive expert knowledge and empirical study to develop. Yet, many of them fail to exhibit consistent improvement, even for LP problems that arise in a single application scenario. In this paper, we propose a learning-based approach for initial basis selection. We employ graph neural networks as a building block and develop a model that attempts to capture the relationship between LP problems and their optimal bases. In addition, during the inference phase, we supplement the learning-based prediction with linear algebra tricks to ensure the validity of the generated initial basis. We demonstrate through extensive experiments with state-of-the-art simplex solvers that the proposed strategy can achieve substantial speedup and consistently outperforms existing rule-based methods. Furthermore, we extend the proposed approach to generating restricted master problems for column generation methods and present encouraging numerical results.

[04683] Interior Point Methods are Not Worse Than Simplex

Format : Talk at Waseda University
Author(s) : Daniel Dadush (CWI)Xavier Allamigeon (Inria, CMAP, CNRS, Ecole Polytechnique)Bento Natura (Georgia Tech)Georg Loho (University of Twente)Laszlo Vegh (London School of Economics)
Abstract : We develop a path-following IPM whose number of iterations is at most $O(n^{1.5} \log n)$ times the number of segments of any piecewise linear curve traversing the wide neighborhood of the central path. Our IPM matches the number of iterations of any path following IPM up to this polynomial factor and admits an $O(2^n n^{1.5} \log n)$ upper bound. The latter result complements an exponential lower bound of Allamigeon et al (SIAGA 18) for IPMs.

[03175] Analysis of Algorithms on Growing Networks

Format : Talk at Waseda University
Author(s) : Shuji Kijima (Shiga University)
Abstract : Real networks are often dynamic. Nevertheless, very few is known about the theoretical analysis of algorithms on dynamic networks. This talk is concerned with some analysis techniques for dynamics on networks with a moderately increasing number of vertices regarding the growing speed.

02445 (2/3) : 3E @A502 [Chair: Stéphane Gaubert]

[03367] Two constructive techniques for producing linear extended formulations

Format : Talk at Waseda University
Author(s) : Yuri Faenza (Columbia University)
Abstract : We will present two constructive techniques for producing extended formulations: one based on communication protocols, the other on Birkhoff's representation theorem for finite distributive lattices. We also show applications to some problems, mostly in combinatorial optimization.

[03641] Interior-point methods on manifolds: theory and applications

Format : Talk at Waseda University
Author(s) : Hiroshi Hirai (Nagoya University)Harold Nieuwboer (University of Amsterdam)Michael Walter (Ruhr University)
Abstract : We extend the theory of self-concordance for manifolds, and establish analogous results as in the Euclidean setting, such as quadratic convergence of Newton's method and polynomial iteration complexity of the path-following method. We show that on symmetric spaces of nonpositive curvature, the squared distance function to a point is self-concordant. These results are applied to norm minimization problems for reductive group actions, and to other geometric problems, such as minimum enclosing balls and geometric medians.

[03069] Alternating Linear Minimization: Revisiting von Neumann's alternating projections

Format : Talk at Waseda University
Author(s) : Gábor Braun (ZIB)Sebastian Pokutta (ZIB / TUB)Robert Weismantel (ETH)
Abstract : In 1933 von Neumann proved a beautiful result that one can compute a point in the intersection of two convex sets (under suitable assumptions) by alternating projections, i.e., successively projecting on one set and then the other. This algorithm assumes that one has access to projection operators for both sets. Here we consider the much weaker setup where we have only access to linear minimization oracles over the convex sets and present

an algorithm to find a point in the intersection of two convex sets. Moreover, we provide a modification of the algorithm to minimize a linear function over the intersection and discuss further extensions.

[03052] Combinatorial and geometric aspects of linear optimization

Format : Talk at Waseda University
Author(s) : Antoine Deza (McMaster University)
Abstract : Worst-case constructions have helped providing a deeper understanding of how the structural properties of the input affect the computational performance of linear optimization. Recent examples include the construction of Allamigeon et al. for which the interior point method performs an exponential number of iterations. In a similar spirit, recent lower bounds on the number of simplex pivots required in the worst-case to perform linear optimization over a lattice polytope are presented.

[05126] On Some Optimization-Related Issues In Deep Learning

Format : Talk at Waseda University
Author(s) : Yin Zhang (The Chinese University of Hong Kong (Shenzhen))
Abstract : Despite many great advances achieved by deep learning, our understandings of it remain sorely limited. In this talk, we discuss a few optimization-related issues in deep learning, including model trainability, gradient stability, over-parameterization, quality of (globally optimal) solutions, interpolation versus extrapolation. We will introduce a new neural-layer architecture using Householder weighting and Absolute-value activating that has a low complexity but guarantees gradient stability and 1-Lipschitz continuity. We empirically evaluate the capacities of the proposed new layer and demonstrate its potential usefulness.

[03071] Creating Collaborative Data Representations Using Matrix Manifold Optimization

Format : Talk at Waseda University
Author(s) : Keiyu Nosaka (University of Tsukuba)Akiko Yoshise (University of Tsukuba)
Abstract : The trade-off between performance and privacy is a pain in the neck for centralized machine learning methods. Fed-DR-Filter and Data Collaboration Analysis (DCA) can overcome this difficulty through Collaborative Data Representation (CDR). We propose an alternative algorithm for CDR creation, utilizing matrix manifold optimization. We devise machine learning models in the DCA setting to evaluate algorithms. The results show that our algorithm outperforms the state-of-the-art approach in mean recognition performance within acceptable computation time.

[03047] Accelerated and Sparse Algorithms for Approximate Personalized PageRank

Format : Talk at Waseda University
Author(s) : David Martinez-Rubio (Zuse Institute Berlin)Elias Wirth (Zuse Institute Berlin)Sebastian Pokutta (Zuse Institute Berlin)
Abstract : It has recently been shown that ISTA, an unaccelerated optimization first-order method, presents sparse updates for the ℓ_1-regularized personalized PageRank problem, leading to cheap iteration complexity.
In this talk I'll explain our work on accelerated optimization algorithms for this problem that also perform sparse updates leading to faster convergence for certain parameter regimes.
Further, we design a conjugate directions algorithm that achieves an exact solution while exploiting sparsity.
Our findings apply beyond PageRank and work for any quadratic objective whose Hessian is a positive-definite M-matrix.

[04893] Optimal Composition Ordering for Linear Functions

Format : Talk at Waseda University
Author(s) : Kazuhisa Makino (Kyoto Univ.)
Abstract : We outline the composition ordering problem of linear functions, i.e.,
given n linear functions $f_1,\dots,f_n:\mathbb{R}\to\mathbb{R}$
and a constant $c\in\mathbb{R}$, we construct a permutation $\sigma:[n]\to[n]$ that
minimizes $f_{\sigma(n)}\circ f_{\sigma(n-1)}\circ\cdots\circ f_{\sigma(1)}(c)$, where $[n]=\{1,\dots,n\}$.

We discuss structural properties of optimal solutions for the problem as well as the current status of the complexity issue. We also consider the multiplication ordering of n matrices.

[02447] Advances in Diesel Engine Design and Control for Industry 4.0

Session Time & Room :

02447 (1/3) : 5B (Aug.25, 10:40-12:20) @E819

02447 (2/3) : 5C (Aug.25, 13:20-15:00) @E819

02447 (3/3) : 5D (Aug.25, 15:30-17:10) @E819

Type : Proposal of Minisymposium
Abstract : With the advent of Industry 4.0, the demand for efficient and eco-friendly engines has increased. This mini-symposium will present recent research in diesel engine design and control to address the challenges and opportunities of Industry 4.0. Speakers will describe current directions of research and methods relating to optimal nozzle design, combustion limits investigation, intake plenum design improvement, in-cylinder combustion investigation, distinguishability of linear control systems, GAs based PID controller parameter tuning, XAI-based fault diagnosis, and intelligent control systems. The symposium will be of interest to those working in the field of diesel engines and related areas.
Organizer(s) : Prof. Dr. Khalid Saifullah, Dr. Athar Kharal
Classification : 74A99, 74M05
Minisymposium Program :

02447 (1/3) : 5B @E819

[03642] XAI Based Fault Diagnosis for Steel Plates Manufacturing

Author(s) : Athar Kharal (Center for Advanced Studies in Pure and Applied Mathematics (CASPAM), Bahuddin Zakariya University, Multan)
Abstract : This work uses Explainable Artificial Intelligence tools to develop a fault diagnosis classifier for steel plates. By incorporating insights from techniques such as Ceteris Paribus, Partial Dependence and Breakdown profiles, IF-THEN rules, and an optimized Random Forest and Association Rule Mining, the methodology sought to achieve a high performance using a single ensemble classifier. The methodology is based on medoids and SMOTE and provides valuable insights for experts in the steel manufacturing industry.

[04142] Distinguishability of linear control systems

Author(s) : Awais Younus (CASPAM, BZU, Multan)Zoubia Dastgeer (CASPAM, BZU, Multan)
Abstract : Consideration of the observabilities of linear hybrid descriptor systems implies the distinguishability of these systems to be imperative. We have obtained some results related to the distinguishability of the descriptor systems. Also, we have attained equivalent criteria for input distinguishability of descriptor systems with a regular pencil.

[04661] Optimizing Flow Parameters in Convergent Diesel Nozzles with Rough Walls

Author(s) : Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)Ms Saima Zainab (The Women University, Multan)
Abstract : Fuel injector nozzle geometry affect the diesel engine spray and combustion characteristics. This paper explores the effects of nozzle geometry parameters, wall roughness parameters and pressure difference on swirl number, mass flow rate, turbulent kinetic energy and vapor volume fraction. Large-eddy simulations and k-ω SST Transient models are used to validate the modelling approach. Response Surface Method and Design of Experiment are used to optimize swirl number, turbulent kinetic energy and their linear combination.

[04696] In-Cylinder Combustion Investigation Against Some Injection Characteristics

Author(s) : Anam Ali (CASPAM BZU Pakistan)Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)
Abstract : This study investigates the impact of fuel injection timing and spray angle on combustion characteristics of a heavy-duty diesel engine. CFD simulations are carried out by employing appropriate models to represent different physical and chemical processes. These parameters have significant role in engine design for enhanced combustion efficiency and engine performance. Late injection results into relatively smooth burning rates and considerably lower temperature and pressure peaks without significantly compromising the combustion quality and engine power.

02447 (2/3) : 5C @E819

[04704] An Intelligent Control System for a Diesel Engine l

Author(s) : Amna Batool Syeda (Mphil scholar, Center For Advanced Studies in Pure and Applied Mathematics, BZU Multan, Pakistan)Khalid Saifullah Syed (Director of Center for Advanced Studies in Pure and Applied Mathematics, BZU Multan, Pakistan)
Abstract : We consider the design of an intelligent, efficient, optimal, robust and hybrid control system based on the adaptive neuro-fuzzy inference system and PID controllers. The system will control air, fuel and EGR for optimal performance and minimum emissions. The system design may involve deep learning of recurrent neural network having several hidden layers with LSTM layer to make the system efficient and more accurate. Optimal control may be incorporated using quadratic programming / genetic algorithm.

[04750] In-Cylinder Combustion Investigation Against Some Injection Characteristics

Author(s) : Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)Anam Ali (CASPAM BZU Pakistan)
Abstract : This study investigates the impact of fuel injection timing and spray angle on combustion characteristics of a heavy-duty diesel engine. CFD simulations are carried out by employing appropriate models to represent different physical and chemical processes. These parameters have significant role in engine design for enhanced combustion efficiency and engine performance. Late injection results into relatively smooth burning rates and considerably lower temperature and pressure peaks without significantly compromising the combustion quality and engine power.

[04780] In-Cylinder Combustion Investigation Against Some Injection Characteristics

Author(s) : Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)Anam Ali (CASPAM BZU Pakistan)
Abstract : This study investigates the impact of fuel injection timing and spray angle on combustion characteristics of a heavy-duty diesel engine. CFD simulations are carried out by employing appropriate models to represent different physical and chemical processes. These parameters have significant role in engine design for enhanced combustion efficiency and engine performance. Late injection results into relatively smooth burning rates and considerably lower temperature and pressure peaks without significantly compromising the combustion quality and engine power.

[04965] Intake Plenum Design Improvement for a 12-Cylinder Diesel Engine

Author(s) : Ms Saima Zainab (The Women University, Multan)Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)
Abstract : The air flow in engine plenum is complex due to multidimensionality and transient nature of engine operation. This study describes the design modification of intake plenum geometry of a V12 diesel engine and analyses the effects on flow parameters. The original design was found to have strict limits, making it difficult to enhance engine efficiency. However, the modified design is more energy efficient, with greater volumetric efficiency, increased mass flow rate, and turbulent kinetic energy.

02447 (3/3) : 5D @E819

[05053] Numerical Investigation of HCCI Combustion in the High Pressure Engine

Author(s) : Rafia Waqar (Bahauddin Zakariya University, Multan)Khalid Saifullah Syed (Centre for Advanced Studies in Pure and Applied Mathematics, Bahauddin Zakariya University, Multan)
Abstract : This study numerically investigates Homogeneous Charge Compression Ignition (HCCI) combustion in a heavy duty engine operating at 4 MPa boosted intake pressure. Effect of variations in charge composition and temperature on combustion performance parameters such as indicated mean effective pressure, indicated torque, indicated power, indicated specific fuel consumption and fuel efficiency are analyzed. Maximum fuel efficiency (~ 47%) is obtained for equivalence ratios between 0.09 – 0.2 for initial temperatures 350 K and 400 K.

[02448] Verified Numerical Computations and Applications

Session Time & Room :

02448 (1/4) : 2C (Aug.22, 13:20-15:00) @E604

02448 (2/4) : 2D (Aug.22, 15:30-17:10) @E604

02448 (3/4) : 2E (Aug.22, 17:40-19:20) @E604

02448 (4/4) : 3C (Aug.23, 13:20-15:00) @E604

Type : Proposal of Minisymposium
Abstract : In recent decades, the concept of verified numerical computations and computer-assisted proofs is gaining increasing attention and importance.
These methods prove mathematically rigorous results using a combination of analytical arguments such as fixed-point theorems and numerical computations.
This minisymposium focuses on some general tools of accurate and verified numerical computations for the solution of linear and nonlinear systems and eigenvalue problems together with their applications to the proof of solvability and uniqueness for ordinary and partial differential equations.
New developments in that area will be presented.
Organizer(s) : Takeshi Ogita, Katsuhisa Ozaki, Siegfried M. Rump, Kazuaki Tanaka
Classification : 65G20, 65G40, Verified Numerical Computations
Minisymposium Program :

[02902] High relative accuracy computing with the Cauchon algorithm

Format : Talk at Waseda University
Author(s) : Juergen Garloff (University Konstanz)Mohammad Adm (Palestine Polytechnic University Hebron)Fatima Rasheed (Palestine Polytechnic University Hebron)
Abstract : We present the condensed form of the so-called Cauchon Algorithm and reformulate the computations in such a way that they can be performed without any subtraction of numbers of equal sign. This provides the basis for an algorithm needing $O(n^3)$ arithmetic operations for the computation of all eigenvalues of an n-by-n nonsingular totally nonnegative matrix, i.e., a matrix having all its minors nonnegative, with guaranteed high relative accuracy, independently of the condition number of the matrix.

[03658] Floating-point matrices with specified solutions for linear algebra problems

Format : Talk at Waseda University
Author(s) : Katsuhisa Ozaki (Shibaura Institute of Technology)Yuki Uchino (Shibaura Institute of Technology)Takeshi Terao (Kyushu University)
Abstract : This research aims to rigorously verify the accuracy of the numerical results for numerical linear

algebra problems. If an exact solution to a problem is known in advance, we can observe the relative error of the computed result. We proposed methods that generate a test problem based on an error-free transformation of floating-point numbers. We focus on liner systems, eigenvalue decomposition, singular value decomposition, and least squares problems with specified solutions.

[05571] Adaptive precision sparse matrix-product and application to Krylov solvers

Format : Online Talk on Zoom
Author(s) : Stef Graillat (LIP6, Sorbonne Université)Fabienne Jezequel (LIP6, Sorbonne Université)Theo Mary (Sorbonne Université, CNRS, LIP6)Romeo Molina (Sorbonne Université, CNRS)
Abstract : We introduce a mixed precision algorithm for computing sparse matrix-vector products and use it to accelerate the solution of sparse linear systems by iterative methods. Our approach is based on the idea of adapting the precision of each matrix element to their magnitude: we split the elements into buckets and use progressively lower precisions for the buckets of progressively smaller elements. We carry out a rounding error analysis of this algorithm that provides us with an explicit rule to decide which element goes into which bucket and allows us to rigorously control the accuracy of the algorithm. We implement the algorithm on a multicore computer and obtain significant speedups (up to a factor 7×) with respect to uniform precision algorithms, without loss of accuracy, on a range of sparse matrices from real-life applications. We showcase the effectiveness of our algorithm by plugging it into various Krylov solvers for sparse linear systems and observe that the convergence of the solution is essentially unaffected by the use of adaptive precision.

[05577] Iterative refinement for an eigenpair subset of real symmetric matrices

Format : Talk at Waseda University
Author(s) : Takeshi Terao (Kyushu University)Toshiyuki Imamura (RIKEN Center for Computational Science)Katsuhisa Ozaki (Shibaura Institute of Technology)
Abstract : Numerical computation for eigenvalue decomposition plays a crucial role in many scientific fields, and highly accurate eigenpairs are required in certain domains. A novel method was proposed in this study for the iterative refinement of the eigenpair of a real symmetric matrix, which is based on the Ogita-Aishima method and uses compact WY representation. The proposed method can refine the accuracy of a partial eigenpair without using a full eigenvector matrix.

02448 (2/4) : 2D @E604 [Chair: Yoshitaka Watanabe]

[05276] Lower Bounds for Smallest Singular-Values of Asymptotic Diagonal Dominant Matrices

Format : Talk at Waseda University
Author(s) : Shin'ichi Oishi (Waseda University)
Abstract : This article presents three classes of real square matrices. They are models of coefficient matrices of linearized Galerkin's equations of first order nonlinear delay differential equations with smooth nonlinearity. This paper shows results of computer experiments stating that the minimum singular values of these matrices are unchanged even if orders of matrices are increased. A theorem is presented based on the Schur complement. Through it, tight lower bounds are derived for the minimum singular values of such three matrices. It is proved that these lower bounds are unchanged even if orders of matrices are increased.

[05029] Error estimation for the FEM solution with a few bad elements

Format : Talk at Waseda University
Author(s) : Kenta Kobayashi (Hitotsubashi University)
Abstract : In conventional error analysis for the finite element method, even one bad element results in poor error estimation. However, numerical results suggest that a few bad elements do not lead to an increase in error. We have provided theoretical proof for this fact, together with the error estimation, that under certain conditions, the presence of a few bad elements does not worsen the error of the finite element method.

[03173] Verified Numerical Computations for multiple solutions of the Henon equation

Format : Talk at Waseda University

Author(s) : Taisei Asai (Waseda University)Kazuaki Tanaka (Waseda University)Shin'ichi Oishi (Waseda University)

Abstract : In this talk, we describe a numerical verification of the Henon equation in which some asymmetric solutions arise due to the nonlinear term.
The existence of multiple solutions is verified on various domains, and the relationship between the domain and the symmetry of the solution will be discussed.

[05290] Rigorous solution-enclosures of elliptic boundary value problems between piecewise linear functions

Format : Talk at Waseda University

Author(s) : Kazuaki Tanaka (Waseda University)

Abstract : Sub- and super-solutions are useful for obtaining stable solutions of elliptic boundary value problems. However, their conventional definition requires smoothness, which makes it difficult to construct sub- and super-solutions using piecewise linear functions. To overcome this issue, we propose a definition that uses a variational inequality and constrained test functions. We show that the generalized sub- and super-solutions enclose the desired solutions, and that even a simple difference method can construct sub- and super-solutions that enclose the true solutions.

02448 (3/4) : 2E @E604 [Chair: Kenta Kobayashi]

[04361] Verified computation for shape derivative of the Laplacian eigenvalues

Format : Talk at Waseda University

Author(s) : Ryoki Endo (Niigata University)Xuefeng Liu (Niigata University)

Abstract : The shape derivative of Laplacian eigenvalues with respect to domain deformations was theoretically investigated by Hadamard in the early 20th century. However, the rigorous computation of these derivatives is not an easy task, since there exists the singularity for repeated eigenvalues. In this study, we propose a verified computation method for the shape derivative of Laplacian eigenvalues using guaranteed computation of both eigenvalues and eigenfunctions.

[04568] Constructive error estimates for a full-discretized periodic solution of heat equation

Format : Talk at Waseda University

Author(s) : Takuma Kimura (Saga University)Teruya Minamoto (Saga University)Mitsuhiro T. Nakao (Waseda University)

Abstract : In this talk, we consider the constructive a priori error estimates for a full discrete numerical solution of the heat equation with time-periodic condition;
$\frac{\partial u}{\partial t} - \nu\Delta u = f(x,t)$ in $\Omega \times J, u(x,t) = 0$ on $\partial\Omega \times J, u(x,0) = u(x,T)$ on Ω.
Our numerical scheme is based on the finite element semi-discretization in space direction combined with the Fourier expansion in time.
Several numerical examples will be shown to illustrate the theoretical results.

[03685] A Numerical verification method for a self-similar solution to the linear elliptic differential equation

Format : Talk at Waseda University

Author(s) : Kouta Sekine (Chiba Institute of Technology)Taiyou Fuse (Chiba Institute of Technology)

Abstract : In this talk, we propose a numerical verification method for self-similar solutions of linear partial differential equations on ({\mathbb R}) using the Galerkin approximation with extended Hermite polynomials. In particular, we derive a Gaussian quadrature method for extended Hermite polynomials to errors in numerical quadrature over infinite interval. Also, we also introduce the projection error constant for obtaining the discretisation error of the Hermite-Galerkin approximation.

[04321] A computer-assisted proof for a nonlinear differential equation involved with self-similar blowup in wave equations

Format : Talk at Waseda University
Author(s) : Yoshitaka Watanabe (Kyushu University)Kaori Nagatou (Karlsruhe Institute of Technology)Michael Plum (Karlsruhe Institute of Technology)Birgit Schörkhuber (University of Innsbruck)Mitsuhiro T. Nakao (Waseda University)
Abstract : An existence proof with its specific shape of a non-trivial solution of a nonlinear ordinary differential equation involved with self-similar blowup in three-dimensional wave equations is presented. The proof is computer-assisted based on a fixed-point and Newton-type formulation, and the result takes into account the effects of rounding errors of floating-point arithmetic in computer.

02448 (4/4) : 3C @E604

[02458] Progress and Challenges in Extreme Scale Computing and Big Data

Session Time & Room :

02458 (1/3) : 2C (Aug.22, 13:20-15:00) @D101

02458 (2/3) : 2D (Aug.22, 15:30-17:10) @D101

02458 (3/3) : 2E (Aug.22, 17:40-19:20) @D101

Type : Proposal of Minisymposium
Abstract : Extreme scale computing efforts have resulted in numerous advances for multicore and accelerator based scalable systems. In addition, large-scale applications must increasingly deal with data management and analysis as a first-class concern. Therefore, new applications often have to manage distributed and parallel computing, and have to manage workflows of different tasks, such as computing, data analytics, machine learning, visualization, etc. In this MS, we present some of the latest work in scalable algorithms, programming paradigms, and libraries for next generation computing platforms. Furthermore, we discuss efforts to better incorporate data science concerns as an important component of our scientific workflows.

[05261] Toward Post-Exascale Software-Ecosystem Sustainment

Format : Talk at Waseda University
Author(s) : Michael Heroux (Sandia National Labs)
Abstract : The US Department of Energy (DOE) Exascale Computing Project (ECP) is ending soon. ECP exhibited the value of sustained and coordinated software development and delivery and DOE is exploring approaches to sustain the ecosystem that ECP produced.

In this talk, we discuss some of the key goals and strategies under consideration for post-ECP software-ecosystem sustainment. We consider organizational and collaboration strategies, processes, and tools that can help the community realize sustainment beyond the end of ECP.

[03388] Task-based hybrid parallel matrix factorization for distributed memory environment

Format : Talk at Waseda University
Author(s) : Tomohiro Suzuki (University of YamanashiUniversity)
Abstract : The task parallel approach provided by OpenMP has achieved great success in shared memory environments. In distributed memory environments, an interoperability issue exists between MPI and OpenMP. Several techniques have been proposed to address the issue. However, these proposed methods require a high level of thread support in MPI, so they can only work in limited environments.
In this presentation, basic experimental results performed on the Wisteria-O system will be presented.

[03651] Accelerating lattice Boltzmann method with GPU and C++ standard parallelization

Format : Talk at Waseda University
Author(s) : Ziheng Yuan (The University of Tokyo)Takashi Shimokawabe (The University of Tokyo)
Abstract : In recent years, with the increasing use of GPUs as accelerators in the HPC platform, using C++ standard parallel language as a GPU programming language has also attracted attention. Compared with traditional parallel programming languages, C++ standard parallel language for programming has advantages such as readability and maintainability of the code. This talk intends to introduce the application of C++ standard parallel language in fluid simulation using the lattice kinetic scheme (LKS), an extended lattice Boltzmann method (LBM), and discusses its performance.

[05041] GPU-accelerated viscoelastic crustal deformation analysis with data-driven method

Format : Talk at Waseda University
Author(s) : Sota Murakami (The University of Tokyoyo)Kohei Fujita (The University of Tokyo)Tsuyoshi Ichimura (The University of Tokyo)Takane Hori (Japan Agency for Marine-Earth Science and Technology)Muneo Hori (Japan Agency for Marine-Earth Science and Technology)Maddegedara Lalith (The University of Tokyo)Naonori Ueda (RIKEN)
Abstract : We developed a viscoelastic analysis solver with data-driven method on GPUs for fast computation of highly detailed 3D crustal structure models. Here, the initial solution is obtained with high accuracy using a data-driven predictor based on previous time-step results, which reduces the number of multi-grid solver iterations and thus reduces the computation cost. The algorithm is designed to be suitable for GPUs. The developed GPU-based solver attained 8.6-fold speedup from the state-of-art GPU-based multi-grid solver.

02458 (2/3) : 2D @D101 [Chair: Kengo Nakajima]

[03035] System-Wide Coupling Communication for Heterogeneous Computing Systems

Format : Talk at Waseda University
Author(s) : Shinji Sumimoto (The University of Tokyo)Takashi Arakawa (CliMTech Inc.)Yoshio Sakaguchi (Fujitsu Ltd.)Hiroya Matsuba (Hitachi Ltd.)Satoshi Ohshima (Kyushu University)Hisashi Yashiro (National Institute for Environmental Studies)Toshihiro Hanawa (The University of Tokyo)Kengo Nakajima (The University of Tokyo/RIKEN)
Abstract : This talk presents a system-wide coupling communication library to couple multiple MPI programs for heterogeneous coupling computing called h3-Open-SYS/WaitIO (WaitIO for short). WaitIO provides an inter-program communication environment among MPI programs and supports different MPI libraries with various interconnects and processor types. We have developed the WaitIO communication library to realize the environments. We present how WaitIO works and performs in such heterogeneous computing environments.

[03261] h3-Open-UTIL/MP: a coupling library for heterogeneous computing

Format : Talk at Waseda University
Author(s) : Takashi Arakawa (The University of Tokyo)Shinji Sumimoto (The University of Tokyo)Hisashi Yashiro (National Institute for Environmental Studies)Kengo Nakajima (The University of Tokyo/RIKEN)
Abstract : Heterogeneous computing is one of the main topics for recent high-performance computing. The reason is that role of HPC has expanded beyond not only simple simulation but also to large-scale data analysis and machine learning. Based on these backgrounds, we are developing a heterogeneous coupling library h3-Open-UTIL/MP. In our presentation, we will describe the structure and function of h3-Open-UTIL/MP and discuss the results of performance measurements and application examples.

[03652] Modernizing the weather prediction model ICON for extreme-scale computing, a librarization effort

Format : Talk at Waseda University
Author(s) : Yen-Chen Chen (Karlsruhe Institute of Technology)Terry Cojean (Karlsruhe Institute of Technology)Jonas Jucker (CSCS Swiss National Supercomputing Centre)Pradipta Samanta (German Climate Computing Centre)Florian Prill (Deutscher Wetterdienst)Sergey Kosukhin (Max-Planck-Institute for Meteorology)Luis Kornblueh (Max-Planck-Institute for Meteorology)Will Sawyer (CSCS Swiss National Supercomputing Centre)Jörg Behrens (German Climate Computing Centre)Claudia Frauen (German Climate Computing Centre)
Abstract : The weather and climate prediction model ICON was operated since 1999 and has become the forecasting model of more than 30 national weather services. However, the legacy Fortran code restricts its portability to GPU clusters and hinders its parallel performance on modern exascale clusters. The ICON consolidated (ICON-C) project and several related projects aim to make ICON more modular, portable, and suitable for modern extreme-scale parallel computing. This talk focuses on a librarization effort of ICON-C.

[03776] Performance Modeling Challenges in Extreme Scale Computing

Format : Online Talk on Zoom
Author(s) : Ayesha Afzal (Erlangen National High Performance Computing Center (NHR@FAU))
Abstract : In extreme scale computing, analytic performance modeling using first-principles is pre-eminent for optimization. However, it is challenging since the implicit presumption of strict synchronization among all processes is not necessarily accurate. Therefore, for programs with rare synchronization points, simply summing the runtimes predicted by computation and communication performance models is often erroneous.
In my talk, I will highlight the most intriguing insights about intricate hardware-software interactions emerging from this model failure. Interestingly, the hardware bottlenecks permits for non-intuitive spontaneous asynchronicity that helps to get the most of the systems' capabilities and mitigates the communication overhead.

02458 (3/3) : 2E @D101 [Chair: Kengo Nakajima]

[05260] Exascale challenges and opportunities for fundamental research

Format : Online Talk on Zoom
Author(s) : Christophe Calvin (CEA)France Boillod-Cerneux (CEA)Valérie Brenner (CEA)
Abstract : With the exascale come new challenges: the processing of massive data coupled with digital simulation becomes intrinsic to science. In addition, the constraints brought by the architectures of calculation for the exascale impose to also rethink the scientific applications. We are therefore faced with two major challenges. The 1st one: how the new exascale calculators, inscribed in a digital continuum, will be able to provide solutions for the processing of complex workflows combining data processing and simulation. The 2nd, how to design or redesign the applications in order to be able to exploit the architectures of the exascale supercomputers. We will illustrate these 2 challenges through different use cases at the CEA's Fundamental Research Division.

[03605] An algorithm reducing by 2 the number of operations for the PageRank method, and its generalisation for stochastic matrix-vector products

Format : Online Talk on Zoom
Author(s) : serge georges petiton (University of Lille, CNRS)Maxence Vandromme (RATP Smart Systems)
Abstract : We propose an efficient PageRank algorithm that reduces the complexity by a factor two. We implement the method using row-major and column-major sparse matrix formats. The experiments are done on two different Intel processors from recent generations. The column-major storage format version of our method shows good scaling and outperforms the standard PageRank in a majority of cases. We also propose generalisations of this algorithm to the multiplication of stochastic matrices by a vector product.

[03705] Accelerating Cardiac Electrophysiology Simulations using novel AI Hardware

Format : Talk at Waseda University
Author(s) : Johannes Langguth (Simula Research Laboratory)Luk Bjarne Burchard (Simula Research Laboratory)Xing Cai (Simula Research Laboratory)
Abstract : Recent advances in personalized arrhythmia risk prediction show that computational models can provide not only safer but also more accurate results than invasive procedures. However, biophysically accurate simulations require solving linear systems over fine meshes and time resolutions, which require significant computational resources. However, by leveraging sophisticated parallelization patterns as well as non-traditional hardware architectures, it is possible to meet the computational demands of these simulations.

A major recent development in computer hardware was the rise of dedicated accelerator hardware for machine learning applications such as the Graphcore IPUs and Cerebras WSE. These processors have evolved from the experimental state into market-ready products, and they have the potential to constitute the next major architectural shift after GPUs saw widespread adoption a decade ago.

In this talk, we present ongoing work on the parallelization of finite volume computations over an unstructured mesh using these new accelerators. We compare them to traditional CPUs and GPUs and point out challenges and opportunities of this new hardware for extreme scale computing.

[05304] A Medical Data Analytics Framework Transforming Big Data to Better Healthcare

Format : Talk at Waseda University
Author(s) : Weichung Wang (National Taiwan University)
Abstract : Incorporating data science is crucial for the next-generation medical workflows that rely on high-performance computing to analyze large-scale medical data for digital and precision medicine. The "Medical Data Analytics Framework" combines project design, multimodality data, intelligent analytics, medical workflows, regulation, ethics, deployment, and operations to achieve an end-to-end R&D life-cycle in medical AI that positively impacts clinical workflows. This interdisciplinary framework reduces physicians' workload and assists in diagnosing with advanced algorithms and software.

[02470] Chaotic Supremacy Revolution

Session Time & Room :

02470 (1/2) : 4C (Aug.24, 13:20-15:00) @G402

02470 (2/2) : 4D (Aug.24, 15:30-17:10) @G402

Type : Proposal of Minisymposium
Abstract : Chaotic supremacy will be discussed from the perspective of applied mathematics such as applied chaos theory and new device technologies such as laser chaos for terahertz generation and off-shell science. Innovative applied chaos research cases from academia as well as industry, which has been studying applied chaos for many years, will also be presented.
Organizer(s) : Ken Umeno, Fumiyoshi Kuwashima, (4) Takashi Isoshima

Classification : 34H10, 65P20, 34Hxx, Chaos
Minisymposium Program :

02470 (1/2) : 4C @G402

[03810] Chaos-like behavior of two-dimensional optical bistable device with external feedback

Author(s) : Takashi Isoshima (RIKEN-CPR)
Abstract : Bistable system with a spatial expanse can provide a wavefront, an interface between two stable states, that can propagate. We investigate a two-dimensional optical bistable device (2DOBD) based on thermo-optical positive feedback for natural computing including maze exploration. Addition of external feedback to the device can realize complex spatio-temporal behavior. Refractory feedback, inspired by the refractory period of a nerve cell, provides propagating pulse generation, and under some condition, chaotic behavior of the pulses.

[03967] Quantification of Orbital Instability of Chaotic Laser Diodes by Modified Orbital Expansion Exponent

Author(s) : Satoshi Ebisawa (Niigata Institute of Technology)
Abstract : Controlling the strength of orbital instability of chaotic laser, is useful for applications. To realize this, it is important to quantify the characteristics. The chaotic laser has three dynamic variables, but only the amplitude can be easily measured experimentally. Then, we introduce a modified orbital expansion exponent that considers the chaotic laser dynamics. By comparing this with the Lyapunov exponent calculated from the rate equations representing its dynamics, we show the usefulness of proposed exponent.

[03992] Development of MLD-TDS applying spintronic THz emitters excited by laser chaos light

Author(s) : Takeshi Moriyasu (University of Fukui)Ryunosuke Noda (University of Fukui)Kaede Miyaguchi (University of Fukui)Shudai Katono (University of Fukui)Masahiko Tani (University of Fukui)Hideaki Kitahara (University of Fukui)Fumiyoshi Kuwashima (Fukui University of Technology)Mitsutaka Kumakura (University of Fukui)
Abstract : A terahertz time-domain spectrometer with a multimode laser diode as light source (MLD-TDS) is an inexpensive terahertz spectrometer, since an expensive pulse laser system is not used. However, MLD-TDS has not been widely adopted in practical applications due to the sub-optimal radiation efficiency and stability etc. We propose the applying of spintronic THz emitters and laser chaos light into the MLD-TDS system, with the aim of compensating for the deficiencies and enhancing the overall performance.

[04023] Application of entropic chaos degree to Lorenz system

Author(s) : Kei Inoue (Sanyo-Onoda City University)
Abstract : The entropic chaos degree was introduced to measure the chaos of a dynamical system in Information Dynamics. It is computable for any time series, even if the dynamical system is unknown. Recently the extended entropic chaos degree was proposed, equal to the total sum of the Lyapunov exponents under typical chaotic conditions. In this study, I try to measure the chaos of the Lorenz system by the extended entropic chaos degree.

02470 (2/2) : 4D @G402

[04036] Stable THz waves using laser chaos

Author(s) : Fumiyoshi Kuwashima (Fukui Univ. of Tech.)Mona Jarrahi (Electrical and Computer Engineering Department, University of California Los Angeles)Semih Cakmakyapan (Electrical and Computer Engineering Department, University of California Los Angeles)Osamu Morikawa (Chair of Liberal Arts, Japan Coast Guard Academy)Takuya Shirao (Fukui Univ. of Tech.)Kazuyuki Iwao (Fukui Univ. of Tech.)Kazuyoshi Kurihara (School of Education., University. of Fukui)Hideaki Kitahara (Research Center for Development of Far-Infrared Region, University of Fukui)Takashi Furuya (Research Center for Development of Far-Infrared Region, University of Fukui)Yuki Kawakami (National Institute of Technology (KOSEN), Fukui College)Takeshi Moriyasu (UniversFaculty of Engineering, University of Fukuiity of Fukui)Kenji Wada (Osaka Metropolitan University)Makoto Nakajima (Institute of Laser engineering, Osaka Univ.)Masahiko Tani (Research Center for Development of Far-Infrared Region)

Abstract : Efficiency of optical beats in a chaotically oscillating laser is confirmed comparing that of free running CW laser using a highly efficient plasmonic photomixer. The great potential of chaotically oscillating lasers is verified for THz systems. This is one of the proof of Chaotic Supremacy in real system.

[04083] Quantum walk analysis of spatial distribution of dressed-photon-phonon

Author(s) : Motoichi Ohtsu (Research Origin for Dressed Photon)Etsuo Segawa (Yokohama National University)Kenta Yuki (Middenii)Seiken Saito (Kogakuin University)
Abstract : This paper analyzes the spatial distribution of a dressed-photon–phonon (DPP) that is confined by a boron (B) atom-pair in a silicon light-emitting diode by using a two-dimensional quantum walk model. It is confirmed that the DPP is confined by the B atom-pair, which is oriented along a direction perpendicular to that of the incident light propagation. The dependence of the confined DPP probability on the length of the B atom-pair is analyzed.

[04616] Quantum Fields as Category Algebras

Author(s) : Hayato Saigo (Nagahama Institute of Bio-Science and Technology)
Abstract : In the present talk we propose a new approach to quantum fields in terms of category algebras and states on categories. We define quantum fields and their states as category algebras and states on causal categories with partial involution structures. Based on this framework, we propose a foundation for off-shell sciences such as dressed phoon studies.

[05241] Exactly Solvable Chaos and Its Use to Realize Chaotic Supremacy

Author(s) : Ken Umeno (Kyoto University)
Abstract : Theory of exactly solvable chaos, whose ergodic invariant measure is explicitly obtained, is firstly reviewed as a key concept to analyze chaotic supremacy analytically. Superefficient
chaotic Monte Carlo computation is one of the key examples to realize chaotic supremacy.
Then we discuss a possible relation between chaotic supremacy and quantum supremacy from the
view point of the connection of chaotic superefficiency realized by primitive root codes (discretization of exactly solvable chaos) with quantum Grover's algorithm.

[02474] Applied and Computational Dynamics

Session Time & Room :

02474 (1/2) : 2D (Aug.22, 15:30-17:10) @F308

02474 (2/2) : 2E (Aug.22, 17:40-19:20) @F308

Type : Proposal of Minisymposium
Abstract : Understanding the long-term behaviour of a dynamical system is an important challenge that requires many mathematical techniques and numerical tools. Dynamical systems are models with a natural time evolution (discrete or continuous). The invariant sets (fixed points, periodic orbits, invariant manifolds, strange attractors, etc) are all objects that persist beyond the transient phase, and thus carry important information. It is also necessary to understand the bifurcations that occur as model parameters are varied. In this minisymposium, we will learn of new results for analyzing dynamical systems. Examples include passive dynamic walking, Fitzhugh-Nagumo neurons, and self-propelled particle systems.
Organizer(s) : Warwick Tucker (University of Melbourne, Australia), Yoshitaka Saiki (Hitotsubashi University, Japan), Hiroe Oka (Ryukoku University, Japan), Hiroshi Kokubu (Kyoto University, Japan)
Classification : 37Cxx, 37Dxx, 37Nxx, 37Gxx, 28Dxx
Minisymposium Program :

02474 (1/2) : 2D @F308 [Chair: Hiroshi Kokubu]

[03364] Connectedness of graphs of dynamical systems

Format : Talk at Waseda University
Author(s) : James A Yorke (Univ. Of Maryland)Roberto De Leo (Howard Univ.)
Abstract : We have been developing the general theory of graphs of maps or differential equations that works for maps, ordinary differential equations and parabolic partial differential equations. We have a complete theory for the logistic map.

```
  We have created axioms for graphs that can be used to prove results about graphs, axioms that hold
for all of the standard definitions. We prove that the graph is connected under mild hypotheses.
```

[03770] Changes in basin of attraction by homoclinic and heteroclinic tangencies in passive dynamic walking

Format : Talk at Waseda University
Author(s) : Kota Okamoto (Kyoto University)Ippei Obayashi (Okayama University)Hiroshi Kokubu (Kyoto University)Kei Senda (Kyoto University)Kazuo Tsuchiya (Kyoto University)Shinya Aoi (Osaka University)
Abstract : In the passive dynamic walking that walks down a shallow slope without any control or input, countless sudden changes appear in the basin of attraction depending on the slope angle. An infinite number of periodic solutions also appear. We investigated the mechanism of the sudden changes in the basin of attraction of the passive dynamic walking based on the homoclinic and heteroclinic tangencies of the manifolds of the periodic solutions.

[04997] A novel bifurcation in hybrid dynamical systems: a model of human locomotion and its generalization

Format : Talk at Waseda University
Author(s) : Hidetoshi Morita (Shitennoji University)Shinya Aoi (Osaka Univeristy)Kazuo Tsuchiya (Kyoto University)Hiroshi Kokubu (Kyoto University)
Abstract : Aiming to understand the coexistence of walk and run in human locomotion, we study a simpler vertical motion of inverted spring-mass model. We observe the coexistence of two limit cycles between which no unstable periodic orbit lies, unlike the usual coexistence of attractors. We analyze the mechanism of this novel type of coexistence. We further consider a generalized hybrid dynamical systems model, and analyze the corresponding, as well as yet other, behaviors.

[03723] Coupled Hopf bifurcations: interaction between Fitzhugh-Nagumo neurons

Format : Talk at Waseda University
Author(s) : Fátima Drubi (University of Oviedo)Santiago Ibáñez (University of Oviedo)Diego Noriega (University of Oviedo)
Abstract : Coupled dynamical systems allow to model a wide range of phenomena. We are interested in models where identical pieces with simple dynamics are coupled through simple mechanisms, wondering about the complexity that interaction may imply. The coupling of identical families of vector fields exhibiting a Hopf bifurcation is paradigmatic. After discussing a general model, we will focus on the interaction between two Fitzhugh-Nagumo planar systems and study the appearance of Hopf-Pitchfork and Hopf-Hopf bifurcations.

02474 (2/2) : 2E @F308 [Chair: Warwick Tucker]

[04209] A method of computing Morse decomposition via approximate ODE solvers and its application

Format : Talk at Waseda University
Author(s) : Tomoyuki Miyaji (Kyoto University)
Abstract : Computing Conley--Morse graphs for dynamical systems defined by ordinary differential equations using rigorous ODE solvers such as Lohner’s method is suffered from wrapping effects and is computationally expensive. It is especially remarkable when applied to Poincaré maps. In this talk, we apply approximate solvers, such as the Runge--Kutta methods, to computing Morse decomposition. We will discuss its application to Poincaré maps for 4D ODEs arising in modeling the motion of a self-propelled particle.

[03407] Finite-resolution recurrence in dynamical models

Format : Talk at Waseda University
Author(s) : Pawel Pilarczyk (Gdansk University of Technology, Faculty of Applied Physics and Mathematics)Justyna Signerska-Rynkowska (Dioscuri Centre in Topological Data Analysis, Institute of Mathematics of the Polish Academy of Sciences)Grzegorz Graff (Gdansk University of Technology, Faculty of Applied Physics and Mathematics)
Abstract : In order to improve the method for rigorous analysis of global dynamics based on a set-oriented topological approach, introduced by Arai et al. in 2009 (SIAM J. Appl. Dyn. Syst. 8, 757-789), we introduce the notion of finite-resolution recurrence, develop an effective algorithm for its computation, and apply it to a two-dimensional model of a neuron. We additionally use machine learning to distinguish between different types of dynamics observed.

[04891] Reconstruction of stationary measures from `cycles’ in random dynamical systems

Format : Talk at Waseda University
Author(s) : Hiroki Takahasi (Keio Institute of Pure and Applied Sciences)
Abstract : One leading idea in the qualitative understanding of deterministic dynamical systems is to use collections of periodic orbits to structure the dynamics. This idea traces back to Poincar'e, and has been supported by Bowen who proved that periodic orbits of topologically mixing Axiom A diffeomorphisms equidistribute with respect to the measure of maximal entropy. We consider an analogue of Bowen's equidistribution theorem of periodic orbits in the context of simple random dynamical systems.

[03823] Computer verifiable criteria for chaos in piecewise smooth dynamical systems

Format : Talk at Waseda University
Author(s) : Paul Glendinning (University of Manchester)
Abstract : Many theoretical results on chaotic behaviour in piecewise smooth maps rely on relatively simple criteria that could in principle be checked by hand. I will describe some of these results and how they can be implemented numerically. This makes it possible to demonstrate the existence of phenomena such as robust chaos and unstable manifold variability in examples. Many of the results presented are from joint work with D.J.W. Simpson (Massey University, New Zealand).

[02479] Recent advances for modeling, numerical algorithm, and applications in electronic structure calculation

Session Time & Room :

02479 (1/3) : 2E (Aug.22, 17:40-19:20) @E711

02479 (2/3) : 3C (Aug.23, 13:20-15:00) @E711

02479 (3/3) : 3D (Aug.23, 15:30-17:10) @E711

Type : Proposal of Minisymposium
Abstract : With the rapid development of the research in the electronic structure calculations, new mechanisms and phenomenon are constantly being discovered, which bring the challenging on mathematical modeling and related analysis. Meanwhile, the development of the computational hardware also provides chances to the new algorithm design and analysis. In this mini-symposium, experts from mathematics, physics, etc., would share their recent progress in the research of the electronic structure calculations, and will discuss together towards the potential applications in areas such as computational quantum chemistry, nano-optics.

Organizer(s) : Zhenning Cai, Guanghui Hu, Hehu Xie
Classification : 65N30, 65N25, 65M55, 65Z05
Minisymposium Program :

02479 (1/3) : 2E @E711 [Chair: Guanghui Hu]

[04686] Numerical method for the Elasticity Transmission Eigenvalues

Format : Talk at Waseda University
Author(s) : xia ji (Beijing institute of technology)
Abstract : We develop a discontinuous Galerkin method computing a few smallest elasticity transmission eigenvalues, which are of practical importance in inverse scattering theory. For high order problems, DG methods are competitive since they use simple basis functions, the numerical implementation is much easier compared with classical conforming finite element methods. In this talk, we propose an interior penalty discontinuous Galerkin method using C0 Lagrange elements (C0IP) for the transmission eigenvalue problem for elastic waves and prove the optimal convergence. The method is applied to several examples and its effectiveness is validated.

[03287] A multi-mesh adaptive finite element method for Kohn--Sham equation

Format : Talk at Waseda University
Author(s) : Yang Kuang (Guangdong University of Technology)
Abstract : We present a multi-mesh adaptive finite element method for solving the Kohn–Sham (KS) equation. Specifically, the KS equation and the Poisson equation corresponding to the Hartree potential is solved in two different adaptive meshes on the same computational domain. With the presented method, we are able to evaluate the Hartree potential and Hartree energy more accurately, so as to reach a better accuracy with less computational cost in the all-electron calculations.

[03432] Mathematical theory and numerical methods for Bose-Einstein condensation with higher order interactions

Format : Talk at Waseda University
Author(s) : Xinran Ruan (Capital Normal University)Weizhu Bao (National University of Singapore)Yongyong Cai (Beijing Normal University)
Abstract : The binary interaction in Gross-Pitaevskii equation, which is a big success in describing Bose-Einstein condensate, is typically chosen as Fermi contact interaction. However, in certain cases, higher order interaction (HOI) needs to be included.

In the talk, I will show new phenomenon introduced by HOI, such as the non-Gaussian type approximations in dimension reduction problems， new types of Thomas-Fermi approximations. Besides, two algorithms for computing ground states, which overcome the stability issue, will be presented.

[03403] Solving Schrodinger equation using tensor neural network

Format : Talk at Waseda University
Author(s) : Hehu Xie (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)
Abstract : In this talk, we introduce a prototype of machine learning method to solve high dimensional partial differential equations by the tensor neural network. Based on the tensor product structure, we can do the direct numerical integration by using fixed quadrature points for the functions constructed by the tensor neural network within tolerable computational complexity. The corresponding machine learning method is built for solving high dimensional Schrodinger equation with high accuracy. Some numerical examples are provided to validate the accuracy and efficiency of the proposed algorithms. This work is collaborated with Yifan Wang and Pengzhan Jin.

02479 (2/3) : 3C @E711 [Chair: Hehu Xie]

[04589] Computations of the ground states and collective excitations of Bose-Einstein condensates

Author(s) : Manting Xie (Tianjin University)Hehu Xie (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Yong Zhang (Tianjin University)
Abstract : In this talk, we'll show some efficient and robust numerical methods to study the ground states and collective excitations of Bose-Einstein condensates.

[03384] Multilevel correction adaptive finite element method for Kohn-Sham equation

Format : Talk at Waseda University
Author(s) : Fei Xu (Beijing University of Technology)
Abstract : An efficient adaptive finite element method is proposed for solving the ground state solution of the Kohn-Sham equation which is based on the combination of the multilevel correction scheme and the adaptive refinement technique. The multilevel correction adaptive finite element method can transform the Kohn-Sham equation into a series of linear boundary value problems on the adaptive partitions and a series of Kohn-Sham equations on very low dimensional spaces. Further, the Hartree potential and the exchange-correlation potential are treated individually, and the algorithm can be performed in an eigenpairwise approach. Therefore, the presented adaptive method for Kohn-Sham equation can arrive at the similar efficiency as that of the adaptive finite element method for the associated linear boundary value problems.

[03227] The Wigner function of ground state and one-dimensional numerics

Format : Talk at Waseda University
Author(s) : Hongfei Zhan (Peking University)
Abstract : In this talk, the ground state Wigner function of a many-body system is explored theoretically and numerically. An eigenvalue problem for Wigner function is derived based on the energy operator of the system. On the other hand, a numerical method is designed for solving proposed eigenvalue problem in one dimensional case. Results of several numerical experiments verify our method, where the potential application for large scale system is demonstrated by examples with density functional theory.

02479 (3/3) : 3D @E711

[02491] Mathematics of Epidemics: modelling, data analysis, and control

Session Time & Room :

02491 (1/2) : 4D (Aug.24, 15:30-17:10) @A201

02491 (2/2) : 4E (Aug.24, 17:40-19:20) @A201

Type : Proposal of Minisymposium
Abstract : Mathematical epidemiology, the modeling of the spread of epidemics, has a distinguished history and continues to be a very active field, with fruitful interaction of mathematical theory, computation, and data analysis. In the wake of the COVID-19 pandemic, modeling has played an important role in providing a framework for understanding empirical data and guiding policy. This mini-symposium will include presentations of recent results related to the mathematical modeling of epidemics, and provide a forum for discussion among researchers. Issues to be addressed include control measures for epidemics, population immunity and vaccination, heterogeneity of populations, and parameter inference for epidemic models.

Organizer(s) : Nir Gavish, Guy Katriel, Yukihiko Nakata
Classification : 92D30, 34H05, 92B05
Minisymposium Program :

02491 (1/2) : 4D @A201 [Chair: Guy Katriel]

[03453] Optimal vaccination at high reproductive numbers: sharp transitions and counter-intuitive allocations

Format : Talk at Waseda University
Author(s) : Nir Gavish (Technion - Israeli Institute of Technology)Guy Katriel (Braude College of Engineering)
Abstract : Optimizing vaccine allocation is crucial for effective vaccination campaigns against epidemics. Contrary to intuition and classic vaccination theory, we show that for leaky vaccines and high basic reproduction numbers, the optimal allocation strategy for minimizing infections prioritizes those least likely to be infected. These findings have important implications for managing vaccination campaigns against highly transmissible infections.

[04794] An epidemic model for reinfection dynamics with heterogeneous susceptibility

Format : Talk at Waseda University
Author(s) : Yukihiko Nakata (Aoyama Gakuin University)
Abstract : Individuals in a population vary in susceptibility. To explore the impact of the distributed susceptibility, we consider an epidemic model, where individuals acquire a degree of susceptibility with a probability after infection. It is shown that heterogeneous susceptibility adds complexity to the reinfection dynamics, and changes in the distribution of susceptibility may cause unexpected epidemics. We revisit the epidemic model studied by Katriel in 2010. The study is partly a joint work with Ryosuke Omori.

[03972] Effective screening with rapid antigen tests for COVID-19 patients: simulation with viral dynamics model

Format : Talk at Waseda University
Author(s) : Yong Dam Jeong (Nagoya University)Keisuke Ejima (Nanyang Technological University)Ajelli Marco (Indiana University School of Public Health-Bloomington)Shingo Iwami (Nagoya University)
Abstract : In this study, we assessed the effectiveness of various screening strategies with rapid antigen tests in schools and workplaces. For this, we developed two models with different scales: a transmission model in the community where those facilities under screening tests belong, and a viral dynamics model of each infected case in those facilities. Those screening strategies were compared through quantitative simulations. Our computational framework will be useful to evaluate screening strategies for infectious disease transmission.

[03510] Evaluation of Effectiveness of Global COVID-19 Vaccination Campaign in 2021

Format : Talk at Waseda University
Author(s) : Daihai He (Hong Kong Polytechnic University)
Abstract : To model estimated deaths averted by COVID-19 vaccines, we used state-of-the-art mathematical modeling, likelihood-based inference, and reported COVID-19 death and vaccination data. We estimated that >1.5 million deaths were averted in 12 countries. Our model can help assess effectiveness of the vaccination program, which is crucial for curbing the COVID-19 pandemic.

02491 (2/2) : 4E @A201 [Chair: Yukihiko Nakata]

[03458] Exploring the dynamics of contagion models with stages

Format : Talk at Waseda University
Author(s) : Guy Katriel (Braude College of Engineering)
Abstract : We study models which are similar to classical epidemiological models, but in which becoming `contagion' involves a  process with several stages. Such mechanisms are natural when considering phenomena of`social contagion' - the transmission of beliefs, behaviors. It is shown that these models display a variety of nonlinear behaviors that are absent in the corresponding `classical' epidemiological models, including: bistability, critical transitions, endogenous oscillations, and excitability. These phenomena, and the bifurcations involved, are studied by a combination of analytical and numerical means. We thus suggest that two-stage (or multi-stage) contagion can serve as a possible explanatory mechanism for some of the complex dynamical phenomena observed in social life.

[04574] Mathematical modeling of COVID-19 transmission with pandemic response in South Korea

Format : Talk at Waseda University
Author(s) : Yongin Choi (National Institute for Mathematical Sciences)Kyeongah Nah (National Institute for Mathematical Sciences)
Abstract : In this study, we investigated the effects of control policies on the COVID-19 outbreak in South Korea using a transmission dynamics model, where its transmission rate is estimated by a machine-learning algorithm. Our findings showed that the effectiveness of these policies varied across different waves of the epidemic and was influenced by various factors, such as vaccination coverage and mobility levels. Our findings emphasize the importance of a data-driven approach to evaluate COVID-19 policies.

[03885] Front propagation in an epidemiological model with mutations

Format : Talk at Waseda University
Author(s) : Hiroshi Matano (Meiji University)Quentin Griette (Université Le Havre Normandie)
Abstract : We consider a reaction-diffusion system describing the propagation of disease that involves mutation of the pathogen. More precisely this is an S-I-S epidemic model with diffusion in which two types of pathogens appear (wild and mutant). We assume that mutation occurs reciprocally between the two types at a certain rate. The resulting reaction-diffusion system has a peculiar feature: it is of the cooperative nature for small density of infected population while it is of the competitive nature for large density. This model was introduced by Q.Griette and G.Raoul in 2016 for a spatially homogeneous environment. Similar systems were also studied slightly later by L.Girardin and by E.Crooks et al, also for the spatially homogeneous case.

In this talk, I will consider this system in spatially periodic environments and present the following results: (1) existence of traveling waves; (2) spreading speed of infection when starting from localized initial data; (3) stability and asymptotic profile of propagating fronts. I will also discuss the homogenization limit of the problem when the spatial period of the environment tends t

[05100] Resolving the enigma of COVID-19 outbreaks in Iquitos and Manaus

Format : Talk at Waseda University
Author(s) : lewi stone (RMIT University)Daihai He (Hong Kong Polytechnic University)
Abstract : The nearby cities of Iquitos (Peru) and Manaus (Brazil) experienced the world's highest infection and mortality rates
during the first 2020 COVID-19 wave. Key studies suggested >70% of the Manaus population was infected, and thus
close to herd immunity and protected. It remains an enigma as to why a deadly second wave followed in Manaus. We
present a data-driven model of epidemic dynamics in Iquitos to help explain and model events in Manaus

[02493] Advanced Modelling of Complex Nonlinear Systems

Session Time & Room : 4E (Aug.24, 17:40-19:20) @G704

Type : Proposal of Minisymposium
Abstract : Complex nonlinear systems with millions and even billions of parameters appear in various fields of science and engineering. These include mechanics, fluid dynamics, and deep neural networks. In order to better understand, predict and optimize the solutions, new mathematical models are required.

In this mini-symposium, we plan to present several approaches from different fields related to modeling large high-dimensional nonlinear systems. This will foster better synergy and collaboration of researchers from various disciplines. Researchers from advanced signal processing, applied mathematics, and fluid mechanics will discuss their contributions. We anticipate new insights and analogies will be gained following this exchange of ideas.
Organizer(s) : Ido Cohen, Guy Gilboa

02493 (1/1) : 4E @G704

[03289] A Minimal Set of Koopman Eigenfunctions -- Analysis and Numerics

Author(s) : Ido Cohen (Technion - Israel Institute of Technology)
Abstract : In this talk, we present the most concise linear representation of nonlinear systems based on the theory of Koopman Operator. Here, we define the “basis” of Koopman eigenfunctions from which the whole spectrum of the Koopman operator can be generated and the dynamic is accurately reconstructed. Numerically, the curse of dimensionality in samples vanishes since the inherent geometry constraints. Thus, the suggested method yields the most reduced representation from samples justifying the term \emph{minimal set}.

[03525] Acoustic Streaming

Author(s) : James Friend (University of California San Diego)
Abstract : Acoustic streaming is a nonlinear effect from an acoustic wave that can generate rapid fluid flows. We show a new, mathematically challenging approach to its analysis that overcomes past limitations, recasting traditional separation of scales in one variable to separation of spatiotemporal scales, with careful treatment of partial derivatives and the definition of compatibility equations to ensure closure. We provide closed-form solutions to transient acoustic streaming for the first time.

[04735] The Underlying Correlated Dynamics in Neural Training

Author(s) : Guy Gilboa (Technion)Rotem Turjeman (Technion)Tom Berkov (Technion)Ido Cohen (Technion)
Abstract : We propose a model of neural-net training which dramatically reduces the dimensionality. Our algorithm, Correlation Mode Decomposition (CMD), yields groups of highly correlated parameters. We achieve a remarkable dimensionality reduction with this approach, where a network of 11M parameters like ResNet-18 can be modeled well using just a few modes. Retraining the network using our model induces a regularization which yields better generalization capacity on the test set.

[05114] A Nonstochastic Control Approach to Optimization

Author(s) : Xinyi Chen (Princeton University and Google AI)Elad Hazan (Princeton University and Google AI)
Abstract : Selecting the best hyperparameters, such as the learning rate and momentum, is an important but nonconvex problem. We propose an online nonstochastic control methodology for optimization that can circumvent this nonconvexity and obtain certain global guarantees. The problem of learning the best optimizer can be framed as a feedback control problem over the choice of optimizers. Our method guarantees that we can compete with the best optimizer in hindsight from a class of methods on a given sequence of problems.

[02499] Machine Learning for dynamics and its applications

Session Time & Room :

02499 (1/4) : 3C (Aug.23, 13:20-15:00) @F308

02499 (2/4) : 3D (Aug.23, 15:30-17:10) @F308

02499 (3/4) : 3E (Aug.23, 17:40-19:20) @F308

02499 (4/4) : 4C (Aug.24, 13:20-15:00) @F308

Type : Proposal of Minisymposium
Abstract : There has been a growing interest in exploiting machine learning to predict the behaviors of complex nonlinear dynamics. It is also of interest to clarify to what extent machine learning can be used to model and predict dynamical system structures that do not appear in training time series explicitly. In this mini-symposium, we will learn of new results on machine learning for dynamics and its applications to complex phenomena such as fluid and climate dynamics. Examples include the prediction of invariant sets (fixed points, periodic points, strange attractors, and invariant manifolds) and their stabilities, tipping point, and missing dynamics.

[04040] Construction of differential equations from scalar chaotic time series

Format : Talk at Waseda University
Author(s) : NATSUKI TSUTSUMI (Hitotsubashi University)kengo nakai (Okayama University)Yoshitaka Saiki (Hitotsubashi University)
Abstract : We propose a method of constructing a system of differential equations of chaotic behavior only from observable scalar time series. The method employs a regression using Gaussian radial basis functions together with polynomial terms. We apply it to several chaotic time series. The obtained model is assessed from the viewpoint of time series forecast, reconstruction of invariant sets, and invariant densities. Delay coordinate and a chaotic saddle have played a big role in the procedure.

[04709] Data-driven inference of Navier-Stokes turbulence from limited observations

Format : Talk at Waseda University
Author(s) : Masanobu Inubushi (Tokyo University of Science)
Abstract : Inference of turbulent states governed by the Navier-Stokes equations is one of the challenging and crucial problems for applied mathematics and industrial applications because of the high dimensionality and nonlinearity of fluid dynamics. In this study, we propose a data-driven inference method of turbulent dynamics from limited observations, which is suitable for industrial applications, and discuss its performance from the viewpoint of dynamical system theory.

[03862] Long-lead prediction of Indian Summer Monsoon onset with reservoir computing

Format : Talk at Waseda University
Author(s) : Takahito Mitsui (Technical University of Munich)Niklas Boers (Technical University of Munich)
Abstract : Although the prediction of the Indian Summer Monsoon (ISM) onset is of crucial importance for water-resource management and agricultural planning on the Indian sub-continent, the long-term predictability, especially at seasonal time scales, is little explored. We propose a method based on reservoir computing that provides skilfull long-term forecasts of the ISM onset. Our study demonstrates that machine-learning-based approaches can be simultaneously helpful for both data-driven prediction and enhancing the process understanding of climate phenomena.

02499 (2/4) : 3D @F308 [Chair: Yoshitaka Saiki]

[03000] Learning Strange Attractors with Reservoir Systems

Format : Talk at Waseda University
Author(s) : Allen Hart (University of Bath)
Abstract : This talk is based on a preprint by myself, Juan-Pablo Ortega, and Lyudmila Grigoryeva, which shows that the celebrated Takens Embedding Theorem is a particular case of a much more general statement according to which, randomly generated Echo State Networks (with linear activations) trained on generic observations of an invertible dynamical system carry in their wake an embedding of the phase space dynamics into the chosen Euclidean state space. This embedding coincides with a natural generalized synchronization that arises in this setup and that yields a topological conjugacy between the state-space dynamics driven by the generic observations of the dynamical system and the dynamical system itself. This result provides additional tools for the representation, learning, and analysis of chaotic attractors and sheds additional light on the reservoir computing phenomenon that appears in the context of recurrent neural networks.

[04147] Dynamical system properties of reservoir computing models

Format : Talk at Waseda University
Author(s) : kengo nakai (Okayama University)Miki U. Kobayashi (Rissho University)Yoshitaka Saiki (Hitotsubashi University)Natsuki Tsutsumi (Tokyo University of Marine Science and Technology)
Abstract : It has been reported that reservoir computing is effective in the inference of time-series and some characteristics. We construct a model from training time-series of dynamical system with tangencies between stable and unstable manifolds or hetero-chaos, coexisting of invariant sets of different number of unstable dimensions. We confirm that these dynamical properties as well as fixed points and periodic orbits can be reconstructed by reservoir computing.

[02889] Predicting tipping point with machine learning

Format : Talk at Waseda University
Author(s) : Ying-Cheng Lai (Arizona State University)
Abstract : Compared with the existing works on model-free prediction of chaotic systems, to predict a tipping point is significantly more challenging, because the training data are from the system when it is in a steady state. The speaker will describe the tipping-point mechanism, discuss how dynamical noise can be exploited in a machine learning scheme to predict the future occurrence of tipping points, and present benchmark examples as well as a real-world application.

[02921] Machine Learning for Predicting Missing Dynamics

Format : Talk at Waseda University
Author(s) : Shixiao Willing Jiang (ShanghaiTech University)
Abstract : We present a framework for recovering missing dynamics using available data and machine learning techniques. The framework reformulates the prediction problem as a supervised learning problem to approximate a map that takes the memories of the resolved and identifiable unresolved variables to the missing components in the resolved dynamics. The map for this non-Markovian transition kernel is represented by appropriate RKHS or LSTM formulation. Supporting numerical results include the Lorenz system, the Kuramoto-Sivashinsky equation, etc.

02499 (3/4) : 3E @F308 [Chair: Kengo Nakai]

[05374] Kernel Flows and Kernel Mode Decomposition for Learning Dynamical Systems from Data

Format : Talk at Waseda University
Author(s) : Boumediene Hamzi (Caltech)
Abstract : Regressing the vector field of a dynamical system from a finite number of observed states is a natural way to learn surrogate models for such systems. We present variants of the method of Kernel Flows as simple approaches for learning the kernel that appear in the emulators we use in our work. First, we will talk about about the method of parametric and nonparametric kernel flows for learning chaotic dynamical systems. We'll also talk about learning dynamical systems from irregularly-sampled time series as well as from partial observations. We will also introduce the method of Sparse Kernel Flows and apply it to learn 132 chaotic dynamical systems. Finally, we extend the method of Kernel Mode Decomposition to design kernels in view of detecting critical transitions in some fast-slow random dynamical systems.
This is joint work with Yang Lu, Xiuwen Sun, Houman Owhadi, Leo Paillet, Naiming Xie

[05420] Discovery of quasiperiodically driven dynamics using kernel methods

Format : Talk at Waseda University
Author(s) : Suddhasattwa Das (Texas Tech University)Shaurya Agarwal (University of Central Florida)Shakib Mustavee (University of Central Florida)
Abstract : Quasiperiodically driven dynamical systems are nonlinear systems which are driven by some periodic source with multiple base-frequencies. Such systems abound in nature, and are present in data collected from sources such as astronomy and traffic data. Such dynamics decomposes into two components - the driving quasiperiodic source with generating frequencies; and the driven nonlinear dynamics. Analysis of the quasiperiodic part presents the same challenges as classical Harmonic analysis. On the other hand, the nonlinear part bears all the aspects of chaotic dynamics, and possibly carry stochastic perturbations. We present a kernel-

based method which provides a robust means to learn both these components. It uses a combination of a kernel based Harmonic analysis and kernel based interpolation technique, to discover these two parts. The technique performs reliably in several real world systems, ranging from analyzing the human heart to traffic data.

02499 (4/4) : 4C @F308 [Chair: Masanobu Inubushi]

[05427] Reservoir Computing Generalized

Format : Talk at Waseda University
Author(s) : Tomoyuki Kubota (The University of Tokyo)
Abstract : Reservoir computing (RC) is a machine learning framework that leverages a dynamical system as an information processor. This framework imposes a constraint on a system where the system must exhibit an identical response against an identical input sequence to work as a reproducible input processor; however, systems that violate the constraint can also process input. In this talk, we introduce a more general theoretical framework called generalized reservoir computing, covering the rest of irreproducible systems.

[05429] Reservoir computing with the Kuramoto model

Format : Talk at Waseda University
Author(s) : Koichi Taniguchi (Tohoku University)
Abstract : The physical reservoir aims to achieve high-performance and low-cost machine learning by using real physical systems as reservoirs, but in general, there is no theoretical guideline for high-performance or optimality. In this talk, we discuss the reservoir computing with the Kuramoto model and the "edge of bifurcation" conjecture which means that its best performance is achieved by taking the model parameters just below the bifurcation point of the dynamical system.

[05431] Embedding bifurcation structures into a soft robotic actuator

Format : Talk at Waseda University
Author(s) : Nozomi Akashi (Kyoto University)Yasuo Kuniyoshi (The University of Tokyo)Taketomo Jo (Bridgestone Corporation)Mitsuhiro Nishida (Bridgestone Corporation)Ryo Sakurai (Bridgestone Corporation)Yasumichi Wakao (Bridgestone Corporation)Kohei Nakajima (The University of Tokyo)
Abstract : We demonstrate that bifurcation structures can be embedded into a McKibben pneumatic artificial muscle, which is a common soft robotic actuator, through closed-loop control of physical reservoir computing. Our experiments reveal that both periodic and chaotic dynamics can be embedded into the artificial muscle by training only one side of these dynamics. Our results provide insight into reducing the amount and types of training data required for robot control through the utilization of bifurcation structures.

[05402] Physical reservoir computing using dynamics of biological neuronal network with modular structure

Format : Talk at Waseda University
Author(s) : Takuma Sumi (Tohoku University)Hideaki Yamamoto (Tohoku University)Yuichi Katori (Future University of Hakodate)Koki Ito (Tohoku University)Shigeo Sato (Tohoku University)Ayumi Hirano-Iwata (Tohoku University)
Abstract : Physical reservoir computing with biological neuronal network (BNN) has recently advanced the understanding of its computational principles. However, the BNN in conventional culture was randomly connected, generating non-physiological dynamics. Here, we employed micropatterning technology to fabricate BNNs with modular topology conserved evolutionarily in animal brains. We showed that the BNN reservoir exhibited higher classification when its network was functionally modular. Our findings provide insights into the link among non-random network connectivity, neuronal dynamics, and computing.

[02514] Developing Performance Portable, Scalable and AI enabled Fusion Energy Physics Framework

Session Time & Room :

02514 (1/2) : 5C (Aug.25, 13:20-15:00) @E606

02514 (2/2) : 5D (Aug.25, 15:30-17:10) @E606

Type : Proposal of Minisymposium
Abstract : The plasma physics and tokomak engineering are widely recognized as a challenging "exascale" multi-scale multi-physics application. Recent advances in exascale computing, artificial intelligence (AI), and machine learning have paved the way for unprecedented opportunities in "in-silico" fusion reactor interpretation and design. Deep learning and the availability of powerful, easy-to-use HPC/ML toolboxes have played a significant role in achieving such breakthroughs. In this minisymposia, we are aiming to present recent advances in general numerical methods with adaptive meshes, AI methods, surrogate modelling, and performance-portable programming techniques for current and future computing architectures.
Organizer(s) : Xiaohu Guo, Jony Castagna, Vignesh Gopakumar, Stanislas Pamela
Classification : 65M25, 68T07, 35Q83, 65M50, 68Q85
Minisymposium Program :

02514 (1/2) : 5C @E606

[04465] Develop next generation CFD tools using AI libraries

Author(s) : Xiaohu Guo (UKRI STFC Hartree Centre)
Abstract : Due to new hardware technologies, increases in computing power and developments in AI software, the benefits of combining AI techniques with traditional numerical methods for solving governing equations of dynamical systems are becoming apparent. This talk introduces a revolutionary approach to the discretization and solution of PDEs. Our approach implements CFD models using neural network with the aim of simplifying the software development and building on the very substantial developments already made in AI software.

[04466] Cheap training sets of gyrokinetic surrogate models with active learning

Author(s) : Xiaohu Guo (UKRI STFC Hartree Centre)Lorenzo Zanisi (UKAEA)
Abstract : Surrogate models of gyrokinetic turbulence play critical role in accelerating integrated models thus leading to faster post-discharge analysis, operations optimisation and flight simulator applications. Training sets for surrogates are obtained by brute-force approaches which may cause unnecessary, expensive oversampling, which limits the dimensionality of the input space and applications to high fidelity codes. We develop two-stage Active Learning pipeline to efficiently sample the input parameter space of gyrokinetic models, benchmark applications in multichannel integrated models.

[04627] Implementation of a finite element PDE solver in AMReX

Author(s) : Karthikeyan Chockalingam (UKRI STFC Hartree Centre)Alex Grant (UKRI STFC Hartree Centre)Xiaohu Guo (UKRI STFC Hartree Centre)
Abstract :

The scope of the current work is to embed a finite element implementation in AMReX. One of the advantages of using block-structured meshes is that each element does not require a unique isoparametric mapping. Initial testing of the implementation on the Poisson problem shows considerable performance gain compared to an unstructured finite element framework. The framework allows for the ease of implementing different types of higher-order elements. It has also been extended for solving Navier-Strokes.

[04652] AI deconvolution operator for plasma turbulent simulations on complex geometries

Author(s) : Jony Castagna (UKRI-STFC Hartree Centre)Francesca Schiavello (UKRI-STFC Hartree Centre)
Abstract : We use Generative Adversarial Networks (GANs) to model the nonlinear terms in partial differential equations on coarse structured grids. The idea is to reconstruct the high-resolution fields exploring the latent space of the GANs after being properly trained on curvilinear coordinates. The nonlinear terms are then found and mapped back to the coarse structured mesh where the filtered equations are solved. Results for Navier Stokes and Hasagawa-Wakatani plasma equations are presented.

02514 (2/2) : 5D @E606

[04741] Performance and scaling of amrPX: a multiphase CFD framework

Author(s) : Alex Grant (UKRI STFC Hartree Centre)Xiaohu Guo (UKRI STFC Hartree Centre)Karthikeyan Chockalingam (UKRI STFC Hartree Centre)
Abstract : amrPX is a modularised, multi-model adaptive mesh refinement framework built using AMReX. Each model has a common structure with Data, Solver, Physics and Problem containers, with shared utility modules such as numerics or materials, to promote code re-use and ease of development. A compressible multiphase Five-Equation model has been implemented and benchmarked. Performance results and scalability across thousands of CPUs and GPUs is discussed.

[05229] A highly parallel simulation of patient-specific hepatic flows

Author(s) : Zeng Lin (Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences)
Abstract : Computational hemodynamics is being developed as an alternative approach for assisting clinical diagnosis and treatment planning for liver diseases. The technology is non-invasive, but the computational time could be high when the full geometry of the blood vessels is taken into account. In this work, we study a highly parallel method for the transient incompressible Navier-Stokes equations for the simulation of the blood flows in the full three-dimensional patient-specific hepatic artery, portal vein and hepatic vein. As applications, we also simulate the flow in a patient with hepatectomy and calculate the portal pressure gradient. One of the advantages of simulating blood flows in all hepatic vessels is that it provides a direct estimate of the portal pressure gradient, which is a gold standard value to assess the portal hypertension. Moreover, the robustness and scalability of the algorithm are also investigated. A 83% parallel efficiency is achieved for solving a problem with 7 million elements on a supercomputer with more than 1000 processor cores.

[02515] Novel deep learning methodologies in Industrial and Applied Mathematics

Session Time & Room :

02515 (1/2) : 5B (Aug.25, 10:40-12:20) @E818

02515 (2/2) : 5C (Aug.25, 13:20-15:00) @E818

Type : Proposal of Minisymposium
Abstract : The proposed mini-symposium is focused on a few novel techniques in IAM, their applications and promising opportunities. The techniques considered rely on artificial intelligence methods to solve problems in engineering, like wind turbine preventive maintenance or predicting molecular weights of industrial polymers using diffusion NMR spectroscopy; to advance in making AI more reliable by enabling it to cope with causality and thereby enhancing its explainability; to promote neural networks capable of directly processing geometric entities and use them for robust deep learning in various domains, including artificial vision; and to tackle with the engineering problems of multiphasic electric power generation.

[05353] Artificial Intelligence for Wind Turbine Predictive Maintenance

Format : Online Talk on Zoom

Author(s) : Yolanda Vidal (Universitat Politècnica de Catalunya. Jordi Girona 31. 08034. Barcelona. VAT: ESQ0818003F)

Abstract : This proposal states a data-driven predictive maintenance (PM) strategy for wind turbines that uses artificial neural networks with Bayesian regularization and Levenberg-Marquardt optimization. The proposed strategy aims to address challenges associated with SCADA data such as high dimensionality, low sampling rate, and unbalanced datasets. The strategy will be validated on real SCADA data from a wind farm consisting of 12 wind turbines and is expected to provide reliable predictions with minimum false alarms and early warnings months in advance. This PM approach can help reduce the levelized cost of energy (LCOE) of wind farms and promote renewable energy as a cost-effective solution to achieve energy independence and combat climate change.

[03575] Innovative Models for Explainable Artificial Intelligence

Format : Online Talk on Zoom

Author(s) : Silvia Franchini (National Research Council of Italy)Francesco Prinzi (University of Palermo)Salvatore Vitabile (University of Palermo)

Abstract : Traditional data-driven ML approaches show very interesting performance even if their internal mechanisms are very cryptic (black box). However, in some critical contexts, model interpretability is mandatory to explain the learned functionality, becoming even a legal requirement. Among the benefits of reformulating neural networks through the geometric calculus paradigm, geometric interpretability could potentially serve as a characteristic that improves model transparency. This work proposes the use of higher-dimensional neurons to reduce computational complexity while preserving model accuracy.

[05376] Applications of Quaternion Monogenic Signal ConvNet Layer

Format : Online Talk on Zoom

Author(s) : E. Ulises Moya-Sanchez (Universidad Autonoma de Guadalajara/Gobierno de Jalisco)Genaro Paredes (Universidad Autonoma de Guadalajara)Sebastian Xambó-Descamps (UPC)Ulises Cortes (BSC)Abraham Sanchez (Gobierno de Jalisco)

Abstract : The monogenic ConvNet layer is a quaternion bio-inspired input layer. This layer creates a new geometric feature space using the Fourier transform. This new representation assigns a structural and geometrical interpretation to each image point and allows the detection of local symmetry elements (such as line-like or edge-like). Its main strength is that it behaves robustly under a variety of illumination transforms. In this work we present the design details and characteristics of this layer and consider a number of situations in which it can be applied.

[05352] Novel deep learning methodologies in Industrial and Applied Mathematics

Format : Online Talk on Zoom

Author(s) : Sebastian Xambó-Descamps (IMTech and BSC)

Abstract : This talk, with the same title as the MS, is meant to be the first and it aims at a broad presentation of the most promising novel methodologies in IAM based on deep learning techniques, with a particular attention focused on those pioneered by the MS speakers.

02515 (2/2) : 5C @E818 [Chair: Marta Barroso]

[05354] AI Lifecycle Zero-touch Orchestration within the Edge-to-Cloud Continuum for Industry 5.0

Format : Talk at Waseda University

Author(s) : Marta Barroso Barroso (Barcelona Supercomputing Center)

Abstract : AI is one of the biggest megatrends towards the 5th industrial revolution. Although these technologies promise
business sustainability as well as product and process quality, it seems that the ever-changing market demands and the complexity of technologies, impede broad application and reuse of Artificial intelligence (AI) models across the industry. KnowlEdge is an European project funded by the Horizon 2020 (H2020) that aims to develop of a new gene-ration of AI methods, systems, and data management infrastructure in order to break the entry barriers for these tech-nologies and unleash its full potential. In particular, knowlEdge project converges techniques from

multiple computing areas, including AI , distributed data analytics, IoT, software engineering, edge and Cloud technologi-es into a unified software architecture. The outcomes of the project not only enable the automated extraction and utilization of data co-ming from multiple and geographically dispersed sources, it also provides a way of reusing and sharing AI models in
an (semi-)automated way in particular companies that are only able to perform the execution of models rather than the training themselves.

[02526] Recent Develoments of Mathematical Economics Focusing on Macroeconomic Dynamics

Session Time & Room : 5D (Aug.25, 15:30-17:10) @D502

Type : Proposal of Minisymposium
Abstract : Successful investigation is highlighted about application of cutting-edge mathematical methodology to traditional macroeconomic models. We will show how modern methodology can fit into these studies. In particular, the session presents an evaluation of a deterministic limit cycle in a stochastic post-Keynesian model, endogenous fluctuations of money and foreign exchange ratio in a Mundell-Fleming international trade framework, applications of nonlinear differential equations for the birth of GDP fluctuations in a three-country Kaldor model with fixed exchange rates and estimation of the natural rate of interest by utilizing various filters, which is one of the significant topics of empirical macroeconomics
Organizer(s) : Akio Matsumoto, Ferenc Szidarovszky
Classification : 91B55, 91-05, 91-10, 62P20
Minisymposium Program :

02526 (1/1) : 5D @D502 [Chair: Akio Matsumoto]

[04358] On growth cycles in a stochastic post-Keynesian model

Format : Talk at Waseda University
Author(s) : Hiroki Murakami (Chuo University)
Abstract : This study evaluates the impact of stochastic disturbances on a deterministic limit cycle in a stochastic post-Keynesian model. It presents an approximation formula for solution paths near the limit cycle and derives an approximated distribution of the limit cycle.

[03425] A Three-Country Kaldorian Business Cycle Model with Fixed Exchange Rates

Format : Talk at Waseda University
Author(s) : Toichiro Asada (Faculty of Economics, Chuo University)
Abstract : This paper analyzes a three-country, fixed exchange rates Kaldorian nonlinear macrodynamic model of business cycle. The country is connected through international trade, and international capital movement with imperfect capital market. Our model is a continuous time version that is formulated by a eight-dimensional nonlinear differential equations. This system is studied both analytically and numerically. This paper is a joint work by R. Zimka, M. Demetrian, T. Asada, and T. Inaba.

[04424] Simple Estimations of the Natural Rate of Interest

Format : Talk at Waseda University
Author(s) : Kazuhiko NAKAHIRA (Meikai University)
Abstract : The natural rate of interest is an important concept since it is a kind of reference for a variety of policy rules to characterize our monetary policy. One of the simple ways of estimating the natural rate of interest is to extract the trend of the real short-term interest rate. We utilize the Hodrick-Prescott filter, the Baxter-King filter, and the Christiano-Fitzgerald filter for our extraction. In addition, we have an inference of expected inflation rate.

[04486] Dynamic Adjustment in the Mundell-Fleming Model

Format : Online Talk on Zoom
Author(s) : Hiroyuki Yoshida (Nihon University)
Abstract : The purpose of this presentation is to show the emergence of perpetual and endogenous fluctuations in the global economy by using the Hopf bifurcation theorem. The model we consider is the dynamic version of the Mundell-Fleming model, which deals with the short-run relationship between output, interest rate, and foreign exchange rate in a small open economy. We show that the steady state is locally stable when the adjustment speed of the foreign exchange market is sufficiently slow.

[02527] AI for Healthcare and Medicine

Session Time & Room :

02527 (1/2) : 1D (Aug.21, 15:30-17:10) @E604

02527 (2/2) : 1E (Aug.21, 17:40-19:20) @E604

Type : Proposal of Minisymposium
Abstract : The minisymposium will explore the various ways in which artificial intelligence is being used in the field of healthcare and medicine, with a focus on the use of privacy-preserving machine learning. The symposium will feature presentations from experts in the field, who will discuss the latest developments and trends in AI for healthcare and medicine, including the use of federated learning and data collaboration for training machine learning models on decentralized data. The symposium will provide attendees with a comprehensive overview of the current state of AI in healthcare and medicine, and will offer insights into the potential future developments in this rapidly evolving
Organizer(s) : Tetsuya Sakurai, Akira Imakura, Weichung Wang, Li-Chen Fu
Classification : 65Fxx, 92Fxx
Minisymposium Program :

02527 (1/2) : 1D @E604 [Chair: Weichung Wang]

[02894] Data Collaboration Cox Proportional Hazards Model for Privacy-preserving Survival Analysis

Format : Talk at Waseda University
Author(s) : Akira Imakura (University of Tsukuba)Ryoya Tsunoda (University of Tsukuba Hospital)Rina Kagawa (University of Tsukuba)Kunihiro Yamagata (University of Tsukuba)Tetsuya Sakurai (University of Tsukuba)
Abstract : In recent years, privacy-preserving machine learning for datasets held by multiple organizations in a distributed manner has been attracted attention. In this study, we focus on privacy-preserving survival analysis for datasets held by multiple medical institutions and propose a data collaboration technique that shares dimensionality-reduced intermediate representations instead of raw data. The proposed DC-COX can calculate the contribution of each feature to survival time and the corresponding p-value. Numerical experiments verify the effectiveness of DC-COX.

[05307] AI-Enhanced Medical Imaging Analysis: Advancing Precision Treatment for NSCLC Brain Metastases

Format : Talk at Waseda University
Author(s) : Cheyu Hsu (National Taiwan University Hospital)
Abstract : In this talk, we discuss the innovative use of radiomics and deep learning in AI-enhanced medical imaging analysis for managing NSCLC brain metastases. Through automated segmentation, we streamline diagnosis and treatment planning. The presentation delves into predicting local recurrence after radiosurgery, detecting EGFR mutations, and evaluating distant metastases or brain metastases velocity in radiosurgery-treated patients. Our focus on AI-driven methodologies fosters tailored, precision treatment strategies, ultimately enhancing patient outcomes for those with NSCLC brain metastases.

[05001] Explainability and Fairness of Distributed Data Analysis

Format : Talk at Waseda University
Author(s) : Anna Bogdanova (University of Tsukuba)Tetsuya Sakurai (University of Tsukuba)Akira Imakura (University of Tsukuba)
Abstract : Ensuring fairness and transparency in machine learning models is critical for their ethical application in the medical field. With the increasing use of distributed machine learning to protect patient privacy, there is a growing need to address the challenges of explainability and fairness in medical data analysis. Machine learning models trained on horizontally or vertically partitioned medical data may present difficulties for explainability, as different participants may have a biased view of the background data or a partial view of the feature space, leading to inconsistencies in the explanations obtained. To address these issues, this paper proposes an Explainable Data Collaboration Framework that combines a model-agnostic additive feature attribution algorithm (KernelSHAP) with a privacy-preserving distributed machine learning method called Data Collaboration. The framework offers three algorithms for various scenarios of explainability in medical data collaboration, which were tested on open-access medical datasets. In addition, we show that our proposed framework can be combined with fairness-sensitive data representation techniques to eliminate data biases at the local level.

[05362] Mitigating Non-IID Data Challenges in Federated Learning for Healthcare Applications

Format : Talk at Waseda University
Author(s) : Fan Zhang (University of Cambridge)
Abstract : Federated Learning has emerged as a promising technique for healthcare applications, enabling collaboration among different healthcare institutions without sharing sensitive data. Data in each healthcare institution usually has a unique distribution, leading to non-IID (independent and identically distributed) data that can impact model performance and convergence in Federated Learning. In this talk, we will present the findings of non-IID challenges in Federated Learning and recommendations for the strategies we evaluated to mitigate these challenges.

02527 (2/2) : 1E @E604 [Chair: Akira Imakura]

[03888] Causal inference and machine learning on distributed data

Format : Talk at Waseda University
Author(s) : Yuji Kawamata (Center for Artificial Intelligence Research, University of Tsukuba)Ryoki Motai (Graduate School of Science and Technology, University of Tsukuba)Yukihiko Okada (Center for Artificial Intelligence Research, University of Tsukuba)Akira Imakura (Center for Artificial Intelligence Research, University of Tsukuba)Tetsuya Sakurai (Center for Artificial Intelligence Research, University of Tsukuba)
Abstract : Utilizing distributed data allows for more reliable estimation of conditional average treatment effects. However, it is difficult to share data owing to privacy concerns. To address this issue, we proposed Data Collaboration Double Machine Learning (DC-DML), which can address horizontally and vertically distributed data and provide point and interval estimation. In experiments using synthetic data, we found that DC-DML could lead to more accurate estimation results than when using distributed data individually.

[05313] Precision Preventive Medicine in Sub-Healthy Population

Format : Talk at Waseda University
Author(s) : Han-Mo Chiu (National Taiwan University Hospital)Hung-Ju Lin (National Taiwan University Hospital)
Abstract : Preventing the onset or progression of non-communicable diseases in sub-health population tremendously impact the population health and the related cost and both primary and secondary prevention play pivotal roles in this aspect. The State-of-the-art digital health and artificial intelligence technologies have been applied widely in the healthcare sector, and are anticipated to play a more proactive role in preventive medicine in terms of risk stratification, adopting clinical, genomic, or metagenomic information, and leveraging lifestyle modification.

[03660] Medical AI, Biosensors and Privacy

Format : Talk at Waseda University
Author(s) : Takeshi Kimura (University of Tsukuba)
Abstract : As Medical AI is expected to improve health care, there is also a concern regarding collecting personal data via AI devices, including biosensors. Advanced biosensors could read and collect inner physiological, emotional, and sensitive conditions. However, patients cannot control their private information collected with biosensors and, once they become data belonging to a hospital or data collection company, cannot have access to their private information. The associated ethical issues are examined.

[05312] HeaortaNet: AI for Quantifying Heart Structures on Non-Contrast CT Images

Format : Talk at Waseda University
Author(s) : Wen-Jeng Lee (Department of Medical Imaging, National Taiwan University Hospital)
Abstract : HeaortaNet is an AI model developed by TW-CVAI for the segmentation of pericardium/aorta and calcium/fat quantification on non-contrast chest CT images. This talk introduces the technology, benefits, and real-world applications of CT data from Taiwan's National Health Insurance Administration. Our research aims to enhance patient care by providing an effective tool for identifying and measuring heart disease, ultimately leading to better treatment and outcomes.

[02533] Reliable and Efficient Numerical Computation of Nonlocal Models

Session Time & Room : 2C (Aug.22, 13:20-15:00) @G709

Type : Proposal of Minisymposium
Abstract : Nonlocal models, which have proven effective in capturing long-range interactions in diverse applications, often involve integrals over a nonlocal horizon. Proper numerical discretization of these integrals is essential to ensure reliable and efficient simulations of the models. This requires addressing issues such as efficiently evaluating nonlocal integrals with domain-specific and computationally suitable meshes, as well as ensuring robustness as the size of the nonlocal horizon approaches zero. This minisymposium provides a platform for researchers to share their experiences and insights on designing reliable and efficient numerical schemes for nonlocal models.
Organizer(s) : Kuang Huang, Xiaobo Yin

02533 (1/1) : 2C @G709 [Chair: Kuang Huang]

[03174] The Effect of Domain Truncation for Nonlocal Models and Asymptotically Compatible Schemes in Numerical Computation

Format : Talk at Waseda University
Author(s) : Xiaobo Yin (Central China Normal University)Qiang Du (Columbia University)Hehu Xie (Academy of Mathematics and Systems Science, Chinese Academy of Sciences)Jiwei Zhang (Wuhan University)
Abstract : Many nonlocal models have adopted a finite and radially symmetric nonlocal interaction neighborhoods. When solving them numerically, it is sometimes convenient to adopt polygonal approximations of such interaction neighborhoods. A crucial question is, to what extent such approximations affect the nonlocal operators and the corresponding nonlocal solutions. While recent works have analyzed this issue for nonlocal operators in the case of a fixed horizon parameter, the question remains open in the case of a small or vanishing horizon parameter, which happens often in many practical applications and has significant impact on the reliability and robustness of nonlocal modeling and simulations. In this report, we are interested in addressing this issue and establishing the convergence of new nonlocal solutions by polygonal approximations to the local limit of the original nonlocal solutions. Our finding reveals that the new nonlocal solution does not converge to the correct local limit when the number of sides of polygons is uniformly bounded. On the other hand, if the number of sides tends to infinity, the desired convergence can be shown. We also apply this finding to discuss of the aysmptotically compatible property of the numerical schemes.

[03775] Global well-posedness of one new class of initial-boundary value problem on incompressible Navier-Stokes equations and the related models

Format : Talk at Waseda University
Author(s) : Shu Wang (Beijing University of Technology)
Abstract : The global well-posedness of the initial-boundary value problem on incompressible Navier-Stokes equations and the related models in the domain with the boundary is studied. The global existence of a class of weak solution to the initial boundary value problem to two/three-dimensional incompressible Navier-Stokes equation with the pressure-velocity relation at the boundary is obtained, and the global existence and uniqueness of the smooth solution to the corresponding problem in two-dimensional case is also established. Some extends to the corresponding incompressible fluid models such as Boussinesq equation/MHD equations and FSI models etc. are given.

[04201] High performance implementation of 3D FEM for nonlocal Poisson problem

Format : Online Talk on Zoom
Author(s) : JIWEI ZHANG (Wuhan University)
Abstract : Nonlocality brings many challenges to the implementation of finite element methods (FEM) for nonlocal problems, such as large number of queries and invoke operations on the meshes. Besides, the interactions are usually limited to Euclidean balls, so direct numerical integrals often introduce numerical errors. The issues of interactions between the ball and finite elements have to be carefully dealt with, such as using ball approximation strategies.
In this talk, an efficient representation and construction methods for approximate balls are presented based on combinatorial map, and an efficient parallel algorithm is also designed for assembly of nonlocal linear systems. Specifically, a new ball approximation method based on Monte Carlo integrals, i.e., the fullcaps method, is also proposed to compute numerical integrals over the intersection region of an element with the ball.

[03599] Asymptotical compatibility of a class of numerical schemes for a nonlocal traffic flow model

Format : Talk at Waseda University
Author(s) : Kuang Huang (Columbia University)Qiang Du (Columbia University)
Abstract : This talk presents a study of numerical schemes for a nonlocal conservation law modeling traffic flows with nonlocal inter-vehicle interactions. We demonstrate the asymptotical compatibility of a class of finite volume schemes with suitable discretizations of the nonlocal integral. The numerical solutions produced by the schemes converge to the weak solution of the nonlocal model with a fixed nonlocal horizon and to the weak entropy solution of the respective local model as the mesh size and nonlocal horizon parameter go to zero simultaneously. Our findings provide insight into the development of robust numerical schemes for nonlocal conservation laws.

[02537] Structured Low-Rank Matrices and Their Applications

Session Time & Room :

02537 (1/2) : 2D (Aug.22, 15:30-17:10) @A601

02537 (2/2) : 2E (Aug.22, 17:40-19:20) @A601

Type : Proposal of Minisymposium
Abstract : Large dense matrices are ubiquitous in engineering and data science applications, e.g. preconditioners for iterative boundary integral solvers, frontal matrices in sparse multifrontal solvers, and computing the determinant of covariance matrices. Such dense matrices have a numerical low-rank structure, which can be exploited to reduce the complexity of matrix multiplication and factorization from cubic to (near-)linear. As mixed-precision and randomized linear algebra become commonplace, such approximations become increasingly important.

[05519] Hierarchical Lowrank Arithmetic with Binary Compression

Author(s) : Ronald Kriemann (Max Planck Institute for Math. i.t.S.)
Abstract : With lowrank approximation the storage requirement for dense data is reduced to linear levels. However, the lowrank factors are often stored using double precision. Newer approaches exploit the different IEEE754 floating point formats in a mixed precision approach. Since these formats show a significant storage (and accuracy) gap, we look beyond the standard formats and use an adaptive precision scheme to further increase the storage efficiency and investigate its effects on the arithmetic of H-matrices.

[05545] Parallel Factorization of Hierarchical Matrices

Author(s) : Wagih Halim Boukaram (Lawrence Berkeley National Lab)
Abstract : Hierarchical matrices allow for memory efficient representation of the data sparse matrices that often appear in scientific applications. The open source H2Opus library provides distributed CPU and GPU implementations of several key operations using the H2-variant of hierarchical matrices, where nested row and column bases allow for asymptotically optimal memory storage requirements. In this talk, we discuss the details of a newly developed parallel hierarchical factorization algorithm using skeletonization.

[05552] Parallel Low-Rank Approximation of High-Dimensional Multivariate Normal Probabilities on Manycore Systems

Author(s) : Xiran Zhang (KAUST)Sameh Abdulah (KAUST)Hatem Ltaief (KAUST)Ying Sun (KAUST)Marc Genton (KAUST)David Keyes (KAUST)
Abstract : The multivariate normal (MVN) probabilities frequently appear in statistics to support applications requiring, for example, the computation of skewed probability density functions or Bayesian spatial probit problems. In the literature, the separation-of-variable (SOV) technique is commonly used to compute the MVN probability by converting the integration region to the unit hypercube, allowing a faster convergence rate. However, the SOV techniques require the computation of the Cholesky factorization of an n x n matrix with O(n^3) computation and O(n^2) space complexity. The computing of the Cholesky factorization operation in higher dimensions is prohibitive in dense structures. Thus, several studies have proposed to include an approximation technique that can help perform the Cholesky factorization faster while preserving the required accuracy. Another direction is to rely on high-performance computing techniques to allow intensive computing on modern parallel systems. In this work, we aim to couple the computing power and the hierarchical approximation to allow faster computation of the MVN probability of high-dimensional problems. We rely on state-of-the-art parallel hierarchical linear algebra algorithms and runtime systems to provide high performance and scalability in computing the MVN probability. We also include a block reordering technique to allow a faster convergence rate than the dense algorithm. Moreover, we assess the performance and the accuracy of the provided method using simulations and real air pollution data.

[05590] A geometry oblivious H-matrix approximation scheme for rectangular matrices

Author(s) : George Biros (The University of Texas at Austin)
Abstract : We propose a novel method for compressing dense matrices. Our method is based on a hierarchical-matrix (H-matrix) approximation. H-matrix approximations have been popular in science and engineering applications. They combine the notion of singular value decomposition (SVD) with appropriate block permutations and recursion. H-matrices are applicable to problems in which the matrix entries correspond to pairwise interactions between sets of points, as for example in kernel matrices. Here we generalize this approximation to arbitrary dense matrices. Our method comprises of a randomized low-rank approximation of permuted blocks along with approximate leverage scores computations that are used to find such

permutations. We introduce theoretical analysis, complexity analysis, and experimental results on kernel matrices.

02537 (2/2) : 2E @A601 [Chair: Hatem Ltaief]

[05551] Dynamic Rupture Simulation Using FDP Method Accelerated by Lattice H-matrices

Author(s) : Takumi Miyajima (The University of Tokyo)Akihiro Ida (Japan Agency for Marine-Earth Science and Technology)Ryosuke Ando (The University of Tokyo)
Abstract : Dynamic rupture simulation with the spatiotemporal boundary integral equation method requires N × N dense matrices in a naive method. In order to reduce the memory consumption and computational cost, we propose a new approximation method called "FDP=LH matrices method" by incorporating travel time approximation into H matrices.
In this minisymposium, we will talk about the algorithm and simulation results.

[02541] Biochemical reaction network reduction methods & multiple timescale dynamics

Session Time & Room :

02541 (1/2) : 2C (Aug.22, 13:20-15:00) @G402

02541 (2/2) : 2D (Aug.22, 15:30-17:10) @G402

Type : Proposal of Minisymposium
Abstract : The last couple of years has seen a flurry of research output on the topic of model reduction based on reactions evolving on disparate timescales. This minisymposium will provide the opportunity to present & discuss the state-of-the-art in this field from multiple angles spanning mathematical theory to synthetic biology and other biochemical applications, and its challenges.

02541 (1/2) : 2C @G402 [Chair: Martin Wechselberger]

[04793] The relationship between deterministic and stochastic quasi-steady-state

Format : Talk at Waseda University
Author(s) : Jae Kyoung Kim (KAIST)
Abstract : The quasi steady-state approximation (QSSA) is frequently used to reduce de- terministic models of biochemical networks. The resulting equations provide a simplified description of the network in terms of non-elementary reaction functions (e.g. Hill functions). Such deterministic reductions are frequently a basis for heuristic stochastic models in which non-elementary reaction functions are used as propensities of Gillespie algorithm. Despite the popularity of this heuristic stochastic simulations, it remains unclear when such stochastic reductions are valid. In this talk, I will present conditions under which the stochastic models with the non-elementary propensity functions accurately approximate the full stochastic models. If the validity condition is satisfied, we can perform accurate and computationally inexpensive stochastic simulation without converting the non-elementary functions to the elementary functions (e.g. mass action kinetics).

[04404] Noise attenuation and ultrasensitivity in biological oscillators utilizing the multiple transcriptional repression mechanism

Format : Talk at Waseda University

Author(s) : Eui Min Jeong (Institute for Basic Science (IBS))Jae Kyoung Kim (Institute for Basic Science (IBS))Yun Min Song (KAIST)

Abstract : In many biological systems, multiple repression mechanisms are used together to inhibit transcriptional activators in many systems. This raises the question of what advantages arise from utilizing multiple repression mechanisms. Here, by deriving Fano factors and equations describing the multiple repression mechanisms, we find that their combination can reduce noise in the transcription while generating an ultrasensitive transcription response and thus, strong oscillation. This rationalizes why multiple repression mechanisms are used in various biological oscillators.

[04800] Reduction of Chemical Reaction Networks with Approximate Conservation Laws

Format : Talk at Waseda University

Author(s) : Ovidiu Radulescu (University of Montpellier)Aurelien Desoeuvres (University of Montpelleir)Alexandre Iosif (Rey Juan Carlos University of Madrid)Christopher Lueders (University of Bonn)Hamid Rahkooy (University of Oxford)Matthias Seiss (University of Kassel)Thomas Sturm (CNRS)

Abstract : Singular perturbation methods are used to reduce multiple timescale chemical reaction networks, but their practical applicability is limited by the manual identification of the small parameters required by the theory. Recently, we have shown that tropical geometry provides ways to rescale CRNs and to identify the small parameters used by singular perturbation theories. Here we consider the case when the fast subsystem has first integrals, not covered by our previous results.

[04454] A deep dive into the quasi-steady-state approximation to the Michaelis-Menten system

Format : Online Talk on Zoom

Author(s) : Justin Spaulding Eilertsen (American Mathematical Society)

Abstract : Although the quasi-steady state approximation (QSSA) is justifiable from singular perturbation theory, the results addressing its accuracy rely on heuristic timescale estimates. We take a different approach. By combining phase plane analysis with differential inequalities, we obtain rigorous bounds on the accuracy of the QSSA. Moreover, under the assumption the QSSA is valid at the onset of the reaction, we obtain an error estimate that is order one in the Segel--Slemrod parameter.

02541 (2/2) : 2D @G402 [Chair: Jae Kyoung Kim]

[04203] Multiple timescales in reaction networks and the parametrisation method

Format : Talk at Waseda University

Author(s) : Martin Wechselberger (University of Sydney)Ian Lizarraga (University of Sydney)Bob Rink (Vrije Universiteit Amsterdam)

Abstract : Many biochemical reaction network problems display distinct temporal features, which can be attributed to processes taking place on multiple timescales. In mathematical terms, such multiple timescale models are in fact singular perturbation problems. We present a parametrisation method for computing slow manifolds and their fast fibre bundles in such singular perturbation problems. In particular, we highlight the emergence of hidden timescales and show how our method can uncover these surprising multiple timescale structures.

[02545] Challenges and Recent Advances in Phylogenetics

Session Time & Room :

02545 (1/4) : 1D (Aug.21, 15:30-17:10) @A508

02545 (2/4) : 1E (Aug.21, 17:40-19:20) @A508

02545 (3/4) : 2D (Aug.22, 15:30-17:10) @A508

02545 (4/4) : 2E (Aug.22, 17:40-19:20) @A508

Type : Proposal of Minisymposium
Abstract : Phylogenetic trees and networks are used to elucidate the evolutionary history of genes or species. Data proliferation due to recent technological advancements has led to the pursuit of more efficient algorithms and novel approaches. Advances in the area can lead to breakthroughs in various disciplines of biology and life sciences, including genetics, cell biology, zoology, botany, microbiology, epidemiology, drug discovery, and biodiversity conservation, to name a few. This mini-symposium will cover recent topics related to phylogenetic research, from both theoretical and practical viewpoints, with results from algebra, algorithms, bioinformatics, combinatorics, computational complexity, geometry, statistics, and software development.

[04132] Navigating the Frontiers of Phylogenetic Research: Challenges and Applications

Format : Talk at Waseda University
Author(s) : Momoko Hayamizu (Department of Applied Mathematics, Waseda University)
Abstract : This talk serves as an introduction to our mini-symposium on phylogenetic research. It emphasizes key challenges and applications in this rapidly evolving field from both theoretical and biological perspectives. After providing a brief overview of the symposium topics and presentations, I will discuss some of the recent results and open problems related to phylogenetic trees and networks, with a focus on combinatorial and algorithmic approaches.

[05050] Advances and challenges in statistical inference of phylogenetic networks

Format : Talk at Waseda University
Author(s) : Luay Nakhleh (Rice University)
Abstract : Evolutionary analyses of various groups of eukaryotic species have revealed evidence for reticulation. Reticulate evolutionary histories are best represented as phylogenetic networks. I will describe the multispecies network coalescent (MSNC) model, which allows for modeling vertical and horizontal evolutionary processes acting within and across species boundaries. I will then discuss progress we have made on developing statistical inference methods under the MSNC as well as challenges facing the inference in practice.

[03613] The Tree of Blobs of a Species Network: Identifiability

Format : Online Talk on Zoom
Author(s) : Hector D Banos (California State University San Bernardino)Elizabeth S Allman (University of Alaska Fairbanks)John A Rhodes (University of Alaska Fairbanks)Jonathan D Mitchell (Univeristy of Tasmania)
Abstract : As genealogical analyses of DNA data have progressed, more evidence has appeared showing that hybridization is often an important factor in evolution. Hybridization has played a crucial role in the evolutionary history of plants, some groups of fish, and frogs, among other species. In such cases, networks are the objects used to represent the relationships between species. The network multispecies coalescent model is a standard probabilistic model describing the formation of gene trees in the presence of hybridization and incomplete lineage sorting. We present a step toward inferring a general species network by showing the identifiability of its tree of

blobs, in which all 'hybrid species relationships' are contracted to nodes, so only tree-like relationships between the taxa are shown.

[03991] Identifiability of phylogenetic networks

Format : Talk at Waseda University
Author(s) : Leo van Iersel (TU Delft)
Abstract : Will we ever be able to reconstruct our own history and the history of other species? What can we reconstruct when we have enough data? And what cannot be reconstructed no matter how much data we collect? Evolutionary histories can be described using directed graphs called phylogenetic networks. Which phylogenetic networks can in principle be reconstructed from data of currently living species, like DNA data, under certain models of evolution? This is an important question to answer in order to be able to develop statistically-consistent methods. I will discuss algorithmic, graph theoretic and algebraic results that are important for answering this question.

02545 (2/4) : 1E @A508 [Chair: Koyo Hayashi]

[04778] Log-concave density estimation on tree space

Format : Talk at Waseda University
Author(s) : Yuki Takazawa (The University of Tokyo)Tomonari Sei (The University of Tokyo)
Abstract : A probability density is log-concave if its logarithm is concave. In recent decades, the maximum likelihood estimation method for log-concave densities has been developed in Euclidean spaces. In this talk, we introduce a generalization of this estimator to the space of phylogenetic trees. We provide a sufficient condition for the existence of the estimator, present the estimation algorithm, and discuss some challenges in the computation.

[03260] Tropical Logistic Regression Model on Space of Phylogenetic Trees

Format : Talk at Waseda University
Author(s) : Ruriko Yoshida (Naval Postgraduate School)George Aliatimis (University of Lancaster)Burak Boyaci (University of Lancaster)James Grant (University of Lancaster)
Abstract : In recent years, tropical geometry has found applications in statistical learning over the space of phylogenetic trees. In this talk, we propose an analogue of the logistic regression model in the setting of tropical geometry. Our proposed method is to classify gene trees over the space of ultrametrics, a tropical linear space. The generalization errors of our model is discussed. Experiment results with simulated and empirical data show our model works well.

[04319] From phylogenetics to semigroups, through set partitions

Format : Online Talk on Zoom
Author(s) : Andrew Francis (Western Sydney University)
Abstract : We show that the set of all phylogenetic trees and forests are in correspondence with the set of all partitions of finite sets, extending Diaconis and Holmes (1998). This correspondence can be further extended to phylogenetic networks through a class of covers of finite sets. Partitions of finite sets can be represented as diagrams in a partition monoid, leading to applications of semigroups in phylogenetics. Joint work with Peter Jarvis and with Mike Steel.

[04284] Learning from phylogenies to uncover evolutionary dynamics

Format : Talk at Waseda University
Author(s) : Olivier GASCUEL (CNRS - Institut de Systématique, Evolution, Biodiversité (ISYEB))
Abstract : I will describe the work done in my group to estimate the parameters of models used in phylodynamics and macroevolution studies. In particular, we use neural networks combined with simulations to learn to predict the parameters of these models. This involves both adequate representations of phylogenies and the use of appropriate neural architectures. The results compare favourably with the state of the art, with extremely fast methods for analyzing very large trees.

02545 (3/4) : 2D @A508 [Chair: Hiroshi Hirai]

[05365] Minimum Number of Leaf-Covering Subtrees Covering Phylogenetic Networks

Format : Talk at Waseda University

Author(s) : Yuki Yoshida (The University of Tokyo)

Abstract : Several deviation measures of non-tree-based phylogenetic networks from tree-based have been defined and their characteristics have been studied. One of the measures is the minimum number of leaf-covering subtrees which cover the phylogenetic network. In this talk, I suggest the first polynomial-time and efficient algorithm to compute both the minimum number and the covering subtrees. This algorithm is based on flow algorithms on several networks transformed from the network used to compute another deviation measure.

[04243] Proximity measures for phylogenetic network classes

Format : Talk at Waseda University

Author(s) : Yukihiro Murakami (TU Delft)Leo van Iersel (TU Delft)Mark Jones (TU Delft)Esther Julien (TU Delft)

Abstract : Orchard networks represent the evolutionary history of species as a tree structure with horizontal arcs. In this talk, we will explore the extent to which a network departs from being orchard. We will examine this deviation through varying graph operations such as adding leaves and removing arcs, as well as via vertex labeling. To provide context, we will compare these findings to proximity measures for other classes of networks, including tree-based and tree-child networks.

[03534] Data reduction rules to compute distances between phylogenetic trees

Format : Online Talk on Zoom

Author(s) : Simone Linz (University of Auckland)Steven Kelk (Maastricht University)Ruben Meuwese (Maastricht University)Simone Linz (University of Auckland)

Abstract : In evolutionary biology, phylogenetic trees are widely used to unravel the ancestral history of entities such as species or viruses. However, it is not uncommon to obtain different trees for the same data set. For example this can be due to methodological reasons. These tree incongruences motivate the use of distance measures in phylogenetics to quantify the dissimilarities between two phylogenetic trees. One popular distance between phylogenetic trees is called the tree bisection and reconnection (TBR) distance. Although this distance is NP-hard to compute, it is also fixed-parameter tractable. In this talk, we describe a series of results on the size of the TBR kernel, i.e. the size of two phylogenetic trees after pre-processing.

[03576] Parsimony and the rank of phylogenetic flattenings

Format : Online Talk on Zoom

Author(s) : David Bryant (University of Otago)

Abstract : The standard models of sequence evolution on a phylogeny determine probabilities for every character or site pattern. A flattening is an arrangement of these probabilities into a matrix, with rows corresponding to all possible site patterns for one set of taxa and columns corresponding to all site patterns for another. Flattenings have been used to prove difficult results in phylogenetic mathematics and form the basis of several methods of phylogenetic inference. We provide an exact formula for the rank of these matrices based on parsimony scores.

02545 (4/4) : 2E @A508 [Chair: Momoko Hayamizu]

[04303] Phylogenetic X-cactuses

Format : Talk at Waseda University

Author(s) : Taoyang Wu (University of East Anglia)

Abstract : In this talk we discuss X-cactus, a type of phylogenetic network which is essentially a cactus graph in which some vertices are labelled by elements from a set X of species. In this talk, we present a way to encode X-cactuses in terms of certain collections of X-partitions, and discuss a partial order on the set of X-cactuses, including an analysis of some properties of its least upper and greatest lower bounds.

[05034] On the Sackin index of galled trees

Format : Talk at Waseda University
Author(s) : Michael Fuchs (National Chengchi University)Bernhard Gittenberger (TU Wien)
Abstract : We will compute the Sackin index of some classes of phylogenetic networks that belong to so-called galled trees. In particular, we consider level-1 networks as well as the closely related one-component galled trees. The Sackin index is the sum of the vertex heights.
The method we approach the problem is specifying the networks in terms of combinatorial structures and performing a singularity analysis on the resulting generating functions.

[04250] Distribution of patterns in ranked tree-child networks

Format : Talk at Waseda University
Author(s) : Michael Fuchs (National Chengchi University)Hexuan Liu (National Sun Yat-sen University)Tsan-Cheng Yu (National Chengchi University)
Abstract : In this talk, I will first review tree-child networks and ranked tree-child networks (RTCN), and then explain our results on the distributional behavior of certain patterns in random RTCNs. These results extend the limit law for cherries and give rise to a conjecture for general patterns. This is the first such study for a class of phylogenetic networks.

[04323] Counting phylogenetic networks with the component graph method

Format : Talk at Waseda University
Author(s) : Michael Fuchs (National Chengchi University)
Abstract : The component graph method was proposed by Louxin Zhang in order to solve algorithmic problems for tree-child networks, galled networks, reticulation-visible networks and extensions. Moreover, the method was also used to obtain exact counting results of the number of networks with n leaves and k reticulations. In this talk, we will explain how we used the method to prove asymptotic counting results for tree-child networks with a fixed number of reticulation nodes and galled networks.

[02557] Collaboration of machine learning and physics-based simulation on earthquake disasters

Session Time & Room :

02557 (1/2) : 1C (Aug.21, 13:20-15:00) @D408

02557 (2/2) : 1D (Aug.21, 15:30-17:10) @D408

Type : Proposal of Minisymposium
Abstract : In Japan, strong-ground-motion data have been accumulated over a quarter of a century by a nationwide observation network. Large-scale physics-based simulations using HPC have enabled evaluations that consider the uncertainties of natural phenomena. Studies have begun to make up for the observation data related to large-scale disasters, which are currently lacking, using these simulation data. Furthermore, as studies toward hazard and risk assessment, surrogate modeling and damage assessment modeling by machine learning using observation and simulation data are being performed. In this mini-symposium, we will introduce the collaborative research of machine learning and physics-based simulation mainly on earthquake disasters.
Organizer(s) : Takahiro Maeda, Takuzo Yamashita, Asako Iwaki, Ryuta Imai
Classification : 86A15, 68T07
Minisymposium Program :

02557 (1/2) : 1C @D408 [Chair: Takahiro Maeda]

[04544] Physics-based long-period ground motion simulation for megaquakes

Format : Talk at Waseda University
Author(s) : Takahiro Maeda (National Research Institute for Earth Science and Disaster Resilience)
Abstract : There are limited seismic observation records directly linked to damage, such as ground motions caused by huge earthquakes and those near seismic faults. In order to evaluate such ground motions, physics-based seismic-ground-motion simulation using the three-dimensional subsurface structure and seismic-source models is carried out, which are used to clarify the causes of damage and predict future seismic motions. In this presentation, we will introduce ground-motion simulation methods and examples of their application to huge earthquakes.

[03695] A smoothing scheme for seismic wave propagation simulation with SDWave

Format : Online Talk on Zoom
Author(s) : Ryuta Imai (Mizuho Research & Technologies, Ltd.)
Abstract : We propose a smoothing scheme SDWave for seismic wave propagation simulation. The SDWave is based on a diffusionized wave equation with the fourth-order spatial derivative term. We mathematically explain some properties of the equation and how the SDWave works for smoothing. Then we give two discretization methods, FDM and mixed FEM, of the SDWave and apply it to the wave equation. This numerical experiment reveals that the SDWave is effective for filtering short wavelength components.

[04162] A quarter century of data from K-NET and KiK-net

Format : Online Talk on Zoom
Author(s) : Shin Aoi (National Research Institute for Earth Science and Disaster Resilience)Takashi Kunugi (National Research Institute for Earth Science and Disaster Resilience)Wataru Suzuki (National Research Institute for Earth Science and Disaster Resilience)Hiroyuki Fujiwara (National Research Institute for Earth Science and Disaster Resilience)
Abstract : Based on the lessons learned from the 1995 Kobe earthquake, the National Research Institute for Earth Science and Disaster Resilience (NIED) has constructed K-NET and KiK-net, nationwide strong-motion observation networks that homogeneously cover the entire country. The strong-motion database obtained from these world's largest strong-motion observation networks contains nearly one million archived records. In this presentation, these observation networks and databases will be introduced and the utilization of the data will be discussed.

[05004] Construction of strong motion database for data-driven ground-motion prediction models

Format : Talk at Waseda University
Author(s) : Asako Iwaki (National Resesarch Institute for Earth Science and Disaster Resilience)Nobuyuki Morikawa (National Resesarch Institute for Earth Science and Disaster Resilience)Takahiro Maeda (National Research Institute for Earth Science and Disaster Resilience)Hiroyuki Fujiwara (National Resesarch Institute for Earth Science and Disaster Resilience)
Abstract : We have been developing a strong-motion observation database as an infrastructural database utilized for seismic hazard assessment, from which data-driven regression models for ground-motion prediction (ground-motion models; GMMs) are to be constructed. The database is “biased” because there are insufficient number of records with large magnitudes and short distances. Consequently, GMMs are incapable of predicting such ground motion. To overcome this issue, we attempt to utilize simulated ground motion data to supplement the observation database.

02557 (2/2) : 1D @D408 [Chair: Takuzo Yamashita]

[03553] Optimal Transport in Seismic Wave Analysis

Format : Talk at Waseda University
Author(s) : Tomohisa Okazaki (RIKEN)
Abstract : An appropriate measure of the similarity between waveforms is crucial for seismic data analysis and modeling. The use of the Wasserstein distance in optimal transport theory has received attention in seismology because it captures time difference of waveforms. This presentation introduces two research directions: (1)

converting acceleration envelopes from long to short periods for predicting ground motions caused by scenario earthquakes; (2) the sliced Wasserstein distance between seismograms to efficiently measure the similarity of oscillating seismic signals. These applications support the effectiveness of the Wasserstein distance as a similarity measure of seismic waveforms.

[03984] Position-dependent inpainting for ground motion interpolation

Format : Online Talk on Zoom
Author(s) : Hirotaka Hachiya (Wakayama University)
Abstract : Acquiring continuous spatial data is essential to assess the damaged area just after the earthquake. To this purpose, we propose a framework of supervised spatial interpolation and apply highly advanced deep inpainting methods with the introduction of position-dependent partial convolution, where convolution kernel weights are adjusted depending on their position on an image based on the trainable position-feature map. We show the effectiveness of our proposed method, through experiments using ground-motion data.

[04967] Linkage of physics simulation and machine learning towards seismic risk assessment

Format : Talk at Waseda University
Author(s) : Takuzo Yamashita (NIED)Jun Fujiwara (NIED)Asako Iwaki (NIED)Hiroyuki Fujiwara (NIED)
Abstract : The authors are developing a seismic risk assessment method with physical simulation and machine learning. Response surfaces of seismic demand are modeled by Gaussian process regression. Low-dimensional features of seismic motions with auto-encoder were used as input data. An active learning method using Bayesian optimization was developed to construct the model with a small number of samplings. As a result, proposed model using samples less than 1/10th of the total data successfully predicted correct values.

[03740] Automated Building Damage Assessment using Multi-scale Siamese Deep Learning Network

Format : Talk at Waseda University
Author(s) : Bahareh Kalantar (RIKEN AIP)Naonori Ueda (RIKEN AIP)
Abstract : Timely information on building damage location is vital for emergency responders after natural disasters. Our proposed Multi-scale Siamese Building Damage Assessment model assesses damage by localizing buildings and classifying damage level into four categories. The model employs a multi-scale block to handle buildings of varying sizes. The results indicate the model's effectiveness, although it struggles with classifying minor and major damage.

[02561] Mathematical Puzzles and Games in Theoretical Computer Science

Session Time & Room :

02561 (1/2) : 1D (Aug.21, 15:30-17:10) @G601

02561 (2/2) : 1E (Aug.21, 17:40-19:20) @G601

Type : Proposal of Minisymposium
Abstract : Research on puzzles and games from the viewpoint of theoretical computer science has continued without any break in the history of theoretical computer science. Sometimes the research on computational complexity classes has proceeded by understanding the tons of puzzles. The wide collection of complete problems for a specific computational complexity class shares a common property, which gives us a deep understanding of the class. In this mini-symposium, we will explore the latest topics, results, and trends related to puzzles and games from the viewpoints of mathematics and theoretical computer science.

Organizer(s) : Ryuhei Uehara
Classification : 03D15, 52C45, 68Q15
Minisymposium Program :

02561 (1/2) : 1D @G601 [Chair: Ryuhei Uehara]

[04517] Uniqueness in puzzles and puzzle solving

Format : Talk at Waseda University
Author(s) : David Eppstein (University of California, Irvine)
Abstract : Many classical pencil-and-paper puzzles are defined in a way that requires the puzzle to have a unique solution. We explore the theoretical and practical implications of this requirement on the difficulty of puzzle-solving and puzzle generation, and the uses of the assumption of uniqueness in puzzle inference rules for puzzles including Sudoku, Slither Link / Loopy, and Map.

[04855] The Complexity of Games and Puzzles with Limited Width

Format : Talk at Waseda University
Author(s) : Tom van der Zanden (Maastricht University)
Abstract : When studying the complexity of games and puzzles, we usually consider generalized versions. For example, chess is played on an 8×8 board but when analyzing the complexity, we consider a version played on an $n \times n$ board. What if instead we consider the $n \times k$ variant, where k is a small number? In this talk, we survey some results on the computational complexity of games and puzzles with small width.

[04898] Mathematical Puzzles for Computer Scientists: Leisure or More?

Format : Talk at Waseda University
Author(s) : Hirokazu Iwasawa (Waseda University)
Abstract : The speaker, a creator of mathematical puzzles including mechanical puzzles, introduces a selection of puzzles that are likely to appeal to computer scientists, chosen from those he has devised in the past. While these puzzles can be enjoyed as leisure, some of them may potentially become subjects of research.

[05028] One Cycle to Rule Them All

Format : Talk at Waseda University
Author(s) : Giovanni Viglietta (University of Aizu)
Abstract : One of the consequences of the classification of the finite simple groups is that, if G is a primitive permutation group of degree n containing a cycle of length $n-3$ or less, then G is either the symmetric group S_n or the alternating group A_n. We will discuss some applications of this result to the theory of token permutation puzzles, as well as some open problems and directions for further research.

02561 (2/2) : 1E @G601 [Chair: Ryuhei Uehara]

[05095] Generalized Jankens

Format : Talk at Waseda University
Author(s) : Hiro Ito (University of Electro-Communications)
Abstract : Janken or rock-paper-scissors, which is a very simple game and it is usually used as a coin-toss in Japan, originated in China, and many variants are seen throughout the world. A variant of janken can be represented by an asymmetric digraph, where a vertex corresponds a sign and an arc (x,y) means sign x defeats sign y. However, not all asymmetric digraphs define useful janken variants, i.e., some janken variants may include a useless sign, which is strictly inferior than another sign in any case. We call a janken variant efficient if it contains no such a useless sign. We also introduced a measure of amusement of janken variants. We show the results of our mathematical research on janken variants.

[05219] Tilings and unfoldings

Format : Talk at Waseda University
Author(s) : Stefan Langerman (Université libre de Bruxelles)
Abstract : A tiling is a covering of the plane with copies of a geometric shape (tiles) without gaps or overlaps. A tiler is a shape that tiles the plane.
An unfolding is obtained by cutting along the surface of a polyhedron through all its vertices, and opening all the dihedral angles between adjacent faces to obtain a single flat non-overlapping geometric shape.
In this talk, I will explore connections between these fascinating concepts, highlight some recent results and mention several still unsolved algorithmic problems,

[05433] A Hardness Framework for Games and Puzzles: Motion Planning through Gadgets

Format : Talk at Waseda University
Author(s) : Erik D. Demaine (Massachusetts Institute of Technology)
Abstract : Many games and puzzles, especially video games, involve one or more characters moving through a changeable environment, like Mario in Super Mario Bros. We describe a powerful framework for proving hardness of such games by characterizing which "gadgets" it suffices to build in the game. A gadget is a local piece of environment with limited traversals, some of which change local state, which in turn change available traversals, similar to a finite automaton. We prove that very simple gadgets suffice to prove NP-hardness, PSPACE-hardness, or EXPTIME-hardness. This framework enables many hardness proofs, old and new, to be distilled down to a single diagram of a single gadget, resulting in new or simplified hardness proofs for games such as Super Mario Bros., Mario Kart, Pokémon, Lemmings, Rush Hour, and Chess. It also opens up a rich study of gadgets themselves, including which gadgets can "simulate" which others, where a "simulation" is a graph representing a reduction algorithm.

[05443] Map Folding

Format : Talk at Waseda University
Author(s) : Yushi Uno (Osaka Metropolitan University)
Abstract : Origami (paper folding) is not only a traditional Japanese entertainment, but also an interesting research topic in both engineering and computer science. One of the special cases of paper folding is map folding, and it has interesting open problems. In this talk, we will introduce the map folding problem and show their latest research results.

[02562] Recent development in data-driven modeling, data assimilation, and applications: meteorology, oceanography ionosphere, hydrology, environment

Session Time & Room :

02562 (1/2) : 2C (Aug.22, 13:20-15:00) @G703

02562 (2/2) : 2D (Aug.22, 15:30-17:10) @G703

Type : Proposal of Minisymposium
Abstract : Mullti-physics problems typically have essential dynamics. Numerical models are often hindered by difficulties in fully
capturing the relevant physics. Nowadays, more attention has been given to data science approaches. A hybrid AI and multiscale physical modeling approach could be the optimal way to provide a dynamic understanding of the governing equations. Data-driven modeling results may find some patterns which are not expected from physical modeling. This session aims at exploring the challenges of physical and data-driven modeling for real-time prediction and applications to geosciences, addressing uncertainty quantification, data assimilation, high-performance
computing, machine learning, numerical methods, and reduced order modeling.
Organizer(s) : Haroldo Fraga de Campos Velho, Fangxin Fang

[04677] Aadaptive mesh atmospheric model development

Format : Talk at Waseda University

Author(s) : Jinxi Li (Institute of Atmospheric Physics, Chinese Academy of Sciences)Fangxin Fang (Imperial College London)Pu Gan (Chengdu University of Information Technology)Christopher Pain (Imperial College London)Xiaofei Wu (Chengdu University of Information Technology)Zifa Wang (Institute of Atmospheric Physics, Chinese Academy of Sciences)Jie Zheng (Institute of Urban Environment, Chinese Academy of Sciences)Jiang Zhu (Institute of Atmospheric Physics, Chinese Academy of Sciences)

Abstract : This study presents the development of a three-dimensional unstructured adaptive finite-element model (Fluidity-Atmosphere) for atmospheric research. To improve the computational efficiency, a LSTM-based three-dimensional unstructured mesh generator is proposed to predict the evolution of the adaptive mesh. To evaluate the performance of adaptive meshes and physical parameterisations in Fluidity-Atmosphere, a series of idealized test cases have been setup and the unstructured tetrahedral meshes are adapted automatically with the specified fields in time and space.

[05293] A fast, high resolution pluvial flood model for risk assessment and real-time flood prediction

Format : Talk at Waseda University

Author(s) : Steven Cocke (Florida State University)Dong-Wook Shin (Florida State University)

Abstract : A high resolution, computationally efficient pluvial flood model has been developed to provide flash flood inundation estimates due to heavy precipitation events. The need for a computationally fast model is critical for estimating flood risk, where a large number of flood scenarios are needed to obtain a reliable probability distribution of flood depths and extents, as well as for real-time prediction where sufficient advance warning must be given to the public.

[04758] Data driven modelling and EnKF for spatial-temporal forecasting: Ozone and PM forecasting in China

Format : Talk at Waseda University

Author(s) : Fangxin Fang (Imperial College London)Meiling Cheng (Imperial College London)Shengjuan Cai (Imperial College London)Christopher Pain (Imperial College London)Yanghua Wang (Imperial College London)Michael I Navon (Florida State University)Jiang Zhu (Institute of Atmospheric Physics, Chinese Academy of Sciences)Jie Zhu (Institute of Urban Environment)Jinxi Li (Institute of Atmospheric Physics, Chinese Academy of Sciences)Xiaofei Wu (Chengdu University of Information Technology)

Abstract : Spatiotemporal forecasting involves generating temporal forecasts for system state variables across spatial regions. Data-driven methods, such as Convolutional Long Short-Term Memory (ConvLSTM) and deep convolutional generative adversarial network (DCGAN), are effective in capturing both spatial and temporal correlations. To further improve the predictive accuracy, the data assimilation EnKF is introduced to data driven modelling. Here, the performance of the data driven models has been demonstrated in hourly and daily spatiotemporal pollutant forecasting in China. The results have been compared to monitoring measurements and physical modelling results.

[05285] Machine learning for data assimilation and predictability to the atmospheric models

Format : Talk at Waseda University

Author(s) : Haroldo Fraga de Campos Velho (INPE: National Institute for Space Research)Rosangela Cintra (INPE: National Institute for Space Research)Steven Cocke (FSU: Florida State University)Vinicius Albuquerque Almeida (UFRJ: Federal University of Rio de Janeiro)Juliana Aparecida Anochi (INPE: National Institute for Space Research)Vinicius Monego (INPE: National Institute for Space Research)

Abstract : Data assimilation is one of the most important challenges for the computational effort of the operational centers for weather and climate predictions. In this talk, the use of machine learning approaches will be shown for numerical weather models. Techniques for data assimilation for global and regional models are addressed by artificial neural networks. The analysis computed by self-configuring a supervised neural network for the COAPS-FSU global model is designed to emulate the Local Ensemble Transform Kalman filter. A deep learning neural network is applied to the WRF-NCAR regional model as a new method for data assimilation, where the 3D-Var scheme is employed as a reference to the machine learning approach. Our numerical experiments show a significant reduction in the CPU-time to calculate the analysis maintaining the precision of the forecasting for both models. Finally, another important issue is to evaluate how good is the prediction, in other words, how we can calculate the forecasting confidence interval. The standard procedure to compute the confidence interval is to apply

the ensemble prediction. A novelty approach to estimate the prediction uncertainty quantification is addressed by using machine learning algorithms: neural networks, and decision tree formulations.

02562 (2/2) : 2D @G703 [Chair: Prof. Fangxin Fang]

[05103] Prediction of Swirling Fluid Flow Pattern in a River

Format : Talk at Waseda University
Author(s) : Haradhan Maity (Rishi Bankim Chandra Evening College)
Abstract : Swirling of water in a river occurs when rocks, holes, obstacles, or sudden changes in the river channel obstruct the flow of the water. The swirl is characterized by turbulent parameters (velocities and Reynolds stresses) and corresponding factors associated with turbulence. The main objective of this study is to obtain the governing equations for swirling flow and to predict the flow pattern. The proposed theoretical models show very good agreement with experimental data.

[02567] Data-driven Computational Mechanics for Structures, Structural Dynamics, and Materials

Session Time & Room :

02567 (1/3) : 4E (Aug.24, 17:40-19:20) @D102

02567 (2/3) : 5B (Aug.25, 10:40-12:20) @D102

02567 (3/3) : 5C (Aug.25, 13:20-15:00) @D102

Type : Proposal of Minisymposium
Abstract : Topics of this mini-symposium include, but not limited to, data-driven methods; incorporation of machine learning techniques; uncertainty quantification, and inverse problems in structures, structural dynamics and materials. Special emphasis is on the fields of structures, structural dynamics and materials with large-scale industry-relevant problems. Potential topics also include integrated modeling and design optimization, multiscale/multi-physics simulation based on the relevant data-driven process. The mini-symposium will bring together researchers working on both fundamental and applied aspects of data-driven computational mechanics to provide a forum for discussion, interaction, and assessment of techniques.
Organizer(s) : Haeseong Cho, Youngsoo Choi, SangJoon Shin

Minisymposium Program :

02567 (1/3) : 4E @D102

[03299] Investigation on the hyper-reduction approach for the contact-impact simulation

Author(s) : SANGJOON SHIN (Seoul National University)Seung-Hoon Kang (Seoul National University)Minho Hwang (Seoul National University)Yongse Kim (Republic of Korea Air Force)Haeseong Cho (Jeonbuk National University)
Abstract : In the multi-body finite element analysis, the contact algorithm usually requires huge computational cost to capture the temporal/spatial discontinuity on the contact surface. This presentation will investigate the projection-based reduced-order model for the contact-impact simulation. Discrete empirical interpolation method (DEIM) will be employed among the hyper-reduction approaches for computation acceleration. Treatment on each nonlinear component, internal and contact force vectors, will be examined for the generation of DEIM basis and sparse sampling.

[03428] Machine learning-based methods for the nonlinear structural analysis

Author(s) : Sangmin Lee (Seoul National University)SiHun Lee (Seoul National University)Haeseong Cho (Jeonbuk National University)SANGJOON SHIN (Seoul National University)

Abstract : Nonlinear structural analysis plays an important role in many fields of engineering, but it requires substantial computational resources to conduct repetitive high-fidelity simulation. In this study, a machine learning based non-intrusive model order reduction (MOR) is proposed for the parameterized structural analysis in which the geometric nonlinearities are involved. For this purpose, the proper orthogonal decomposition (POD) is carried out to gather the reduced bases from the full-order snapshot matrix. Then, the modified nouveau variational autoencoder (mNVAE) is conducted to interpolate such POD coefficients.

[05003] Manifold-Augmented Deep learning-based Approach for Prediction of Airfoil Aerodynamic Performance at Low Reynolds Number

Author(s) : Seongwoo Cheon (Jeonbuk National University)Hyejin Kim (Jeonbuk National University)Seokhui Ryu (Gyeongsang National University)Haeseong Cho (Jeonbuk National University)Hakjin Lee (Gyeongsang National University)

Abstract : Computational fluid dynamics (CFD) analysis usually gives an accurate performance, better reliability, but it requires intensive computational time and cost. In this study, the deep learning-based MOR framework is proposed to predict the aerodynamic performance of airfoils. For this purpose, the proper orthogonal decompostion (POD), autoencoder (AE), and variational autoencoder (VAE) is carried out to gather the latent vectors from full-order snapshot matrix. Moreover, a novel generative model using projection-based manifold learning is proposed to overcome the lack of data due to the computational cost of CFD analysis and augment the training data.

02567 (2/3) : 5B @D102

[03424] Model Order Reduction for Fluid-Structure Interaction Analysis via the Data-driven Machine Learning

Author(s) : SiHun Lee (Seoul National University)Sangmin Lee (Seoul National University)Haeseong Cho (Jeonbuk National University)SANGJOON SHIN (Seoul National University)

Abstract : Analysis on the multi-disciplinary analysis such as a fluid-structure interaction usually requires huge computational time due to nonlinearity and interpolation. In this research, a completely data-driven model order reduction method is considered that is capable of the parametric estimation regarding fluid-structure interaction analysis. The proposed method first constructs a snapshot matrix that contains various parametric result and then, singular value decomposition (SVD) is conducted. By SVD, proper orthogonal decomposition (POD) modes and coefficients will be gathered, which is interpolated by the machine learning technique.

[05031] Data-driven Model Reduction Approach for Multiscale Homogenization of Microstructure

Author(s) : Hyejin Kim (Jeonbuk National University)Dahan Song (Jeonbuk National University)Seongwoo Cheon (Jeonbuk National University)Haeseong Cho (Jeonbuk National University)

Abstract : Given the heterogeneous nature of composite materials at the microscopic level, computational multiscale homogenization can be employed to obtain effective macroscopic material properties. However, it requires significant computational resources for recursive procedures. In this study, an efficient data-driven homogenization method is proposed. Herein, a clustering-based data-driven model reduction and autoencoder are utilized to alleviate high-dimensional data, followed by the application of a recurrent network model to predict the stress field of microstructure from loading conditions.

[05220] An efficient neural network approximation of entropy solutions

Author(s) : Donsub Rim (Washington University in St. Louis)Gerrit Welper (University of Central Florida)Randall J LeVeque (University of Washington)

Abstract : We show that a family of neural networks with fixed number of layers and degrees of freedom, can approximate any entropy solution to scalar conservation laws and furthermore, the embedded dynamics in the free parameters is linear regardless of the complexity of the solution.

02567 (3/3) : 5C @D102

[04471] Hypernetwork-based low-rank neural ordinary differential equations for solving parameterized partial differential equations

Author(s) : Kookjin Lee (Arizona State University)Youngsoo Choi (Lawrence Livermore National Laboratory)Guangting Yu (Arizona State University)
Abstract : In this work, we propose a hypernetwork-based reduced order modeling approach for solving parameterized partial differential equations. The hypernetwork is trained to produce model parameters of latent dynamics models, which governs the evolution of reduced states in a low-dimensional manifold. We parameterize the latent dynamics as neural ordinary differential equations (NODEs). To improve the hypernetwork's inference capability, we develop a variant of NODEs, low-rank NODEs, where the model parameters are approximated in low-rank.

[05436] High-dimensional regression using partition of unity networks (POU-Net)

Author(s) : Eric Felix Darve (Stanford University)Tiffany Fan (Stanford University)Nathaniel Trask (Sandia National Laboratories)Marta D'Elia (Stanford University)
Abstract : High-dimensional regression problems present challenges in scientific and engineering applications. Conventional approaches like polynomial interpolation become computationally expensive as the dimensionality increases exponentially. Sparse grids and radial basis function regression have been developed as alternatives, but they suffer from high computational costs, low accuracy, and instability in some cases. Deep Neural Networks (DNNs) have proven to be a reliable regression method for high-dimensional problems. However, designing an optimal DNN structure, weight initialization, and achieving high accuracy with the optimizer pose difficulties, making error control challenging in engineering and scientific applications. Additionally, reproducibility is often problematic. To address these issues, we introduce POU-Net and its variants. POU-Net takes advantage of DNNs' dimensionality reduction and regression capabilities. Additionally, it utilizes the reliability, accuracy, and computational efficiency of polynomial interpolation within the reduced dimension. Our approach enables robust and accurate regression across a wide range of input dimensions. We evaluate the proposed method using various benchmarks and applications, comparing its performance to state-of-the-art techniques.

[05408] An augmented Lagrangian method to accelerate constrained optimization using hyperreduction

Author(s) : Tianshu Wen (University of Notre Dame)Matthew Zahr (University of Notre Dame)
Abstract : We present a numerical method to efficiently solve constrained optimization problems governed by large-scale nonlinear systems of equations using an augmented Lagrangian framework. A globally convergent, hyperreduced trust-region framework is embedded in the proposed framework to accelerate the optimization process in each major iteration. The trust-region framework constructs a hyperreduction model via empirical quadrature procedure on-the-fly, which completely avoids an offline training phase.

[02569] Quantification of Business Uncertainties through Industrial Mathematics

Session Time & Room :

02569 (1/2) : 3C (Aug.23, 13:20-15:00) @D101

02569 (2/2) : 3D (Aug.23, 15:30-17:10) @D101

Type : Proposal of Industrial Minisymposium
Abstract : We are living in exceptional times, as trade conflicts, climate change and crises-related-pandemic are creating uncertainties that may influence the current business environment. Businesses face risks that are difficult to be measured. However, collaborative efforts among academia, industries, government and civil society through industrial mathematics will facilitate IN creating new sustainable ways of doing business in an unstable

environment. This APCMfI minisymposium will discuss the handling and managing business uncertainties. Firstly, identification of challenges introduced by the uncertainties at operational and decision making, and secondly, the deliberation on the techniques in quantifying uncertainties and tackling the challenges.

[03389] Mathematics behind performance estimation of multiscale structures

Format : Talk at Waseda University
Author(s) : Yichao Zhu (Dalian University of Technology)
Abstract : In business involving commercial products carrying multiscale structures, utilisation of uncertainty quantification tools that are both reliable and efficient is still needy. In this talk, appropriate use of mathematical techniques of asymptotic analysis is proposed to resolve the issue. As an example, uncertain behaviours of fibre-reinforced composite laminates are considered. Through asymptotic analysis, it is shown that the building blocks of such thin plate configurations are two-dimensional slices, and analytical solutions are even available in the situation in consideration. Correlations between the confidence interval about the plate bending stiffness and manufactural uncertainties can then be established with relative ease.

[04204] Handling Uncertainties in Decision Making

Format : Online Talk on Zoom
Author(s) : ZAITUL MARLIZAWATI ZAINUDDIN (UTM CENTRE FOR INDUSTRIAL AND APPLIED MATHEMATICS (UTM-CIAM))NORSHELA NOH (UNIVERSITI TUN HUSSEIN ONN MALAYSIA (UTHM))ARIFAH BAHAR (UTM CENTRE FOR INDUSTRIAL AND APPLIED MATHEMATICS (UTM-CIAM))
Abstract : This study highlights the importance of incorporating uncertainty quantification of stochastic parameters in stochastic programming compared to expert judgement approach. It proposes a methodology for integrating stochasticity of input parameters into two-stage stochastic programming. The approach involves constructing a binomial scenario tree, which combines a binomial tree for each stochastic parameter and discretizes the continuous probability distribution of the underlying stochastic process. The scenario tree consists of all possible scenarios to explain future situations.

[04896] Aggregation value regression and its application to household demand forecasting

Format : Talk at Waseda University
Author(s) : Kei Hirose (Kyushu University)Hiroki Masuda (University of Tokyo)Hidetoshi Matsui (Shiga University)
Abstract : In recent years, a number of sensor data have been collected, and some researchers are interested in the aggregation values, such as congestion levels and electricity demand. This study constructs a regression modeling specifically designed for aggregation value forecasting. The proposed modeling is applied to household demand forecasting.

[04885] Ensemble based approaches for business uncertainty quantification

Author(s) : Heri Kuswanto (Institut Teknologi Sepuluh Nopember)
Abstract : Uncertainty quantification becomes a crucial work in business modelling. Ensemble approaches have been proposed as one of the ways to quantify the uncertainty and has been proven to be a powerful method to generate more accurate predictions. The method belongs to the class of model combination, where the uncertainty is quantified by combining the information from several models through different ways. This talk will give an overview of ensemble-based approaches with some examples of applications.

02569 (2/2) : 3D @D101 [Chair: OSAMU SaEKI]

[04526] Topological methods for detection of uncertainties in Artificial Intelligence

Format : Talk at Waseda University
Author(s) : Hiroaki Kurihara (Artificial Intelligence Laboratory, Fujitsu Research, Fujitsu)
Abstract : Recently, with the development of AI technology, AI has been increasingly used for decision-making in various domains where sophisticated knowledge is required. Although well-trained AI models are used in such situations, AI has a weakness in that its predictive ability is reduced for data that was not included during training. In this talk, we will introduce a method to verify the uncertainty of the output of AI by observing the topological information of trained models.

[04919] Consecutive eigenvalues distribution of asymmetric quantum Rabi models

Format : Talk at Waseda University
Author(s) : MASATO WAKAYAMA (NTT Institute for Fundamental Mathematics)
Abstract : We focus spectral structure of the asymmetric quantum Rabi models (AQRM), which are widely studied as one of the most fundamental models of light-matter interaction. Particularly, we will discuss the symmetric structure of the consecutive (i.e., nearest) eigenvalues of the AQRM when we vary the flip term, which is the symmetric-breaking parameter of the Hamiltonian.

[05125] Changing the Misconception of Subsea Cable Laying Norm

Format : Talk at Waseda University
Author(s) : Kamaudin Ismail (Ifactors Sdn Bhd)
Abstract : The world today is undeniably heavily reliant on technology. As a result of the continuous advancement in technology, the demand for data transmission services is at an all-time high.

Subsea cables are one of the major foundation of global connectivity. It is responsible for transmitting 99% of international data traffic systemwide.

However, despite being crucial factor in global connectivity, the process of laying subsea cables is still widely misunderstood.

This paper aims to address this misconception and to shed lights on the real process of subsea cable laying.

A conventional cable laying concept is by mobilizing a dedicated cable lay vessel. However, the main issue in this equation is that the vessel can only be used for cable lay process alone.

The above concept above gave an opportunity for Ifactors to venture into an unknown open concept. It is a new technique/process which is modular and easier to setup for a short distance cable lay.

[04095] Handling Uncertainties for Wastewater Treatment in Oxidation Pond

Format : Online Talk on Zoom
Author(s) : Zainal Abdul Aziz (Universiti Teknologi Malaysia)Arifah Bahar (Universiti Teknologi Malaysia)Amir Syafiq Hamzah (Universiti Teknologi Malaysia)
Abstract : Oxidation pond techniques are effective for wastewater treatment process due to low operational cost. A stochastic model accommodates the correlation between the phototrophic bacteria mPHO and pollutant existing in oxidation pond. The model analyses and handles the uncertainties of this process, particularly the effect of mPHO on the degradation of pollutant. The model parameters estimation use simulated maximum likelihood based on the real data collected from an oxidation pond located in Taman Timor, Johor, Malaysia.

[02570] Parameter Estimation, Targeted Observation, and Data Assimilation in Coupled Systems

Session Time & Room :

02570 (1/3) : 5B (Aug.25, 10:40-12:20) @D407

02570 (2/3) : 5C (Aug.25, 13:20-15:00) @D407

02570 (3/3) : 5D (Aug.25, 15:30-17:10) @D407

Type : Proposal of Minisymposium
Abstract : This minisymposium focuses on the coupled weather/climate prediction systems, whose components are atmosphere, land surface, chemistry, etc.; topics include but not limited to parameter estimation, data assimilation, targeted observation, sensitivity analysis, uncertainty quantification, and predictability in the coupled systems.
Organizer(s) : Sujeong Lim, Ji Won Yoon, Xiaohao Qin, Ting-Chi Wu, Shigenori Otsuka
Classification : 86-10, 86A10, 47N50, 47N60, 90C31
Minisymposium Program :

02570 (1/3) : 5B @D407 [Chair: Shigenori Otsuka, Ji Won Yoon]

[04638] Improving Numerical Forecast Skill: Combinational Parameter Optimization and Coupled Data Assimilation

Format : Talk at Waseda University
Author(s) : Seon Ki Park (Ewha Womans University)
Abstract : Numerical weather prediction (NWP) requires coupled modeling and data assimilation, and its forecast skill depends on uncertainties in physical parameterizations and initial conditions. This study illustrates that NWP skill can be improved through optimization of physical parameterizations and data assimilation; the former includes combinational optimization which seeks for the optimal set of parameterizations followed by optimal parameter estimation, whereas the latter develops the coupled data assimilation systems such as the WRF-Noah LSM and the WRF-Chem.

[05388] Application of the CNOP-PEP method in hydrological ensemble prediction in China to reduce model parameter uncertainties

Author(s) : Guodong Sun (Institute of Atmospheric Physics, Chinese Academy of Sciences)Mu Mu (Fudan University)
Abstract : In this talk, a conditional nonlinear optimal parameter perturbation ensemble prediction (CNOP-PEP) method is proposed. The CNOP-PEP method is employed to carry out ensemble prediction of evapotranspiration (ET) over Tibetan Plateau (TP). The numerical results show that ensemble prediction experiments conducted with the CNOP-PEP method exhibit better prediction skills compared to the reference ET over the TP. The prediction skill by employing the CNOP-PEP method is more excellent than those of the traditional methods.

[05401] The effect of Westerly Wind Burst on ENSO

Author(s) : Youmin Tang (University of Northern British Columbia)
Abstract : Westerly wind bursts (WWBs), as a semi-stochastic process, play a vital role in El Niño–Southern Oscillation (ENSO). However, current dynamical models have large challenges in the representation of WWBs. In this study, we introduced and developed several WWB parameterization schemes, including a novel scheme developed using the deep learning technique. The effect of these parameterization schemes on ENSO simulation and prediction was comprehensively evaluated and systematically compared using coupled models with varied complexity.

[04422] Improving Model Uncertainty in Physical Parameterizations: Combinational Optimizations Using Genetic Algorithm in the Coupled Atmosphere-Chemistry Model

Format : Talk at Waseda University

Author(s) : Ji Won Yoon (Ewha Womans University)

Abstract : The Asian dust storm is one of the important air pollution problems in South Korea; thus, it is significant to improve the air quality forecasting skill using a numerical prediction system. In this study, we developed an optimization system by applying the micro-genetic algorithm (μGA) interfaced with the Weather Research and Forecasting model coupled with Chemistry (WRF-Chem) to enhance air quality forecasting skills in East Asia. We introduce the results of the combinational optimizations.

02570 (2/3) : 5C @D407 [Chair: Xiaohao Qin]

[03616] A novel approach of data assimilation: application to ENSO diversity predictions

Author(s) : Wansuo Duan (Institute of Atmospheric Physics, Chinese Academy of Sciences)

Abstract : The talk introduces an approach of data assimilation (DA) entitled nonlinear forcing singular vector (NFSV) to neutralize combined effect of initial and model errors. The approach is applied to an intermediate-complexity ENSO model and reproduces the conditions of the emergence of both EP- and CP-El Niño events, eventually distinguishing El Niño types at two-season lead time in predictions. The NFSV-DA is a useful DA approach for offsetting initial and model error effects for ENSO predictions.

[04195] Exploring data-driven sparse sensor placement for determining rain gauge locations

Author(s) : Daiya Shiojiri (Chiba University)Eiryo Kawakami (Chiba University)Shunji Kotsuki (Chiba University)

Abstract : This study explores the data-driven sparse sensor placement (SSP) to determine rain gauge locations for efficiently estimating the spatiotemporal interpolation of precipitation. The SSP determines the rain gauge locations using dominant modes extracted from spatiotemporal precipitation data over a training period. Through evaluations using radar-analyzed precipitation, we found that the SSP-based rain gauges enable to provide more accurate precipitation fields compared to the current operational rain gauge network in Japan.

[04176] The Conditional Nonlinear Optimal Perturbation method and it's application to the targeting observation for tropical cyclones

Author(s) : Xiaohao Qin (LASG, Institute of Atmospheric Physics, Chinese Academy of Science)Mu Mu (Fudan University)Feifan Zhou (LACS, Institute of Atmospheric Physics, Chinese Academy of Science)Boyu Chen (Chinese Meteorology Administration)Jie Feng (Fudan University)

Abstract : To augment the routine observational network for better forecasts of tropical cyclones (TCs), targeting observations (TOs) have developed rapidly during the past several decades over China. In consequence, TC forecasts have benefitted a lot from these field campaigns. In this talk, research work and field campaigns of TOs are briefly overviewed. After that, we introduce a method named the conditional nonlinear optimal perturbation (CNOP), which is utilized to identify those areas should be additionally observed with priority in TOs. Using some examples, we explain how to use the CNOP method in mathematics, its impacts on improving TC forecasts, and its latest application in real time operational forecasts.

[04998] Towards targeted observations of meteorological state for improving PM2.5 forecasts

Author(s) : Lichao Yang (Institute of Atmospheric Physics, Chinese Academy of Sciences)Wansuo Duan (Institute of Atmospheric Physics, Chinese Academy of Sciences)

Abstract : An advanced approach of conditional non-linear optimal perturbation (CNOP) was introduced to identify the sensitive area for targeted observations of meteorological fields associated with PM2.5 concentration forecasts of a heavy haze event that occurred in the Beijing–Tianjin–Hebei (BTH) region, China. We show numerically and physically that preferentially deploying additional observations in the sensitive areas identified by the CNOP approach can greatly improve the forecasting skill of PM2.5 forecasts.

[03679] A case study of a dust event using the RAMS-MLEF atmosphere-aerosol coupled data assimilation system

Author(s) : Ting-Chi Wu (Central Weather Bureau/International Integrated Systems, Inc.)Milija Zupanski (Colorado State University/Cooperative Institute for Research in the Atmosphere)
Abstract : This study demonstrates the capability of an atmosphere-aerosol coupled data assimilation RAMS-MLEF (Regional Atmospheric Modeling System - Maximum Likelihood Ensemble Filter) using a dust event over the Arabian Peninsula, which is an area known to be severely under-sampled. One important lesson learned is that the location and timing of observations largely determines the improvements achieved by data assimilation. The lack of observations also makes it very challenging to perform a quantitative verification of results.

[04249] Impact of Soil Moisture Observation in the Coupled Atmosphere-Land Data Assimilation System

Format : Talk at Waseda University
Author(s) : Sujeong Lim (Ewha Womans University)Seon Ki Park (Ewha Womans University)Milija Zupanski (Colorado State University/Cooperative Institute for Research in the Atmosphere)
Abstract : Soil moisture is important in a coupled atmosphere-land surface model because it propagates to atmospheric variables in the planetary boundary layer through the latent and sensible heat fluxes. In this study, we introduce the results of the assimilation of both atmospheric and soil moisture observations within a strongly coupled data assimilation system, taking into account the cross-covariance between the atmosphere and land.

[04599] Application and improvement of Land Data Assimilation System at CWB

Author(s) : PO-HSUN LIN (CWB / International Integrated Systems, Inc. (IISI))
Abstract : Interactions between land and atmospheric components are critical for coupled model forecasting. Improved accuracy of soil initial conditions has been shown to enhance land-atmosphere interactions in coupled processes. The Central Weather Bureau of Taiwan has collaborated with the National Center for Atmospheric Research to optimize the use of the High-Resolution Land Data Assimilation System in order to improve the deterministic forecast over Taiwan. The results of this collaboration will be presented in this summary.

[02578] Interfaces and Mixing – Conservation Laws and Boundary Value Problems

Session Time & Room :

02578 (1/4) : 1E (Aug.21, 17:40-19:20) @G704

02578 (2/4) : 2C (Aug.22, 13:20-15:00) @G704

02578 (3/4) : 2D (Aug.22, 15:30-17:10) @G704

02578 (4/4) : 2E (Aug.22, 17:40-19:20) @G704

Type : Proposal of Minisymposium
Abstract : Interfaces and interfacial mixing and their non-equilibrium dynamics control a broad range of processes in nature, technology, industry, from supernovae and fusion to alternative energy sources and purification of water. Mathematically, these problems are extremely challenging to study in theory and in simulations. Analytically, one needs to solve the conservation laws, augmented with singular boundary value problem and ill-posed initial value problem. Numerical modeling imposes high demands on the accuracy, precision and the scale of computations. The mini-symposium builds upon recent achievements in understanding the dynamics of interfaces and mixing, and reports solutions for long-time challenges in fundamentals and applications.

Classification : 35Q35
Minisymposium Program :

02578 (1/4) : 1E @G704

[03293] Interaction between a particle and a liquid surface

Author(s) : Alexander Nepomnyashchy (Technion - Israel Institute of Technology)
Abstract : The interaction of a particle with a liquid interface takes place in many engineering processes. We consider the motion of a spherical particle rising in a viscous fluid towards the interface. The particle mobility can be significantly modified
by a surfactant adsorbed on the interface. Upon the particle attachment to the interface, the spatial inhomogeneity of
the wetting properties on the particle surface strongly enhance the duration of the system equilibration.

[03383] Smooth Navier-Stokes Solutions

Author(s) : James Glimm (Stony Brook University)
Abstract : Smooth Navier-Stokes solutions require a non-physical choice of entropy minimization, achieved constructively as a mean value relative to turbulent fluctuations. Other solutions are not smooth. Drivers of the proof are a turbulence analogue of renormalized perturbation theory, adapted from Quantum Field theory, and shown to be Borel resummable convergent on a dense set of turbulent states, together with the Foias theory of Young measures.

[03416] Determining control parameters for unsteady pulling of mass-spectrometry emitters

Author(s) : Yvonne Stokes (The University of Adelaide)Gagani Pathumika Ranathunga (Oktal Sydac)Michael Chen (The University of Adelaide)
Abstract : Asymptotic modelling is used to examine the heating and pulling of an axisymmetric glass tube with an internal overpressure to form a taper with near-uniform bore and small wall thickness at the tip, as desired for mass-spectrometry emitters. There is no unique choice of pulling force and pressure to achieve the desired geometry, which is sensitive to the parameters. Phase plane plots are used to understand the dependence of the geometry on the control parameters.

[03716] Front Tracking Simulations of reshocked Richtmyer-Meshkov Instability

Author(s) : Tulin Kaman (University of Arkansas)Ryan Holley (University of Arkansas)
Abstract : In this talk, we present an increasingly accurate and robust front tracking method for the numerical simulations of re-shocked Richtmyer-Meshkov Instability (RMI) of an air/SF6 interface. The front-tracking with the weighted essentially non-oscillatory (WENO) schemes are compared with Collins and Jacob (2002) shock tube experiments. We study the effects of high-resolution high-order WENO simulations on the fine detail complex vortex roll-up structures and perform verification and validation studies to achieve good agreement between simulations and experiments.

02578 (2/4) : 2C @G704

[03735] Can environmental and intrinsic mechanisms of quantum mixing be distinguished experimentally?

Author(s) : Alexander Y Klimenko (The university of Queesnland)Alexander Y. Klimenko (The university of Queesnland)
Abstract : This presentation considers the possibility of quantum experiments that can, at least in principle, allow us to distinguish intrinsic and environmental mechanisms of decoherence. This experiment can be interpreted as a quantum-mechanical version of non-equilibrium mixing between two volumes separated by a thin interface. Decoherence is understood here as a general process that does not involve any significant exchanges of energy and is governed by a particular class of Kraus operators. This presentation considers different regimes of quantum tunnelling in the presence of different types of decoherence and shows that, at least under some conditions,

intrinsic and environmental types of decoherence affect the tunnelling rates differently and, therefore, can be distinguished experimentally.

[03969] Exact solutions to nonlinear difference equations associated with Henon maps

Author(s) : Chihiro Matsuoka (Osaka Metropolitan University)Koichi Hiraide (Osaka Metropolitan University)
Abstract : We present exact solutions in non-integrable systems, taking the Henon map as an example. The obtained solutions describe the stable and unstable manifolds at saddle fixed points and make it possible to calculate such invariant manifolds with complex structures. Using the obtained functions, we visualize the hyperbolic system encircling KAM tori and the Henon attractor, in which chaotic orbits are captured accurately.

[03994] Nonlinear interaction of two nonuniform vortex interfaces and large vorticity amplification

Author(s) : Katsunobu Nishihara (Osaka University)Chihiro Matsuoka (Osaka Metropolitan University)
Abstract : Vortex dynamics is an important research subject for geophysics, engineering and plasma physics. The nonlinear interaction of two nonuniform vortex interfaces with density stratification is investigated using the vortex sheet model. When a strong vortex sheet approaches a weaker vortex sheet with opposite-signed vorticity, a locally peaked secondary vorticity is induced on the latter sheet. This emerging secondary vorticity results in a remarkable vorticity amplification on the stronger sheet, forming pseudo vortex pairs.

[04164] Compressible Kelvin-Helmholtz and Rayleigh-Taylor Instabilities

Author(s) : Yasuhide Fukumoto (Kyushu University)Rong Zou (Zhejiang Normal University)Kazuo Matsuura (Ehime University)Nobutaka Taniguchi (University of Tokyo)
Abstract : For an incompressible fluid, an interface of tangential-velocity discontinuity suffers from the Kelvin-Helmholtz instability (KHI), with growth rate proportional to velocity discontinuity. Compressibility acts to stabilize KHI and, if limited to two dimensions, suppresses KHI for the Mach number larger than $\sqrt{8}$. We extend this analysis to include the gravity effect, with allowance made for density discontinuity and surface tension. Numerical simulations of a compressible mixing layer, being desingularization, exhibit complex vortical structures in turbulence.

02578 (3/4) : 2D @G704

[04478] Compressible Vortex Sheets and Free Boudary Problems

Author(s) : Gui-Qiang George Chen (University of Oxford)
Abstract : We are concerned with the nonlinear stability/instability of compressible vortex sheets and related interfaces in compressible fluid flows governed by the Euler equations and related nonlinear PDEs. Such problems can be formulated as characteristic free boundary problems for nonlinear hyperbolic conservation laws and related equations. In this talk, we will discuss some recent developments in the analysis of their stability/instability and explore stabilizing mechanisms such as magnetic, relativistic, and compressibility effects.

[04545] Special self-similar class in Rayleigh-Taylor interfacial mixing

Author(s) : Snezhana Abarzhi (University of Western Australia)
Abstract : Rayleigh-Taylor mixing governs a broad range of processes in nature and technology. We discover special self-similar class in Rayleigh-Taylor mixing with variable accelerations, by exploring its symmetries, scaling laws, correlations and fluctuations. We find that Rayleigh-Taylor mixing can vary from super-ballistics to sub-diffusion depending on the acceleration and retain memory of deterministic conditions for any acceleration. We explain high Reynolds number experiments in Rayleigh-Taylor mixing and provide new insights for processes driven by the mixing.

[04546] Interface dynamics in ideal and realistic fluids

Author(s) : Dan V. Ilyin (California Institute of Technology)Snezhana Abarzhi (University of Western Australia)
Abstract : Interfaces and mixing and their non-equilibrium dynamics are ubiquitous to occur in nature and technology. We develop theory of interface dynamics, directly linking flow fields and interfacial transport and discovering fluid instabilities never previously discussed. In ideal and realistic fluids, the interface stability is set by

the interplay of the macroscopic inertial mechanism balancing the destabilizing acceleration, whereas microscopic thermodynamics create vortical fields in the bulk. The interface is the place where balances are achieved.

[05008] Generalized Ideal Momentum Jet Model for Non-Circular Nozzle Geometries in Turbulent Pressure-Atomized Liquid Jets: Theoretical and Experimental Comparison

Author(s) : Fermin Franco-Medrano (Autonomous University of Baja California)
Abstract : We propose a generalized mathematical model for turbulent pressure-atomized liquid jets with non-circular nozzles and compare to experimental data. We obtain analytical expressions for the locally homogeneous two-phase flow properties as a function of gauge pressure, nozzle dimensions, and fluid densities. Interestingly, we find that the equations describing elliptical and rectangular nozzles are generalizations of those for circular nozzles. Strong correlation is observed between the experimental data and our model function for the elliptical nozzle jet velocity.

02578 (4/4) : 2E @G704

[05070] A novel data analysis method for Rayleigh-Taylor mixing

Author(s) : Kurt Christian Williams (The University of Western Australia)Snezhana Abarzhi (University of Western Australia)
Abstract : A recent data analysis method has shed new light on the isotropy and dynamics of Rayleigh-Taylor mixing; the late-stage behavior of two fluids accelerated against their density gradient. In this talk, we elaborate this data analysis method, which employs Whittle estimates based on a new goodness-of-fit test statistic generated from Monte-Carlo methods. Employing a fitting function from isotropic turbulence, the method finds the isotropy of Rayleigh-Taylor
mixing and captures a broad dynamic range.

[02591] Recent advances in data-driven modeling and computational methods

Session Time & Room :

02591 (1/2) : 5C (Aug.25, 13:20-15:00) @G301

02591 (2/2) : 5D (Aug.25, 15:30-17:10) @G301

Type : Proposal of Minisymposium
Abstract : The minisymposium "recent advances in data-driven modeling and computational methods" covers a wide range of topics including topological data analysis, physics-informed neural networks, and data-driven modeling and numerical methods. It provides a platform for experts and junior researchers to exchange ideas and share knowledge in these areas.

This minisymposium is organized by the East Asia section of SIAM (EASIAM), and the organizers and speakers represent a broad list of countries covered by SIAM. We hope the minisymposium would provide an ideal opportunity for communication among EASIAM members, and to promote EASIAM internationally.

[02896] Topological Data Analysis Experience in Malaysia: A Survey

Format : Talk at Waseda University
Author(s) : Fatimah Abdul Razak (Universiti Kebangsaan Malaysia)Mohd Salmi Md Noorani (Universiti Kebangsaan Malaysia)
Abstract : Topological Data Analysis (TDA) is used to detect qualitative features in datasets. It is often combined

with techniques from Machine Learning, Time Series Analysis as well as Complex Network Analysis to achieve better predictions and classifications. This presentation outlines our experiences of using TDA to investigate several Malaysian data sets in order to predict floods and financial crises, classify different levels of air quality within a certain time window as well as detecting critical transitions.

[03038] A Reaction Network Analysis of Insulin Signaling

Format : Talk at Waseda University
Author(s) : Angelyn Lao (De La Salle University)
Abstract : The insulin signaling system is an important metabolic system that initiates the uptake of glucose into the cell. This reduced ability of cells to use available insulin for energy metabolism is viewed as a common factor in diseases such as obesity, type 2 diabetes, metabolic syndrome, and cancer, and more recently to brain insulin resistance in connection with mild cognitive impairment and Alzheimer’s disease (AD). The complexity of the insulin signaling system, both in terms of the number of molecular components involved as well as the intricate combination of positive and negative feedback loops, clearly warrants the application of mathematical modeling and computational tools. This talk presents the construction of the insulin signaling reaction network and the analysis of its robustness and stability using Chemical Reaction Network Theory.

[03583] Comparing Lagrangian Particle Dispersion Models in Turbulent Flows: A Data-Driven Approach

Format : Talk at Waseda University
Author(s) : Nurul Huda Mohd Ramli (Universiti Brunei Darussalam)Haziq Jamil (Universiti Brunei Darussalam)
Abstract : This talk introduces a data-driven method for comparing two Lagrangian stochastic particle models in turbulent flows: the random flight model (RFM) and the simpler random displacement model (RDM). The RFM offers a more realistic representation of eddy velocities but can pose computational challenges. Using a Bayesian approach to infer the models' parameters, the objective is to provide a better understanding of their dynamics and assist researchers in selecting the appropriate model for their specific needs.

[03912] Error estimates of numerical methods for the Dirac equation

Format : Talk at Waseda University
Author(s) : Ying Ma (Beijing University of Technology)Jia Yin (Lawrence Berkeley National Laboratory) Yue Feng (Sorbonne Université) Lizhen Chen (Beijing Computational Science Research Center)
Abstract : The Dirac equation is a relativistic wave equation which plays an important role in relativistic quantum physics and provides a natural description of relativistic spin-1/2 particles. In this talk, we present numerical methods including several finite difference methods, the symmetric and asymmetric exponential wave integrator Fourier pseudospectral methods and establish the error estimates for the discretization of the Dirac equation in different regimes. Extensive numerical results are reported to support our error estimates.

02591 (2/2) : 5D @G301 [Chair: Tao Zhou]

[04021] A learning-based projection method for model order reduction of transport problems

Format : Talk at Waseda University
Author(s) : ZHICHAO PENG (Hong Kong University of Science and Technology)Fengyan Li (Rensselaer Polytechnic Institute)Min Wang (University of Houston)
Abstract : Due to the slow decay of the Kolmogorov n-width for transport problems, classical linear reduced order model (ROM) may be inefficient. To address this issue we propose a learning-based projection method following an offline-online decomposition framework. A moving low dimensional subspace is learned offline, and in the online stage, the full order problem is projected onto the learned subspace to reduce computational cost. We also numerically demonstrate the performance of the proposed method.

[04197] An iterative algorithm for POD basis adaptation

Format : Talk at Waseda University
Author(s) : Zhizhang Wu (The University of Hong Kong)Zhiwen Zhang (The University of Hong Kong)
Abstract : To construct reduced-order models using POD for convection-diffusion equations, fine-grid solvers are needed to obtain accurate solution snapshots for small diffusivities, while coarse-grid solvers are sufficient for large diffusivities. We develop an iterative algorithm that adapts the POD basis functions extracted at large diffusivities

for the construction of reduced-order models at small diffusivities without resorting to fine-grid solvers. Convergence analysis and numerical results are provided to confirm the effectiveness of our method.

[04384] Heat on hypergraph and its application to network analysis

Format : Talk at Waseda University
Author(s) : Masahiro Ikeda (RIKEN)
Abstract : In this talk, I will introduce the joint works with Atsushi Miyauchi (Tokyo Univ.), Yuuki Takai(KIT) and Yuichi Yoshida (NII). They are about heat on hypergraph and its application to network analysis. I will introduce the background of their papers and the fundamental notions for community detection of networks. First I review the notion of Laplacian and Cheeger's inequality for the usual undirected graph. After that, I introduce the definition of the (submodular) Laplacian for hypergraphs and the heat on them. I also introduce several properties of the Laplacian and heat such as maximal monotonicity of the Laplacian. Especially I explain well-definedness of the heat and the Personalized PageRank for hypergraphs. Moreover, I introduce applications of their properties to the community detection on hypergraphs. If time permitted, I will introduce recent works about submodular Laplacian with Uchida (Oita Univ.).

[04987] Convergence Rate Analysis for Deep Ritz Method

Format : Talk at Waseda University
Author(s) : Jerry Zhijian Yang (Wuhan University)
Abstract : We provide a rigorous numerical analysis on deep Ritz method (DRM) for second order elliptic equations with Neumann boundary conditions. We establish the first nonasymptotic convergence rate in H1 norm for DRM using deep networks with ReLU2 activation functions. Our study also shed light on how to set the hyperparameter of depth and width to achieve the desired convergence rate in terms of number of training samples.

[02600] Applied and computational discrete algorithms

Session Time & Room :

02600 (1/2) : 3D (Aug.23, 15:30-17:10) @G404

02600 (2/2) : 3E (Aug.23, 17:40-19:20) @G404

Type : Proposal of Minisymposium
Abstract : Combinatorial and discrete mathematical problems arise in many real-life applications. Their solution requires designing, analyzing and implementing discrete algorithms. The research in this area therefore brings together mathematicians, computer scientists, statisticians, domain scientists and engineers to solve problems of applied and computational combinatorics. The proposed two-part minisymposium covers scientific computing, machine learning, and graph algorithms. The objective is to summarize the latest discrete algorithmic developments and their applications with computational studies on the applications. This minisymposium follows similar ones held in ICIAM 2019, ICIAM 2015, and ICIAM 2011 on combinatorial aspects of sparse matrix computations.

[04306] Parallel Batch-Dynamic Graph Algorithms

Format : Online Talk on Zoom
Author(s) : Julian Shun (MIT)
Abstract : There has been significant interest in graph analytics due to their applications in many domains, including social network and Web analytics, machine learning, biology, and physical simulations. Real-world graphs today are massive and also dynamic. As many real-world graphs change rapidly, it is crucial to design

dynamic algorithms that efficiently maintain graph statistics upon updates, since the cost of re-computation from scratch can be prohibitive. Furthermore, due to the high frequency of updates, we can improve performance by using parallelism to process batches of updates at a time. This talk presents new graph algorithms in this parallel batch-dynamic setting.

Specifically, we present the first parallel batch-dynamic algorithm for approximate k-core decomposition that is efficient in both theory and practice. Our algorithm is based on our novel parallel level data structure, inspired by the sequential level data structures of Bhattacharya et al. and Henzinger et al. Given a graph with n vertices and a batch of B updates, our algorithm maintains a (2 + epsilon)-approximation of the coreness values of all vertices (for any constant epsilon > 0) in O(B log^2(n)) amortized work and O(log^2(n) loglog(n)) span (parallel time) with high probability. We implement and experimentally evaluate our algorithm, and demonstrate significant speedups over state-of-the-art serial and parallel implementations for dynamic k-core decomposition.

We have also designed new parallel batch-dynamic algorithms for low out-degree orientation, maximal matching, clique counting, graph coloring, minimum spanning forest, single-linkage clustering, some of which use our parallel level data structure.

[03109] Approximation: a Paradigm for Designing Parallel Graph Algorithms

Format : Online Talk on Zoom
Author(s) : Alex Pothen (Purdue University)S M Ferdous (Pacific Northwest National Lab)
Abstract : We describe a paradigm for designing parallel algorithms by approximation techniques. Instead of solving a problem exactly, for which parallel algorithms may not exist, we seek a solution with provable approximation guarantees. Furthermore, we design these algorithms to be concurrent. We discuss linear and submodular matching and edge cover problems for which such algorithms have been designed, and describe their use in solving problems in sparse matrix computations and load balancing problems in quantum chemistry.

[02991] Nested dissection ordering on GPUs

Format : Talk at Waseda University
Author(s) : Xiaoye Sherry Li (Lawrence Berkeley National Lab)
Abstract : Nested dissection ordering is an important preprocessing step in sparse matrix factorizations. It is effective in reducing the amount of fill in the factored matrices. As of now, there is no good algorithm nor software to compute such an ordreing on GPUs. We have made some progress in this direction. We will present our new algorithms designed for GPUs, including multilevel graph coarsening and finding small separators at each level, and the results of parallel runtime and ordering quality.

[05454] Accelerating AI using Fast and Feasible Matrix Multiplication

Format : Online Talk on Zoom
Author(s) : Oded Schwartz (The Hebrew University)
Abstract : AI requires large resources, both for training and for inference. It involves significant time spent on matrix multiplication, typically between 45%-95%. Most current math libraries (for CPU and GPU) and all state-of-the-art hardware accelerators (such as Google's TPU and Intel's / Habana Lab's Gaudi) are based on the cubic-time classic matrix multiplication algorithm, despite more than five decades of research on sub-cubic time algorithms. In this talk I will review several of the challenges in utilizing fast matrix multiplication algorithms, and recent solutions that can allow faster application in practice.

02600 (2/2) : 3E @G404 [Chair: X. Sherry Li]

[03099] On heuristics for the Birkhoff--von Neumann decomposition

Format : Online Talk on Zoom
Author(s) : Bora Ucar (CNRS and ENS de Lyon)Jeremy Cohen (CREATIS, CNRS)
Abstract : The Birkhoff--von Neumann decomposition expresses a doubly stochastic matrix as a convex combination of permutation matrices. This talk will be an introduction to this decomposition. We will discuss algorithmic and combinatorial problems associated with this decomposition.

[03435] Recent Advances in Streaming (Hyper)Graph Partitioning

Format : Online Talk on Zoom
Author(s) : Christian Schulz (Heidelberg University)
Abstract : Partitioning a (hyper)graph into balanced blocks such that few edges run between blocks is a key problem for large-scale distributed processing.
Currently there is a gap observed in the space of available partitioning algorithms. On the one hand, there are streaming algorithms that have been adopted to partition massive graph data on small machines. In the streaming model, vertices arrive one at a time including their neighborhood and then have to be assigned directly to a block. These algorithms can partition huge graphs quickly with little memory, but they produce partitions with low solution quality. On the other hand, there are offline (shared-memory) multilevel algorithms that produce partitions with high quality but also need a machine with enough memory to partition huge networks.

In this talk, we present recent advances in the area of streaming algorithms for the problem. First, we present a buffered streaming approach: this model allows to read more than one node and its neighborhood at the time. This enables our algorithm to leverage multilevel techniques, and thus significantly improve solution quality while surprisingly also enhancing the overall complexity of the algorithm.

On the other hand, we present a shared-memory streaming multi-recursive partitioning scheme that performs recursive multi-sections on the fly without knowing the overall input graph to compute hierarchical partitionings. If the topology of a distributed system is known, it is possible to further optimize the communication costs by mapping partitions onto processing elements.

[04746] Efficient Data Structures for Sparse Dynamic Graphs

Format : Talk at Waseda University
Author(s) : Helen Xu (Lawrence Berkeley National Laboratory)
Abstract : Sparse graphs underlie many key applications such as social networks analyses and scientific computing. This talk discusses dynamic graph data structures and how to choose data structures that optimize for locality, which is key to performance in graph computations. The focus is on how different use cases, which can cause different data patterns and access patterns, can influence the design of these structures and how to exploit these differences to maximize performance.

[04669] Communication Efficient Stratified SGD on Distributed-Memory Systems

Format : Online Talk on Zoom
Author(s) : Nabil Abubaker (Bilkent University)Ozan Karsavuran (Lawrence Berkeley National Lab)Cevdet Aykanat (Bilkent University)
Abstract : Stratified Stochastic Gradient Descent (SSGD) enables stale-free low-rank approximation of sparse matrices on distributed-memory systems. We present a framework to efficiently scale SSGD on HPC systems. The framework leverages point-to-point communications to reduce the bandwidth overhead, and a novel combinatorial algorithm to reduce the upper bound on the number of messages from O(K^2) to O(K logK), where K is the number of processors. Our experiments show an order of magnitude performance gap in favor of our framework-enabled SSGD compared to the state-of-the-art.

[02612] Mathematical modeling of biofilm systems and applications

Session Time & Room :

02612 (1/2) : 4C (Aug.24, 13:20-15:00) @D514

02612 (2/2) : 4D (Aug.24, 15:30-17:10) @D514

Type : Proposal of Minisymposium
Abstract : The majority of microbial life on Earth occurs in biofilms, heterogeneous microbial communities embedded in layers of a self-produced extracellular matrix. Biofilms have a detrimental role in industrial and medical applications, via antibiotic-resistant infections, corrosion and fouling. On the other hand, they are also widely used in bioremediation technologies to improve water quality and generate renewable resources. The non-

linear, multidimensional and multiscale nature of these complex microbial systems provides ample opportunity for investigation with theoretical modeling. This minisymposium focuses on continuum deterministic models, and brings together different biofilm applications, modeling approaches, and methods for model analysis.

[03848] Simulation of ultrasonic biofilm detachment in membrane aerated bioreactors

Author(s) : Maryam Ghasemi (University of Waterloo)Sheng Chang (University of Guelph)Sivabal Sivaloganathan (University of Waterloo)
Abstract : Controlling biofilm thickness in an aerated membrane biofilm reactor (MBfR) has been recognized as a key for MBfRs to achieve a long-term stable performance. In this context, acoustic cavitation is an effective strategy that can be used for controlling biofilm thickness. However, to maintain the biofilm thickness at an optimum value, it is necessary to understand the effect of acoustic parameters and cavitation bubble distribution on biofilm detachment and establish a link between biofilm detachment and regrowth. The purpose of this study is to provide an integrated mathematical model that describes biofilm development in an aerated membrane biofilm reactor using a nonlinear reaction-diffusion model and its response to mechanical stress generated from acoustic cavitation. The simulation results show that amplitude and frequency of transducer are two key factors that affect biofilm detachment. Moreover, uniform distribution of cavitation along the biofilm surface is critical to achieve an even biofilm thickness. Furthermore, periodic cavitation detachment with an appropriate resting time in between is important for maintaining the biofilm thickness at a desired value. Therefore, the proposed integrated modeling approach can be used to optimize acoustic cavitation parameters and achieve effective biofilm thickness control in MBfRs.

[04151] Bacterial Biofilms across scales and applications

Format : Online Talk on Zoom
Author(s) : Nicholas Cogan (Florida State University)
Abstract : This talk will describe mathematical modeling of biofilm dynamics in general. This should set the stage for the talks in this session that include models that focus on the physics of fluids, materials, and biology. Applications range from environmental to engineering as well as scales from millimeters to meters and time scales that range from seconds to weeks. Because of the wide variety in scales and applications, mathematical aspects must be both flexible and precise. This tension has driven an explosion in interest in biofilm models in the past 30+ years and there are a handful of broadly studied models which will be discussed in this talk.

[04177] Microbially-influenced transport in sea ice

Author(s) : Isaac Klapper (Temple University)
Abstract : Sea ice, which covers a significant portion of the earth's surface, is an interestingly complicated material consisting of a mixture of solid ice and liquid brine phases which are coupled by thermodynamic considerations, It also is a platform for microbial life. A model will be presented that hypothesizes that, in turn, the sea ice resident microbial population
might impact ice sheet structure and, in particular, its transport properties including notably heat transport.

[04844] Computational simulations of biofouling on ship hulls

Author(s) : Rosalind Allen (Friedrich Schiller University Jena)Patrick Sinclair (University of Edinburgh)Jennifer Longyear (AkzoNobel)Kevin Reynolds (AkzoNobel)Alistair Finnie (AkzoNobel)Chris Brackley (University of Edinburgh)Martin Carballo Pacheco (University of Edinburgh)
Abstract : We use computer simulations to investigate two coating technologies for ship hulls. Simulating microbial colonization of a surface that releases a biocidal chemical we find intrinsic stochasticity with an important role for immigration of biocide-resistant species. Further, computational fluid dynamics simulations of flow across a textured (riblet) surface show that removal of biofouling by flow may be ineffective if the flow is not well aligned. Simulations can help understand marine biofouling on advanced surface coatings.

02612 (2/2) : 4D @D514

[05492] Long time behaviour of a thin-film model for early biofilm development

Author(s) : John Ward (Loughborough University)
Abstract : We will present a model describing the interaction of a thin, surface growing biofilm and planktonic cells. Assuming the biofilm can be described as homogeneous, thin, highly viscous fluid, a coupled system of nonlinear reaction-diffusion equations is derived, one of which having a fourth-order ``diffusion'' term. Key results using numerical computation and asymptotic analysis will be presented that indicate the dominant processes in early biofilm expansion and the subtle complxities of the travelling wave solutions.

[02613] Advances in Variational and Hemivariational Inequalities: Modeling, Analysis, and Applications

Session Time & Room :

02613 (1/3) : 5B (Aug.25, 10:40-12:20) @G606

02613 (2/3) : 5C (Aug.25, 13:20-15:00) @G606

02613 (3/3) : 5D (Aug.25, 15:30-17:10) @G606

Type : Proposal of Minisymposium
Abstract : This minisymposium highlights recent developments in the mathematical analysis, numerical solution, and real-world applications of variational and hemivariational inequalities. The focus is on the modeling of problems leading to such inequalities, the well-posedness and properties of their solutions, numerical analysis, optimal control and optimization, and their applications in mechanics and physics. The related topics include, but are not limited to, dynamical systems, fixed points, nonconvex and nonsmooth analysis, nonlinear inclusions, and numerical methods. The overall goal of the minisymposium is to foster collaboration and knowledge-sharing among researchers working in the area of variational and hemivariational inequalities and their applications.
Organizer(s) : Stanislaw Migorski, Fei Wang
Classification : 35L87, 47J20, 49J52, 65K15, 65N30
Minisymposium Program :

02613 (1/3) : 5B @G606 [Chair: Fei Wang]

[04082] Recent Advances on Partial Differential Variational Inequalities

Format : Talk at Waseda University
Author(s) : zhenhai Liu (guangxi minzu university)
Abstract : In this talk, we consider a partial differential complex system obtained by mixing an evolution partial differential equation and a variational inequality. This kind of problems may be regarded as a special feedback control problem. Firstly, we give our research motivation and examples. Then, based on the theory of semigroups, Filippov implicit function lemma and fixed point theory for set-valued mappings, we show several existence results of solutions to the mentioned problem. Finally we point out some problems for the further research.

[03283] Optimal contol for variational inequalities of obstacle type

Format : Talk at Waseda University
Author(s) : Zijia Peng (Guangxi Minzu University)
Abstract : This talk is concerned with optimal control of obstacle problems whose weak formulations are nonlinear variational inequalities. Under appropriate assumptions, existence of optimal solutions is proved. Moreover, the necessary optimality conditions of first order are derived by regularization techniques.

[03248] Approximation techniques for solving hemivariational inequalities arising from contact mechanics

Format : Talk at Waseda University
Author(s) : Li Zhibao (Central South University)
Abstract : Frictional contact phenomena are common in various industrial processes and engineering applications, and they can be described by variational or hemivariational inequalities. Most of these inequality problems lack analytical solutions. Hence, developing effective numerical methods to solve these inequalities is important. Hemivariational inequality is a useful tool to study nonlinear boundary value problems with nonsmooth and nonconvex functionals. With finite element discretization, HVIs become nonconvex optimization problems. In this talk, I will present some numerical methods based on approximation techniques to solve the nonconvex optimization problem for the hemivariational inequality arising from the frictional contact mechanics problem. These methods include the smooth quadratic regularization method, as well as the first and second order approximation methods for the nonconvex functions. I will also evaluate and compare these methods using numerical experiments at the end.

[03265] A virtual element method for a quasistatic frictional contact problem

Format : Talk at Waseda University
Author(s) : fang feng (East China Normal University)Weimin Han (University of Iowa)Jianguo Huang (Shanghai Jiao Tong University)
Abstract : We consider the numerical solution of an abstract quasistatic variational inequality arising in the study of quasistatic physical processes. The temporal discretization is carried out by the backward difference method, while the spatial discretization is based on the virtual element method. A general framework is provided and a quasistatic contact problem is studied and the optimal order error estimates are derived for the lowest-order virtual element method.

02613 (2/3) : 5C @G606 [Chair: Zhenhai Liu]

[04032] The interior penalty virtual element method for the fourth-order elliptic hemivariational inequality

Format : Talk at Waseda University
Author(s) : Jiali Qiu (Xi'an Jiaotong University)Fei Wang (Xi'an Jiaotong University)Min Ling (School of Mathematical Sciences, Peking University)Jikun Zhao (Zhengzhou University)
Abstract : We develop the interior penalty virtual element method (IPVEM) for solving a Kirchhoff plate contact problem, which can be described by a fourth-order elliptic hemivariational inequality (HVI). With certain assumptions, the well-posedness of the discrete problem is proved. Furthermore, a priori error estimation is established for the IPVEM for the fourth-order elliptic HVI, and we show that the lowest-order VEM achieves optimal convergence order. Finally, some numerical examples are presented to support the theoretical results.

[03325] Virtual element method for a frictional contact problem with normal compliance

Format : Talk at Waseda University
Author(s) : Bangmin Wu (Xinjiang University)
Abstract : We study the virtual element method for solving the frictional contact problem with the normal compliance condition, which can be modeled by a quasi-variational inequality. Existence and uniqueness results are obtained for the discretized scheme. Furthermore, a priori error analysis is established, and an optimal order error bound is derived for the lowest order virtual element method. One numerical example is given to show the efficiency of the method and to illustrate the theoretical error estimate.

[03328] Well-posedness and Numerical Analysis of a Stokes Hemivariational Inequality

Format : Online Talk on Zoom

Author(s) : Min Ling (School of Mathematical Sciences, Peking University)

Abstract : This talk is devoted to the development and analysis of a pressure projection stabilized mixed finite element method, with continuous piecewise linear approximations of velocities and pressures, for solving a hemivariational inequality of the stationary Stokes equations with a nonlinear non-monotone slip boundary condition. We present an existence
result for an abstract mixed hemivariational inequality and apply it for a unique solvability analysis of the numerical
method for the Stokes hemivariational inequality. An optimal order error estimate is derived for the numerical solution under appropriate solution regularity assumptions. Numerical results are presented to illustrate the theoretical
prediction of the convergence order.

[03157] Well-posedness of parabolic variational-hemivariational inequalites with unilateral constraints

Format : Online Talk on Zoom

Author(s) : Stanislaw Migorski (Jagiellonian University in Krakow)Dong-ling Cai (School of Mathematical Sciences, University of Electronic Science and Technology of China)

Abstract : In this talk we discuss a novel class of variational-hemivariational inequalites with a unilateral constraint of parabolic type. Results on existence, uniqueness and the continuous dependence of the weak solution with respect to perturbations in the data are proved. As an application we examine a mathematical model of nonsmooth quasistatic viscoelastic frictional contact problem with the Signorini unilateral contact condition and a generalization of the static Coulomb law of dry friction.

02613 (3/3) : 5D @G606 [Chair: Stanislaw Migorski]

[03234] Duality Arguments in Analysis of Viscoelastic Contact Problem

Format : Online Talk on Zoom

Author(s) : Anna Ochal (Jagiellonian University in Krakow)

Abstract : We consider a mathematical model which describes the quasistatic frictionless contact of a viscoelastic body with a rigid-plastic foundation. We provide three different variational formulation of the model in which the unknowns are the displacement, the stress and the strain, respectively. We prove that they are pairwise dual of each other and they are well-posedness. The proofs are based on recent results on history-dependent variational inequalities and inclusions.

[03636] Frictional contact problem for electrorheological fluid flows

Format : Online Talk on Zoom

Author(s) : Dariusz Pączka (Warsaw University of Technology)

Abstract : We study the stationary flow of an isothermal, homogeneous and incompressible electrorheological fluid with slip boundary conditions of frictional type. The variational formulation of the flow problem has the form of a hemivariational inequality. Existence and uniqueness of a weak solution to the hemivariational inequality is proved for a material function $p(\cdot)$ of an electric field without any condition of monotonicity type on the extra stress tensor. This result is established by abstract theorems on existence and uniqueness of a solution to a subdifferential operator inclusion and a hemivariational inequality in the variable exponent Sobolev space.

[03327] Numerical analysis of history-dependent variational-hemivariational inequality by virtual element method

Format : Online Talk on Zoom

Author(s) : Wenqiang Xiao (School of Mathematical Sciences, Peking University)

Abstract : In this talk, we mainly introduce the virtual element method for solving two types of history-dependent variational-hemivariational inequalities arising in contact problems. In the first model, we consider an elastic material. The contact is modelled with a total slip-dependent version of Coulomb's law of dry friction. In the second model, we consider viscoelastic material. We introduce fully discrete schemes for the above two problems,

where the temporal integration is approximated by trapezoidal rule and the spatial variable is approximated by the virtual element methods. An optimal order error estimates is derived under appropriate solution regularity assumptions. Finally, numerical examples are reported, providing numerical evidence of the optimal convergence order theoretically predicted.

[03250] Stability analysis for nonstationary Stokes hemivariational inequality

Format : Online Talk on Zoom
Author(s) : Changjie Fang (Chongqing University of Posts and Telecommunications)
Abstract : In this talk, we consider hemivariational inequality problem for the evolutionary Stokes equations with a nonlinear slip boundary condition. We assume the slip boundary condition together with a Clarke subdifferential relation between the stress tensor and velocity. The existence of weak solutions is obtained by Galerkin method. In addition, stability is analyzed for a perturbed hemivariational inequality. We also present a result on the existence of a solution to an optimal control problem for the nonstationary Stokes hemivariational inequality

[02616] Recent Developments in Applied Inverse Problems

Session Time & Room :

02616 (1/3) : 1C (Aug.21, 13:20-15:00) @G808

02616 (2/3) : 1D (Aug.21, 15:30-17:10) @G808

02616 (3/3) : 1E (Aug.21, 17:40-19:20) @G808

Type : Proposal of Minisymposium
Abstract : This minisymposium addresses both theoretical and algorithmic aspects of inverse problems arising in tomography as well as their applications. We will bring together well established scientists and young researchers to provide a forum to discuss new ideas and developments in the field of applied inverse problems.
Organizer(s) : Hiroshi Fujiwara, Kamran Sadiq
Classification : 35R30, 65Nxx, 74Jxx, 78Axx, 45Exx
Minisymposium Program :

02616 (1/3) : 1C @G808 [Chair: Kamran Sadiq]

[04397] Perturbation of Surface Waves in Piezoelectric Media

Format : Talk at Waseda University
Author(s) : Kazumi Tanuma (Gunma University)Xiang Xu (Zhejiang University)Gen Nakamura (Hokkaido University)
Abstract : We study Bleustein-Gulyaev (BG) waves which propagate along the surface of a homogeneous C_6 hexagonal piezoelectric half-space under the mechanically-free and electrically-closed condition at the surface. We prove stability of the BG waves, to investigate the perturbations of their phase velocity and polarization when a fully anisotropic perturbation is added to the hexagonal material constants. The inverse problem to obtain material information from measurements of BG waves will be discussed.

[04646] Quantitative Parameter Reconstruction from Optical Coherence Tomographic Data

Format : Talk at Waseda University
Author(s) : Leopold Veselka (University of Vienna)
Abstract : We discuss the quantification of the refractive index from data obtained by optical coherence tomography - an imaging modality based on the interferometric measurement of back-scattered light. We consider samples with layered structure, where the refractive index as a function of depth is a piece-wise constant function. The applicability of the reconstruction method, where the refractive index is obtained layer-by-layer via least squares minimization, is verified by numerical examples for both simulated and experimental data.

This is a joint work with Peter Elbau (University of Vienna, Austria) and Leonidas Mindrinos (Agricultural University of Athens, Greece).

[04241] Landweber-Kaczmarz for full datacube modelling in Extragalactic Archaeology

Format : Talk at Waseda University
Author(s) : Fabian Hinterer (JKU Linz)
Abstract : We consider the problem of reconstructing a galaxy's stellar population distribution function from spectroscopy measurements. These quantities can be connected via the single-stellar population spectrum, resulting in a very large scale integral equation with a system structure. To solve this problem, we propose a projected Nesterov-Kaczmarz reconstruction (PNKR) method, which efficiently leverages the system structure and incorporates physical prior information such as smoothness and non-negativity constraints.

02616 (2/3) : 1D @G808 [Chair: Hiroshi Fujiwara]

[03014] Principles and Examples of Magnetic Resonance Elastography for Distribution Measurement of Viscoelasticity

Format : Talk at Waseda University
Author(s) : Mikio Suga (Chiba University)
Abstract : The mechanical property of a tissue is related to physiological and pathological states. Magnetic resonance elastography (MRE) is an imaging technique that can noninvasively measure the physical properties of biological soft tissues by using a magnetic resonance imaging system. Measuring the mechanical properties of tissues is expected to be helpful in diagnosing diseases such as hepatic fibrosis and cancer. In this minisymposium, I will talk about the principles and examples of MRE.

[04180] Inverse scattering technique for a defect in anisotropic plates

Format : Talk at Waseda University
Author(s) : Takahiro SAITOH (Gunma University)
Abstract : In recent years, plates with anisotropic properties, such as CFRP, have been increasingly used in the engineering industry. In general, it is known that the elastic wave propagation is very complicated in anisotropic plates, due to the anisotropic properties and the generation of some types of wave modes between the incident wave and both upper and lower surfaces. In this study, the author proposes an inverse scattering technique for reconstructing a defect in anisotropic plates.

02616 (3/3) : 1E @G808 [Chair: Hiroshi Fujiwara]

[03045] Source Reconstruction from Partial Boundary Data in Radiative Transport

Format : Talk at Waseda University
Author(s) : Kamran Sadiq (Johann Radon Institute for Computational and Applied Mathematics (RICAM))
Abstract : This talk concerns the source reconstruction problem in a transport problem through an absorbing and scattering medium from boundary measurement data on an arc of the boundary. The method, specific to two dimensional domains, relies on Bukgheim's theory of A-analytic maps and it is joint work with A. Tamasan (UCF) and H. Fujiwara (Kyoto U).

[03961] Numerical challenges to optical tomography by the stationary radiative transport equation

Format : Talk at Waseda University
Author(s) : I-Kun Chen (National Taiwan University)Hiroshi Fujiwara (Kyoto University)Daisuke Kawagoe (Kyoto University)
Abstract : We discuss quantitative feasibility of optical tomography based on the stationary radiative transport equation which is a mathematical model of particle migration with absorption and scattering by medium. The key idea is the use of discontinuity of its solution induced by a proper boundary condition and discontinuous Galerkin

methods. Numerical examples are exhibit to show a possibility of reconstruction of the attenuation coefficient without a priori information on the scattering kernel.

[04301] Inversion of the momenta X-ray transform of symmetric tensor fields in the plane.

Format : Online Talk on Zoom
Author(s) : Alexandru Tamasan (University of Central Florida)Kamran Sadiq (Johann Radon Institute for Computational and Applied Mathematics (RICAM))David Omogbhe (University of Vienna)Hiroshi Fujiwara (Kyoto University)
Abstract : The X-ray transform of symmetric tensor fields recovers the tensor field only up to a potential field. In 1994,
V. Sharafutdinov showed that augmenting the X-ray data with several momentum X-ray transforms establishes uniqueness, with a most recent work (2022) showing stability of the inversion. In this talk, I will present a first reconstruction method, which stably recovers sufficiently smooth symmetric tensor fields compactly supported in the plane.
The method is based on the extension of Bukhgeim's theory to a system of A-analytic maps. This is joint work with H. Fujiwara, D. Omogbhe and K. Sadiq.

[02618] Recent Developments in Hyperspectral and Multispectral Imaging

Session Time & Room : 5C (Aug.25, 13:20-15:00) @E605

Type : Proposal of Minisymposium
Abstract : Hyperspectral and multispectral images contain plenties of spatial–spectral information, which brings a substantial opportunity to explore and understand their features. This Mini-symposium provides a platform for researchers to share innovative ideas about algorithm developments associated with this type of imaging. Attendees can expect to learn about the latest techniques from model-based and data-driven perspectives and their applications in remote sensing, computational imaging, and medical imaging.
Organizer(s) : Chao Wang, Jizhou Li
Classification : 65K10, 68U10, 49N45
Minisymposium Program :

02618 (1/1) : 5C @E605 [Chair: Chao Wang]

[03524] Multi-Dimensional Signal Alignment using Local All-Pass Filters

Format : Talk at Waseda University
Author(s) : Christopher Gilliam (University of Birmingham)
Abstract : The estimation of a geometric transformation that aligns two or more signals is a problem that has many applications. The problem occurs when signals are either recorded from two or more spatially separated sensors or when a single sensor is recording a time-varying scene, e.g., image registration, motion correction in medical imaging and time-varying delay estimation. In this talk we estimate the transformation by approximating it using a set of local all-pass (LAP) filters.

[03596] Noise reduction in X-ray microspectroscopy

Format : Online Talk on Zoom
Author(s) : Jizhou Li (City University of Hong Kong)
Abstract : Investigating nanoscale morphological and chemical phase transformations is essential for a wide range of scientific and industrial applications across various disciplines. The emerging TXM-XANES imaging technique combines the strengths of full-field transmission X-ray microscopy (TXM) and X-ray absorption near edge structure (XANES) to generate chemical maps by capturing a series of multi-energy X-ray microscopy images and fitting them accordingly. However, its effectiveness is hindered by low signal-to-noise ratios due to system errors and insufficient exposure illuminations during rapid data acquisition. In this study, we present a straightforward and

robust denoising method that capitalizes on the inherent properties and subspace modeling of TXM-XANES imaging data to significantly improve image quality, paving the way for fast and highly sensitive chemical imaging. Comprehensive experiments using both synthetic and real datasets showcase the remarkable performance of our proposed approach.

[03540] Remote Sensing Image Reconstruction from the Subspace Perspective

Format : Talk at Waseda University
Author(s) : Jie Lin (University of Electronic Science and Technology of China)
Abstract : Remote sensing images cover abundant spatial-spectral information while the images usually suffer from different degradations during the imaging and transmission. Image reconstruction is a fundamental step for subsequent applications. With improved imaging accuracy, the larger sizes of acquired images bring a greatly increased computation burden in reconstruction. In this talk, I will present matrix and tensor subspace-based methods for remote sensing image reconstruction, which enjoy satisfactory effects and lower computational complexity.

[03879] Nonlocal Self-Similarity-Based Hyperspectral Remote Sensing Image Denoising With 3-D Convolutional Neural Network

Format : Talk at Waseda University
Author(s) : Zhicheng Wang (The University of Hong Kong)Michael Kwok-Po NG (The University of Hong Kong)Lina Zhuang (Key Laboratory of Computational Optical Imaging Technology, Aerospace Information Research Institute, Chinese Academy of Sciences, Beijing)Lianru Gao (Key Laboratory of Computational Optical Imaging Technology, Aerospace Information Research Institute, Chinese Academy of Sciences, Beijing)Bing Zhang (Aerospace Information Research Institute, Chinese Academy of Sciences, Beijing 100094, China, and also with the University of Chinese Academy of Sciences, Beijing)
Abstract : Deep-learning-based denoising methods for hyperspectral images have been comprehensively studied and achieved impressive performance. Compared with deep-learning-based methods, the nonlocal similarity-based methods are more suitable for images containing edges or regular textures. We propose a powerful denoising method, termed non-local 3-D convolutional neural network, combining traditional machine learning and deep learning techniques. The numerical and graphical denoising results of the simulated and real data show that the proposed method is superior to the state-of-the-art methods.

[02628] Mathematical Modeling on waste reduction through sustainable developmnet.

Session Time & Room : 3D (Aug.23, 15:30-17:10) @D502

Type : Proposal of Minisymposium
Abstract : This study explores the use of sustainable inventory modeling as a tool for waste reduction in the context of manufacturing industries. Traditional inventory management models tend to prioritize cost reduction and efficiency, often leading to excess inventory and waste generation. The results suggest that sustainable inventory modeling can be a valuable approach for waste reduction and sustainability in manufacturing industries, providing a framework for organizations to achieve economic and environmental benefits while balancing the needs of various stakeholders.
Organizer(s) : Prof. Shiv Raj Singh, Dipti Singh.

[02644] Black box methods for efficient learning in high-dimensional scientific computing

Session Time & Room : 1D (Aug.21, 15:30-17:10) @F310

Type : Proposal of Minisymposium

Abstract : The past decade has seen an explosion of interest in the use of black box modeling techniques in scientific computing. Driven by advances in hardware and software, researchers have begun to harness the power of these techniques to solve a wide range of complex and high-dimensional problems arising in computational science and engineering. This minisymposium aims to bring together experts from various fields including data science, high-dimensional approximation, deep learning, optimization, control, and scientific computing to share their latest research and developments in this exciting and rapidly evolving area of computational science.

[05120] Is Monte Carlo a bad sampling strategy?

Format : Online Talk on Zoom

Author(s) : Ben Adcock (Simon Fraser University)Simone Brugiapaglia (Concordia University)

Abstract : When approximating smooth, high-dimensional functions from limited samples using polynomials, it is common to use Monte Carlo (MC) sampling to lessen the curse of dimensionality. However, it is well known that MC is theoretically suboptimal. This has led to a concerted effort to design improved strategies with near-optimal sample complexities. In this work we demonstrate, both theoretically and numerically, that MC is actually an eminently suitable strategy in sufficiently high dimension despite its apparent suboptimality.

[05196] CAS4DL: Christoffel Adaptive Sampling for Deep Learning in data-scarce applications

Format : Online Talk on Zoom

Author(s) : Ben Adcock Juan M. Cardenas (Simon Fraser University)Nick Dexter (Florida State University)

Abstract : Many problems in computational science and engineering require the approximation of a high-dimensional function from data. In many such applications, data is costly to generate: for example, it each sample may require a costly PDE solve. Therefore, it is imperative to develop highly sample efficient algorithms. Recently, deep neural networks and deep learning have shown great promise to provide breakthrough performance in challenging function approximation tasks. In this work, we propose an adaptive sampling strategy, CAS4DL (Christoffel Adaptive Sampling for Deep Learning) to increase the sample efficiency of DL. Our novel approach is based on interpreting the second to last layer of a DNN as a dictionary of functions defined by the nodes on that layer. With this viewpoint, we then define an adaptive sampling strategy motivated by adaptive sampling schemes recently proposed for linear approximation schemes, wherein samples are drawn randomly with respect to the Christoffel function of the subspace spanned by this dictionary. We present numerical experiments comparing CAS4DL with standard Monte Carlo (MC) sampling. Our results demonstrate that CAS4DL often yields substantial savings in the number of samples required to achieve a given accuracy, particularly in the case of smooth activation functions. These results therefore are a promising step towards fully adapting DL towards scientific computing applications.

[05283] Exploiting the local parabolic landscapes of adversarial losses to accelerate black-box adversarial attack

Format : Talk at Waseda University

Author(s) : Hoang Anh Tran (Oak Ridge National Laboratory)

Abstract : Machine learning models, and convolutional neural networks (CNNs) in particular, have demonstrated remarkable performance in many classification tasks. However, deep learning technology also exposed certain security risks, as they are susceptible to malicious inputs, which are small, human-imperceptible perturbations to

the inputs designed to fool the model prediction. In this talk, we present an investigation into the vulnerability of CNN classifiers from the shape of the loss's landscape perspective. We theoretically and experimentally justify that the adversarial losses of many standard and robust image classifiers behave like parabolas with respect to perturbations in the Fourier domain, but not in the pixel domain. Then, we exploit the parabolic landscape to design a new black-box adversarial attack methods with improved query efficiency, compared to the other state-of-the-art baselines. We demonstrate the efficiency of our method on MNIST, CIFAR-10 and ImageNet datasets for various standard and robust models.

[05315] A Mathematical Approach Towards Physical Law Learning

Format : Online Talk on Zoom
Author(s) : Gitta Kutyniok (LMU Munich)Philipp Scholl (LMU Munich)Aras Bacho (LMU Munich)Holger Boche (TU Munich)
Abstract : For most of human history, scientists had to derive physical laws by hand. Recently, due to the data deluge, several learning-based approaches to infer the governing laws from experimental data have been suggested. However, a theoretical foundation is at present missing. In this talk, we will discuss our first stage of a mathematical framework for physical law learning, in particular, how to derive well-definedness of the learning problem, both theoretically and numerically.

[02671] Recent advances on the analysis of hyperbolic balance laws

Session Time & Room :

02671 (1/2) : 5C (Aug.25, 13:20-15:00) @G605

02671 (2/2) : 5D (Aug.25, 15:30-17:10) @G605

Type : Proposal of Minisymposium
Abstract : Hyperbolic balance laws are of great interest owing to their importance in applications, such as the Euler equations, magnetohydrodynamic system, Boltzmann equations, and in applied mathematics. Recently, there have been a lot of advances in ascertaining the global well-posedness of such systems. The generic breakdown of classical solutions requires one to enlarge the space to hope for well-posedness or add `good' source terms.
The mathematical studies of these PDEs pose significant analytical/numerical challenges. This minisymposium seeks to bring together researchers to promote exchange of ideas, and present recent developments on the mathematical analysis and novel methods in this area.

[03611] Existence and Stability of Traveling Waves of Boussinesq-Burgers Equations

Format : Online Talk on Zoom
Author(s) : Kyle Kun Zhao (Tulane University)Anita Yang (Chinese University of Hong Kong)Zhian Wang (Hong Kong Polytechnic University)
Abstract : We introduce rigorous mathematical results concerning the existence and stability of traveling wave solutions to the Cauchy problem of the one-dimensional Boussinesq-Burgers equations modeling the propagation of weak tidal bores. Existence of traveling waves is obtained by means of phase plane analysis and geometric singular perturbation. Local stability of traveling waves with arbitrary strength is proven by spatially weighted energy methods.

[04963] Global dynamics and photon loss in the Kompaneets equation

Format : Talk at Waseda University
Author(s) : Hailiang Liu (Iowa State University)
Abstract : The Kompaneets equation governs dynamics of the photon energy spectrum in certain high temperature (or low density) plasmas. We present several results concerning the long-time convergence of solutions to Bose–Einstein equilibria and the failure of photon conservation due to shock formation at the zero-energy boundary. This talk is based on a joint work with J. Ballew, G. Iyer, D. Levermore and R. Pego.

[03629] HYPOCOERCIVITY OF STOCHASTIC GALERKIN FORMULATIONS FOR STABILIZATION OF KINETIC EQUATIONS

Format : Talk at Waseda University
Author(s) : Hui Yu (Tsinghua University)Stephan Gerster (Universit`a degli Studi dell'Insubria)Michael Herty (RWTH Aachen University)
Abstract : We consider the stabilization of linear kinetic equations with a random relaxation term. The well-known framework of hypocoercivity by J. Dolbeault, C. Mouhot and C. Schmeiser (2015) ensures the stability in the deterministic case. This framework, however, cannot be applied directly for arbitrarily small random relaxation parameters. Therefore, we introduce a Galerkin formulation, which reformulates the stochastic system as a sequence of deterministic ones. We prove for the gamma-distribution that the hypocoercivity framework ensures the stability of this series and hence the stochastic stability of the underlying random kinetic equation. The presented approach also yields a convergent numerical approximation.

[04154] Traveling Wave Solutions in Keller-Segel Models of Chemotaxis

Format : Online Talk on Zoom
Author(s) : Tong Li (The University of Iowa)
Abstract : We study global existence and long-time behavior of solutions for hyperbolic-parabolic PDE models of chemotaxis.
We show the existence and the stability of traveling wave solutions to systems of nonlinear conservation laws derived from the Keller-Segel model. We construct biologically relevant oscillatory traveling wave solutions to an attractive chemotaxis system of mixed-type. Traveling wave solutions of chemotaxis models with growth are also investigated.

02671 (2/2) : 5D @G605 [Chair: Hailiang Liu]

[04448] On the Riccati dynamics of 2D Euler-Poisson equations with attractive forcing

Format : Online Talk on Zoom
Author(s) : Yongki Lee (Georgia Southern University)
Abstract : The multi-dimensional Euler-Poisson system describes the dynamic behavior of many important physical flows. In this talk, a Riccati system that governs pressureless two-dimensional EP equations is discussed. The evolution of divergence is governed by the Riccati type equation with several nonlinear/nonlocal terms. Among these, the vorticity accelerates divergence while others further amplify the blow-up behavior of a flow. The growth of these blow-up amplifying terms are related to the Riesz transform of density, which lacks a uniform bound makes it difficult to study global solutions of the multi-dimensional EP system. We show that the Riccati system can afford to have global solutions, as long as the growth rate of blow-up amplifying terms is not higher than exponential, and admits global smooth solutions for a large set of initial configurations. Several recent works in a similar vein will be reviewed.

[04918] Critical thresholds in spherically symmetric Euler-Poisson systems

Format : Talk at Waseda University
Author(s) : Manas Bhatnagar (University of Massachusetts Amherst)
Abstract : We will see an introduction to the concept of Critical Threshold Phenomena (CTP) and how it plays a role in the Euler-Poisson systems. We will go over some of the existing results in this area and how the techniques have developed over time. In the end, we will see some new results on the multidimensional spherically symmetric Euler-Poisson systems.

[04518] On multi-dimensional rarefaction waves

Format : Talk at Waseda University
Author(s) : Tianwen Luo (Tsinghua University)Pin Yu (Tsinghua University)
Abstract : We study the two-dimensional acoustical rarefaction waves under the irrotational assumptions. We provide a new energy estimates without loss of derivatives. We also give a detailed geometric description of the rarefaction wave fronts. As an application, we show that the Riemann problem is structurally stable in the regime of two families of rarefaction waves. This is a joint work with Prof. Pin Yu in Tsinghua Univerisity.

[04947] Nonlocal traffic flow models

Format : Talk at Waseda University
Author(s) : Thomas Hamori (University of South Carolina)Yongki Lee (Georgia Southern University)Yi Sun (University of South Carolina)Changhui Tan (University of South Carolina)
Abstract : In this talk, I will discuss a family of traffic flow models. The conventional Lighthill-Whitham-Richards model is notorious for exhibiting finite-time shock formation for all generic initial data. To address this issue, I will introduce a family of nonlocal traffic flow models, which incorporate look-ahead interactions. These models can be derived from discrete cellular automata models. Interestingly, we will explore how the nonlocal slowdown interactions prevent the shock formation, under certain suitable settings. Furthermore, I will also discuss the extension of these nonlocal models to second-order traffic flow models.

[02700] Recent developments on Infinite Dimensional Analysis, Stochastic Analysis and Quantum Probability

Session Time & Room :

02700 (1/2) : 1C (Aug.21, 13:20-15:00) @E501

02700 (2/2) : 1D (Aug.21, 15:30-17:10) @E501

Type : Proposal of Minisymposium
Abstract : There has been a great achievement of the theory in both white noise analysis (as an infinite dimensional analysis) and quantum probability theory starting from the seventies of the last century. These two theories have been developed and unified in order to get important directions on the quantum information theory, quantum computation and etc. In this session we would like to discuss connections between white noise analysis and quantum information theory through the experts' talks in each fields including the mathematical finance.
Organizer(s) : Isamu Doku, Kimiaki Saito
Classification : 60H40, 81P45, 60H30, 46L53, 68Q11, White Noise Theory, Quantum Information, Applications of stochastic analysis, Noncommutative probability and statistics, Information complexity
Minisymposium Program :

02700 (1/2) : 1C @E501 [Chair: Kimiaki Saito, Isamu Doku]

[02940] Note on complexities for the quantum compound systems

Format : Talk at Waseda University
Author(s) : Noboru Watanabe (Tokyo University of Science)
Abstract : In order to discuss the efficiency of information transmission of the quantum communication processes consistently, we consider the entropy type functional and the mutual entropy type functional with respect to the initial state and the quantum communication channel. In this study, the mutual entropy type measures are constructed by the compound states between the initial and final systems.
We modify the compound states and examine the entropy functional and the mutual entropy functional defined by the modified compound states by means of the initial state and the completely positive channel to study the efficiency of information transmission of the quantum communication processes.

[03589] Asymptotics of densities of first passage times for spectrally negative Lévy processes

Format : Talk at Waseda University
Author(s) : shunsuke kaji (meijo university)
Abstract : We study a first passage time of a Lévy process over a positive constant level. In
the spectrally negative case we give conditions for absolutely continuity of the distributions of the first passage times. The tail asymptotics of their densities are alsoclarified, where the asymptotics depend on tail behaviour of the corresponding Lévy measures.

[03953] A combinatorial formula of the moments of a deformed filed operator

Format : Talk at Waseda University
Author(s) : Nobuhiro ASAI (Aichi University of Education)
Abstract : We shall construct the two parameterized deformed Fock space obtained from the weighted q-deformation technique. We shall explain a combinatorial moment formula of a Poisson type filed operator defined on this Fock space by using the set partitions with their statistics. In addition, we shall mention relationships with the recurrence formula for the orthogonal polynomials of the deformed Poisson distribution. This talk is based on the joint work with H. Yoshida (Ochanomizu Univ, Tokyo).

02700 (2/2) : 1D @E501 [Chair: Kimiaki Saito]

[02981] Multiplication Operators by White Noise Delta Functions and Associated Differential Equations

Format : Talk at Waseda University
Author(s) : Un Cig Ji (Chungbuk National University)
Abstract : We establish explicit forms of the multiplication operators induced by white noise delta functions, which are closely related to the Bogoliubov transformation and a quantum analogue of Girsanov transform. Then we study the differential equations for operators associated with the multiplication operators by the white noise delta functions. This talk is based on a joint work with L. Accardi and K. Saito.

[03986] Positivity of Q-matrices and quadratic embedding constants of graphs

Format : Talk at Waseda University
Author(s) : Nobuaki Obata (Tohoku University)
Abstract : Let $G=(V,E)$ be a graph. Positivity of the Q-matrix $Q=Q_q=[q^{d(x,y)}]$ is essential for q-deformed vacuum state of a graph and q-deformed CLT for a growing graph. Positivity of Q_q is profoundly related to conditional negativity of the distance matrix $D=[d(x,y)]$. It is shown that the positivity region of Q_q contains $

[0,1]$ifandonlyifthequadraticembeddingconstant(QEC)of$G$ is non-positive. We report some results in this line and discuss open questions.

[03056] Data-driven methods to discover within-host biological dynamics

Session Time & Room : 5D (Aug.25, 15:30-17:10) @E804

Type : Proposal of Minisymposium

Abstract : Our minisymposium brings together researchers whose goal is to develop and apply algorithms towards discovering and documenting within-host dynamics of the immune system and infectious disease. One of the common challenges of this field is the degree to which existing databases of prior knowledge should be incorporated to enhance the analysis of new bioinformatic data sets. Presenters will discuss their varied research projects in this space. Throughout the minisymposium, we aim to foster a dialogue among the presenters, as well as minisymposium participants, from which the nuances of this field can be discussed.

[03279] How to find a pertinent research question: the identification and exploration of known unknowns

Format : Online Talk on Zoom

Author(s) : Mayla R Boguslav (Colorado State University)Nourah M Salem (University of Colorado Anschutz Medical Campus)Elizabeth White (University of Colorado Anschutz Medical Campus)Katherine J Sullivan (University of Colorado Anschutz Medical Campus)Michael Bada (University of Colorado Anschutz Medical Campus)Teri L Hernandez (University of Colorado Anschutz Medical Campus)Sonia M Leach (National Jewish Health)Lawrence E Hunter (University of Colorado Anschutz Medical Campus)Michael Kirby (Colorado State University)

Abstract : Scientific discovery progresses by exploring new and uncharted territory. More specifically, it advances by a process of transforming unknown unknowns first into known unknowns, and then into knowns. Over the last few decades, researchers have developed many knowledge bases to capture and connect the knowns, which has enabled topic exploration and contextualization of experimental results. But recognizing the unknowns is also critical for finding the most pertinent questions and their answers. Little work has focused on how scientists might use them to trace a given topic or experimental result in search of open questions and new avenues for exploration. We present methods and tools to help researchers automatically uncover these unknowns through the illumination of specific goals for scientific knowledge.

[05174] A summary of algorithms for sparse feature selection for Biological Data

Format : Online Talk on Zoom

Author(s) : Michael Kirby (Colorado State University)

Abstract : Biological data sets such as transcriptomics, proteomics or metabolomics are characterised by their high dimension n and small sample size p.   Realistically, it is a daunting challenge to deduce meaningful biological mechanisms when p<

[03409] Improving decoy detection for protein-protein interaction models

Format : Online Talk on Zoom

Author(s) : Corey OHern (Yale University)

Abstract : Computational prediction and design of proteins is a difficult task that results in models with a wide variation in quality. Decoy detection algorithms seek to classify computational models as high-quality or low-quality without knowledge of the experimental structures. Recently, dramatic improvements have been made in decoy detection of models for single proteins, but decoy detection of protein-protein interface (PPI) models is still challenging. To assess the current state-of-the-art for PPI decoy detection, we scored computational models generated using rigid-body docking software, ZDOCK, from a dataset of 33 heterodimeric high-resolution x-ray crystal structures against a standard measure of similarity to the x-ray crystal structures. We found that for some targets there is a strong correlation between the docking and ground truth scores (i.e. easy targets), whereas for other targets there are only weak correlations (i.e. difficult targets). We show that a metric that characterizes the "flatness" of the target interfaces can distinguish easy from difficult targets, where flat targets possess only weak correlations between the docking and ground truth scores. In addition, most rigid docking software methods generate highly imbalanced datasets containing mostly low-quality computational models. Balanced datasets of PPI models reduce sampling bias, which makes it easier to identify the physical features that can classify PPI computational models.

[05206] Early Detection of Disease: An intersection between artificial intelligence and biomathematics

Format : Online Talk on Zoom

Author(s) : Juan B Gutierrez (University of Texas at San Antonio)

Abstract : Many states of disease are progressive, having a silent phase in which pathogenesis advances without the manifestation of any symptoms. However, small perturbations can be detected by a complex signal such as electrocardiography. In this talk, I will present how to approach the detection of subtle physiological signals through the systematic design of the architecture of an artificial neural network capable of detecting liver-stage malaria with an accuracy of +90%.
